hydrolyze polygalacturonate, a major constituent of plant cell wall pectin. *A. niger* is a plant pathogen fungus that has been used as a model organism for studying the role of the pectin degrading enzymes (PDEs) for many years. Dr. Bergmann's lab has centered on the degradation of pectins by fungal enzymes during pathogenesis and plant mechanisms to alter the rate at which that degradation occurs. In order to do this, the lab has been expressing and purifying enzymes from *A. niger*, some of which are native and some of which are site directed mutants, and to characterize them in terms of purity and relative activity. Last spring I successfully worked out the methodology to purify *A. niger* EPG-I. I will be continuing the work on this enzyme and will characterize the pectin cleavage by this enzyme and identify the product of this enzyme.

Technique of Soil Fractionation for AMS Radiocarbon Analyses

Rachel Ehlinger
Dr. Alexander Cherkinsky, Geology, Franklin College of Arts & Sciences

On earth, soils hold more carbon than any other component of the carbon cycle, including the atmosphere. Fractionation and accelerator mass spectrometry are used to study the turnover of the organic matter in soil from its death in the biosphere to its decay into the atmosphere. In order to successfully radiocarbon date the matter in samples, the sediment must be converted to a form suitable for measuring carbon 14. Our study analyzes different carbon pools, including bulk composition, humic acid, and residue of the sediment. These pools are separated through different chemical processes in order to evaluate the mean residence time of the samples through mass spectrometry. The mean residence time allows us to calculate the age of the soil and measure its tendency to react to climate change.

Male Mate Choice between Sympatric and Allopatric Populations of *Drosophila subquinaria* and *Drosophila recens*

Randall English, CURO Graduation Distinction
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

In a system of two species of fruit flies native to North America, *Drosophila subquinaria* and *Drosophila recens*, which have come into secondary contact since speciation, we examined the role that male mate choice plays in asymmetrical reproductive character displacement between *Drosophila* populations of the same species for both *D. subquinaria* and *D. recens*. For each species, we used males from sympatric and allopatric populations, which were individually placed in chambers with a choice of a manipulated fresh female corpse from either population to observe the patterns of their mating behaviors. We found that in *D. subquinaria*, both sympatric and allopatric males tended to pay more attention to their own population, but found that sympatric *D. subquinaria* males were choosier and less active than allopatric males. In *D. recens*, however, neither sympatric nor allopatric males tended to choose one female population over the other with significance.

Comparison of Spinal Motions Used during Running to Their Spinal Flexibility

Cristian Escalera, CURO Research Assistant
Dr. Kathy Simpson, Kinesiology, College of Education

Understanding the biomechanics of the spine that occur during running could be useful in developing rehabilitation plans for spinal-injured patients. The goal of this study was to compare the spinal motions used during running to individuals' spinal flexibility. For 20 participants, the spatial locations of the reflective markers placed on the spine and body were recorded by a motion capture system while the participant ran at maximum

speed and then performed maximum spinal flexion tasks. More spinal motion occurred in the lower compared to the upper half of the spine, with spinal twisting exceeding the corresponding static flexibility value. This implies that running at maximal speed could potentially be problematic for people with low-back problems.

Characterization of Leigh's Syndrome Patient Human Induced Pluripotent Stem Cells for Clinical Research

Christina Ethridge, CURO Research Assistant
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Background: Leigh's Syndrome is an inherited disorder of mitochondrial energy metabolism that affects the central nervous system. Symptoms include muscular and neurological degradation leading to death within the first few years of life. No curative treatments are currently available. The reprogramming of mitochondrial diseased fibroblasts into induced pluripotent stem cells will allow for their differentiation into multiple cell types and tissues. If reprogramming is possible, this will function as an invaluable tool for studying disease pathophysiology *in vitro* with the intention of designing future gene therapies and pharmacological treatments for affected patients. *Objective:* Our goal in this study was to generate and characterize induced pluripotent stem cells (iPSCs) derived from skin fibroblasts of Leigh's Syndrome patients. *Methods:* Generated LS-iPSCs using a non-viral, non-integrating mRNA and microRNA system, then characterized iPSCs using immunofluorescence staining for pluripotency markers (Oct4, Sox2, Nanog, Tra-181, Tra-160, and SSEA4). iPSCs were differentiated and stained for endoderm (VIM, AFP), ectoderm (MAP2, TUBB3), and mesoderm (ACTA2, Desmin) germ layer markers. *Results:* The generated LS-iPSCs expressed markers of pluripotency as seen by immunofluorescence staining. Differentiated iPSCs staining showed expression of tissue markers from all three germ layers. *Conclusion:* Characterization of the iPSCs derived from Leigh's Syndrome patient fibroblasts demonstrated that the LS-iPSCs possess characteristics of true stem cells.

Effect of O-GlcNAc Expression on Cancer Stem Cells and the Role of LGR6

Sarah Evans, CURO Summer Fellow, CURO Research Assistant
Dr. Michael Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Studies have shown that colon cancer stem cells are subject to regulation by post-translational modification, such as by glycosylation. The addition of the monosaccharide O-linked ß-N-acetylglucosamine (O-GlcNAc) to serine or threonine residues on proteins by the enzyme OGT and its removal by OGA have been seen to cycle in response to cellular changes. It has been shown that changes in O-GlcNAc may regulate oncogenic signaling in cancer stem cells, and an elevated expression of O-GlcNAcylation has been found in some tumors, such as those of breast and colon cancer. O-GlcNAc has also been shown to play a role in the epigenetic regulation of some genes and has been implicated in the regulation of stem cells by modifying transcription factors. In particular, the gene LGR6 was found to be hypermethylated in colon cancer and may function as a tumor suppressor. The goal of this study is to determine if LGR6 levels are directly affected by a change in expression of O-GlcNAc in colon cancer stem cells. This objective will be carried out by performing a Western Blot to compare control samples to samples of colon cancer stem cells with OGT knocked out. Cancer stem cells are known to drive tumor formation, progression, and recurrence, and have also been shown to contribute to resistance to chemotherapy and radiation treatments. The results of this study will

provide a basis for studying the potential of OGT as a target for small molecule therapeutic development in colon cancer.

Escherichia coli Uses an IlvA/TrpD-Dependent Mechanism for Thiamine Synthesis

Kristen Farley, CURO Research Assistant, CURO Graduation Distinction
Dr. Diana Downs, Microbiology, Franklin College of Arts & Sciences

Phosphoribosylamine (PRA) is an intermediate in the biosynthesis of both thiamine and purines in *Escherichia coli* and *Salmonella enterica*. PRA is synthesized by the enzyme phosphoribosylpyrophosphate amidotransferase (PurF), and a null mutation in the gene encoding PurF leads to a purine auxotrophy in both organisms as expected. Despite the conservation of metabolic components between *S. enterica* and *E. coli*, *purF* mutants of *E. coli* are able to synthesize sufficient thiamine for growth, while *S. enterica purF* mutants are conditional thiamine auxotrophs. The conditional auxotrophy in *S. enterica* has been exploited to identify and characterize multiple alternative mechanisms of PRA formation that can be enhanced by mutation. This study was initiated to determine if PurF-independent mechanism(s) of PRA formation used by *E. coli* share characteristics with those identified in *Salmonella*. Nutritional studies with *E. coli* mutants lacking PurF showed that addition of isoleucine decreased the growth of these strains in the absence of thiamine (i.e. reduced PRA formation). This and other nutritional characteristics suggested that PRA was formed by a pathway of recruited enzymes that was defined in a *ridA* mutant strain of *S. enterica*. In this pathway, an enzyme from isoleucine biosynthesis and one from tryptophan biosynthesis are involved. Specifically, the 2-aminocrotonate intermediate formed by threonine dehydratase (IlvA) is used by the TrpD enzyme to generate PRA. Genetic studies described here revealed that the IlvA-, TrpD-dependent pathway defined in *Salmonella* is functional and highly integrated in the metabolic network of *E. coli* even when the RidA protein is present. These data indicate the metabolic makeup of *Salmonella* and *E. coli* are distinct enough to cause significant growth differences. Labeling studies following the incorporation of threonine into PRA will further probe the use of this mechanism for thiamine biosynthesis by *E. coli*. Studies like these emphasize the fact that different metabolic network configurations can be achieved while using the same components, which is important for evolutionarily related organisms that inhabit separate niches like *S. enterica* and *E. coli*.

The Effects of Ethinylestradiol and Levonorgestrel on the Central Nervous System and Behavior in Rats

Nathan Farr, Foundation Fellow
Jean Simone, Graduate Student
Dr. Philip Holmes, Psychology, Franklin College of Arts & Sciences

This represents the ideas and work of Jean Simone and Philip Holmes. My writing serves to consolidate and summarize the research for the express purpose of my own learning rather than to introduce new ideas or present those ideas as my own. Synthetic chemical contraceptives are the most commonly utilized form of reversible female contraception. Such drugs prevent pregnancy by modifying levels of gonadal steroids. Ample research details the somatic effects of such drugs, and a large body of work defends the benefits of restoring normal levels of circulating gonadal steroids, for example in post-menopausal women. Yet the literature fails to explain the effects that chronic use of chemical contraceptives may have on behavior and its underlying neurochemistry. To this aim, a single dose of ethinylestradiol, levonorgestrel, or saline vehicle was administered subcutaneously to

female Sprague Dawley rats daily. Rats were then tested in novel object (NOR), place (NOP), and context (NOC) recognition paradigms to assess learning and memory. Rats were also evaluated using the rotarod performance test to assess balance and coordination. Serum estradiol and ovarian weights were measured and brain tissue was preserved for analysis of tyrosine hydroxylase (TH) and gonadotropin-releasing hormone (GnRH) by ELISA method. No significant effects of drug treatment were found for NOP. Low dose (10 μg/day) ethinylestradiol impaired NOR while high dose (30 μg/day) improved performance. Low dose (20 μg/day) levonorgestrel improved NOC performance while high dose (60 μg/day) impaired it. All drug treatments lowered estradiol levels. Future studies anticipate the use of immunohistochemistry and other assays to inquire into a possible mechanism for the effects seen in the behavioral studies.

Insects in Shakespeare's Works

Giselle Fernandez
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

My research explores the effects of insects on Shakespeare's life and works. When it comes to the past, bugs are usually the ones responsible for huge changes in populations—whether those changes are massive amounts of death, like the plague and famines caused by harvest failures (usually due to bugs), or large boosts in population brought on by bounteous harvests and surpluses of food. Just these few things are integral in several of Shakespeare's most popular plots and themes: the plague that prevents Friar Laurence from delivering a life-changing letter in *Romeo and Juliet*, along with the many feasts that are mentioned and hosted in many of Shakespeare's plays, for starters. People are captivated and repulsed by insects, and their enchanting nature as well as their ability to destroy has never ceased to affect us. In Shakespeare's *A Midsummer Night's Dream*, the fairies with insect-like features and abilities are creatures of intrigue and magic, and butterflies are mentioned as things of wonder and beauty, while in the very same play, other insects such as beetles are described as frightening and harmful things. Insects have all sorts of influence over our lives today, and they have shaped and molded history into the present. Insects are far more important than most people realize, and a small (but very powerful) part of that importance is in Shakespeare's works, which stand at the very base of Western theatre as we know it today.

Evaluating Pre-Medical Students' Experience with/Understanding of Autism Spectrum Disorders

Allison Fialkowski, CURO Honors Scholar, CURO Research Assistant
Dr. David Gast, Communication Sciences & Special Education, College of Education

One in 68 children is diagnosed by age eight as being on the autism spectrum according to the Centers for Disease Control and Prevention (Baio, 2014). Because autism spectrum disorders (ASD) and co-morbidities frequently associated with ASD result in more healthcare visits for those with ASD than for their neurotypical peers, those working in healthcare need to have a high comfort level and understanding of ASD to ensure this population receives adequate care (Gurney, McPheeters, & Davis, 2006; Liptak, Stuart, & Auinger, 2006). Research supports that the earlier in a medical student's education the student is introduced to psychological concepts, the more the student will integrate psychological concepts with clinical ones (Williams, Milton, Strickland, Ardagh-Walter, Knapp, Wilson, et al., 1997). In order to evaluate pre-medical students' comfort level and experience working with those with autism, I have developed a survey using Qualtrics software. Using the results of this

survey, I will analyze the data to see what resources pre-medical students may need and would use to obtain information about autism. In providing adequate, relevant information about autism, students will be able to integrate these psychological concepts into their learning prior to formal medical education.

The Role of Executive Functioning in Adherence for Pediatric Solid Organ Transplant Recipients

Kelsie Flanigan, Charlotte Goldman, Tyler Stollman
Graduate Students: Ana Gutierrez-Colina, Cyd Eaton, Julia LaMotte
Dr. Ronald Blount, Psychology, Franklin College of Arts & Sciences

Executive functioning (EF) involves higher-level cognitive skills, including those needed for planning and management of tasks. Pediatric transplant patients are responsible for maintaining a complex medical regimen, which often involves taking different medicines multiple times a day. As a result, those who have problems with EF may be at a higher risk for nonadherence. No prior research has considered EF in this population or how it might affect medication adherence. The purpose of this study was to measure EF in a sample of adolescent and young adult transplant recipients and explore possible relationships between EF, adherence, and barriers to adherence. Thirty-six participants (M age =16.64) with a solid organ transplant (heart, liver, or kidney) and their caregivers (M age= 54.64) were evaluated in this study. Participants completed both self- and caregiver proxy-report measures of EF, medication adherence, and barriers to adherence. T-test analyses indicated more difficulties with EF in adolescent and young adult transplant recipients than in members of a normative sample (M difference -14.61; $t(35)=5.9$; $p<.000$). Forty-seven percent of participants had clinically significant problems in EF. Further analyses demonstrated positive correlations between EF problems and barriers to adherence ($r= .39$, $p< .05$), and also between EF problems and nonadherence ($r= .43$, $p< .05$). Early detection of deficits in EF could pinpoint individuals at risk of nonadherence. Finally, future studies in EF could lead to early identification of patients at risk for nonadherence and to the creation of adherence interventions designed to improve medical outcomes in this population.

Metabolism and Blood Flow in 4 Regions of the Gastrocnemius

Alyssa Ford, CURO Research Assistant
Alia Church, CURO Research Assistant
Dr. Kevin McCully, Kinesiology, College of Education

Purpose: To measure blood flow, metabolism, and oxidative capacity in four locations (lateral, medial, proximal, distal) of the gastrocnemius muscle during progressive exercise. *Methods:* A four-channel near infrared spectroscopy device was used to simultaneously measure oxygen saturation of hemoglobin in four locations. Plantar flexion was performed for 280 seconds at three levels of resistance. After exercise, blood flow was measured using a venous (65 mmHg) occlusion and metabolic rate using an arterial (250+ mmHg) occlusion. Following a short bout of plantar flexion, muscle oxidative capacity was measured as the rate of recovery after muscle oxygen consumption (mVO2). Rapid inflation of a blood pressure cuff was utilized to measure mVO2 at least 20 times during recovery. *Results:* Blood flow and oxidative capacity remained constant in each region during rest and progressive exercise, while metabolic rate increased with increasing exercise intensity. The proximal portions of the gastrocnemius had higher metabolic rates than distal. The lateral portion had higher metabolic rates than the medial in their respective portions (proximal and distal). *Conclusion:* Simultaneous measurement of

metabolism and blood flow in four locations in the same muscle was successfully performed. The gastrocnemius showed a 5-6 fold increase in metabolism during progressive exercise. Based on preliminary analysis, proximal regions of the gastrocnemius do more work during progressive exercise than the distal portions. Blood flow is restricted in the medial region of the gastrocnemius when compared to the lateral during exercise. Future studies can use this approach when studying muscle or cardiovascular disease.

Image Effects on Young Women's Perceptions and Engagement in Healthful Behaviors

Sophie Frankham-Smith, CURO Research Assistant
Dr. Maria Len-Rios, Grady College of Journalism & Mass Communication

This paper will investigate whether images that depict healthfulness as sexy and alluring can actually have unintended effects on young women's motivations and feelings about engaging in healthful behaviors. Health communicators use visuals to increase audience understanding of health problems, assess health risks, and to make the information more personally relevant. Visuals may increase emotional response to the health message, increase satisfaction with the communication, and aid in information recall (Frish, Camerini, & Schulz, 2013). The purpose of this research is to use an experimental design to pick apart how these "typical images" that accompany text on health promotion fliers and emails aimed at young women may, in the short-term, affect participants' body image attitudes, information recall, message satisfaction, and perceived ability to self-regulate one's health behaviors. This research will manipulate images of females (beautiful/sexy, fit/muscular, average, and overweight) accompanying health information intended for late teens. This research is guided by Bandura's social cognitive theory and Festinger's social comparison theory. Exposure to less fit and attractive bodies should be more motivating to females with lower body image. Individual factors are expected to moderate the effect (e.g., body dissatisfaction, mood). The experiment will be conducted with college-age females ages 18-19. This research is significant because it will add to how public relations professionals should use images in health messaging to most effectively share their message and engage women in healthful behaviors.

Cutting Commercial Energy Costs in Atlanta – One LED Retrofit at a Time

Shreya Ganeshan, Ramsey Scholar
Dr. Meghan Skira, Economics, Terry College of Business

The city of Atlanta prioritizes energy efficiency and sustainability among office spaces, and, in 2012, adopted the DOE's Better Buildings Initiative to reduce energy and water consumption by 20% in 2020. Currently, lighting upgrades to efficient technologies target halogen, incandescent, and old T12-fluorescent fixtures, upgrading them to newer T8-fluorescent bulbs. However, even buildings that have undergone renovation do not operate at optimal efficiency. Because lighting is the lowest hanging fruit in terms of decreasing electrical energy demand, LED lighting, the most efficient commercial technology, should replace existing lighting to maximize efficiency. LED lights have longer lifetimes than other bulbs and emit brighter light, reducing the required number of bulbs per square-foot of office space. Cost-benefit analyses indicate that through four-year phase-ins (typical payback period for LED retrofits) commercial developers should benefit from returns on investments, even after the first year because LED bulbs annually cost less than alternatives. First

performing LED retrofits on participants in the Atlanta Better Buildings Challenge (BBC) will allow the 111 (out of 129) offices already approved for or undergoing renovation to reduce energy consumption by 20% before or by 2020. These offices will serve as leaders and case studies, allowing commercial developers to extend this proposal to their other properties requiring renovation. In the long run, implementation should attract more manufacturers of LED products into the market to reduce installation costs and drive down the price of energy efficient technologies to the point where higher efficiency standards can be enforced through future commercial building codes.

GATA Transcription Factors Substituting HANABA TARANU in *Arabidopsis* Embryo Development

Julian Gendreau, CURO Research Assistant
Dr. Wolfgang Lukowitz, Plant Biology, Franklin College of Arts & Sciences

The GATA transcription factor HANABA TARANU (HAN) is a known regulator of flower, shoot apical meristem, and more recently embryo development. Recent unpublished work has found that the GATA transcription factor HAN functions redundantly with two closely related GATA factors, HAN LIKE 1 (HANL1) and HAN LIKE 2 (HANL2), in embryo development. Knockouts for HAN, HANL1, and HANL2 together produce embryos with striking defects: they fail to form a shoot or root and accumulate abnormally enlarged cells around their periphery, eventually arresting. My research is aimed at understanding whether other members of the GATA family of transcription factors might also play a role in embryogenesis. I have conducted gene swap experiments in which the following eight factors – GATA29, GATA16, GATA17, GATA17-LIKE, GATA22, GATA21, GATA23, and GATA1 – were placed under the control of the HAN promoter and expressed in triple mutants. Preliminary results indicate that GATA29 rescues the triple mutant phenotype and is biochemically equivalent to other HAN genes. We are currently conducting experiments to identify whether this factor plays a role in embryogenesis.

Parenting Intervention Targeting Emotion Communication: Characteristics of Completers and Non-Completers

Jessica Giannotti, Elizabeth Tiarsmith
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

This study aims to explore differences in parenting characteristics between mothers who completed a parenting intervention versus mothers who enrolled in the parenting course but dropped out early. The 6-session parenting intervention course (Shipman & Fitzgerald, 2005) aimed to improve emotion communication between the mother and child, with a goal of preventing emotional maltreatment. Consistent with past research, we expected that mothers reporting higher levels of stress and emotion dysregulation and more external locus of control, would experience less treatment engagement and thus be more likely to drop out of treatment. We also sought to compare baseline emotion communication skills between treatment completers and non-completers. Our hypotheses were tested using independent *t*-tests to compare treatment completers (n=20) and non-completers (n=10) from a sample of mothers and school-aged children. There were no group differences on mother or child age, mother education, or household income. Results indicated a marginally significant difference in emotional regulation ($t(28)$=-1.71, p=.09), with treatment completers reporting more problems regulating their emotions compared with non-completers. There were no group differences on locus of control or parenting stress. Mothers who completed the intervention reported higher

baseline levels of emotion coaching on all emotional scales, although the difference was only statistically significant ($t(28)=-2.79$, $p=.01$) regarding coaching of fearful emotions. Results suggest that mothers who stay engaged with the course report both strengths (i.e., greater emotion coaching) and vulnerabilities (i.e., higher emotion dysregulation). Further analyses will investigate potential group differences in observations of parent-child interactions completed at the baseline assessment.

Examining Perceptions and Expectations of African American Faculty and Students

Victoria Glover
Dr. Rosemary Phelps, Counseling & Human Development Services, College of Education

Researchers have documented the importance of African American faculty members and mentors in the retention and graduation of African American undergraduate students. Scholars have also identified mentoring as a positive factor in the retention and completion rates of students attending postsecondary institutions (Blackwell, 1989; Faison, 1996; Lee, 1999). Many higher education institutions, especially Predominantly White Institutions (PWIs), have focused on the recruitment and retention of faculty of color in order to diversify their institutions, provide different perspectives in the academy, and to provide a more welcoming and inclusive environment for students. Many PWIs have been successful in their efforts to recruit African American faculty and students, and the importance of having African American faculty involved in higher education continues to be evident. Yet, little research has been conducted examining the interactions and mentoring relationships between African American faculty and students. This is especially true when examining the perceptions and expectations that African American faculty and students have of each other in these interactions and relationships at PWIs. As the number of African American faculty and students increases, the lack of information in this area is problematic for several reasons: (a) little is known about the role of perceptions and expectations in the successful and effective outcomes of African American faculty and student interactions, (b) little is known about how these interactions facilitate growth and development for African American students, (c) little is known about best practices in this area, and (d) little is known about how African American faculty think through and frame these interactions. The current study aims to address the gap in the literature in the area of African American faculty and student interactions, especially as it relates to perceptions and expectations of each other in mentoring relationships at PWIs. By examining the views of African American students and faculty about their perceptions and expectations, we may gain new knowledge and insights into what factors may hinder or facilitate these relationships. This presentation will provide an overview of the theoretical underpinnings and research on African American mentoring relationships, discuss findings from the current study with African American faculty and undergraduate students at a Predominantly White Institution, and discuss future directions in this area of research.

Pre-Camp Characteristics Predicting Camp Outcomes for Children with Tourette Syndrome

Charlotte Goldman, Kelsie Flanigan, Tyler Stollman,
Graduate Students: Julia LaMotte, Ana Gutierrez-Colina, Cyd Eaton
Dr. Ronald Blount, Psychology, Franklin College of Arts & Sciences

Camps for children with Tourette Syndrome (TS) are a unique experience for campers to socialize with other children living with the same disorder. However, individual

differences may contribute to children having different camp experiences. The aim of this study was to determine which child characteristics predicted positive camp experiences for children with TS. Pre-camp attitudes towards having TS and self-competence were evaluated as predictors of post-camp outcomes for children who attended Camp Twitch and Shout. Thirty-one children (M age = 12.32 years) with TS participated. Prior to attending camp, children reported on their attitudes towards having TS and perceived social and general self-competence. After camp, children completed the Pediatric Camp Outcome Measure. A hierarchical regression analysis was conducted to identify predictors of post-camp outcomes, with attitude towards having TS entered in Step 1 and social and general self-competence entered in Step 2. The overall model accounted for 47.8% of the variance in children's camp experience. Attitude towards having TS was found to be a significant predictor of camp outcome, and the addition of social and general self-competence in Step 2 accounted for additional significant variance in predicting camp experiences. However, social self-competence was the only significant predictor at Step 2. These results indicate that children's attitudes towards TS and their perceived social-self competence are predictive of overall camp experience. Conversely, our conclusion indicates that children with lower social self-competence may benefit from extra attention at camp. Finally, additional factors associated with positive camp outcomes should be examined in future research.

Effect of Feeding Method (Breastfeeding vs. Formula) on Postpartum Weight Retention

Randi Goldstein
Dr. Leann Birch, Foods & Nutrition, College of Family & Consumer Sciences

Excessive gestational weight gain (GWG) and postpartum weight retention contribute to obesity among childbearing women. One factor that can affect postpartum weight loss is infant feeding method; the additional energy requirements of breastfeeding can promote postpartum weight loss, especially if infants are exclusively breastfed for several months. *Research Question:* Does the effect of feeding method (breast feeding vs. formula) affect postpartum weight retention? *Methods:* Body weight and body composition data (by BODPOD) were obtained from 12 women at 2, 8, and 16 weeks postpartum; height, initial pre-pregnancy weights, and delivery weights were recorded. The gestational weight gains were compared to Institute of Medicine guidelines. Weight, BMI, %Body Fat, and %Fat Free Mass were analyzed to compare postpartum weight retention loss between groups. *Results:* The sample included 8 participants who exclusively breastfed and 4 who exclusively formula fed. The mean GWG for breastfeeding mothers was 15.6kg, compared to 11.7kg for formula feeding mothers. By 16 weeks postpartum, breastfeeding mothers had lost 3.9 kg and weighed on average 1.4kg above their pre-pregnancy weight, while formula moms had gained 4.1 kg and weighed 7.1kg above their pre-pregnancy weight. *Conclusion:* Although both groups' GWG exceeded the IOM guidelines, by 16 weeks breastfeeding mothers were close to their pre-pregnancy weight, while formula-feeding moms gained even more weight postpartum.

Development of a Lightweight Weeding Robot

Delmaries Gonzalez, CURO Summer Fellow, CURO Research Assistant
Dr. Changying Li, College of Engineering

Nowadays, millions of US dollars are spent in the process of getting rid of weeds by the use of herbicides and manual labor in organic farms. The problem becomes more acute

when many weeds develop resistance to herbicides. To address this important issue, a lightweight robot was developed in this project. The robotic platform used was NI Robotic Starter Kit 2.0, along with a Kinect Sensor to sense depth and color, Arduino Uno microcontroller and a servo motor for the actuators, and a Mintbox 2 PC. Using the Kinect sensor, the robot can detect distance up to twelve feet to avoid any obstacles along its path, as well as detect the color green to differentiate weeds from dirt or plastic mulch. The actuators are made of a spinning brush mounted on a servo motor controlled by an Arduino Uno microcontroller. The navigation is autonomous, using a combination of time intervals and sensors to move along a predetermined path. With the help of the Kinect sensor, not only will navigation be more precise and efficient, but it will provide data on the environment being worked on, which can later be studied and quantified. This lightweight weeding robot provides an alternative to weed control in organic farming, contributing to a more sustainable food production system.

Policy Solutions to Cycles of Poverty and Food Insecurity in Athens, GA

Carver Goodhue, Foundation Fellow
Dr. Susan Tanner, Anthropology, Franklin College of Arts & Sciences

The rate of food insecurity in Athens, GA is significantly larger than both state and federal levels. Food insecurity in Athens can be largely attributed to the high prevalence of poverty, a condition which decreases food security by restricting the financial resources available for food purchases. Food security and poverty are linked in a self-perpetuating cycle; food insecurity can lead to cognitive impairment and poor academic performance in children, reducing income earning potential and reproducing conditions of poverty. There are already several organizations in Athens-Clarke County which address food insecurity. I suggested certain reforms or new uses of these established systems which could more effectively address food insecurity. I created three different policy proposals and examined their theoretical strengths and weaknesses as they related to sustainability, effectiveness, and cost. I chose a final policy which focused on providing nutritious food and nutrition education through school gardens. I judged this policy to be superior to others due to its low cost, high degree of sustainability, and its ability to address nutritional deficits at an early age before they affect educational and professional prospects.

Understanding the Mating Systems of the Fungi Causing Gummy Stem Blight of Cucurbits

Thomas Gottilla, CURO Research Assistant
Dr. Marin Talbot Brewer, Plant Pathology, College of Agricultural & Environmental Sciences

Gummy stem blight of cucurbits, an economically devastating disease, has recently been discovered to be caused by three fungal species: *Stagonosporopsis cucurbitacearum*, *Stagonosporopsis citrulli*, and *Stagonosporopsis caricae*. These species are genetically distinct but morphologically indistinguishable, and may have important biological differences including different mating systems. A critical aspect to understanding mating systems includes an investigation of the mating-type locus (*MAT1*). The *MAT1* locus is conserved among species within the phylum *Ascomycota*, with clear structural differences for self-compatible and self-incompatible species. The objectives to this study are to: (i) identify the *MAT1* locus in all three species, (ii) identify the mating-type genes at each locus, and (iii) compare the mating systems of the three species. Currently, there are draft genomes for three isolates from each of the three species causing gummy stem blight. By cross-referencing the genomes against known mating-type genes, we can identify the *MAT1*

locus. There are two genes in each species responsible for mating type, *MAT1-1-1* and *MAT1-2-1*. The presence of both genes in a single isolate would support self-compatibility; the presence of one gene would indicate self-incompatibility. The locus is likely flanked by the genes *APN2* and *SLA2,* as is the case with most *Ascomycota*. These genes will aid in the identification of the mating-type locus. The structure of the *MAT1* locus for each species is expected to be different, which would further confirm the distinction between these species. Genomic approaches are necessary because mating has not been successfully observed in the laboratory.

Field Test Significance in Adolescents with Chronic Ankle Instability

Morgan Green, CURO Honors Scholar
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Ankle sprains are the most common sport injuries among athletes and can lead to Chronic Ankle Instability (CAI). Easy to apply, field tests can screen athletes for CAI and assess performance; however, field tests were developed for adults and have not been applied to an adolescent population. The purpose of this study was to determine if functional performance ability is decreased in adolescents with CAI in the single-leg hop test (SLHT), using age as a covariate. We hypothesized that the CAI group would perform significantly slower than the control group, and that age would be a statistically significant covariate. Adolescent soccer players (30 male, 22 female, 15.7±1.4 yrs) completed standardized questionnaires to determine their perceived ankle instability status. Each subject performed two trials of the SLHT, jumping 10 times across a 30cm distance. An ANCOVA analysis was completed ($\alpha<0.05$). The 19 CAI subjects (17.5±4.1s) took significantly longer than the 33 control subjects (11.5±2.8s) ($p<0.001$). Age was identified as a significant covariate at $p=0.004$. Overall, subjects with CAI performed significantly worse in SLHT performance times; however, age appeared to influence performance times. These results demonstrate that SLHT can be used in an adolescent population, while accounting for age, and that CAI in adolescents decreases performance. Future research may assess the use of other field tests in adolescents and the effects of age on performance.

Natural Epigenetic Variation of SVP Results in Acceleration of the Floral Transition in *Arabidopsis thaliana*

Patrick Griffin, CURO Summer Fellow, CURO Research Assistant
Dr. Robert Schmitz, Genetics, Franklin College of Arts & Sciences

With the advent of high-throughput sequencing technologies, the identification of genetic variants and their association with phenotypic diversity is actively being pursued. Largely absent from these efforts is the identification of natural epigenetic alleles (epialleles). From previous experiments, a candidate epiallele was identified in the *SVP* (SHORT VEGETATIVE PHASE) gene of the accession Dja-1, which is a natural strain of *Arabidopsis thaliana* that displays an early-flowering phenotype. *SVP* influences the floral transition in *Arabidopsis*, and mutant alleles of this locus lead to an early-flowering phenotype. Interestingly, the *SVP* alleles are methylated in Dja-1 (hereafter referred to as *SVPepi*) compared to all other surveyed Arabidopsis strains, which leads to the following hypothesis: the methylated alleles of *SVP* in the Dja-1 strain are causative for the early flowering phenotype observed in nature. We have characterized the expression of *SVP* in Dja-1 using RNA-seq, which has revealed that it has the lowest expression in any accession. Furthermore, genetic complementation analysis revealed the Dja-1 allele fails to complement null T-DNA knockout alleles. Treatment with

demethylating agents demonstrates significant reduction of genomic methylation in seedlings; however, phenotypic data of treated adult tissue failed to show significant difference in *SVPepi* expression or flowering time.

Carbon Encapsulated and Magnesiothermically Reduced Diatoms as a Lithium-Ion Battery Anode

Bryan Grommersch, CURO Research Assistant
Dr. Ramaraja Ramasamy, College of Engineering

The chemical technology inherent in lithium-ion batteries has not kept pace with the portable electronics and automobiles that depend on them. Fossilized silica (SiO_2) frustules, or shells, of the fresh-water diatom Aulacoseira feature intricate pores and shapes which make them a promising template for a lithium battery anode. It is believed that retaining these intricacies after a magnesiothermic reduction to silicon and subsequently encapsulating the microparticles in carbon will yield batteries of superior capacity and cyclability.

Multi-Walled Carbon Nanotubes Alter the Acute Toxicity of Diclofenac to *Ceriodaphnia dubia* in Sediment: Water Exposures

Madison Hamilton, CURO Research Assistant
Dr. Marsha Black, Environmental Health Science, College of Public Health

Multi-walled carbon nanotubes (MWCNTs) are a new material with many industrial applications, strong binding properties to hydrophobic compounds, and no demonstrated acute toxicity to aquatic invertebrates at low concentrations. When MWCNTs enter aquatic environments as pollutants, they are predicted to precipitate and interact with sediment but also could bind to water-borne hydrophobic pollutants, reducing their bioavailability to aquatic organisms. Interactions between hydrophobic pollutants, MWCNTs, and sediment could lead to a greater reduction in pollutant toxicity than pollutant interactions with either CNTs or sediment alone. To test this hypothesis sediment elutriate tests were conducted, exposing *Ceriodaphnia dubia* to diclofenac, an anti-inflammatory pharmaceutical with known toxic effects, in the presence of different combinations of sediment, MWCNTs, and natural organic matter (NOM). The greatest reduction in *C. dubia* mortality occurred in the presence of MWCNTs and sediment, resulting in a 25% reduction in mortality compared to the diclofenac exposure. In contrast, the sediment and diclofenac treatment only reduced mortality by 10%. Unexpectedly, the combination of MWCNTs, NOM, and diclofenac increased mortality by 55%, and MWCNTs were clearly visible in the gut tracts of all *C. dubia* in these exposures. Increased toxicity is possibly due to NOM stabilizing CNTs in the water column, allowing for increased interactions between NOM, MWCNTs, and diclofenac followed by consumption of NOM-MWCNT-diclofenac complexes by *C. dubia*. However, sediment decreases the bioavailability of these hydrophobic toxic complexes. Therefore, MWCNT bioremediation efforts should take into account MWCNT stability in the water column and sediment interactions to avoid potential aquatic organism consumption.

Thomas Cole's Architectonic America

Connor Hamm, CURO Summer Fellow, CURO Research Assistant
Dr. Janice Simon, Lamar Dodd School of Art

This research project examines the representations of eclectic architectural forms in the paintings of the early 19th century American landscape painter Thomas Cole. Particular attention is given to *The Architect's Dream* (1840) and his five-part series *The*

Course of Empire (1833-36), which together lament what Cole believed was a faltering America. By examining these six seminal paintings and the representations of Egyptian, Classical, Gothic, and fantastical architectural idioms therein, I propose that Cole blurred the lines between painter and architect and, in turn, between landscape and built environment. I use the following research strategies: (1) formal visual analysis of the paintings themselves; (2) conventional art historical examination of primary/period sources as well as subsequent scholarship; and (3) face-to-face consultation with my mentor. Through such examination of Cole's architectonic paintings, this research project supplements and deepens Cole's artistic legacy as a landscape painter, putting into relief such issues as the relationship between Cole and his patrons, Cole's contribution to the developing American narrative and myth, and Cole's critique of Jacksonian politics. The rendering of architecture is therefore treated as the most apparent and compelling component of Cole's visual jeremiad for America, providing a focused and novel understanding of these paintings and of Cole's oeuvre.

Towards a Parametric Architecture?
Connor Hamm, CURO Summer Fellow, CURO Research Assistant
Dr. Amitabh Verma, College of Environment & Design

This research project examines the architectural philosophy and practice of Parametricism through comparative analysis of two buildings designed by Zaha Hadid Architects: the MAXXI Museum in Rome, Italy and the Heydar Aliyev Cultural Center in Baku, Azerbaijan. I posit that these two buildings allow me to critically examine the growing role of Parametricism as the preeminent architectural style. Comparative examination of these buildings elucidates not only the aesthetic development of Parametricism over the past twenty years (Parametricism-as-style), but also the concomitant structural changes to the built environments of Rome and Baku (Parametricism-as-practice). I use the following research strategies: (1) traditional examination of scholarly materials, including master plans, digital and physical models, architectural reviews, and critical essays; and (2) the design-based methodologies of the Architectural Association Design Research Laboratory, including computational and material analyses, face-to-face critique and feedback modules, and public presentations and critiques. Such robust methodological pluralism allows me to complicate the claim that Parametricism is the architectural style and practice *par excellence*, while also uncovering the ways in which the ubiquity of digital-based design practice has impacted the field of Architecture and the built environment writ large.

The Effects of Size on Development Time and Fecundity in *D. subquinaria*
Joan Han, CURO Research Assistant
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

Organism body size affects evolutionary fitness by influencing maturation rate, reproductive potential, mating, and life expectancy. To better understand the causes and consequences of body size variation, I investigated the effect of body size on development time and fecundity using two populations of the mushroom-feeding fruit fly *Drosophila subquinaria*. Previous research has shown that flies from west of the Canadian Rockies are significantly larger than flies from the eastern side of these mountains. However, the other physiological characteristics connected to this size discrepancy remain unclear. Through observing the length of time required for flies to mature from time of oviposition to adult emergence out of pupa, I found that the larger population had a longer

development time compared to the smaller one. In addition, by measuring total viable offspring produced by single females, the results showed the larger population to have greater reproductive capacity. This study provides a foundation for further studies on the genetic and evolutionary basis behind body size control. Although larger flies have more offspring, their overall fitness may be hindered by their longer development time. This research may not only help provide insight into mammalian size control due to the similarities between *Drosophila* and vertebrate growth pathways, it may also aid in biodiversity conservation efforts by helping us better understand the mechanisms behind speciation.

Describing Scrambling in Japanese
Spencer Hanlin
Dr. Vera Lee-Schoenfeld, Germanic & Slavic Studies, Franklin College of Arts & Sciences

The syntax of the Japanese language has created controversy in the Japanese community for a number of years due to the rather flexible and somewhat unpredictable nature of its "scrambling" syntax, allowing speakers seemingly to be able to rearrange words and other elements freely. In order to shed some light on the exact nature of this syntactic process, I have conducted a pair of studies to establish a possible set of typologies for possible scrambling sentences and sought native speaker impressions to establish the efficacy of these typologies and what meanings these typologies convey. Based on the data collected and the information gathered from native speakers, I have concluded that there is a significant focus on the use for emphasis and a possible location-focused use that scrambling of sentence elements employs.

Correlation between Narcissism and Turnover within the Workplace
Dennis Hardigree, Alex Cole
Dr. Brian Hoffman, Psychology, Franklin College of Arts & Sciences

This study looks at the relationship between narcissism of chief executive officers (CEOs) and turnover within their companies. The significance of the study is to explore relationships with turnover in an organization in hopes of reducing turnover. We hypothesized that the narcissism scores of the CEOs would be positively correlated with employee turnover. The data were collected via an online survey of Italian company CEOs (N=155) and their followers (N=494). The Narcissism Personality Inventory (NPI-40) was used to measure narcissism of CEOs (Raskin and Hall, 1979), and turnover data was aggregated through AIDA, which records yearly financial records. Narcissism levels of CEOs correlated positively with turnover at 0.78. This finding could have practical implications for the selection process of CEOs.

Hurricane Forecasting and Healthcare Facility Evacuations
Elizabeth Hardister, CURO Honors Scholar
Dr. Curtis Harris, Institute for Disaster Management, College of Public Health

Hurricanes have the potential to produce mega mass casualty and mass fatality events in addition to catastrophic structural damage. The state of Georgia is located in an area vulnerable to hurricanes originating in both the Atlantic Ocean and the Gulf of Mexico; however, Georgia's response to a major hurricane has not yet been tested. The successful evacuation of healthcare facilities in response to an impending hurricane requires advanced notice, timely decision making, and an unprecedented coordination effort between coastal and inland facilities. As a starting point for determining whether

forecasts provide the advanced warning necessary to coordinate evacuations, we evaluated predictive models by comparing historical track data from hurricanes after 1990 to concurrent forecasts. Although emergency managers have benefited from developments in forecasting techniques, the limitations of individual predictive models necessitate special considerations for those that require greater notice for evacuations, specifically patients and residents of healthcare facilities and other individuals with functional medical needs.

Localization of Rv3351c Protein in *Mycobacterium smegmatis* and BCG

Jennifer Hardister, CURO Honors Scholar
Dr. Frederick Quinn, Infectious Diseases, College of Veterinary Medicine

Development of protective strategies against *Mycobacterium tuberculosis* (*Mtb*), a disease that kills nearly 2 million people annually and is the leading cause of death for individuals with HIV, requires an understanding of the mechanisms of host invasion employed by the pathogen. A component of the innate defense of the lung against inhaled infectious agents is the respiratory epithelium. Our laboratory previously showed that *Mtb* strains with mutations in genes *Rv3351c*, *esxBA,* or *hbhA* produce 30-70% less necrosis in human alveolar epithelial cell monolayers compared to the parent strains. Of the products encoded by these genes, only Rv3351c's function is unknown. The long-term goal of this project is to investigate this gene's regulation and its protein product's function. The aim of this current study is to identify the functional location of Rv3351c in the mycobacterial cell using faster-growing and nonpathogenic surrogate hosts, *Mycobacterium smegmatis* and *Mycobacterium bovis*, Bacillus Calmette–Guérin (BCG). To accomplish this task, plasmid vectors expressing *Mtb* Rv3351c will be transformed into these strains. The first vector, pET-19b, contains a polyhistidine tag, which allows for rapid identification by western immunoblots of successfully cloned genes. The second, pMV261, contains an Rv3351c-DsRed fusion that produces a fluorescent product allowing for microscopic analyses. Transformed cultures of the host strains will be separated into cytoplasmic, cell membrane, and secreted fractions and tested for the presence of Rv3351c. The location of the Rv3351c protein product in *M. smegmatis* and BCG provides information for subsequent studies and has implications for the protein's function.

Necessity of Universal Pre-Operative Blood Work in Otherwise Healthy Canines

Kayla Hargrove
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

The objective of this retrospective research study was to determine if performing pre-operative blood work in otherwise healthy dogs influences anesthetic decision making. These decisions include fluid rates, additional procedures, cancellation of surgery, management and monitoring techniques, avoidance of NSAIDs, change in current risk status, changes to client communication, and repetition of blood work. It was hypothesized that few surgeries would be cancelled based on abnormalities, but their effect on other anesthetic decisions would be greater. Cases were identified by the anesthesia records of 100 dogs that underwent elective orthopedic surgeries. Data collected from each case includes: name, age, weight, breed, diagnosis/problem, ASA status, reason for anesthesia, date of procedure, and abnormalities found in blood work. All cases were reviewed by 5 board certified veterinary anesthesiologists. Out of 100 dogs, 0% would have additional surgeries or procedures, 6% would have their procedure cancelled or postponed, 38% would have fluid therapy altered, 31% would have blood work

repeated, 9% would have changes made to monitoring while anesthetized, 50% would have management techniques altered, 12% would have further tests conducted, 10% would have their risk status changed, 42% would have changes in client communication, and 59% would have NSAIDs eliminated from treatment. Results were congruent with the hypothesis. A large number of patients had anesthetic decisions altered on the basis of pre-operative blood work. It is recommended that current blood work requirements remain in place in order to ensure best patient care.

Genetic Determination of Serum Growth Differentiation Factor 15 throughout Lifespan

Elizabeth Harris, CURO Research Assistant
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

The Centers for Disease Control and Prevention estimates that 117 million Americans have at least one chronic disease. Cardiovascular disease is the most prevalent chronic condition, especially among people ages 65 and older, causing 1 in every 4 deaths in the United States per year. As the American population steadily ages, it is critical to elucidate the mechanisms by which aging promotes cardiovascular disease. Serum concentrations of growth differentiation factor-15 (GDF15) increases with age and serves as a predictor of cardiovascular disease and all-cause mortality in humans. However, the effect of genetic background on GDF15 levels is undefined. Our hypothesis predicts that genetic background regulates the age-associated increase in circulating GDF15. To test this hypothesis, serum GDF15 levels will be measured in young, middle-aged, and old cohorts of two classical inbred strains: C57BL6/J (B6) and BALB/cByJ (BALB). If our hypothesis is correct, it will demonstrate that GDF15 concentrations and their changes due to aging are genetically-regulated. Success in this study will inform future studies to identify genes and alleles that regulate GDF15 concentrations and, therefore, cardiovascular disease risk in older populations.

Chief Executive Officers' Personality Characteristics and How These Characteristics Affect Marketing in Their Company

Samantha Harris, CURO Research Assistant
Dr. Sundar Bharadwaj, Marketing, Terry College of Business

Our study focuses on the relationship between Chief Executive Officers' (CEOs) narcissistic tendencies and marketing spending (advertising and promotions) undertaken by the companies they are part of. We start with analyzing how narcissistic the CEOs are based on prior scales developed in managerial research. This is done through two studies. The first one entails analyzing each CEO's picture in the annual report based on a number of characteristics, such as the size and positioning of the picture within the report and the presence or absence of other executives in it. The second study is an in-depth analysis of each CEO's "Letter to the Shareholders," investigating the ratio of single to plural personal pronouns. In terms of statistical analysis, we use a multivariate regression approach in order to study whether narcissism exhibited by the CEO is associated with an increased marketing spending, as our hypotheses suggest. We control for a number of different variables, such as firm size, CEO compensation orientation, CEO stock ownership, and CEO tenure at the firm. Overall, we aim to contribute towards a deeper understanding of the impact of chief executive officers' personality characteristics on marketing. Our predication is that if the CEOs are more narcissistic, then they tend to spend more on marketing, even if this is not in the best interest of the firm.

Investigating Resting State Oscillatory Dynamics Associated with Schizophrenia and High and Low Cognitive Control

Rachael Hart
Graduate Students: Anastasia Bobilev, William Oliver, Matthew Hudgens-Haney, Lauren Hayrynen, David Parker
Peter Buckley, MD, Dean, Medical College of Georgia, Georgia Regents University
Dr. Brett Clementz & Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Individuals with schizophrenia (SZ) have cognitive deficits that manifest in poor performance on tests of executive function compared to healthy persons. Levels of executive function are associated with performance on working memory capacity (WMC) tasks. Performance on these tasks varies greatly within healthy populations and, similarly to persons with schizophrenia, those with low WMC perform poorly compared to high WMC individuals. This study examines differences in resting state neural activity between persons with schizophrenia and healthy subjects with high and low WMC. In the current study, WMC was determined by a conglomerate score based on performance on computerized operation-, symmetry-, and reading tasks. Persons with schizophrenia, as well as healthy individuals with high and low WMC scores, completed a five-minute eyes-open resting state paradigm while 142 Sensor magnetoencephalography (MEG) data were collected. Time-frequency analysis of resting state activity demonstrated differences in activation between all groups (SZ, High WMC, and Low WMC) across frequency bands. The Low WMC group exhibited commonalities with both the High WMC and SZ groups. Notably, High WMC demonstrated regionalized power differences in the alpha frequency band (8-12 Hz) compared to both Low WMC and SZ groups. Future analyses will employ additional statistical tools to further elucidate differences in oscillatory dynamics across groups. Results from this study suggest that frequency-specific intrinsic activity may markedly contribute to differences in working memory capacity in both healthy persons and those with schizophrenia, while other features of intrinsic activity may be distinctly characteristic of schizophrenia.

***The Motion Picture Story Magazine*: Early Niche Markets, "Fan Communities," and Multi-Platform Transmedia Storytelling in the 20th Century**

Chelsea Harvey, CURO Research Assistant
Dr. James Hamilton, Grady College of Journalism & Mass Communication

This exploratory study seeks to explore how advertisers construct and encourage the creation of "fan communities" for particular products and industries, taking advantage of niche markets and consumer enthusiasm. It also examines the extent to which consumer communities were involved in professional content creation prior to the emergence of the Internet. My research mentor and I analyzed a random sample of nine issues from the 1911 and 1912 publications of one such film industry fan magazine entitled *The Motion Picture Story Magazine*, and placed relevant content, editorials, and advertisements into different categories of reader (or "user") involvement. Results identify "supplier" and "contributor" as the most frequent forms of user involvement by far. The study suggests that the early cinema fan communities organized and aggregated by fan magazines engaged in a form of multi-platform storytelling and the movie industry that went far beyond simply viewing movies. This study lends credence to the claim that convergent storytelling is a long-standing phenomenon, and not only a recent one made possible only via online or digital innovations in technology and media platforms. Furthermore, this study suggests how filmmakers and advertisers used early film fan magazines like *The Motion Picture Story Magazine* to create the consumer

communities that would best benefit them, introducing ways for audiences to interact with films across multiple platforms and in creative ways more than a century before the emergence of digital transmedia.

Effectiveness in Curing Existing Intramammary Infections and Preventing New Cases in Bred Holstein Heifers

Courtney Haviland, CURO Research Assistant
Dr. Stephen Nickerson, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Bacterial infections in the cow's udder result in mastitis, the chronic inflammation of developing milk-producing tissues. Protecting these tissues during the greatest development of the mammary gland (1st gestation) from pathogenic bacteria will guarantee maximum milk production. Nonlactating cow antibiotics are effective in curing infected mammary quarters and preventing new cases of mastitis in uninfected quarters. In addition, teat sealant products have proven effective in preventing new infections and in reducing the chances of contracting clinical mastitis at the time of calving. For this study, mammary secretions were collected from bred heifers prior to treatment and processed for bacteriology, differential leukocyte counts, and total white blood cell counts (WBC) to determine initial infection status. Four treatments (untreated control, nonlactating cow antibiotic, teat seal, and nonlactating cow antibiotic + teat seal) were administered to each of 23 heifers 30-60 days prior to expected calving date. Responses to treatment were monitored at 3 and 10 days postpartum. Significant treatment differences for cure rate, new intramammary infection rate, and WBC were determined with PROC GLM (SAS 9.3). Compared to the control, use of antibiotic and antibiotic + teat seal resulted in higher cure rates ($P<0.05$); no differences were observed among treatments for new intramammary infection rate. Compared to the control, use of antibiotics, teat seal, and antibiotic + teat seal resulted in lower WBC on day 3 postpartum ($P<0.05$). Results demonstrated that treatment with antibiotic, teat seal, or antibiotic + teat seal resulted in less mastitis and lower WBC after calving.

An Overexpression Screen to Determine How *Legionella pneumophila* Effector Protein LegC7 Disrupts Class C Tethering Complex Formation

Chetan Hebbale, CURO Research Assistant
Dr. Vincent Starai, Microbiology, Franklin College of Arts & Sciences

Legionella pneumophila is a Gram-negative bacterial species that causes a severe pneumonia known as Legionnaires' disease. During infection, *L. pneumophila* secretes nearly 300 effector proteins into host cells in order to evade lysosomal degradation by remodeling the host's membrane trafficking pathways. One of these effector proteins, LegC7, has been shown to be lethal upon expression in the budding yeast *Saccharomyces cerevisiae* by disrupting normal vesicle trafficking and vacuole morphology. It is hypothesized that LegC7's toxicity is dependent on an interaction with one or more endosomal genes due to its disruption of cargo localization that transits through endosomes to the vacuole. I examine the relationship between LegC7 and the Class C Tethering Complexes – CORVET (class C Core vacuole/endosome tethering) and HOPS (homotypic fusion and vacuole protein sorting). The CORVET and HOPS complexes have been identified as a set of universally conserved proteins which are essential for early-to-late endosome transition and endo-lysosomal trafficking pathways by tethering membranes, proof-reading SNARE assembly to drive membrane fusion, and interacting with Rab GTPases. Using homologous recombination, 4 different genes will be overexpressed in yeast: *vps8, vps16, vps21* and *vps41*. By assaying whether

overexpression of CORVET/HOPS subunits can suppress LegC7 toxicity, we can determine which specific subunit(s) LegC7 may have binding interactions with.

Superparasitism as a Strategy to Overcome Resistance in an Aphid-Parasitoid Interaction

Alexander Hedaya, CURO Research Assistant
Dr. Kerry Oliver, Entomology, College of Agricultural & Environmental Sciences

Insects are attacked by many natural enemies, promoting selection for resistant phenotypes in natural populations. Pea aphids, *Acyrthosiphon pisum*, for example, maintain significant variation in resistance to a common parasitoid wasp, *Aphidius ervi*, which may be achieved through intrinsic, aphid-encoded means or infection with the protective bacterial endosymbiont *Hamiltonella defensa*. Both resistance types are found in populations of alfalfa-infesting pea aphids, but it remains unclear whether there are conditional differences between aphid-encoded or symbiont-encoded resistance. It was demonstrated that *A. ervi* can detect and selectively superparasitize (two or more oviposition events) aphids with *Hamiltonella*-based protection to overcome their resistance, but is not known if wasps can overcome aphid-encoded resistance via superparasitism. Recently, we found that another pea aphid parasitoid, *Praon pequodorum*, was not susceptible to either aphid- or symbiont-encoded resistance. Aphids maintaining both types of resistance may, however, benefit when facing this parasitoid. In this study we aim to answer: (1) can *A. ervi* overcome aphid-encoded resistance by superparasitizing aphid hosts? (2) are aphids harboring both aphid-encoded and symbiont-based resistance protected against *P. pequodorum*? The answers to these questions will aid our understanding of the basic biology of aphid-symbiont-parasitoid interactions, which is important for the successful implementation of biological control.

Women's Participation in Non-State Militaries Founded on a Secular or Religious Ideology: The Case of Chechnya and Dagestan, Hamas, The PKK

Sarah Hedges
Dr. Lihi Ben Shitrit, International Affairs, School of Public & International Affairs

Women's involvement in militaries has traditionally been limited to positions of support, not engaging in combat or participating in combat-oriented roles. Over time, especially within the last two decades, external pressures and internal demands have led different militaries to incorporate women more heavily. The purpose of this research paper is to examine the roles of women in non-state militaries or armed groups operating from a primarily secular or religious ideology. Three groups will be studied in depth; this includes the major Islamist militant groups in Chechnya and Dagestan, Hamas, and the Kurdistan Workers Party (PKK) fighting in Turkish Kurdistan. The primary question addressed is whether women's participation is greater in armed groups with a secular ideology or armed groups of a religions ideology. This paper reviews multiple sources that offer extensive research on specific militant groups and their involvement in regional conflicts, recruitment measures, the involvement of women in these organizations, and the response of media and the public to these groups' activities. These sources include academic journals, interviews with family members of female militants, and regional newspapers. The results indicate that non-state militaries with a secular foundation provide more opportunities for women in combat-oriented positions; direct military engagement is often limited, but when women do participate in combat it is primarily through conventional means. Conversely,

religious non-state militaries largely use women in unconventional warfare, meaning suicide bombings. While these non-state militaries varied in the positions available to female members, the motivations that women had for participating in these groups were often similar.

Something Old, Something New? A Postfeminist Analysis of the Myth of the "Big Day"

Kristin Henry
Dr. Belinda Stillion Southard, Communication Studies, Franklin College of Arts & Sciences

In this essay, I perform an analysis of the rhetoric that idealizes the wedding as "the big day" for women, rooted in a history of many traditions of marriage and gender roles that now emerge as sources of feminine empowerment. This analysis focuses on two of the most prominent wedding planning websites in the United States, TheKnot.com and WeddingWire.com. The rhetoric of wedding advertising reinforces standards of successful upper-class, white women and continues to treat femininity as the emblem of female competence, inhibiting diverse images of women through false empowerment. Broadly, this study aims to contribute to studies of the tensions between feminism and femininity in postfeminist media outlets.

The Role of Kinesins in Meiotic Spindle Development in Zea Mays

Amy Hodges, CURO Research Assistant
Dr. Kelly Dawe, Genetics, Franklin College of Arts & Sciences

Cell division is a process in which chromosomes are equally divided amongst two daughter cells. A key component of the cell division process is a family of proteins called kinesins. These molecular motors are responsible for pulling chromosomes apart and collecting them in the newly formed cells. Maize (*Zea mays*) has been used for nearly a century as a model for cytogenetic studies. Two specific kinesins of the maize genome, Kinesin6 (ZM-Kin6) and Kinesin11 (ZM-Kin11), are very similar in structure, though they are expressed in different tissues of the plant. ZM-Kin6 is responsible for properly collecting chromosomes during cell division leading to meiocyte (pollen) formation; mutations in ZM-Kin6 cause errors in cell division leading to multi-nucleate daughter cells. Due to the high homology between the two proteins, we predict that the deleterious effects caused by mutations in ZM-Kin6 can be overcome by the over-expression of ZM-Kin11. A maize line in which ZM-Kin11 is highly expressed was crossed with a ZM-Kin6 mutant line. qRT-PCR will be used to confirm the over-expression of ZM-Kin11 in maize meiocytes, and the spindle morphology of these mutant meiocytes will be visualized using immunolocalization. Because kinesins play such a vital role in cell division, learning more about them will provide more information about this complex process at the core of biology.

Investigating Heat Treatment of Serum and Plasma Samples as a Means to Improve the Detection Sensitivity of Heartworm Diagnosis in Dogs

Katherine Hogan
Dr. Ray Kaplan, Infectious Diseases, College of Veterinary Medicine

Dirofilaria immitis, the canine heartworm, can cause serious and sometimes life-threatening pulmonary and vascular disease in dogs. Diagnosis of heartworm is performed by detecting the presence of antigens secreted by female heartworms' reproductive tracts in the blood of dogs, using either Enzyme Linked Immunosorbent Assay (ELISA) or immunochromatography. False negative results may sometimes occur, resulting in heartworm positive dogs being untreated. False negatives may arise when the antigen is bound in an antibody complex, rendering it

unable to bind to the capture antibody in the test. Recently it was discovered that heat treatment can break up the antibody-antigen complex, thus freeing the antigen and allowing its detection. Heat treatment might therefore be able to eliminate false negative results, thereby improving the accuracy of heartworm diagnosis. In currently published work, serum and plasma were used interchangeably without considering impact on results. To test whether use of serum vs. plasma might impact results following heat treatment, serum and plasma from five dogs of infected, uninfected, and unknown *D. immitis* status were collected and tested. Serum, serum-heated, plasma, and plasma-heated samples from each dog were tested using ELISA. Four dogs yielded results consistent with their known infection status for all sample types. However, the fifth dog yielded positive results for plasma and plasma-heated, but negative results for serum and serum-heated. These results are particularly interesting since this dog had been experimentally infected with heartworms but had not been positive on previous tests. Further research is ongoing to examine this discrepancy in results.

3D Printing the Trefoil Knot and its Pages

Frederick Hohman, CURO Research Assistant, CURO Graduation Distinction
Dr. David Gay, Mathematics, Franklin College of Arts & Sciences

Observing the physical geometry of shapes that are particularly tough to visualize in topology has been made easier by visualization techniques such as 3D printing. The work presented here describes the creation of a 3D printed puzzle of the open-book decomposition of the trefoil knot. The open-book decomposition of the trefoil knot describes an object where the trefoil knot is equivalent to the spine of the book. Typical pages of an ordinary book are rectangular and are joined from one edge to the spine; when the equivalent pages of a book are added to the trefoil knot they become surfaces winding inside and outside of the knot. After working through the mathematical theory behind the creation of the puzzle, imploring various concepts such as stereographic projection, we created and printed primitive models, such as the trefoil knot alone, the trefoil knot plus one page, and the trefoil knot plus three pages spaced equiradially. Using Mathematica, a symbolic mathematics computer programming environment, high resolution 3D models of the knot and pages were created. With the aid of other modeling software, namely Blender, the inclusion of twelve pages was made possible by digitally cutting each page in half. From here, holes were removed from the 3D mesh of each half-page to provide space for small magnets. Once printed, magnets are glued into the holes to allow each page and piece of the knot to join together to construct the desired puzzle. The puzzle can be taken apart and rebuilt in various ways that demonstrate properties of the trefoil knot and the accompanying surfaces. The primitive models have been published on Thingiverse.com: the official website dedicated to sharing user-created digital design files for 3D printing, and have been viewed and downloaded thousands of times. Current results have also been posted on the well-known 3D printing blog MakerHome.com, and Wolfram Community, and were written about by 3DPrint.com and other maker websites.

Cas Protein Function in Adaptation of *Streptococcus thermophilus* Type II-A CRISPR-Cas System

Erin Hollander, Foundation Fellow, CURO Research Assistant
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

For bacteria and archaea, constant attack by invading genetic elements requires the evolution of novel defense systems. The

recently discovered CRISPR-Cas system mediates phage resistance through a three-step process of (1) adaptation, involving integration of DNA sequences known as spacers from nucleic acid invaders into CRISPR loci; (2) expression, the transcription of small crRNAs from the loci; and (3) interference, in which crRNAs guide effector complexes to recognize and cleave invaders. Cas genes in the CRISPR locus encode proteins involved in the three stages. The Type II-A CRISPR system in *Streptococcus thermophilus*, a key bacterium used in the dairy industry, has one of the simplest systems with only four proteins. This project focused on delineating the function of these four Cas proteins through the functional testing of mutant strains of *S. thermophilus* with deletions of Cas1, Cas2, Csn2, or Cas9. Phage infection of Cas1 and Cas9 deletion strains resulted in loss of function in spacer incorporation, whereas transformation with and without matching spacers retained function in the Cas1 deletion strain but lost function in the Cas9 deletion. These results indicate Cas1 is involved primarily in adaptation, while Cas9 is involved in defense and possibly adaptation. Additionally, functional testing of a Cas1, Cas2, and Csn2 deletion mutant determined all three proteins were necessary for successful adaptation in *S. thermophilus*. Greater understanding of the Cas genes will give insight into the underlying processes of the CRISPR-Cas system as a whole.

Fighting Pain with Pills: Overprescribing and the Opioid Addiction Epidemic

Erin Hollander, Foundation Fellow, CURO Research Assistant
Dr. Amanda Abraham, Health Policy & Management, College of Public Health

Drug overdose deaths increased 117% between 1999 and 2012. Almost three-fourths of all deaths caused by prescription drug overdoses are caused by prescription painkillers, or opioids (CDC.gov, 2014). Increased opioid overdoses are paralleled by a 450% increase in prescriptions from 2007 to 1991 (HHS.gov, 2008). Overprescribing by physicians enables non-medical use of opioids, either by the prescription holder or more commonly by a friend or family member. Current policy centers on the Controlled Substances Act of 1970, which created a framework of "Schedules" for increased regulation of more abusable substances along with the Drug Enforcement Administration for enforcement ("State-by-State Opioid Prescribing Policies," n.d.). However, the rapidly increasing overdose rate and high societal cost indicate these policies are failing. To combat overprescribing, three policy alternatives were proposed and analyzed along with the status quo: (1) mandate usage of Prescription Drug Monitoring Programs (PDMPs), (2) place a hard time limit on opioid prescription, and (3) crack down on pill mills. After extensive analysis, the first alternative was chosen as the most effective, feasible, and cost-beneficial. All but one state currently has the legislation for or a working PDMP, making implementation smooth. Success stories from states which have independently mandated usage will aid in convincing states as well as doctors that PDMPs are worth the cost and effort. A date would be set by which all prescribers must be enrolled in the program, then after a trial learning period weekly logs of patient and prescription information would be required.

Abundancy and Multiply Perfect Numbers

Jackson Hopper, CURO Research Assistant
Dr. Paul Pollack, Mathematics, Franklin College of Arts & Sciences

Two of the oldest questions left in mathematics are related to perfect numbers: whether there is a finite number of them, and whether any of them are odd. We approach these questions by studying arithmetical

property of integers called *abundancy*, which is the sum of an integer's divisors divided by the integer. A perfect number is a number whose abundancy is two. The abundancy of an integer can be found with a simple formula, given its prime factors, but finding all of the integers with a given abundancy is more difficult. An algorithm called solveBA, available on OEIS, quickly returns all integers less than an upper bound whose abundancies are equal to a given rational number, but the algorithm requires a complete list of multiply perfect numbers up to that bound. It is widely believed that all multiply perfect numbers up to 10^{100} are known, but to our knowledge there is no systematic proof any such list is complete. We begin by generating a complete list up to 10^{100} using a modification of solveBA, then use this list to determine which rational number are the abundancy of integers in that range. Additionally, we use recursive criteria to determine many rational numbers, known as abundancy outlaws, which cannot be the abundancy of any integer. We find that available lists of multiply perfect numbers are complete, but determine the abundancy status of more rational numbers than previously known.

Measuring Willingness to Pay for Sea Level Rise in Coastal Communities of Georgia

Kirstie Hostetter, Foundation Fellow, CURO Research Assistant
Dr. Craig Landry, Agricultural & Applied Economics, College of Agricultural & Environmental Sciences

Forces associated with climate change have caused sea levels to rise at an unprecedented rate with much uncertainty about what the exact magnitude of the rising oceans will be. This makes low-lying coastal areas increasingly vulnerable to flooding and infrastructure damages that put both property and people at risk. Currently, FEMA has a program in place called the Community Rating System that offers reductions on flood insurance premiums in proportion to the amount of mitigation and resiliency measures a community enacts to protect themselves against rising sea levels. Our research uses a survey distributed throughout different coastal counties in Georgia to determine whether or not people are more willing to pay for sea level rise adaptation measures if they receive a message of empowerment as opposed to simply facts about how sea level rise affects coastal communities. We do this by sending people to one of two websites with the same formatting but different uses of rhetoric, and then asking similar questions about their willingness to pay for various levels of adaptation measures. This research question comes from psychology literature that indicates people are more likely to take action against a large threat if they believe that their efforts will actually influence the outcome. We hope that our results will contribute to the effort to enroll more communities in the Community Rating System and encourage a larger demand for sea level rise adaptation measures.

Apicoplast Function in *Plasmodium falciparum*

Nathan Howell, CURO Research Assistant
Dr. Vasant Muralidharan, Cellular Biology, Franklin College of Arts & Sciences

Malaria causes nearly 600,000 deaths each year, and it is a mosquito-borne disease caused by *Plasmodium* parasites. Ongoing development of new anti-malarial drugs is very important because of wide spread drug resistance. In fact, the parasite is already resistant to the frontline drug artemisinin. A key characteristic to look for in potential drug targeting is specificity, particularly when treating humans. The deadly malaria parasite, *P. falciparum,* has a unique organelle known as the apicoplast. The apicoplast is required for the synthesis of isopentyl pyrophosphate (IPP), an essential metabolite that is required for parasite survival, and parasites grown in

the presence of IPP can lose their apicoplast. IPP is the metabolic precursor required for synthesis of ubiquinones, polyprenols, and dolichols. We set out to identify which of these metabolic pathways utilizing IPP are important to the survival of the parasite. It was previously known that the downstream synthesis of ubiquinone is essential, and its requirement for parasite survival can be bypassed through the expression of a yeast enzyme. We discovered that exogenous supplementation with dolichols and polyprenols was unable to rescue parasite growth. We are further testing new drugs that can inhibit the IPP synthesis pathway. These results will eventually lead to the development of new anti-malarial drugs through the identification of ideal drug targets.

Ankle Joint Laxity in Those with Chronic Ankle Instability

Katherine Hsieh, CURO Research Assistant, CURO Graduation Distinction
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Ankle sprains are the most prevalent sports-related injury, with approximately thirty percent of those injured developing Chronic Ankle Instability (CAI). Ankle ligamentous laxity has been demonstrated in those with CAI. Mechanical laxity may be used to help evaluate effectiveness of treatments and outcomes in those with CAI. The purpose of this study was to determine if differences exist in anterior talofibular ligament displacement between individuals with and without CAI. Twenty-one participants (6 CAI, 15 controls, age=22.5 ± 2.2 yrs, height=169.6 ± 9.6 cm, mass=68.5 ± 13.5 kg) completed the Cumberland Ankle Instability Tool (CAIT) and were classified as CAI if they scored ≤24 and as controls if they scored ≥28. Anterior displacement was measured via an instrumented ankle arthrometer. A 150 Newton force was applied to the ankle joint and the amount of anterior displacement was obtained. Three trials were performed on each limb and the last two trials were averaged. Independent samples t-tests were performed to assess for group differences. No statistically significant differences were found between the CAI (16.7 ± 3.2 mm) and control groups (16.2 ± 2.3 mm, p=0.384). Anterior talofibular laxity does not appear in those with CAI. Calcaneofibular laxity and functional deficits may need to be examined in conjunction with anterior talofibular laxity to diagnose CAI. Understanding ankle ligamentous laxity may help provide clinicians with better rehabilitation strategies for those with CAI.

Design of Novel Reporters for Monitoring CaaX Proteolysis

Jesse Hu, CURO Research Assistant
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The CaaX motif is a crucial C-terminal protein motif consisting of a cysteine residue, two aliphatic residues, and one variable residue. The clinical applications of CaaX biology are well documented in the literature. Members of the Ras family of GTPases all contain a CaaX motif and help mediate signal transduction events pertaining to cell growth, differentiation, and survival. Mutations leading to permanent activation of human Ras are found in 25% of all types of cancer, 60% of solid tumors, and up to 90% of pancreatic cancers. The CaaX motif directs addition of an isoprenyl group to the cysteine residue. Canonically, this event is followed by proteolysis between the Cysteine and first aliphatic residue by the Ste24p or Rce1p CaaX protease, and carboxylmethylation by Ste14p. These modifications yield the mature isoprenylated protein. This research seeks to better understand the modifications associated with CaaX motifs. We propose a new "shunt" pathway that forgoes the steps of proteolysis and carboxylmethylation for certain proteins such as Ydj1p. Using the yeast *Saccharomyces*

cerevisiae as a model, we have designed approaches and are building plasmid to be used for monitoring the CaaX proteolysis of Ydj1p, Chs4p, and Nap1p. These plasmids will be used for genetic, biochemical, and biophysical studies. For example, we will evaluate the impact of changing the Ydj1p CaaX motif on the Ydj1p-related phenotypes of temperature sensitivity and mitochondrial function. Similar studies will investigate the impact of changing the Chs4p CaaX motif on chitin deposition through calcofluor binding studies. We will also describe efforts toward purifying the aforementioned proteins for use in mass-spectroscopy studies aimed at identifying the specific modifications occurring to the CaaX motif.

Increasing Adoption of an Internet Standard: Internet Protocol Version 6

Heather Huynh, Ramsey Scholar
Dr. Brad Barnes, Computer Science, Franklin College of Arts & Sciences

Internet Protocol version 6, or IPv6, determines how information is sent over the Internet. Even with the benefits of migrating to Internet Protocol version 6, or IPv6, the United States is still lacking in public adoption of IPv6 as a standard for internet protocols due to the public's reliance on IPv6's predecessor: IPv4. The U.S. government has acknowledged the issue, but their course of action is to promote IPv6 as a standard internally, which means only adopting it within the federal government agencies. This policy isn't detrimental, but it doesn't focus on public adoption of IPv6, which is the most important aspect of IPv6 adoption. Three policy alternatives were evaluated in addition to the status quo: incentives for ISPs to adopt IPv6, incentives for content creators to adopt IPv6, and an extension of the status quo to a small group of businesses. The best way to solve this issue is to get the government to incentivize ISPs to adopt IPv6. This is both the cheapest policy to implement and the policy that will result in the greatest number of people gaining access to IPv6 in the shortest time possible. While the policy has a good chance of accelerating IPv6 adoption, there are still issues like where to get the money to fund this policy as well as how cooperative ISPs will be when implementing this policy; however, the first step to implementing this policy is getting the money to incentivize the ISPs.

Upregulation of Transferrin Receptor in *Trypanosoma brucei*

Stacey Ikebudu, CURO Research Assistant
Dr. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts & Sciences

The bloodstream form of *Trypanosoma brucei*, causative agent of human sleeping sickness, internalizes host transferrin as its primary source for iron through receptor-mediated endocytosis. Uptake of host transferrin is dependent on a heterodimeric transferrin receptor encoded by two genes, ESAG6 and ESAG7, which has no sequence similarity to the mammalian transferrin receptor. Iron is needed by *T. brucei* for viability, making transferrin a crucial growth factor. Levels in both transferrin receptor and transferrin uptake can be regulated in the trypanosome by the iron chelator deferoxamine, thus suggesting that the expression of transferrin receptor may perhaps be regulated by iron availability. This hypothesis was tested by first incubating trypanosomes over a 48-hour period with several concentrations of deferoxamine in order to arrest cell proliferation. Flow cytometry and Western blot were used to quantify transferrin binding to trypanosome transferrin receptors. The ability for *T. brucei* to overexpress its transferrin receptor in iron-limiting conditions may contribute to the ability of the parasite to thrive in different mammalian hosts. Transferrin uptake, due to its importance, may be targeted in anti-trypanosome drug discovery efforts.

Abstracts

The Strategy of the Early British Feminist Movement: Emily Davies and Feminist Networks, 1865-1905

Caroline Jackson, CURO Research Assistant
Dr. Steven Soper, History, Franklin College of Arts & Sciences

The significance of networks among participants in the women's movement of the latter half of the nineteenth century has been largely unexplored. This paper will argue that networks were widespread between women active in a variety of different feminist campaigns, and that they were of vital importance in their successes. Networks were important because they enabled the leaders of feminist operations to acquire powerful contacts and large bases of support. Though there was a considerable variety of views on the appropriate goals of the women's movement, networks helped to create a galvanized generation of women pushing for a more important role in society. Consequently, issues pursued by different organizations – such as greater education and professional opportunity – became linked. There was strategic purpose to the creation of networks: credentialist tactics – appeals to equal rights for the sexes – were often unsuccessful in breaking down male power structures, but they helped to accrue a web of interested parties. The power of combination then aided in legalistic struggles over the creation of female-oriented or female-only institutions. This paper will use the efforts of Emily Davies and her circle in the field of higher education as a case study in feminist networks; it will then gesture towards the importance of these networks in the women's movement as a whole.

Embedded Bi-Directional FBG Curvature Sensor

Aneek James, CURO Research Assistant
Dr. Mable Fok, College of Engineering

The research involves designing and investigating the properties of a Fiber Bragg Grating (FBG) sensor embedded in a silicone material for bi-directional curvature sensing. An FBG optical cable spectral response is affected by the FBG's environment, and thus can be used to sense its surroundings. Unfortunately, FBG sensors are fragile, and existing techniques usually involve the use of a bulky non-flexible fixture, making the FBG based curvature less attractive. Our research involves developing an FBG sensor that is embedded in a silicone material, making the sensor flexible and robust. To investigate this, we will compare the responses of five identical FBG sensors embedded in the material, all at different positions. We then will record the sensors' responses to bending by placing them on seven substrates of varying curvatures (30° to 360°). Through plotting the wavelength shifts versus the curvatures, we can examine the slopes of the curves and see how the experimental sensitivity trend compares to the theoretical model we constructed using the concepts of pure bending and the Bragg wavelength condition. The Bragg wavelength's relationship to curvature is highly linear over a large range of values, and its sensitivity seems related to the sensor's position in the silicone material as well as the bending direction. Our preliminary study shows a very promising breakthrough in bi-directional curvature sensing and this novel FBG sensor has potential uses in civil engineering for structural health monitoring, shape sensing, and biomedical engineering.

The Genetic Basis of Leaf Phenolic Content in Cultivated Sunflowers

Amna Jamshad
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

This research works to understand the genetic basis of variation in leaf phenolics in cultivated sunflower (*Helianthus annuus*).

Phenolics are a diverse group of secondary metabolites, many of which act as effective chemical defenses against herbivores and pathogens. From an agricultural perspective, understanding the genetic basis of leaf phenolics will provide plant breeders with resources to develop more pest and disease resistant crop varieties. This research employed a 288-line association mapping panel of cultivated sunflowers that captures ~90% of the genetic diversity across all crop sunflower varieties. After extracting and preparing the samples, the Folin-Ciocalteu assay was used to quantify total leaf phenolic content, and variation in total phenolics was mapped to the sunflower genome using published genotype data for the sunflower association mapping population. This data was used to evaluate hypotheses about the genetic structure underlying the variation in these traits, including (1) that phenolic content will be associated with many genomic regions of small effect, rather than a few regions of large effect, and (2) that regions associated with total phenolic content will cluster due to shared biosynthetic pathways.

The Predictive Power of Self-Reported Computer Usage on Processing Speed and Reasoning Scores

Kharine Jean
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

This study examined computer usage experience in older adults toward predicting processing speed and reasoning scores measured by computerized neuropsychological testing, the CNS-Vital Signs (CNSVS). The participants' ages ranged from 64 to 99 with 28 males and 42 females. Participants were grouped based on their self-reported computer usage: frequent and non-frequent computer users. Processing speed was determined by a Symbol Digit Coding task requiring participants to pair symbols with a corresponding number. Reasoning was determined by a Non-Verbal Reasoning test requiring identification of missing objects based on a pattern within a time frame. Both tasks required participants to use a keypad. An independent samples t-test found no significant difference in reasoning scores between frequent (M=2.19, SD=4.08) and non-frequent self-reported computer experience (M=1.22, SD=4.54; t(68)=.845, p=.401). There was a significant difference in processing speed scores between those with frequent (M=40.73, SD=9.74) and non-frequent computer experience (M=32.39, SD=12.17; t(68) = 2.93, p=.005). Hierarchical multiple regression revealed a near-significant effect of previous computer experience relating to processing speed (2.5% variance accounted, p=.069) when controlling for age and clinical dementia rating. Although findings found no difference in reasoning score means between frequent and non-frequent computer users, it suggests that prior computer familiarity may have some power in predicting processing scores. Findings suggest a need to control for previous experience when giving computer-based tasks to older adults that require more than a basic level of computer-participant interaction.

Tissue Factor-Altered Mice Show Upregulated Pro-Inflammatory Cytokine Gene Expression in Experimental Cerebral Malaria

Tiffany Jenkinson
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Cerebral malaria (CM) is a devastating neurological condition caused by sequestration of *Plasmodium falciparum*-infected erythrocytes in the brain microvasculature. The disease has a high mortality rate and mainly affects children under 5 years of age. Previous studies have shown a pro-coagulant and pro-inflammatory state in patients with CM. As inflammation and coagulation are known to interact, the effect of altered TF

expression on the production of pro-inflammatory cytokines was investigated in a murine model of CM. Tissue factor (TF), a principle initiator of the coagulation cascade, is dramatically upregulated in areas of excessive fibrin deposition, a hallmark of CM brain pathology. 6-8 week old transgenic female mice were infected with 10^6 *P. berghei* ANKA, a CM-inducing murine malaria species. Mice with a null mutation (1% expression), those heterozygous (50% expression) for mouse TF, and a TNF knockout strain were used for these experiments. Weight, hematocrit, and parasitemia were taken daily, and the mice were serially sacrificed between days 4 and 6 post-infection. Brains were harvested and homogenized, and mRNA expression of several critical pro-inflammatory cytokines was assessed by qPCR, including TNF-a, IL-6, IL-1b, and MCP-1. We suspect that in response to the localized sequestration of infected erythrocytes in the microvascular region of the brain, levels of these inflammatory mediators will be significantly increased. The pro-inflammatory response may elicit a chain of events that lead to increased coagulation and fibrin deposition in the brains of these mice, which would contribute to the breakdown of the blood-brain barrier.

Biosynthesis of Base J

Melissa Jennings, CURO Honors Scholar
Dr. Robert Sabatini, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanasoma brucei (*T. brucei*) is a parasitic protozoa that causes African Trypanasomiasis, aka Sleeping Sickness, in humans. *T. brucei* is part of a larger class called kinetoplastids, which are responsible for other deadly human diseases, such as Leishmaniasis and Chagas' disease, that are found all over the world. These kinetoplastids contain a modified T nucleotide, called base J, which regulates RNA polymerase II transcription and gene expression. Base J is not synthesized in the host, but it is essential to the parasite. By understanding base J synthesis and function, researchers may one day be able to develop a specific treatment that will manipulate base J and kill these protozoa. The initial step of J synthesis is catalyzed by two thymidine hydroxylases, JBP1 and JBP2, which add a hydroxyl group to thymine. The second step of base J biosynthesis involves the addition of a glucose to the hydroxylated thymidine by a glucosyl transferase (JGT). What is unknown about this mechanism is how the enzymes recognize specific regions of the parasite genome and modify the thymidine base. The hypothesis is that J biosynthetic enzymes are part of a larger complex that regulate recruitment to specific chromatin regions of the genome. To address this we will identify proteins that interact with each of the enzymes *in vivo* using two approaches: tandem affinity purification and BioID. We will present current data resulting from recombinant parasite cell lines and the search for JBP associated proteins involved in J biosynthesis.

Social Dynamics Affect Learning of a Technical Skill in Infant Capuchins

Thomas Johnston, Ramsey Scholar, CURO Summer Fellow
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

In the wild there are instances of nonhuman animals learning skills socially and passing these skills on as traditions. I am interested in the factors that promote or inhibit social learning in young capuchins. In a previous study, captive capuchin monkeys, *Sapajus* spp. developed a technical skill (solving a mechanical apparatus for juice reward) and passed it on as a tradition. The data were collected in twelve 30-minute sessions of video with each of four groups of tufted capuchin monkeys. Because proximity to the

device increases the chances of an infant observing a solution, I examined several factors predicted to affect proximity and in turn affect the time (t1) of an infant's 2nd solution (criterion for mastery). The monkeys' presence near the apparatus and interactions with the vending device were coded using one-zero sampling in ten-second intervals. I first created social network matrices to visualize relationships among members of the group. Second, I examined the factors (age, sex, presence of mother, and/or social status) that affect the frequencies of proximity and other factors related to solving. Third, I fitted a linear model for solutions over nine sessions of one group. Infants appear to interact with the apparatus more often than adults, and nearly all infants achieved mastery. Maternal presence increased infant interaction with the device. Higher status males had higher proximity counts but not more solutions. Infants' solutions increased linearly with time. These findings reveal how social dynamics could affect the learning of a technical skill in infant capuchins.

PCR Detection of SRY Gene of Male Dog Mesenchymal Stem Cells in Female Dog Brains with Acute Ischemic Stroke

Susan Jones, Foundation Fellow
Dr. Elizabeth Howerth, Pathology, College of Veterinary Medicine

Intra-carotid-delivered mesenchymal stem cells (MSCs) may improve functional neurological outcomes after acute ischemic stroke (AIS). However, a large animal model is essential before beginning human clinical trials for patients with AIS. This study uses a dog stroke model in which female dogs with experimentally induced AIS receive male-derived MSCs via intra-carotid injection. It is hypothesized that the MSCs will successfully move to the site of infarction and participate in repair of damaged tissue. The objective of the present study is to target the Y chromosome in order to track the migration of the male-dog derived MSCs to various locations by using PCR. To detect the MSCs, techniques were developed or modified from those in the literature to amplify the SRY gene on the Y chromosome by PCR. These techniques were tested and optimized using male dog bone marrow. Two PCR techniques, an original semi-nested technique and one modified from a previously described technique, were then tested using fresh brain samples from female dogs with experimentally induced AIS that were subsequently injected with male MSCs on the side of the stroke. Both techniques were effective at detecting the Y chromosome in the brain samples and are suitable for tracking male-derived MSCs in this dog model of stroke. The next step of this study will be to modify these techniques for use in paraffin embedded samples using a laser capture technique to specifically identify cells containing the Y chromosome in the area of the stroke.

Regional Sourcing of Obsidian Artifacts through Chemical Analysis (pXRF): A Case Study in Western Canada

Travis Jones
Dr. Jeff Speakman, Director, Center for Applied Isotope Studies

In January of 2015, researchers from the Royal Alberta Museum, Canada, and the University of Georgia's Center for Applied Isotope Studies collaborated on what is arguably the largest chemical analysis of archaeological obsidian via portable X-Ray Fluorescence (pXRF) to date in Western Canada. This technique has been successfully implemented in places such as the Mediterranean, Alaska, and the American Southwest. One region of the world, however, rich with prehistoric artifacts made from obsidian, which has lacked any large scale analysis is Western Canada.
The analyzed sample set consisted of approximately 750 artifacts found in various archaeological contexts throughout Alberta.

Comparing trace element concentrations generated through this analysis with those of known geologic sources provides insight into obsidian procurement and use by prehistoric humans in the region. Preliminary data demonstrate that most of the samples' geologic origins are from known sources in the northwestern United States (primarily Idaho), British Columbia, and Alaska. This study is a first step toward expanding our understanding of human utilization of this historically important natural resource in Western Canada.

Who Saved Thad Cochran?: Racial Politics and Voter Mobilization in a Deep South Runoff

Zachary Jones, CURO Research Assistant, CURO Graduation Distinction
Dr. Charles Bullock, Political Science, School of Public & International Affairs

The June 3, 2014 Mississippi Republican Senate Primary saw State Senator Chris McDaniel defeat 40-year incumbent Senator Thad Cochran with 49.5% of the vote to Cochran's 49.0%. Because neither candidate received a majority, the two were forced into a runoff election three weeks later on June 24. Defying expectations, Cochran defeated the Tea Party-backed McDaniel to secure the Republican nomination. Many claimed that Cochran's unlikely victory was the result of his campaign's appeals to traditionally Democratic African-American voters to "cross over" and vote for Cochran in the Republican runoff. This research investigates those claims, as well as the potential impact of African-American voters on the outcome of the runoff election. Simple linear regression and Pearson-R correlation statistics suggest the possibility of African-American influence on the runoff. A closer analysis using ecological inference provides conclusive evidence that black voters in Hinds County were essential to Cochran's victory. This research also draws upon relevant literature, news articles, and historical data to provide perspective on runoff elections, turnout, and racial voting patterns in the Deep South.

Structural and Cultural Factors Influencing HIV Testing and Risky Sexual Behaviors in Young Liberian Women

Taylor Jordan, CURO Research Assistant
Dr. Tamora Callands, Health Promotion & Behavior, College of Public Health

The civil war in Liberia from 1999-2003 destroyed the nation's political and social infrastructure. The purpose of this study was to examine the structural and cultural factors that influence HIV testing and sexual health outcomes among young Liberian women in order to develop effective and culturally sensitive interventions. Five focus groups with 49 women and 16 key informant interviews were conducted. This qualitative data provided insight into the contexts surrounding gender-based violence, mental health, adolescent pregnancy, and HIV risk sexual behaviors among young Liberian women. The interviews reveal poor education, poverty, and mistrust of the Liberian healthcare system influence HIV testing and sexual health outcomes. Findings also suggest that women's increasing role as the primary breadwinners for their families serves as a major driver of lack of HIV testing and sexual health outcomes.

Role of RGS10 in Regulating Neuroinflammation in Microglia

Mugdha Joshi, CURO Summer Fellow, CURO Research Assistant
Dr. Shelley Hooks, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Microglia are the resident immune cells of the central nervous system. Dysregulation of their inflammatory pathways causes chronic neuroinflammation, which is implicated as a cause for neurodegenerative diseases such as

Multiple Sclerosis, Parkinson's, and Alzheimer's, as well as neuropathic pain. Regulator of G-Protein Signaling (RGS) 10 has emerged as an important suppressor of the microglial inflammatory response. Studies have shown that RGS10 exerts a neuroprotective effect by regulating the NF-κB signaling pathway. The NF- κB signaling pathway is also activated by lipopolysaccharide (LPS), a component of bacterial cell walls and a potent activator of the microglial inflammatory response. LPS binds to Toll-like Receptor 4 (TLR4), which is not a G-protein coupled receptor. Even so, its effect seems to be suppressed by the presence of RGS10. To explain this paradox, we hypothesize that a secondary G-protein coupled receptor (GPCR) regulated by RGS10 intersects with the TLR4 pathway and facilitates LPS induced production of inflammatory cytokines. Through methods of cell culture, transient transfection with siRNA, nuclear fractionation, western blotting, and qualitative real time PCR, this study aims to demonstrate the existence of such a facilitative GPCR and investigates GPR84 as a candidate for this receptor. While results do support the existence of a facilitative GPCR regulated by RGS10, they suggest that GPR84 is not the identity of this receptor.

Integrating of Human Neural Progenitor Cells into a Developing Chicken Embryo for a Toxicology Model

Piyush Joshi, CURO Research Assistant, CURO Graduation Distinction
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

The goal of this project is to establish a developmental toxicology model system, which can be used in the field of toxicology and regenerative medicine. Human neural progenitor stem cells (hNPs) will be injected into the developing chicken embryo and multimodally tracked with MRI and fluorescence microscopy. To accomplish this, hNPs will be labeled with iron nanoparticle MRI contrast agents and injected into the chicken embryo at stage 15. The cell will then instigate into the central nervous system (CNS) of the chicken. At specific endpoints, the chicken embryo will be imaged to assess cellular integration. When successful, this will provide a novel developmental toxicology model for further studies aimed at assessing the impact of endocrine active compounds (EACs) and other toxins on neural development.

Mechanism of Developmental Regulation of Base J Synthesis in *Trypanosoma brucei*

Megha Kalia, CURO Honors Scholar
Dr. Robert Sabatini, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Kinetoplastids are a group of unicellular flagellate protozoa, some of which cause serious diseases in humans. *Trypanosoma brucei*, causive agent of African sleeping sickness, is spread by the tsetse fly and affects more than 60 million people. A unique feature of kinetoplastids is a DNA modification known as base J. Base J is a hypermodified thymidine that is synthesized in two steps. First, a thymidine residue is hydroxylated into HOMedU by a thymidine hydroxylase (JBP1 and JBP2). Second, a glucose moiety is added by a glucosyl transferase (JGT) to form base J. The life cycle of *T. brucei* can be divided into two main stages: mammalian (bloodstream form) and insect (procyclic form). The mammalian life stage produces base J, but procyclic does not. It is known that the enzymes that synthesize base J are down regulated in the procyclic stage. However, it is unclear if this explains the complete lack of the modified base in the PC life-stage. To address this, we will re-express the enzymes in the parasite and follow the production of base J. An epitope tagged version of JGT was

eptopically expressed in procyclic *T. brucei*. A Western blot analysis showed expression of the tagged enzyme. Our next step is to quantify the levels of base J by doing an anti-base J dot blot. However, while the same construct leads to high levels of the enzyme in BS cells, very little of JGT is produced in PC cells. This suggests an additional level of regulated gene expression in this life stage. Understanding the biosynthesis of base J will help broaden our understanding of this DNA modification in trypanosomes.

A New Analysis Strategy for Designs with Complex Aliasing

Andrew Kane, Samantha Cao
Dr. Abhyuday Mandal, Statistics, Franklin College of Arts & Sciences

In this project we propose a new data analysis strategy for designs with complex aliasing. In many non-regular designs, factorial effects are often partially aliased with each other. Identifying the correct underlying model from the experimental data is a challenge. Both frequentist and Bayesian solutions to this problem are subjective in nature. Here we propose the Lasso (least absolute shrinkage and selection operator) variable selection method to identify the correct model in the presence of complex aliasing. Given a particular dataset generated from a non-regular design, regression methods are commonly used to select the model with the most significant predictor variables. The standard approach for fitting a linear regression is the ordinary least-squares (OLS) method, which minimizes the error sum of squares between the observed and predicted response values. However, OLS does not perform well on high dimensional data, where the number of variables is large compared to the number of observations. On the other hand, Lasso and adaptive Lasso perform variable selection to reduce the number of variables by adding a penalty to the coefficients, shrinking certain predictor coefficients to zero and thereby eliminating extraneous variables. We demonstrate the use of adaptive Lasso techniques on real and simulated datasets to establish the superiority of the proposed technique over standard methods available in the literature.

Republicanism in the American South: From Strom Thurmond to Lindsey Graham

Daniel Kanso, CURO Summer Fellow, CURO Research Assistant, CURO Graduation Distinction
Dr. Charles Bullock, Political Science, School of Public & International Affairs

In order to understand the complex dynamics within the modern Republican Party, its ideological core, and the platform on which its base of voters is built, it is necessary to evaluate the full scope of its development. Throughout American history, South Carolina's national profile has outsized its geographic territory, its significance consistently overshadowing the state's long median-sized population. From 1878 to 1980, more than 85% of the 46 senators and 124 members of the South Carolina House of Representatives caucused with the Democratic Party. Measured Republican electoral growth began in the 1960's, driven by a multitude of factors that parallel South Carolina's development as a state. In the past 115 years, Republicans in South Carolina have accounted for five governors, four U.S. Senators, nineteen members of the U.S. House of Representatives, two majority leaders of the state senate, and two speakers of the house. Although seemingly dominant, the Republican Party is relatively new in establishment in South Carolina and projects a growing identity of republicanism that is visible across the nation. My thesis is focused on the election and governorship of Mark Sanford, who currently represents South Carolina's 1st District in the United States House of Representatives. The GOP

gained control of the South Carolina House of Representatives in 1994, and under Democratic Governor Jim Hodges the South Carolina Senate transitioned to Republican control in 2001. Mark Sanford is the first governor in modern history to oversee a Republican majority in both chambers of the state legislature. I have conducted personal interviews with Mark Sanford, his former Chiefs of Staff Fred Carter, Scott English, and Senator Tom Davis, Sanford's Chairman of the Board of Economic Advisors John Rainey, and his Legislative Liaison Senator Chip Campsen. Additionally, I have interviewed more than 70 individuals involved in South Carolina politics, ranging from Assistant Democratic Leader James Clyburn to Senator Jim DeMint.

Characterizing the Novel 1,2-Propanediol Dehydratase and its Activating Enzyme from *Roseburia inulinivorans*

Suraj Kapoor, CURO Research Assistant
Dr. William Lanzilotta, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Glycyl radical enzymes (GREs) represent a diverse superfamily of enzymes that utilize radical mechanisms to catalyze difficult, but often essential, chemical reactions. In this work, we present biochemical and structural data for the GRE-dependent diol dehydratase from *Roseburia inulinivorans* (RiDD) and the glycerol dehydratase from *Clostridium butyricum* (CbGD). We demonstrate that these enzymes have very different substrate and enantiomer selectivity despite high sequence identity (48%). Specifically, the CbGD catalyzes the dehydration of glycerol and *(S)*-1,2-propanediol but not *(R)*-1,2-propanediol. In contrast, the RiDD does not utilize glycerol but will utilize both *(S)*-1,2-propanediol and *(R)*-1,2-propanediol as a substrate. Interestingly, the RiDD also produces some acetone with either enantiomer of 1,2-propanediol. We also report the crystal structure of the RiDD that, when considered in light of the biochemical data, provides an explanation for the observed substrate and enantiomer selectivity as well as new insight into the radical-catalyzed dehydration reaction of both enzymes. These observations provide a framework for rational enzyme engineering towards the application of GREs in commodity chemical production from renewable resources.

The Effects of Prior Knowledge of Trial Type on Saccade Task Behavior

Megan Kelley
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Rapid eye movements (saccades) are commonly used for studying top-down cognitive control. Following presentation of a peripheral stimulus, two saccadic responses are possible: simple, stimulus-directed prosaccades and more complex antisaccades directed toward the mirror location of the stimulus, which require inhibition of the impulse to look toward the stimulus. This study explored how explicit knowledge of task conditions affected behavior by manipulating the probability (10, 30, 50, 70, or 90%) of antisaccades versus prosaccades in a run, with one group of participants (explicit, n=32) being informed of the probability prior to a run, and a second group (implicit, n=33) remaining uninformed. Thus, the current study examined how cognitive preparation affected latency and proportion of incorrect responses. It was hypothesized that participants would perform better (shorter latencies, fewer errors) on saccade trials when their respective trial type was highly probable compared to runs when each type was improbable. The explicit group was expected to perform better than implicit on high probability trials (e.g. antisaccades in 90% AS run) and the same or worse than implicit on low probability trials (prosaccades in 90% AS run). The preliminary results show that groups

do not significantly differ, implying that knowing the likelihood of a desired response type does not improve performance. This could be because individuals who are unaware of the probability may still be able to determine that the stimuli are occurring in different probabilities and thus may still be cognitively preparing for the appropriate tasks.

Highly Mobile Kenyan Runners: Transnationalism through Sport

Jacob Kennedy, Foundation Fellow
Dr. Jepkorir Rose Chepyator-Thomson, Kinesiology, College of Education

Since the mid-1960s, Kenyans have dominated long distance running. Presently, over 2000 Kenyan runners live, train, and race abroad using various migratory patterns. In recent years academic and public efforts have sought to explain Kenyan running, usually in biological terms. Yet, few studies have examined the athlete experience as it relates to how mobility influences ties to home, how transnational relationships have been constructed and negotiated, and extent of impact on the athlete and his or her home community. The purpose of this study is to examine Kenyan runners' lived experiences and connections with their home communities, specifically focusing on Kenyan athletes training in the United States. The entirety of the Kenyan running phenomenon involves three small towns in the Rift Valley—Iten, Eldoret, and Kapsabet. Those who decide to become athletes move from their home seeking to join a training camp, acquire a manager, and make money racing internationally. Throughout this process athletes and their communities exchange remittances and support, and negotiate identity. Data collection methods will include qualitative surveys, interviews, and utilization of GIS mapping techniques. Data analysis will involve triangulation of data derived from interviews and qualitative surveys. The insights from this research will contribute to the literature on athlete migration, broaden understanding of the East African running phenomenon, and generate new ways to build theory using anthropological lenses.

Nano Formulation of Platin-A and Associated Inflammation

Samuel Kennedy, CURO Research Assistant
Dr. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Prostate cancer is the most common cancer found in the male population in the United States. In the late stages, metastasis and chemo-resistance induces tumor recurrence, and that significantly affects the morbidity and mortality of a huge group of prostate cancer patients. Moreover, chronic inflammation associated with tumor tissues plays a key role in the metastasis of prostate cancer. In our continuing efforts to provide therapeutic options for metastatic prostate cancer, we recently constructed a Pt(IV) prodrug, Platin-A, with the ability to release cisplatin, a widely used chemotherapeutic, and aspirin, an anti-inflammatory agent. However, clinical translation of small-molecule based therapeutics requires a suitable delivery system to achieve pharmacokinetics parameters and appropriate biodistribution. Activation of various proteins causes mitochondrial dysfunction, resulting in mitochondrial reactive oxygen species production and downstream signaling that promote inflammation-associated cancer. Using a mitochondria-targeted polymeric-nanoparticle as a delivery vehicle, we anticipated that Platin-A could be rerouted to the mitochondria of cancer cells and attack the mitochondrial DNA, thereby designing a targeted pathway for the well-established drug cisplatin. Platin-A exhibited anticancer and anti-inflammatory properties which were better than a combination of cisplatin and aspirin. This result highlights the advantages of co-delivering an anti-inflammatory agent

with a chemotherapeutic agent in a single prodrug. The enormous potential of Platin-A encouraged the design of additional Pt(IV) prodrugs to co-deliver cisplatin and aspirin. A promising design will be discussed here.

O-Linked Glycosylation Patterns at the Interface of Cervical Mucins and HIV Infection

Hammad Khalid, Foundation Fellow, CURO Research Assistant
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Mucosal surfaces, well known for their role in sensing their environment (nose, mouth), nutrient absorption (gut), gas exchange (lungs), and reproduction (vagina and uterus), also function as a complex immunological barrier at these common sites of entry for pathogens and viruses. However, surprisingly little is known about the complex post-translational modifications of the mucin proteins expressed at these surfaces and about how these modifications provide protection. This project focuses on an in-depth characterization and comparison of the glycans found on cervical mucins from HIV and non-HIV patients aimed at identifying unique modifications that may play a role in mucosal immunity. Samples were collected and prepared to analyze by direct injection nanospray ionization mass spectrometry (NSI-MS). Glycan structures were probed using collision induced disassociation (CID) and assigned using software developed in-house for high-throughput analysis. Preliminary data suggest an increase in sialylated and fucosylated structures in HIV patients, indicating a possible defect in terminal processing of glycans. Interestingly, preliminary data from lectin blots indicate an increase in the abundance of anti-inflammatory mucins in non-HIV patients. The analysis of more patient samples is ongoing. By understanding the fine structural features of the mucosal interface, new approaches for eliciting mucus-tethering antibodies can be considered. Additionally, this research has the potential to develop a more efficient, standardized platform for evaluating the mucus barrier, which could enhance future research on natural and vaccine-induced defenses against other sexually transmitted infections.

The Impact of Sugar during Larval Development on Growth Rate, Energy Stores, and Behavior

Maha Khan, CURO Research Assistant
Dr. Patricia Moore, Entomology, College of Agricultural & Environmental Sciences

The recent invasive pest species, *Drosophila suzukii*, differs from other drosophilids in that its larvae develop in ripening fruit, which is low in protein compared to the rotting fruit and its associated microbes utilized by other drosophilids such as the well-studied *D. melanogaster*. However, ripening fruit may also differ in terms of sugars and thus we are interested in examining how sugar amount and composition of the larval diet affects performance. My previous work on the effects of varying types and amounts of sugars on the development time, survival rate, and body size of the *D. suzukii* demonstrated that *D. suzukii* growth is optimum with moderate to high levels of sugars. However, the type of sugar is also important. I found that a high level of fructose not balanced by high glucose is lethal for *D. suzukii* larvae. My current research project extends these findings by examining development, fat storage, and behavior of both *D. suzukii* and *D. melanogaster* under varying carbohydrate diets. I will first examine development and fat stores upon adult emergence of *D. suzukii* and *D. melanogaster* under four different sugar treatments: fructose, glucose, sucrose, and high fructose corn sugar. I will also undertake a larval choice experiment to determine if larvae are able to adaptively choose the diet

that optimizes development and fat stores. Results from this experiment will help us to understand the nutritional ecology of *D. suzukii* and the role larval diet, particularly related to its unique host, plays in the biology of this invasive pest species.

Alleviating Inequities in Georgia's Public School Funding

Christine Kil
Dr. Jack Parish, Lifelong Education, Administration & Policy, College of Education

Although education is primarily the responsibility of state governments, states entrust a significant portion of education funding responsibility to local governments, who derive revenue for education primarily from property and sales taxes. This shared responsibility of education funding perpetuates a disparity, as raising local revenue and funding varies widely between districts. Any immediate and impacting solution to inequitable funding systems in US states will require full funding of the states' existing education funding formulas. Providing more state funds for education can come from increasing tax revenue or reform of other state social services to provide more money for education. This paper critically examines the impacts of the existing status quo of public school funding in Georgia and proposes three policy alternatives. I consulted primary sources of Georgia's education funding mechanism and spoke with education experts on the current state of public school finance and recommendations for creating a more equitable system. For Georgia specifically, a student-based budgeting (SBB) formula is a transparent alternative to the current Quality Basic Education (QBE) formula that will ensure greater equity in funding students. Traditional funding methods such as the QBE formula allocate funds based primarily on staff positions of different program segments; SBB allocates money based on student characteristics, such as socioeconomic status, limited English proficiency, and disability. Supplements to local revenue, robust funding, and transparent funding formulas will help ensure that investments in education pay back the community and break the cycle of low tax revenues and persistent income inequality.

Identifying Virulence Genes Associated with Emergent *Avibacterium paragallinarum* Isolates Associated with Acute Endocarditis in Chickens Using a Bioinformatic Approach

Christian Kim
Dr. John Maurer, Population Health, College of Veterinary Medicine

Avibacterium paragallinarum is a Gram-negative bacterium known to be the primary etiological agent of infectious coryza, an upper respiratory tract infection with significant detrimental effects on the poultry industry. However, *A. paragallinarum* strains have recently been isolated that instead cause endocarditis in affected birds. In order to characterize the unique pathogenicity of these strains, a bioinformatic approach using a variety of common web-based tools such as RAST and NCBI BLAST was utilized to analyze the genomes of the strains in question, primarily focusing on the identification of potential virulence factors. Once isolated, these factors were compared to those possessed by *A. paragallinarum* reference strains, as well as those of closely related bacterial species, in order to better comprehend the pathogenicity of the endocarditis-causing strains. In our analysis of the genomes of the *A. paragallinarum* strains, several virulence factors characteristic of *A. paragallinarum* were identified, including a three-region capsule locus and a three-gene cytolethal-distending toxin operon. A Type VI secretion system unique to the endocarditis-causing strains was also discovered. In addition, genes coding for RTX toxin, which

is believed to play a major role in *A. paragallinarum* virulence, were found to be absent in the genomes of the endocarditis-causing strains. Further identification and analysis of potential virulence factors will be performed in order to obtain a more complete understanding of *A. paragallinarum* pathogenicity.

A Synthetic Lethal Mutant Screen in *Salmonella* Typhimurium to Identify Genes whose Products Cooperate with RNA Ligase, RtcB, in RNA Repair

Justin Kimsey
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

Many stress conditions are known to damage nucleic acid. The pathways for DNA repair are well characterized in bacteria, but no RNA repair pathways have been defined. In *Salmonella* Typhimurium, a sigma 54-dependent operon, *rsr-rtcBA*, encodes proteins that are homologues of known RNA repair enzymes from metazoans and archaea. RtcB is an RNA ligase that seals broken RNA molecules containing 2'3'-cyclic phosphate and 5'-OH ends, and RtcA converts 3'-P to 2'3'cyclic phosphate. The physiological role of these RNA repair proteins in bacteria is not known. The goal of this project is to use a synthetic lethal mutant screen in *Salmonella* to identify genes encoding proteins/RNA that cooperate with RtcB in RNA repair. A strain with *rtcB* deleted has been transformed with an unstable plasmid that has *rtcB* transcriptionally fused with *lacZ* under the control of the *lac* promoter, and will be mutagenized with a transposable element. To screen for mutants that require the maintenance of *rtcB* for viability, the transposon-mutant library will be grown on LB agar plates in the presence of mitomycin C (MMC), which induces the RNA repair operon, and X-Gal IPTG, which indicates expression of *rtcB-lacZ*. The current focus of the project is to define the concentration of MMC to be used in the selection agar that provides enough stress to induce the operon, as measured by qRT-PCR, and affect cell growth in the absence of RNA repair, as measured by viable cell counts. Transposon insertions in synthetic lethal mutants will be mapped by arbitrary primed PCR.

Inefficiencies of Water Use in Animal Agriculture

Catherine Klein, CURO Research Assistant
Dr. Jeffrey Mullen, Agricultural & Applied Economics, College of Agricultural & Environmental Sciences

In 1977, the United Nations Water Conference resolved that access to fresh drinking water to meet basic needs is a fundamental human right. Since that time, population growth, economic development, and environmental degradation have put increasing pressure on our water resources, raising demand and shrinking supply. In effect, fresh water is an increasingly scarce resource. This scarcity has and will continue to vary around the world depending on environmental factors (eg., precipitation and evapotranspiration rates) and economic factors (eg., income levels and prices), as reflected by the spatial variation in water scarcity indices. A major concern for the future is the dietary shift away from plant-based proteins toward animal-based proteins that often accompanies increases in household incomes. This research study focuses on the cascading effects of rising incomes on the demand for animal-based protein – meat, dairy, and eggs – and the implications for water scarcity. Using country-specific estimates of the income elasticity of demand for meat, dairy, and eggs, and projections of income growth, projected changes in water use for animal agricultural production are developed on a nationwide scale. The effect of projected changes in water demand on a country's water scarcity index are then examined. In addition, expected water quality

impacts of expanding animal agriculture are identified. The study concludes with a discussion of a variety of policy options for mitigating the water scarcity and water quality effects of expanding animal agricultural production.

Oklahoma!: The Building of the Dream Ballet in Two Different Mediums

Hannah Klevesahl
Dr. Marla Carlson, Theatre & Film Studies, Franklin College of Arts & Sciences

In 1943, Richard Rodgers and Oscar Hammerstein II wrote a musical that opened on Broadway and stayed in continuous production in the USA for the next 16 years. This musical was called *Oklahoma!*, and today it remains a staple of many international theatre companies, as well as an example of the first modern musical. It is for this reason that I choose to focus on two specific versions of *Oklahoma!*. The first production I will be examining is the 1955 film, and the second version is the filmed stage production of the 1998 London revival by the National Theatre. The 1998 London revival of *Oklahoma!* as well as the 1955 film both include dream ballets that take place in an alternate dream world, but their methods of building and maintaining those worlds differ. The London revival relies heavily on its ensemble to create the dream, and maintain it, during the fight with Curly and Jud. Since that version is a filmed copy of a live performance, it makes sense that the stage production would utilize their ensemble in order to establish the convention of a dream world. In contrast, the film uses special visual effects for its dream sequence and fight. These effects are utilized to show the audience that the dream sequence does, in fact, take place in a dream. Both productions' methods achieve their goal of establishing the convention of a dream world, but are altered slightly to fit their medium.

Size Labeling for Infant Clothing: Cultural Perspectives on Childhood Growth

Allison Koch, Foundation Fellow, CURO Research Assistant
Dr. Susan Tanner, Anthropology, Franklin College of Arts & Sciences

Previous research has suggested that childhood nutrition and growth patterns are strongly associated with current and future health outcomes, but little is known about how parents understand and evaluate the size and growth of their children. A literature review found that pediatric growth charts are not widely understood or implemented by parents. Instead, research suggests that parents use characteristics of their child and sociocultural norms about appropriate size to evaluate growth. This study explores if clothing size is an additional way through which parents evaluate the size and growth of their infants. Because Latino populations in the U.S. are more than twice as likely as the average consumer to purchase clothing in the birth-to-preschool market, this research will focus on Latino parents in Southeast Georgia. Semi-structured interviews will determine what growth assessment mechanisms, including clothing sizes, are most useful and important to parents. The qualitative and quantitative data will be evaluated to assess *to what extent* Latino parents use clothing size labels to assess the growth of their infants. It is expected that clothing labels are frequently used by parents in gauging infant growth, but parents may not be overly concerned if they must purchase clothing outside of their child's age or weight designation. This research has implications for understanding how the social environment could shape parents' understanding and evaluation of child growth and health.

Clearing Natural Forest Lowers Decomposition Rates and Results in Less Diverse Macrofauna and Mesofauna Communities

Allison Koch, Foundation Fellow, CURO Research Assistant
Dr. Scott Connelly, Odum School of Ecology

Global climate change and increasing demands on world resources continue to lead to concomitant transformations of land use and the widespread loss of biodiversity. These global factors may be threatening local ecosystem functions—the various ways in which biotic and abiotic components interact to maintain the health of the system. This study explored the effects of anthropogenic change on the essential process of decomposition. Mesh leaf litter bags were placed at two sites near San Luis, Costa Rica: in natural forest and in an area that had been converted to pasture. Some mesh bags were filled with homogenous leaf clusters, which contained the plant taxa *Cecropia*, *Rubiaceae*, or *Solanaceae*. Others were categorized as heterogeneous and contained all three plant taxa mixed. This was done to simulate diversity loss. Bags were collected at four intervals over 37 days, re-weighed, and emptied of decomposers—the macrofauna and mesofauna community—for further analysis. Leaves in the forest decomposed faster than their counterparts in the open pasture, and on all collection days, leaves placed in the forest hosted a more diverse fauna community than leaves placed in the pasture. Heterogeneous leaf groups did not show significantly greater levels of fauna diversity than homogenous leaf groups, suggesting that biodiversity loss may not affect decomposition. Clearing the natural forest, however, does impact ecosystem function by leading to slower decomposition rates and less diverse macrofauna and mesofauna communities.

Child Neglect, Depressive Symptoms, and Substance Use among Children and Adolescents Reported to Child Protective Services

Stephanie Kors, CURO Research Assistant
Dr. Assaf Oshri, Child & Family Development, College of Family & Consumer Sciences

Children who have experienced parental neglect are at significant risk for the development of depressive symptoms and substance use behaviors in adolescence. Using the self-medication hypothesis, we aim to test whether increased adolescent drug abuse is a result of a maladaptive coping strategy neglected youth use in an effort to reduce stress-associated with depressive symptoms. In addition, gender differences in this hypothesis were examined. A longitudinal sample of 796 children from the National Survey of Child and Adolescent Well-Being was examined at three time points (aged 11-13 at wave 1, 12-15 at wave 2, and 14-16 at wave 3). Structural equation modeling was used to test a mediation model in which child neglect is associated with adolescent substance use through increased levels of depressive symptoms. Statistical model fit was satisfactory ($\chi 2$ (20) = 75.55, p = .01 CFI =.91; RMSEA = .03; SRMR = .05). Multiple group analyses revealed significant moderation by gender. For males, supervision neglect at time 1 significantly predicted depressive symptoms at time 2 (β = .22; p < .05) and depressive symptoms at time 2 significantly predicted cannabis use at time 3 (β = .26; p < .05). Mediation analyses confirmed an indirect effect from supervision neglect to increased substance use via depressive symptoms among males (β = .08; p < .01). These results suggest the need for interventions for neglected children via preventive programs that address depressive symptomatology during early adolescence in order to modify risk for subsequent

involvement in substance use behaviors during adolescence.

Studying the Kinetics of N-glycan Release by PNGase F with MRM Quantitation of the Glycopeptides from Human Serum Glycoproteins

Adam Kramer
Dr. Ron Orlando, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Peptide-N-Glycosidase F, PNGase F, is an endoglycosidase that cleaves the linkage between the asparagines residue and innermost GlcNAc of N-linked glycans. Because this enzyme releases all mammalian N-linked glycans, it is widely used in the analysis of glycoproteins. While performing glycomic studies, we determined that the PNGase F release introduces the largest source of quantitative variation, which led us to conduct a more detailed study of this enzyme system. Here we investigated the kinetics of glycan release, to determine the effect of glycan structure and amino acid sequence on the rate of glycan release as this would be a reasonable explanation for the observed quantitative variations. Human serum was subjected to a standard trypsin digestion protocol, followed by PNGase F digestions. Aliquots of the digestion mixture were taken at various time points and were analyzed by LC-MS using a Penta-HILIC column on Shimadzu Nexera LC system interfaced to a Q-trap 4000 MS analyzer (ABSciex). Selected reaction monitoring methods were utilized to quantitate every known glycoform of each tryptic peptide from the major serum glycoproteins, for example 20 glycoforms for each of the human serum IgG subclasses (i.e., IgG1, IgG2/3, and IgG4). We have utilized this method to determine the changes of glycopeptide residues after various PNGase F digestion times. We are currently developing SRM methods to investigate the glycoforms of the other major serum glycoproteins to determine if larger changes in the amino acid sequence flanking the glycosylation site alter the rate of glycan release.

The Potential Protective Effects of Anthocyanins on Liver Insulin Signaling

Madison Krieger
Dr. Claire de La Serre, Foods & Nutrition, College of Family & Consumer Sciences

Obesity is a rising epidemic in the United States, effecting up to one third of its population. Obesity and its comorbidities, such as diabetes and cardiovascular diseases, are associated with low-grade inflammation. Recent work has notably found that inflammation is causally linked with insulin resistance or pre-diabetes, especially affecting liver insulin sensitivity. The use of bioactive foods, namely ones with anti-inflammatory properties, could produce beneficial effects. In this study we examine the potential protective effect of blueberries, a food rich in anti-inflammatory anthocyanins, on insulin sensitivity and liver functions. Rats were fed three different diets for 8 weeks: low-fat(LF), high-fat(HF), and high-fat supplemented with 10% blueberry(HF-BB). The HF and HF-BB diets were matched for fiber and calories while all three were matched for sucrose content and amount of food. After 7 weeks on the diets, animals underwent on oral glucose tolerance test and at the end of the study livers were harvested. Insulin signaling was investigated by western- blotting. H & E staining and Oil-Red O staining were completed and evaluated to determine fat infiltration in the liver. Additionally, immunohistochemistry will be performed using an F4-80 antibody to determine the amount of macrophage presence in the liver, signifying inflammation. The hypothesis is that the rats fed an HF-BB diet will have significantly less macrophage infiltration and fat infiltration than those fed an HF diet. If this is the case, then we can conclude that anthocyanin-enriched diets can reduce the

impacts of inflammation and therefore improve insulin signaling.

Changes in Neural Activation Following Daily Practice of Saccade Tasks

Mitra Kumareswaran
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Cognitive control relies on contextual cues and existing perceptions to enable neural mechanisms to respond to parameters of a cognitive task and produce the appropriate behaviors. The ocular motor system, the neural circuit that guides eye movements, serves as a model of cognitive control with two opposing tasks: prosaccades are directed gazes toward a peripheral cue while antisaccades are gazes toward the mirror image location of the cue. Since antisaccades involve suppressing the instinct to view the stimulus in order to generate a saccade in the opposite direction, they require higher levels of cognitive control and greater neural activation in saccade circuitry than stimulus-driven prosaccades. In the current study, the probability of antisaccades presented within a given trial was varied to observe changes in neural activation in saccade circuitry as a result of context. Thirty-five subjects performed five saccade tasks in the functional MRI environment where the percent of antisaccades to prosaccades was 0%, 25%, 50%, 75%, or 100%. Brain scans were collected at baseline and after four days of saccade practice to compare changes in activation over time. With practice, the subjects were faster, made fewer errors, and decreased neural activation, notably in the cuneus, supplementary eye fields, and prefrontal cortex. Correlations between behavioral measures and brain activation suggest that participants increased task efficiency by utilizing cognitive control cues following practice. A better understanding of the relationship between cognitive control and the ocular motor system can be utilized to detect deviations from normal functioning that may occur in neurological disorders.

Addressing the Lack of Access to Public Assistance for Adults with Autism

Mitra Kumareswaran
Dr. Jay Rojewski, Career & Information Studies, College of Education

Under the status quo, individuals with autism who have an IQ score below 70 and display severe cognitive disabilities are eligible to receive state and federal services such as group homes, job training, and case management upon aging out of the school system. Individuals with autism who have mild to moderate cognitive impairments may also need such services but are very unlikely to receive the services or may not even be eligible to receive the services. Within the past twelve years, the rate of children diagnosed with autism has increased by 228%, and the nation is ill-equipped to take care of the current population of autistic adults let alone the future population of these individuals. To improve upon the status quo, alternativ policies were analyzed based on political feasibility, cost-effectiveness, and equity. The policies evaluated were the status quo, a policy to change the method used to determine service eligibility and provision, a policy to allow autistic students to attend public school until age 25 instead of age 21, and a policy to pass a federal autism health insurance mandate. Of the four policies, the policy that entailed providing needed services based on the needs and cognitive impairments of the adult with autism was the most effective to implement. To implement the selected policy, Congress and state governments must pass legislation to change how adults with autism are provided public assistance and additional funding must be allocated toward providing increased public services to a larger population of beneficiaries with autism.

Abstracts

Speed Effects on Angular Displacement of Back during Gait

Eric Kure, CURO Research Assistant
Dr. Kathy Simpson, Kinesiology, College of Education

According to the American Chiropractic Association, as many as 80% of the population will experience a back problem at some point in their lives. Therefore, understanding the mechanical demands on the back of various physical activities is important. The purpose of this study was to determine which back region (upper, middle, and lower) demonstrates greater angular motions as running speed increases. Twenty healthy, physically active volunteers (age = 22.4 ± 3.0 yr, mass = 67.4 ± 12.9 kg, height = 1.7 ± 0.1 m) ran at 3 different speeds (natural, 110% of natural, and maximum). Reflective markers on the back region were used to capture spinal movements by seven infrared cameras. From ANOVA results, (p <.05), it was determined that the amount of rotation in all regions of the back increased (p<.01), with the exception of the upper back during flexion and extension (p=.26). The lower back twisting motion showed the greatest increased motion at faster speeds, suggesting that lower back tissues may have greater strains placed on them. These findings could be beneficial for individuals with low back problems.

Factors Influencing Gut Microbial Community Structure in Mosquitoes

Kip Lacy
Dr. Michael Strand, Entomology, College of Agricultural & Environmental Sciences

It is well established that microbes are integral to insect biology. Mosquitoes are important insects because many species are vectors which transmit disease-causing pathogens in humans and other vertebrates. Recent studies indicate that mosquitoes host a community of bacteria (microbiota) in their digestive system that influences their development, reproduction, and vector competency. This community is acquired by larvae from their aquatic environment and persists to the adult stage. However, the factors determining community composition and the relative abundance of community members are not well understood. In this study, we examined the influence of the aquatic microbiota on gut community structure and mosquito development using *Aedes aegypti* mosquitoes reared under sterile conditions in a controlled bacterial environment. Our results support a strong role for the aquatic environment in determining mosquito gut community composition and identify specific community members as key factors influencing bacterial abundance and diversity in the gut. These results have important implications for ongoing studies to describe microbial communities in populations of vector mosquito species in the field.

Financial Literacy in College Students

Benjamin Landes
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

It is commonly conceived that college students have poor financial competency, yet little is known about the severity, cause, or ramifications of this issue. Therefore, the purpose of Dr. Cude's study is to determine how well college students understand financial vocabulary and concepts, where this knowledge or lack thereof derives from, and the impact of this level of knowledge on their debt, financial self-perception, social comparison, delay of gratification, and more. To answer this question, Dr. Cude administered a 30-item pre-test and Likert scales, which previous research has proven to test financial literacy and other items of interest, to 1,000 college seniors in her classes. I then assisted Dr. Cude in importing and analyzing this data through Microsoft Excel and IBM SPSS, creating frequency tables,

regression analyzes, chi squared values, and other relevant statistics. While research is still in progress, we have determined that among Dr. Cude's students, the mean grade on a finance pre-test is a failing 50%, only half own credit cards (while previous research suggests this number is as high as 75%), and only 7% report having financial education in high school. Further research will be done with the ultimate goal being to acquire a greater understanding of college students' financial matters in order to determine the necessary actions to improve students' financial well-being.

Drug Discovery and Structural Studies of an Essential Transcriptional Regulator, ACIAD0746

Paige Lane
Dr. Cory Momany, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The LysR-type transcriptional regulator ACIAD746 is an essential regulator in *Acinetobacter baylyi* that is not functionally well-characterized. The goal of this project is to discover compounds that will interact with this protein and to characterize the structural changes associated with the binding of regulatory ligands using X-ray crystallography. Crystals of ACIAD746 protein were prepared from protein incubated with the potential ligands (cysteine, methionine, and sulfite), and the crystals revealed different habits that were analyzed using X-ray diffraction. Several atomic structures with cysteine were obtained, but the bound ligand was not identified and the results appear inconclusive. Similar studies with sulfite are in progress. The purpose of this research is to understand whether bound ligands to ACIAD746 will alter the DNA conformation of the protein and consequently alter transcription. The essentiality of this protein suggests that it is a potential drug target. Studies are in progress to identify small molecules from natural plant extracts that may prevent the activation process where the protein recruits RNA polymerase to the promoter of genes controlled by the protein. Such small molecules would represent a new class of antibiotics. Because ACIAD746 has homologs in numerous pathogenic bacteria, compounds identified in these studies could have broad spectrum activities as therapeutics.

Syrian Civil War Victims Receiving Medical Care in Israel: Humanity in a War Torn Region

Sarah Lane
Dr. Richard Schuster, Health Policy & Management, College of Public Health

The Syrian Civil War began in the spring of 2011, and the availability of healthcare in the country has been declining rapidly ever since. Due to the lack of healthcare and general stability, more than 1.5 million Syrians have fled to refugee camps in nearby countries. Although Syria shares a border with Israel, civil war victims aren't able to seek refugee status in Israel due to a policy that refuses asylum to "subjects of enemy or hostile states." However, this has not kept Israel from providing medical care to injured Syrians. Since March of 2013, Syrians with traumatic war injuries who are found near the Syrian-Israeli border are brought into the country by the Israel Defense Forces and taken to various hospitals in the Galilee region. This study examines the demographics, diagnoses, procedures, and resource utilization of Syrian patients that have been admitted through the emergency department to the Galilee Medical Center, a large general hospital in Nahariya, Israel. These findings were then compared to a random sample of Israeli trauma cases. We found that the Syrian patients were younger and more predominately male than Israeli trauma patients, and they had longer lengths of stay, underwent more procedures, and had a higher mortality rate. As a result, the Syrians'

medical bills were on average 350% more than Israeli patients'. These findings can be used to help Israeli hospitals prepare both clinically and financially for Syrian Civil War victims who will continue to be brought into the country with traumatic injuries.

Identification of the Mechanism for Ciliary Gliding in Heterotrophic Euglenids

Jeffery Lanier, CURO Research Assistant
Dr. Mark Farmer, Biological Sciences, Franklin College of Arts & Sciences

In this study, the gliding motility of unicellular eukaryotic organisms was studied to determine the mechanism by which the organisms attach themselves to a substrate and propel themselves along it. Despite its widespread occurrence among protists, ciliary gliding is the least well-characterized form of flagellar-associated cell motility. The euglenid flagellate *Paranema trichophorum* is an ideal study organism due to the fact that gliding is its primary form of locomotion. Lectins are plant-derived carbohydrate-binding proteins, usually with preferred sugar specificities. By utilizing lectins and observing their effect on cell velocity, we can identify possible sugars present on ciliary membranes that may facilitate substrate adherence and gliding motility. If lectins attach to sugars of the flagellar hairs that extend from the cilium and thus interfere with gliding, the velocity of lectin-treated cells should decrease. Observing cell velocity without lectins provides a control. After incubating *Peranema* with increasing concentrations of the lectin Concanavalin A, the lectin-treated cells showed significantly decreased gliding velocity. Fluorescently tagged lectins were observed with confocal microscopy to confirm the lectin binding to the ciliary surface. Our study suggests that flagellar hairs play a role in ciliary gliding, and expanding upon this research may finally reveal the mechanism of ciliary gliding.

Worried, Concerned, and Untroubled: Patterns of Adolescent Worry

Rebecca Lanier
Dr. Jay Mancini, Child & Family Development, College of Family & Consumer Sciences

During adolescence, many situational and cognitive changes occur that enable youth to anticipate and conceptualize future events and outcomes, which may increase susceptibility to worry development and maintenance. Although the majority of adolescents seem to worry infrequently, or only have typical adolescent worries, roughly 25% experience frequent worry. Worry becomes particularly problematic when it co-occurs with other internalizing/externalizing symptoms, such as low self-efficacy and delinquent behaviors. This suggests a need to study adolescent worry and differentiate the levels of worry youth experience. Our research is expected to indicate youth groupings by differing levels and topics of worry. We hypothesize that specific individual, environmental context, and relational characteristics will create distinct groupings of worry and that group designation is associated with other well-being aspects. We investigated worry patterns among an adolescent sample using a latent profile analysis (n=273). Youth responded to eight items from the Generalized Anxiety Subscale of the Revised Version of the Screen for Child Anxiety Related Emotional Disorders (SCARED-R; Muris et al., 1999), which created profiles describing the intensity and focus of adolescents' worry. The results indicated the existence of three distinct groups varying in intensity, probable causation, probable association, and worry topics. Three groups were identified: *worried* (23.8%), *concerned* (37.7%), and *untroubled* (38.5%), respectively. *Worried* youth were comparatively more nervous, more worried about the future, and more worried about previous occurrences; *concerned* youth reported moderate levels of worry about personal

ability and about others liking them; *untroubled* youth reported relatively little concern about typical sources of adolescent worry.

Storytelling for Social Justice: Fostering Activism through Collective Memory Work

Jose Leandro, CURO Research Assistant
Dr. Corey Johnson, Lifelong Education, Administration & Policy, College of Education

Storytelling has been central to social justice movements, with stories becoming a method of potential and actual transformation of oppression and injustice. With the acknowledgement of the need for advocacy for the LGBTQ community in bridging the gaps in equality, self-identified LGBTQ activists will be introduced to Collective Memory Work. This study intends to introduce Collective Memory Work to investigate and answer the questions: 1) what motivates LGBTQ activists to resist internalizing anti-LGBTQ oppression? and 2) how do memories keep activists engaged and energized to do the work of social justice? Collective memory work encourages participants to recall, examine, and analyze earlier memories and experiences in a broader cultural context to see how individual experiences link to collective, shared experiences of similar and/or different groups in society (Haug, 1992). Two focus groups will be conducted with each involving 4-8 participants. The researchers anticipate that participants will increase their knowledge about leisure, LGBTQ activism, self-identity, culture, the diversity among fellow participants, and the influence that they have on others as activists. By engaging in collective memory work, participants will also learn about a new tool for building a sense of understanding, unity, and collectivism in moving their causes forward and in sustaining activism for a more socially just society.

Change the Channel: Can Firms Influence Consumer Channel Choice through Marketing Contacts?

Lyndon Lee, CURO Research Assistant
Dr. Sue Chang, Marketing, Terry College of Business

With the recent proliferation of various channels, such as the Internet, many companies have adopted a multichannel strategy. Today, consumers can purchase a product through more than one channel and will often switch channels based on their channel preference at a specific time. Consumers' fluidity between channels makes it difficult for a firm to determine which channel a consumer prefers at a certain moment and how to contact its individual customers most effectively. Emails and catalogs, currently two of the most common methods of contacting consumers, may increase brand awareness and purchase intention. However, depending on marketing contact strategy (e.g. method used (catalog versus email), frequency of contact), the marketing contacts may result in different purchase and channel choice decisions of consumers. While previous research exists studying various relationships between the channels in a multichannel environment, few papers separate the effects of discrete marketing contact methods (e.g. email versus catalog). Using a dataset from an undisclosed retailer, we built a model to analyze the different impacts of email contacts and catalog contacts on the performance of each channel in a multichannel environment. We also examine other critical factors influencing the channel decisions of consumers such as the convenience of product return and the consumer's distance from a physical store.

The Impact of Foreign Aid on Democracy in Africa

Benjamin Leigh
Dr. Laura Zimmermann, International Affairs, School of Public & International Affairs

This paper seeks to address the impact of foreign aid on the democratization of recipient countries in the African context. There is some evidence in the academic literature that governments are less responsive to the people, and the people care less about government actions, when government income comes from sources other than direct taxation. With most foreign aid tied to the goal of promoting democracy, there are serious implications for policy if foreign aid reduces the likelihood of a recipient country democratizing. Using a variety of sources on foreign aid receipts and democracy scores over time for different countries, this paper seeks to analyze the impact of foreign aid on democracy. The paper begins with a review of literature, followed by a discussion of the relevant questions. Methods are discussed and followed by data, which is then interpreted. A conclusion follows to tie all parts of the paper together.

Design of a 1,5-Substituted Triazolyl-Bridged Peptide to Inhibit EGFR Activation

Peter Liaw, CURO Research Assistant
Dr. Eileen Kennedy, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The Epidermal Growth Factor Receptor (EGFR) signaling is tightly controlled and involved in many cell activities such as growth, differentiation, and migration; however, overexpression of EGFR has been linked to many carcinomas such as breast, prostate, and colorectal. A significant step in the activation of EGFR involves a region termed the "dimerization arm" within domain II. Dimerization arm interactions between two EGFR monomers lead to trans-autophosphorylation of the intracellular domains and subsequent downstream signaling events. Our lab aims to inhibit EGFR by disrupting important protein-protein interactions for receptor activation. In this project, I have synthesized a dimerization arm mimic using 1,4- and 1,5-substituted 1,2,3-triazolyl bridges to lock the peptide into a beta-loop conformation. A medicinal chemistry approach will be used to compare the 1,5-substituted peptide with the 1,4-substituted peptide. The peptides were synthesized using conventional Fmoc solid phase peptide synthesis with a ruthenium-catalyzed azide-alkyne cycloaddition to form the triazolyl-bridge. Two ruthenium catalysts were tested under different reaction conditions. The structure of the peptide will be characterized and cellular activity will be tested. This research offers a medicinal chemistry approach to inhibit EGFR by synthetically blocking the dimerization interface. Furthermore, this approach can be applied towards other peptide-peptide interactions, especially ones that utilize a beta-loop conformation.

How Did Female Candidates Fare in the 2014 Election?

Alexandra Lilly
Dr. Charles Bullock, Political Science, School of Public & International Affairs

Females are still vastly underrepresented in governments around the world, and specifically in the United States. While women make up about 50% of the population, they make up 19.4% of our national legislature. This paper researches how successful women were in gaining seats in both the House of Representatives and Senate in the 2014 midterm elections and which factors affected their success. I will be comparing the data from the most recent election to traditional national trends pertaining to the success of women in these elections. A variety of factors will be analyzed. First, I will identify the percentage of women elected to each house of Congress, which parties elected them, and their success in primaries as well as in runoffs. I will also further study the freshman female legislators: how many there were and which factors

contributed to their success. Next, I will find where women obtained funding for their campaigns. Lastly, I will examine trends in the original careers of female legislators. This information can all be found in online databases. The midterm election is significant, as it is the last national election before a major Presidential election year. This election is unique because traditionally, more women are elected from the Democratic Party, but with the strong Republican climate in the nation, more female Republicans found success in the 2014 midterms. There are 100 women for the first time ever, and this data can give a clearer insight of the factors contributing to this trend.

Disruption of Signaling at Oocyte MTOCs Leads to Meiotic Division Errors and Embryonic Loss

Mallory Little, CURO Graduation Distinction
Dr. Maria Viveiros, Physiology & Pharmacology, College of Veterinary Medicine

Aneuploidy (an abnormal chromosome number) in oocytes before fertilization can lead to pregnancy loss and birth defects such as Down syndrome. Aneuploidy can result from meiotic chromosome segregation errors owing to spindle defects and inaccurate chromosome-microtubule attachments. Potential underlying causes of spindle defects include disrupted microtubule-organizing center (MTOC) associated proteins. This study tested the function of a key MTOC-associated protein, pericentrin. Using a unique transgenic RNAi oocyte-conditional knockdown mouse model, we tested the impact of pericentrin loss on meiotic division and female fertility. Q-PCR confirmed lack of *Pcnt* transcripts in oocytes from transgenic females, and fertility was determined by mating with control males for 6 months. Moreover, metaphase-II oocytes were collected to evaluate spindle and chromatin configurations by immunofluorescence. The mean number (± SE) of viable pups/litter was significantly lower in transgenic females (4.89 ± 0.78 *vs.* 11.62 ± 0.93), and timed mating analysis on day16 (E16) of gestation revealed that embryonic loss occurs post-implantation in utero. Immunofluorescence confirmed pericentrin expression at MTOCs in oocytes from control, but not transgenic, females. The *Pcnt*-depleted oocytes showed increased spindle disruption and chromosome misalignment as well as a higher incidence (18.8 ± 4.6 *vs* 8.3 ± 2.7) of attachment errors, as indicated by chromosome lagging. These defects potentially contribute to chromosome segregation errors that lead to aneuploidy. This study confirms effective depletion of pericentrin in oocytes from *Pcnt* RNAi transgenic female mice. Notably, pericentrin loss in oocytes is associated with increased meiotic errors and significant embryonic loss. Funding: NIH (HD 0713330)

Electronic and Photonic Modeling of GaN/InGaN Multiple Quantum Well Light Emitting Diodes

Bhaskar Lokanathan, CURO Research Assistant
Dr. Lawrence Hornak, College of Engineering

LEDs (Light Emitting Diodes) play a vital role in most optoelectronic devices, and recently there has been great interest in the development of efficient Group III Nitride Light Emitting Diodes, as they allow a wide range of wavelengths. Much research has gone into quantum wells, as they increase efficiency and allow tuning in emission wavelength. The time and cost of fabricating these devices hinders further research in optimization of these devices, so Technology Computer Aided Design (TCAD) simulation tools have been crucial in aiding engineers in the early design phase. These tools may be used to model the materials, device physics, and quantum effects of multiple quantum well LEDs. In this research project, TiberCAD and Optiwave FDTD will be used to design

and analyze device components of multiple quantum well (MQW) LEDs. The effects of electronic and photonic device characteristics including: variations of mole fraction and well width on MQW energy levels and optical emission wavelength, impact of device layout on light extraction, and current-voltage (I-V) characteristics will be examined. The results will be compared to fully grown and fabricated GaN/InGaN MQW LEDs in order to optimize their performance.

The Presentation of Victimhood and Virtue in the Holocaust-Focused Works of George Tabori

Kelsey Lowrey, Foundation Fellow
Dr. Martin Kagel, Germanic & Slavic Studies, Franklin College of Arts & Sciences

I studied the works of the Hungarian-German Jewish playwright George Tabori and their relationship to the late feminist concept of oppression as a social position, specifically through the lens of the Holocaust, as well as their value as works for confronting and making sense of loss under the Nazi regime and continuing injustices in the world today. To do this I compared two of Tabori's best-known works with a play by his contemporary and known inspiration Bertolt Brecht, whose unique style of critiquing oppression is already well-studied. I also applied theories from second-wave feminist essays to Tabori's works and to his literary portrayal of victimhood. I ultimately found Tabori's works to propagate an oppressive idea of victimhood and virtue being necessarily indistinguishable, with strongly misogynistic undertones, making his works at best useful for coping with the realities of the Holocaust in the late 20th-century Germany for which he wrote them, and at worst not useful and potentially harmful to apply to instances of oppression in the modern world. Tabori is a celebrated author in Germany and his works hold great cultural significance there, but few critiques of the modern social implications of his writing have been made – critiques which are necessary when dealing with works that influence national opinion over topics as significant as the Holocaust and the social position of the victim.

Use of a Breath-Hold Paradigm to Remove FMRI Variability due to Vascular Factors in Older Adults

Joshua Lukemire, CURO Summer Fellow
Dr. Lawrence Sweet, Psychology, Franklin College of Arts & Sciences

Functional Magnetic Resonance Imaging (FMRI) is one of the principle methods used to investigate cognition. FMRI analyses are based on the blood-oxygen-level-dependent (BOLD) signal, which depends on blood flow and volume and is considered a proxy for neural activity. For inference based on FMRI to be reliable, it is important that BOLD differences between subjects be due to neural activity and not physiological factors. If a condition such as cardiovascular disease causes participants to have compromised neurovasculature, their BOLD responses could show systematic differences from healthy adults. Methods correcting for differences in neurovasculature are needed to overcome this. One such method is breath-hold scaling, which uses a breath-hold task to elicit a robust increase in blood flow. Due to the cognitive ease of the task, most of the BOLD change induced should reflect physiology. The response to another task is scaled using the response from the breath-hold task, and the resulting data is less confounded by physiological differences. In this study we investigate the effects of breath-hold scaling in 18 older adults. We scaled the response to a working memory task and examined regions of interest (ROIs) in 15 task-related areas, as well as 3 control areas. All but 2 of the task-related ROIs showed a significant reduction after scaling; however, no significant changes were observed in the control ROIs. These findings suggest that

scaling is having the intended effect of producing a signal that more accurately represents the neural component of the BOLD response by removing physiological confounds.

Type of Infant Feeding, Weight, and Body Composition Changes in Early Infancy

Joy Maduka
Dr. Alex Kojo Anderson, Foods & Nutrition, College of Family & Consumer Sciences

Childhood obesity and rapid weight gain has been linked to feeding practices during the formative stages of life. The purpose of this study is to examine the influence of types of infant feeding (breastfeeding, mixed feeding, and formula) on infant weight gain and body composition changes in early infancy. This is part of a pilot study that enrolled pregnant women and followed them through 16 weeks postpartum. Infants born at full-term and normal birth weight were scheduled for weight and body composition measurements via the PEA POD at 2, 8, and 16 weeks postpartum. Mothers were required to keep a bi-weekly 24-hour feeding log. At birth, breastfed newborns weighed slightly higher than formula fed infants (3.64 kg vs 3.04 kg, $p=0.029$) and the rate of weight gain was slower among breastfed compared to formula fed infants, although not statistically significant ($p>0.05$). There was a statistically significant difference in percent body fat (adiposity) between breastfed and formula fed infants at 8 weeks postpartum (19.36% vs 12.98%, $p=0.03$) but not at 2 weeks (13.27% vs 12.60%, $p=0.10$) and 16 weeks (22.56% vs 16.63%, $p=0.14$) postpartum. Our preliminary results show that the rate of change in adiposity is faster for breastfed infants compared to formula fed infants, though not statistically significant. Initial observation suggests that early infant body composition is associated with infant feeding type. A further examination of the influence of feeding mode is likely to improve our understanding of the differences in changes in adiposity between breastfed and formula fed infants.

Mammary Gland Specific Deletion of Rac1 on MMTV-PyVT

Eric Malaney, CURO Research Assistant
Dr. Tamas Nagy, Pathology, College of Veterinary Medicine

Rho family G proteins have been found to be integral for regulation of a myriad of functions in the cell. One such function is a role in gene expression. Through lamellipodia extension, the regulation of Rac protein of the Rho family GTPases allows these proteins to be found in the body in both active and inactive states; in the GTP-bound state, these GTPases are active, and in a GDP-bound state, they are inactive. Initially, Rac1 was identified as an essential player in β1-integrin signaling in cultured mammary epithelial cells. More recently, Rac1 was found to be indispensable for prolactin signaling during secretory maturation of the mammary epithelium. Overexpressing Rac1 has been found to promote tumor development of the mammary gland in mice. Our current work in the laboratory focuses on further delineating the precise role of Rac1 in mammary carcinogenesis using mutant mice with mammary gland-specific deletion of Rac1 and mammary gland-specific expression of the polyoma middle T antigen (PyVT), a known oncogene. We found that mice having both PyVT expression and Rac1 deletion in the mammary epithelium develop mammary tumors significantly later than mice that only have PyVT expression in the mammary epithelium. The research was performed by purposefully breeding different mouse lines to generate offspring with desired genotypes, PCR genotyping of offspring, and immunoblotting. The goal of the research is to further characterize the role of Rac1 in mammary carcinogenesis in order to explore possible new avenues in anticancer therapy.

The Relationship between Adverse Child Experiences, Family Needs, and Child Outcomes

Emily Maloney, Foundation Fellow
Dr. Stacey Neuharth-Pritchett, Educational Psychology, College of Education

Children living in poverty are exposed to a number of adverse childhood experiences (ACEs), placing them at-risk for prolonged negative cognitive, emotional, physical, and mental health issues (Sacks, Murphey, & Moore, 2014). Research from neuroscience suggests children living in toxic stress conditions resulting from ACEs demonstrate decreased executive functioning skills – the higher cognitive functions responsible for memory, inhibitory control, and mental flexibility (Center on the Developing Child, 2011). The Head Start program serves as a stabilizing preschool environment for children with ACEs to attenuate these harmful side effects of living in poverty. When applying for Head Start, families supply background information on the number of ACEs in relation to identified family needs. Head Start then theoretically uses the family needs assessment to help the family set attainable goals realized by program exit. The research question for this causal-comparative study was: What is the relationship between number of ACEs, family needs and goals, and child developmental outcomes? Results indicated the number of ACEs experienced by families was statistically and significantly related to needs expressed by parents including employment, finances, mental health resources, parent/child bonding, and education. Children with more ACEs had parents who specified goals consistent with addressing such needs, but not in all cases. Children in families experiencing more ACEs had poorer cognitive development scores at the beginning of the intervention year. This study illuminates the complex relationship between ACEs, family goal setting, and child outcomes in designing intervention for children and families living in poverty.

Reducing Teen Pregnancy: The Case for Comprehensive Sex Education in Georgia

Emily Maloney, Foundation Fellow
Nneka Ewulonu
Mallory Harris, Foundation Fellow
Dr. Stacey Neuharth-Pritchett, Educational Psychology, College of Education

Georgia's current policy on middle school sex education stresses abstinence and focuses on the negative effects of premarital sex, requiring coverage on sex and HIV but not contraceptives or sexual coercion (Georgia Parents for Responsible Health Education). Although abstinence-only education has some short-term effectiveness in pregnancy and disease prevention, this approach has been shown to have little to no impact on future sexual attitudes (Devaney, Fortson, Quay, Wheeler & Clark, 2007). The state of sex education standards in Georgia is significant because of the negative consequences it has for both teenagers and taxpayers. Teenagers clearly suffer physical, social, and economic consequences of inadequate sex education. Costs associated with Georgia's teen birth rate totaled over $395 million in 2010, accounting for 19,029 teen pregnancies (Georgia Campaign for Adolescent Power and Potential). This research is intended to explore implementable comprehensive sex education policy alternatives to the current standards for sexual education in Georgia. The primary method in this research was analyzing the effectiveness of different types of sex education and basing the policy on previous comprehensive programs in other states and countries. Based on our findings, we believe the Georgia Department of Education should revise and improve the Quality Core Curriculum Standards and Resources to require comprehensive sex education and institute a system of 30 certified educators, each teaching sex

education in 16 or 17 geographically clustered schools, covering all 485 Georgia public middle schools.

Perception of Student-Athletes on UGA's Campus

Jillian Maloney, Cara Smith, Mackin D'Amico
Dr. Billy Hawkins, Kinesiology, College of Education

When student-athletes are being recruited, coaches convey the idea that they will be universally admired as student-athletes on campus. In our personal experience, most non-student-athletes perceive student-athletes as arrogant, receiving special treatment, and as being at a lower academic level than the average UGA student. So, are student-athletes admired or detested, and what is the cause of this perception? To measure the true perceptions of student-athletes, we surveyed non-student-athletes, student-athletes, and instructors, asking questions about their experiences with student-athletes and the amount of benefits that student-athletes receive. The implications of this study are that student-athletes may be conditioned, through the recruiting and athlete orientation process, to have an inflated sense of importance on campus, especially revenue-generating student-athletes. We believe that non-student-athletes and even instructors sometimes hold student-athletes in a negative light. Even student-athletes sometimes have negative perceptions of their fellow athletes, finding them more arrogant than the average student. We also explored the difference in observations for revenue-generating student-athletes and non-revenue-generating student-athletes. The student-athletes in revenue-generating sport are subject to the most polarized perceptions and seemed to experience the admiration of non-student-athletes, while also being judged for their attitudes and academic levels by student-athletes and non-student-athletes alike. We believe that student-athletes are often held in a negative light because non-student-athletes exaggerate the amount of benefits student-athletes received while underestimating the amount of sacrifices student-athletes must make.

Impact of Intermittent Glucose Oscillations on Vascular Endothelial Cell Inflammation

Meagan Marshburn, CURO Research Assistant
Dr. Nathan Jenkins, Kinesiology, College of Education

People with type 2 diabetes are at elevated risk for cardiovascular diseases, in part due to intermittent extreme high and low oscillations in blood glucose levels. Exercise has been shown to improve glycemic control, yet the implications of this effect for cardiovascular health are not known. The aim of this study is to determine the effect of intermittent high and low glucose oscillations on vascular endothelial cell inflammation using an in vitro model system. Cultured endothelial cells will be exposed to a variety of glucose solutions based on research-supported postprandial glycemic fluctuations over two and a half hours to mimic the blood glucose response to a high carbohydrate meal in humans. Experimental conditions include conditions mirroring the typical responses observed in people with (i) normal glucose metabolism, (ii) mild type 2 diabetes, (iii) severe type 2 diabetes, and (iv) when people with diabetes perform a light walk 30 minutes after a meal. The endothelial response will be quantified by examining the expression of inflammatory markers (vascular adhesion molecule 1, intercellular adhesion molecule 1, E-selectin, and tumor necrosis factor-alpha). Expression of these markers will be assessed at the mRNA level by PCR and the protein level via flow cytometry. We hypothesize that there will be a significant reduction in endothelial cell inflammation under exercising postprandial glucose conditions compared to

the type 2 diabetic condition. The results of this study could contribute to the understanding of mechanisms underlying the beneficial effects of exercise on cardiovascular health among individuals with type 2 diabetes.

Expanding Polymer Usage for 3D Printing in Tissue Engineering

Andrew Martin, CURO Research Assistant
Paul Cray
Dr. Jason Locklin, Chemistry, Franklin College of Arts & Sciences

Tissue engineering has incorporated the use of 3D printing, most commonly Fused Deposition Modeling, to direct and develop cells and tissues both *in vitro* and *in vivo*. The current number of choices for polymers to be used in medical device implants remains small, especially in load bearing cases. Several new and previously uninvestigated polyesters and blends – Polyhydroxybutyrate Acid, Polylactic Acid/Polycapralactone, and Polyhydroxybutyrate Acid/Polycapralactone – have been provided in pellet form from Meridian Holdings Group, MHG, for investigation. Optimal printing and extrusion conditions were investigated for the construction of high quality 3D printed constructs. Variables such as extrusion temperature, cooling rate, and tension were investigated to generate 3D printed filament 1.70 ± 0.05 mm. Once the filament generated, 3D print temperatures and extrusion rates become variables for optimization Young's Modulus. Trials investigating filament extrusion temperatures began at 190 degrees C. Extrusion temperature displayed a direct relationship with ductility, exemplifying the need for constant tension with filament development. Measurements are taken of cooled filament once steady state has been reached. Cell viability testing of these polymers will be completed in future work.

Effects of Tempol, a Superoxide Dismutase Mimetic, in Alleviating *Plasmodium chabaudi* Oxidative Stress during Pregnancy

Omar Martinez-Uribe, CURO Research Assistant
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Plasmodium chabaudi AS-infection in pregnant C57BL/6J mice results in mid-gestational pregnancy loss associated with increased systemic pro-inflammatory response and oxidative stress. It is well known that oxidative damage is one of the most important pathological consequences of malaria infections. This study aims to assess the effects of Tempol, a superoxide dismutase mimetic and pleiotropic intracellular antioxidant, in alleviating *Plasmodium chabaudi* AS-induced oxidative stress and its associated complications during pregnancy. Gestational Day 0-infected and -uninfected pregnant C57BL/6J mice were treated with Tempol (100mg/kg) or vehicle from Gestational Day 6 to 12 via drinking water. The drug was safe, evidenced by the absence of significant differences of clinical parameters in Tempol-treated mice versus vehicle-treated mice. More importantly, 4-hydroxynonenal, an α,β-unsaturated hydroxyalkenal that is produced by lipid peroxidation in cells, was significantly reduced in conceptuses of infected pregnant Tempol-treated mice. However, Tempol treatment did not rescue pregnancy loss in this model, suggesting that oxidative stress may not be the only pathological mechanism by which *P. chabaudi* AS-infected mice abort at mid-gestation. Experiments are underway to further elucidate the mechanisms of antioxidant therapy in malaria during pregnancy.

Elucidating the Functional Role of Chondroitin Sulfate Proteoglycans in the Extracellular Matrix for Use in Rationally Designed Glycomaterials

Hannah Mason, CURO Research Assistant
Dr. Lohitash Karumbaiah, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Chondroitin sulfate proteoglycans (CSPGs) are a family of extracellular matrix proteins that play a variety of roles in growth and development. CSPGs are also thought to be potent inhibitors of neuronal regrowth after injury. However, contrasting evidence also suggests that they are key components of the neural stem cell (NSC) niche, where they are thought to be responsible for the maintenance and self-renewal of neural stem cells. We hypothesize that the seemingly paradoxical roles played by CSPGs are largely due to the diversity of their sulfated glycosaminoglycan (GAG) side chains. In order to uncover the diversity and functional attributes of CSPG associated CS-GAGs, we purified CSPGs from mice brains and analyzed CS-GAG content via SAX-HPLC. Contrastingly, results from these preliminary assays revealed a significantly higher expression of dermatan sulfate when compared to chondroitin sulfate. In ongoing studies, we are investigating the effects of presenting monosulfated or oversulfated CS-GAGs on 2D substrates, and in 3D hydrogels on human neural stem cell homeostasis.

Financial Stress among College Students

Blake Mathews, CURO Research Assistant
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

Previous studies have shown a negative correlation between financial stress and academic performance, so the feasibility and practicality of measuring financial stress appears to be a worthwhile research question. Using data gathered in survey results of UGA students since 2008, the pre-existing financial stress instrument used in this study assesses 13 different components of the financial stress of students. Students that took this financial stress survey also provided other information, such as their college of study, age, gender, and whether they took out student loans. Students were asked to indicate a stress level of between one and four for the 13 different components of the test, which resulted in an average total of 24.576. The maximum and minimum potential scores were 52 and 13, respectively. Certain traits seem to impact stress in different ways. Using regression analysis, two factors seemed to impact overall stress levels the most: student loans and the college that a student is a part of. On average, students who had taken out student loans for which they were responsible showed significantly higher levels of overall financial stress, while majors in the college of business showed lower levels. Age and gender also impacted certain elements of financial stress. The instrument used has a Cronbach's alpha of 0.82, which suggests that it is a reliable measure. Such a measure could be useful to ascertain students most in need of assistance, allowing for the provision of limited resources to those that would benefit from them the most.

Changing Cones: Students' Images of a Dynamic Situation

Kathryn Mauldin, CURO Research Assistant
Dr. Kevin Moore, Math & Science Education, College of Education

The Common Core State Standards for Mathematics (CCSSM) emphasize the importance of students reasoning quantitatively and modeling, but there is limited research on students' activity as they model dynamic situations, including their images of such situations. Researchers have found that students' quantitative reasoning and images of situations have the potential to

play an important role when students engage in modeling. The goal of this study was to explore the images students leveraged as they made sense of and modeled a relationship between two quantities in a dynamic situation. We used semi-structured task-based clinical interviews to obtain data of ten undergraduate students representing the relationship between the height and the outer surface area of a computer generated dynamic cone that was growing and shrinking. Students relied on various images as they completed this task. Two out of the ten students only leveraged images of quantities changing constantly with respect to time when constructing any relationship within the situation. The remaining students relied on the use of more sophisticated images, such as 2-D and 3-D representations of the cone. Although both the 2-D and 3-D images permitted students to develop feasible solutions, neither type of image guaranteed a correct solution. The results indicate that students developed idiosyncratic images that greatly impacted their solution to the task. Thus, teachers need to be attentive to students' images as they model situations in order to support students in reasoning quantitatively.

The Effects of TnAV-2a on the Complex Interactions between the Parasitoid *Microplitis demolitor* and Various Lepidopteran Species

Johnathan Mayfield, CURO Research Assistant
Dr. Gaelen Burke, Entomology, College of Agricultural & Environmental Sciences

Ridding a crop of devastating agricultural pests requires comprehensive approaches to find an effective solution. One alternative solution to harmful insecticides involves parasitoids, which are insects that parasitize other insects and kill them, all the while completing some of their development within the host. Moreover, many parasitoids are more successful in parasitizing because of mutualistic viruses that evolved from previously pathogenic ones. Thus, studying viruses and their role in the complex interactions between insect parasitoid and host proves beneficial economically and environmentally. The purpose of this study was to explore the complex interactions between the parasitoid wasp *Microplitis demolitor*, the lepidopteran hosts it parasitizes, and TnAV-2a, an ascovirus. TnAV-2a is a pathogenic ascovirus, but there is another ascovirus that is mutualistic with a species of parasitoid wasps, supporting the idea that TnAV-2a could evolve to become mutualistic with *M. demolitor*. Five lepidopteran species were used as potential hosts for *Microplitis demolitor* and include *Pseudoplusia includens*, *Heliothis viriscens*, *Spodoptera frugiperda*, *Trichoplusia ni*, and *Helicoverpa zea*. These same five species were used as hosts for TnAV-2a. *M. demolitor* attempted oviposition in all five species, but *S. frugiperda* and *T. ni* were unsuccessfully parasitized. Furthermore, all species were inoculated with TnAV-2a and showed characteristics of TnAV-2a infection which include arrested development, white hemolymph, and premature death. Preliminary trials of TnAV-2a injections on parasitized lepidopterans show 100% mortality of the wasp larvae within the host. Further research is necessary to fully understand the elaborate interactions between TnAV-2a, parasitoid wasps, and lepidopteran hosts.

The Impact of Severe Weather Events on Market Returns

Thomas McBrearty, CURO Research Assistant
Dr. Bradley Paye, Banking & Finance, Terry College of Business

This paper examines the impact of the monsoon season on equity and bond markets in Southeast Asia. Data consist of daily equity and bond market index returns from six Asian markets (China, Indonesia, Philippines, Japan,

South Korea, Vietnam, Singapore), seasonal indicators capturing the monsoon season, and daily precipitation data from the National Oceanic and Atmospheric Administration. I will test whether variables capturing the effects of the monsoon season relate to equity and bond market returns in affected countries, and whether weather-related variables impact the risk (volatility) associated with these assets. Specifically, I will be measuring the deviation of daily precipitation levels from the annual mean and exploring this deviation's relation to equity and bond returns. This empirical analysis is novel for several reasons. First, most existing studies relating weather conditions to asset prices focuses on US and European markets. Second, much existing research focus on behavioral and psychological channels connecting weather to asset prices. Our study emphasizes the real effects of flash floods, severe drought, and the infrastructure damage associated with the monsoon season in Southeast Asia.

Algorithmic Forecasting through Big Data Analytics

Thomas McBrearty, CURO Research Assistant
Daniel Sanchez, Andrew Angoyar, Carson Aft
Dr. Qing Zhang, Mathematics, Franklin College of Arts & Sciences

"A spontaneous urge to action rather than inaction, and not as the outcome of a weighted average of quantitative benefits multiplied by quantitative probabilities." In these timeless words, John Maynard Keynes described the "animal spirits" by which our economies move and grow. Prior to the advent of the Internet, it was impossible to accurately measure, but thanks to the exponential growth of data from search engines and social networks, it is now possible to gauge the spirits behind the movements. Harnessing data from social networking and search engines, we intend to use multivariate regressions to measure the impact of keyword frequency (e.g. debt, inflation, iPhone, mortgage, retirement) on market indices. It is our intention to parse data in real-time, then measure amplitude of deviation from the predicted numbers as a forecasting tool. Based on a literature review of this relatively new forecasting method and preliminary findings, we expect to find a strong relationship between keyword trends and market movement. Beyond generalities, we believe that there will be strong emergent relationships as the degree of specificity grows, both with the type of index and the keywords analyzed. The significance of this research goes to building more predictive ways of quantifying finance beyond the tools used today. While this may not be viable as an absolute predictor, it will help to explain the underpinnings of the increasingly complex marketplace of the 21st century.

Procedural Polarization: Examining Changes in the Construction of the Roll Call Voting Record, 1877-2012

Jordan McKissick, CURO Research Assistant
Dr. Anthony Madonna, Political Science, School of Public & International Affairs

Scholars of congressional politics frequently report that polarization is at an all-time high. However, these observations are almost exclusively based on longitudinal analyses of roll call vote data. While this has given scholars an accurate impression on how roll call voting has changed over time, less attention has been given to changes in the roll call generating process. We argue this has led to biased inferences about ideology and American political institutions. To gain leverage on this topic, we utilize an original dataset of all amendments to major legislation from congresses sampled from the 45th Congress (1877-1879) to the 111th Congress (2009-2011). Utilizing these data, we examine the link between the ideology of the amendment sponsor and the likelihood a recorded vote was taken. We hypothesize that

desirability of a roll call vote has not been constant across time and amendment sponsor.

The Photodissociation of SH+ in the Interstellar Medium

Elizabeth McMillan, CURO Research Assistant
Dr. Phillip Stancil, Physics & Astronomy, Franklin College of Arts & Sciences

Photodissociation is a chemical reaction that uses photons to break down a chemical compound. This reaction is an important mechanism for the destruction of molecules in the interstellar medium. In the search for novel molecular species in interstellar and circumstellar environments, sulfur-containing molecules have been observed and identified in diffuse and translucent clouds. The sulfur-bearing molecules SH and SH+ have recently been detected in the interstellar medium. SH and SH+ facilitate the formation of other sulfur-bearing molecules, so information about their concentrations is necessary for the investigation of the chemical composition of astrophysical environments. As searches for new molecular species continue, molecular destruction processes involving sulfur are of considerable interest. These molecular destruction processes, along with other processes, can be used to create a chemical network that can predict the concentrations of major sulfur species in various astrophysical environments. Using ab initio molecular potential energy curves and transition moments, as well as quantum-mechanical processes, we have carried out calculations for the photodissociation of SH+. Prior to this study, no calculation of the destruction rate of SH+ through photodissociation had been performed. This calculated photodissociation rate can be used to improve sulfur chemical network models, giving astronomers a better idea of the concentrations of sulfur-bearing molecules in various astrophysical environments.

Examination of Localization of *Mycoplasma pneumoniae* in relation to Tethered Mucins MUC1 and MUC4

Alison McWhorter Anderson, CURO Honors Scholar
Dr. Duncan Krause, Microbiology, Franklin College of Arts & Sciences

Walking pneumonia is a chronic infection most commonly seen in young adults and children, caused by the bacterium *Mycoplasma pneumoniae*. Infections are transmitted by aerosol, allowing the bacteria to infect the ciliated epithelium of the conducting airways. We use Normal Human Bronchial Epithelial (NHBE) cells in an *in vitro* model because they create a mucocilliary barrier comparable to the one that forms in the human airway *in vivo*. Previous studies demonstrated that *M. pneumoniae* attaches initially to the cilia and then slowly spreads laterally on the epithelial surface. In addition, it is also known that localization of the tethered mucins MUC1 and MUC4 differs on cilia from the rest of the cell surface. Based on this knowledge, we hypothesize that the localization of MUC1 and MUC4 affects the speed by which *M. pneumoniae* spreads on infected cells. We predict that the cells in this study will show distinct colonization patterns consistent with this hypothesis, and our goal here is to test that hypothesis by correlating *M. pneumoniae* infection patterns on NHBE cells with MUC1 and MUC4 distribution. We infected underdeveloped and terminally differentiated NHBE cells with *M. pneumoniae* for four hours and then examined *M. pneumoniae* localization in relation to that of MUC1 and MUC4 by using immuno-histochemical staining and fluorescent and scanning laser confocal microscopy. Preliminary results have shown that MUC1 and MUC4 localization patterns differ on both underdeveloped and terminally differentiated NHBE cells.

Abstracts

Concussive Traumatic Brain Injury Therapy Using iPSC-NSCs in a Porcine Model

Mary Mehegan, CURO Research Assistant
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

In the year 2000, 2.5 million people suffered from a TBI. In the United States alone, approximately 50,000 deaths result from TBI annually, with toddler-age children being the most affected demographic. At this time, there is no adequate TBI treatment available. Recently, the West Laboratory developed induced pluripotent stem cell-derived neural stem cells (iPSC-NSCs). These iPSC-NSCs may potentially serve as a regenerative cell replacement therapy, as they are capable of differentiating into neurons, astrocytes, and oligodendrocytes and produce regenerative factors such as VEGF. These cells have been shown to lead to significant structural and functional improvement in rodent models that have suffered similar neural injuries. However, treatments that have been developed in rodent models have regularly failed in clinical trials, and therefore more predictive large animal models are needed. The pig serves as a potentially excellent large animal model, with a large gyrencephalic brain that has gray-white matter composition similar to humans, unlike rodent models. In this study, we propose to develop a novel piglet concussive TBI module. We hypothesize that piglets receiving a corticalimpact at 2, 4, and 6 meters per second will develop brain lesions, show changes in inflammatory response, macrophage infiltration, and glial scaring, and show changes to motor function deficits ranging from mild to severe based on impact speed. Development of this model will allow for the testing of efficacy and safety of novel stem cell therapies as well as traditional pharmacological and device approaches.

Evolution of Root System Morphology and Nitrogen Uptake in Genus *Helianthus*

Benjamin Miller, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

The acquisition of nutrients from the earth to the plant is a key function of the root system; however, how plant root systems have evolved across soil fertility gradients is not well understood. We examined three pairs of *Helianthus* species chosen as phylogenetically independent contrasts with respect to native soil fertility to further understand the relationship between local adaptation, root morphology, and nitrogen (N) uptake levels. Morphology was measured using the appropriate length measurements, and N uptake was tracked through isotope 15N. While N supply in all experiments remained the same in all species, species native to low nutrient soils exhibited a higher rate of N uptake, higher root tissue density, and lower overall root mass relative to their high nutrient adapted sister-species. In contrast, species native to high nutrient soils had a higher root/mass ratio and a higher total root length. The consistent differences detected between species native to soils differing in nutrient availability indicate repeated evolution of root morphology and nutrient uptake traits across nutrient gradients. The significance behind this study is that N uptake and root morphology likely play an important role in adaptation to soil fertility levels. This study provides information for breeding crops which can efficiently use soil resources and prevent wasted products.

Practical Grant Writing

Jennifer Milley
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

This research project centered around the methods and practices of writing a successful

grant. Grants are awarded throughout the academic and professional world as means to fund a broad spectrum of projects, studies, etc., and are an integral part of the financial structure of our world. Thus, as a skill, grant writing is a highly valuable and useful tool for nearly every profession and area of study. The research took two directions: research into grant-writing and research into three children's theatre companies. The culmination of this research was to write a mock grant which requested funding to start an international children's theatre festival in Athens with the purpose of providing community outreach and education. The festival would last for three days and incorporate performance and workshops from three children's theatres which have a strong educational component. The oral presentation will discuss the different parts of a grant and the steps to take to gather the appropriate information in order to write a successful grant. Examples of each step will concern the theatre companies, why they were chosen, and the benefits of having such a festival in the Athens area.

Purification of Hirano Bodies in *Dictyostelium discoideum*

Sandip Minhas, Foundation Fellow
Dr. Marcus Fechheimer, Cellular Biology, Franklin College of Arts & Sciences

Hirano bodies are paracrystalline structures that have been found in the post-mortem examination of human brain tissue. They have been shown to be associated with aging, diabetes, alcoholism, cancer, and neurodegenerative diseases such as Alzheimer's disease. Hirano bodies are composed primarily of filamentous actin and actin-associated proteins. The study of the physiological significance of Hirano bodies has been hampered by the lack of a model in living cells. Our laboratory induced the formation of model Hirano bodies in *Dictyostelium*, cultured mammalian cells, and transgenic mice. Hirano bodies protect cells from death induced by the intracellular amyloid precursor domain, enhance death due to forms of tau in frontotemporal dementia, and cause impaired spatial memory in mice. The goal of this project is to purify model Hirano bodies in *Dictyostelium* in order to determine the protein composition of these inclusions. The cells were lysed, and the Hirano bodies were collected using low speed sedimentation and fractionation with iodixanol gradients. The fraction containing the Hirano bodies was analyzed for purity of the inclusions by searching for the presence of various other cellular components such as cell nuclei and mitochondria. Gel electrophoresis and western blotting was used to initially identify possible proteins present in the Hirano bodies following the density gradient purification. Mass spectroscopy was subsequently utilized to identify the candidate proteins from the fraction containing the Hirano bodies. Future research conducted in this area will examine and verify the roles of the suspected proteins in the formation of Hirano bodies.

Promoting Products, Cutting Costs: Advertising Industry Strategies and Tactics in the United States, 1973-1976

Sapna Mistry, CURO Research Assistant
Dr. James Hamilton, Advertising & Public Relations, Grady College of Journalism & Mass Communication

The purpose of this study is to a) explore possible relationships between specific advertising strategies and tactics, and overall national economic health, and b) document specific ways in which consumers were directly involved in marketing communication prior to the rise of the Internet and user-generated content. The assumption guiding research design was not only that advertising strategies and tactics change to adapt to times of economic hardship, but that building relationships with consumers and involving

them more directly in marketing communication has long been a key cost-cutting measure in place, not only recently instituted with the rise of the Internet. To investigate this assumption, researchers examined 105 randomly selected issues of the advertising trade journal *Advertising Age* from the years 1973-1976, which was a time of national recession and stagflation. Every item was coded that mentioned a form of direct consumer involvement in marketing. Frequencies of different forms were plotted over time and compared with each other. The data lend support to the assumption. At the start of 1973, *Advertising Age* stories noted the value of contests, sweepstakes, and other games that directly engaged their target markets. By the end of 1973 and into 1974, the frequency of items that mentioned the use premium incentives also increased. By the end of 1976, as the national economy came out of the recession, the frequency of mentions of premium incentives decreased as presumably greater resources were now available to engage in more costly forms of marketing communication, such as traditional advertising.

***Gracilaria vermiculophylla's* Impacts on Herbivory in Georgia's Coastal Ecosystems**

Timothy Montgomery
Dr. Jeb Byers, Odum School of Ecology

There are an unprecedented number of non-native species, with the potential to alter critical ecosystem functions or services, colonizing habitats around the world. *Gracilaria vermiculophylla* (hereafter referred to as *Gracilaria*) is an invasive red seaweed that is highly tolerant of various physical stresses such as temperature and salinity. These tolerances enable it to persist in a wide range of conditions. Georgia is relatively void of any native seaweed species, thus *Gracilaria* represents a source of primary production with potential to alter key ecosystems. Georgia's coastal marine communities have historically been fueled by detritus and the microphytobenthos; however, with the introduction of *Gracilaria*, there is potential for food webs to be based off of macrophyte primary production instead. We conducted a series of feeding experiments consisting of isolated non-choice and choice (*Gracilaria* vs *Ulva*) trials with local marine herbivores: *Eurypanopeous depressus, Ilyanassa obsoleta*, *Lagodon rhomboids*, and the invasive *Synidotea laevidorsalis*. All listed species are locally abundant and categorized as generalist herbivores. Our results suggest that native herbivores do not consume *Gracilaria*; however, the invasive *S. laevidorsalis* significantly consumed *Gracilaria*. This suggest that *Gracilaria* may be largely avoided by generalist because of its chemical defenses, since they are likely yet to develop methods of dealing with such chemical defenses.

Cloning, Expression and Purification of MexT and AmpR from *Pseudomonas aeruginosa*

Kathryn Moore
Dr. Cory Momany, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Pseudomonas aeruginosa is a prevalent hospital pathogen and a leading cause of death in patients with cystic fibrosis. One feature of its high virulence is attributed to its innate antibiotic resistance. Two LysR-type transcriptional regulators (LTTR's) found in *P. aeruginosa,* MexT and AmpR, are known to regulate the transcription of molecules involved in this antibiotic resistance. MexT is a transcriptional activator of the drug efflux pump gene, *mexEF*. Expression of the MexEF transporter leads to the activation of antibiotic resistance against multiple drugs, but significantly against tetracycline. AmpR is a regulator of the gene encoding a β-lactamase, AmpC, which provides penicillin resistance. The *mexT* gene was successfully cloned, and the MexT protein purified from

E. coli cells overexpressing the protein. Additionally, the gene encoding AmpR was cloned, and purification of the protein is in progress. Ultimately, the goal is to crystallize both MexT and AmpR and then to determine their atomic structures by X-ray crystallography. Thyme extracts, which have antibiotic activity against *P. aeruginosa*, will be evaluated as a source of small molecule inhibitors of MexT and AmpR function. Small molecules that bind to MexT or AmpR and inhibit transcriptional activation could be lead compounds for the development of the next generation of antibiotics.

Exploring Evolution in the Classroom: Developing a Hands-On Activity Using *Mimulus guttatus*

Ananya Moorthy, CURO Research Assistant
Dr. Andrea Sweigart, Genetics, Franklin College of Arts & Sciences

My research project aims to create a hands-on laboratory activity for local high school biology students that teaches important concepts in genetics and evolution. The activity I have developed focuses on adaptation to serpentine soils in the yellow monkeyflower (*Mimulus guttatus*). This wildflower species shows tremendous ecological variation in nature, and certain populations have evolved tolerance for the metal saturated environment that characterizes serpentine soils. Currently, I am working to optimize assays to measure serpentine tolerance in *M. guttatus*. I have developed a hydroponic solution to test for differences in seedling germination and survival between individuals collected from natural populations that occur on and off serpentine soils. Previous research has shown differences in serpentine tolerance among adult plants, but a focus on seedlings will allow the experiment to be easily reproduced in a classroom with limited resources. Throughout this project I will be working on a lesson plan to be used in local high school classrooms. This experiment will allow teachers to supplement their evolution unit in the classroom, as well as give students in the Athens area a glimpse of a university science research lab.

Assessment of Proteomic and Glycomic Profiling of Medaka (*Oryzias latipes*) to further the Understanding of the Physiological Response to Low Level Ionizing Radiation

Jason Moraczewski, CURO Summer Fellow, CURO Research Assistant
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Ionizing radiation (IR) is recognized to cause proteomic changes in various organisms. Most prominent studies performed in the field of proteomics primarily focus on the effect of radiation at acute, high doses. However, very little is known about the biological responses when organisms are exposed to chronic, low levels of ionizing radiation. Using medaka (*Oryzias latipes*) as the model aquatic organism, this study will examine the physiological responses to chronic, low-dose IR. Specifically, the proteome and glycome of medaka will be analyzed to quantify any changes that have occurred due to the low levels of IR. The first part of the project is aimed to standardize the methodology for protein extraction and protein fractionation using a control group and a high dose group. Mass spectrometry and bioinformatics will be used to help elucidate any metabolic pathways associated with adaptation to IR exposure. This will advance the understanding of how IR can affect evolutionary processes.

The Effects of Travel on Team-Based Performance

Christopher Morgan, Kyle Ledesma, Rebekah Trotti, Parker Thomas
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

We examined the relationship between distance traveled to work and job performance. As teams in the workforce are required to go on longer trips, the impact of travel is becoming more relevant. Current research indicates that travel induces stress, but there has been little to no research on how travel influences job performance. Using team-based sports data, we examined the relationship between distance traveled and job performance. In addition, we evaluated how the total accumulated miles that teams travel impacts the relationship between travel and performance. Similarly, we looked at how a team's average job experience affects the relationship between travel and performance. Our study shows that the further teams travel for their job, the worse they perform. However, our research indicates that employees are less sensitive to trips over time. The findings of our study are important because there are tangible consequences of travel for one's job. Based on our findings, employers should seek alternative methods for long distance work. However, if travel is inevitable, organizations should be aware that with more trips the negative effects of traveling are weakened. Organizations can further reduce these adverse effects by selecting teams with more average job experience.

High Dynamic Range Imaging For X-ray Image Acquisition

Logan Morrison, CURO Research Assistant
Dr. Mark Haidekker, College of Engineering

X-ray images made from objects with very dense and less dense materials (e.g., bone and muscle tissue) often require a balance between long exposure times that make details in the dense material visible and shorter exposure times that prevent overexposure of the background and less dense regions. In quantitative x-ray images, such as DEXA images for bone densitometry, background information is crucial for normalization of the measured intensities, and overexposure cannot be accepted. High dynamic range imaging (HDRI) is a method presently becoming popular in digital visible-light photography. It involves combining well-exposed pixels from a bracketing series of photographs into one image that represents the actual physical irradiance of the scene. We have adapted this principle to x-ray images, whereby multiple images of the same specimen were taken with varying exposure times. These images were then combined into a composite with only the best exposed pixels from the series accepted into the composite. Moreover, pixel intensities were scaled to match that of the background intensity, and the composite image reflects actual sensor irradiance in exposure regions where otherwise there would be only noise. Accuracy and effectiveness of this method have been demonstrated with calibration phantoms, bone phantoms, and common specimens that contain extremely inhomogeneous densities. HDRX, as we call this method, can be universally applied to any biomedical x-ray imaging system and for non-destructive materials testing purposes to increase the density range in which useful x-ray data can be obtained.

The Effect of Race and Household Structure on Adolescent Alcohol Use

Santana Mowbray
Dr. Natasha Ganem, Sociology, Franklin College of Arts & Sciences

Past research has examined two-parent versus single-parent homes and the delinquency of teens from these households, but few have examined in depth, household structure and

race and its effect on the use of one substance in particular: alcohol. The data for this research was drawn from 5,935 teens who completed a survey on the evaluation of the Gang Resistance Education and Training Program (GREAT) conducted between 1995 and 1999. There are three questions to be addressed in this research: 1) Does race impact the likelihood of teens drinking alcohol? 2) Does household structure (Mother only vs. Both Mother and Father) have an impact on the likelihood of teens drinking alcohol? 3) Does household structure as a third variable have any impact on race in determining a teen's likelihood to drink alcohol? Responses to questions regarding household makeup, race, and alcohol use were drawn from the survey and statistical measures were used to determine the significance of the results. Based on the Social Bond Theory and previous research examining alcohol use, it was hypothesized that teens from "Mother only" households will be more likely to use alcohol. Additionally, it was hypothesized that due to differences in how households are broken up within different racial groups, White teens will be more likely to use alcohol than Black teens. All hypotheses were supported in this research. The results show that household structure amplifies the effects of alcohol use, particularly among teens in single, "Mother only" homes and more specifically among White teens.

Function of Kinesin Proteins in *Toxoplasma gondii*

Kurt Mueller
Dr. Boris Striepen, Cellular Biology, Franklin College of Arts & Sciences

Toxoplasma gondii is a parasitic protozoan and an important human pathogen that causes toxoplasmosis. It is estimated that *T. gondii* infects up to 33% of the world's population. This disease is usually asymptomatic, but can greatly affect individuals with weakened immune systems, such as pregnant women and those with AIDS. Toxoplasmosis has been linked to numerous neurological diseases and can cause encephalitis. *T. gondii* is also a good model for understanding diseases caused by similar parasites such as malaria. This parasite uses a variety of conserved proteins, such as kinesins, that are common to other organisms. Kinesins are motor proteins that move along microtubule filaments and serve a variety of cellular functions such as meiosis, mitosis, and cellular transport. We hypothesize that kinesin proteins play a role in each step of endodyogenous replication of *T. gondii*. Using epitope tagging, protein markers, transformation, and immunofluorescence assay microscopy, we localized and characterized various kinesin proteins throughout the *T. gondii* cell cycle. Proteins such as Kinesin-5 and Kinesin-14S localize to the centromere during metaphase and anaphase of mitosis, while proteins such as Kinesin-14 and Kinesin-8-Kinesin-4/10 localize to the conoid of daughter budding cells during mitosis. Kinesin-14L localizes to the leading edge of daughter buds in replicating cells. The data will also show that inducible knock down of these proteins results in decreased viability, structural morphology, and invasive ability of *T. gondii*. Further studies will determine which proteins are most essential for parasite viability and may have significant medical implications.

Neural White Matter Alterations in Schizophrenia

Megan Murphy, Ramsey Scholar
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Cognitive control (CC) refers to the management of processes such as working memory, attention, and task flexibility. Patients with schizophrenia (SZ) frequently exhibit low CC. Some healthy subjects from the general population, however, exhibit similarly low CC. Deficits in CC are apparent

at the level of neural white matter (WM) connections such as the superior longitudinal fasciculus (SLF), which connects frontal, parietal, and temporal regions, mediating several CC processes. Reduced WM integrity in SLF is linked to lower scores on CC tasks. In this study, we assessed WM integrity in patients with SZ and otherwise healthy individuals with high or low CC (HCC, LCC). We hypothesized that WM integrity of SLF would be greater in the HCC group than the SZ group but would not differ between the LCC and SZ groups. We recruited 24 patients with SZ; 49 healthy participants were recruited and divided into HCC (n = 24) and LCC (n = 25) groups based on performance on a working memory task (SSPAN). Diffusion tensor imaging scans were performed and analyzed using fiber tracing software to obtain fractional anisotropy (FA) values for the SLF. FA is a measure of WM integrity with higher values indicating more efficient myelin structure. FA was significantly higher in the SLF for the HCC group than the SZ group, but no FA differences were found between the LCC and SZ groups. This suggests that WM differences in SLF between healthy and SZ groups may be more attributable to CC differences than to disease.

Carbohydrate T cell Recognition and Presentation

Seema Mustafa, CURO Research Assistant
Dr. Fikri Avci, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The overall purpose of our research is to identify the mechanism of molecular interactions involved in how carbohydrate antigens are taken in by the cell, processed and presented by antigen presenting cells (APCs). My aim in this project is to isolate and characterize T cells specific for the synthesized Pn3-TT antigen and aid in characterizing their corresponding epitopes from the carbohydrate moieties. It was demonstrated in Dr. Avci's *Nature Medicine* paper, "A mechanism for glycoconjugate vaccine activation of the adaptive immune system and its implications for vaccine design" that carbohydrates that were previously considered to be "T-cell independent" antigens are in fact recognized by carbohydrate specific CD4+ T cells (Tcarbs). Recent research has shown monosaccharides and oligosaccharides that are glycosidically linked to peptides can be recognized by T cells. T cell recognition of these glycopeptides depends on the structure of both the peptide and glycan portions of the antigen. Based on the findings, Dr. Avci explores the role that carbohydrate epitopes generated from glyconjugate vaccines had in activating helper T cells. It was then found that these epitopes are presented to specific carbohydrate recognizing T cells through a unique mechanism that is broadly summarized in his paper. Based on the discovery of T cell specific recognition of carbohydrates that induce adaptive humoral immune response and the scientific literature on the existence and function of glycan specific broadly neutralizing antibodies (bNAbs) against HIV-1, our lab hypothesized that the human CD4+ T cell repertoire contains a population of these T cells that is able to recognize epitopes generated from the N-glycan shield of gp120, and by characterizing them and isolating their glycan epitopes, the lab hopes to design and develop glycoconjugate vaccines that are enhanced for T-cell specific stimulating epitopes, whose immunizations will produce strong and long lasting immune response to protect from HIV-1. Flow cytometry, immunofluorescence, T cell proliferation, and ELISASPOT are the primary experimental techniques utilized in the lab. Immunofluorescence is a technique used for light microscopy with a fluorescence microscope. This technique uses the specificity of antibodies to their antigen to target fluorescent dyes to specific biomolecule targets within a cell, and therefore allows visualization of the distribution of the target molecule through the sample. ELISPOT is a

laboratory technique for detecting cells that make (or "secrete") various substances, more specifically in our case detecting cytokine secretion. Flow cytometry is a laser-based technology employed in cell counting, cell sorting, biomarker detection and protein engineering, by suspending cells in a stream of fluid and passing them by an electronic detection apparatus. A common variation is to physically sort particles based on their properties, so as to purify populations of interest and it was used for the purposes of our lab to determine optimal antibody titrations. Western Blot analysis is used to detect protein and Northern Blot is used to detect RNA.

Analysis of Cancer Mutations in Protein Kinases using Semantic Web Technologies

Anish Narayanan, CURO Summer Fellow, CURO Research Assistant
Dr. Natarajan Kannan, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Protein kinases comprise an extensive superfamily of proteins. These complex biological entities are critical in initiating diverse signal transduction pathways, effecting activation of cellular processes through the phosphorylation of target substrates. In order to improve our ability to study kinases, our lab has developed the Protein Kinase Ontology (ProKinO), which captures and aggregates kinase data from a large variety of publicly available data sources into a queryable format. Using this data, it is possible to create large-scale SPARQL queries which can probe interesting questions and elucidate the fundamental nature of the kinome. In this project, a two-pronged approach is taken to analyzing protein kinases. First, with the assistance of an alignment of all of the protein kinase sequences to PKA, a mutational co-occurrence study is performed to identify interacting residues and key motifs in the kinase domain. Second, the breadth of available data currently available in databases, while vast, is limited to a handful of curated, tabulated tables. By performing a large-scale text-mining analysis of Pubmed Central's Open Access Subset containing over one million articles, it is possible to dramatically increase the knowledge base available in ProKinO. Through the careful and judicious use of NLP (Natural Language Processing) algorithms and skilled curators, the impacts of mutations are effectively extracted from the latest primary literature and research, information which can be used in the future to analyze patient cancers in personalized medicine and prescribe ideal, calculated treatments.

Investigating the Influence of Rac1 and Rho Family GTPases in Hair Follicle Biology

Nina Navalkar, CURO Research Assistant
Dr. Tamas Nagy, Pathology, College of Veterinary Medicine

Rac1 is a small G protein in the RhoA family of small G proteins and is expressed ubiquitously throughout the tissues of the body. Rac1 has been known to promote the cell cycle and oncogenic transformation, hence the interest in its role in mammary carcinogenesis. We previously created a mutant mouse line that has mammary gland specific deletion of Rac1 in the mammary epithelium, using the Cre-LoxP system. In analyzing the phenotype of our mutant mice, we found that Rac1 deletion also occurs in the skin as well as results in a phenotype. Thus, the additional goal of our research has become to understand the role of Rac1 in the maintenance of skin and hair follicles. So far we have tested the deletion of Rac1 using PCR, primers, western blotting, and immunohistochemistry and pursued other experiments in order to learn more about the molecular basis of the observed phenotype. We observed that mice lacking Rac1 (skin specific deletion) displayed early onset

alopecia while displaying no lesions in the epidermis. These results provide evidence for the indispensable role of Rac1 in the maintenance of hair follicles and have advanced existing knowledge of Rho family GTPases in hair follicle biology.

"Please Excuse Me as I Am in Need:" Bondage and Freedom in Civil War-Era Athens

Laura Nelson, CURO Summer Fellow, CURO Graduation Distinction
Dr. Christopher Lawton, History, Franklin College of Arts & Sciences

Studying the lives of slaves challenges outmoded, monolithic mythologies of the past and instead recognizes the enormous struggles and equal contributions of both black and white Americans. This research does so by reconstructing and examining the life of Aggy Mills (1827-1900), an Athenian woman enslaved by the elite Cobb family. She was remarkably literate, and through several extraordinary letters that she wrote to her owners, aspects of her life in slavery and freedom, like her role in her master's home and her place in the multicultural Athenian community, become apparent. Trace details of her life were first seen in these letters, but these only recount a portion of her life. To see Aggy as more than a servant, these letters are examined in conjunction with sources in the Athens-Clarke County Heritage Room, property deeds at the courthouse, census records, and various other local sources. Studying Aggy's life helps to give a more multifaceted version of the antebellum South, one where slaves' and whites' lives were intertwined, and slaves managed to define their own lives outside of the realm of their bondage. This research has been transformed into a digital sketch of Aggy's life as a part of the Georgia Virtual History Project. Viewers can hear Aggy's story and see the places connected to her life via a downloadable app for smartphone or tablet.

Giving Up Appointment Television: How Millennials Are Changing What It Means to Watch Television

Kim Nguyen, CURO Research Assistant
Dr. Karen Whitehill King, Grady College of Journalism & Mass Communication

With the increasing popularity of online streaming services, such as Netflix and Hulu, and the increased price of cable television subscriptions, many millennials are changing the way they watch television content. Selecting alternatives to cable television has given rise to a generation of audience members who have discontinued their cable subscriptions (cord-cutters) and people who have never had cable subscriptions (cord-nevers). While advertisers often target millennials, this generation poses a new challenge for advertisers since reaching them through traditional media is no longer as viable as it was for previous generations. Interviews conducted with college-aged millennials provide insight on the motivations that give rise to these trends, television show viewing habits of cord-cutters and cord-nevers, and what implications their decisions have for the advertising and television industries.

A #whitewashed Landscape: Internalized Racism, Linguistic Discrimination, and the Policing of Ethnic Identity on Twitter

Minh Nguyen, CURO Graduation Distinction
Dr. Chad Howe, Romance Languages, Franklin College of Arts & Sciences

The microblogging platform, Twitter, has enabled individuals to create an online community of searchable conversations by means of the hashtag (#), allowing users to find others who share common interests and values. Using data extracted from Twitter, this study analyzes the English expression *whitewashed* as it occurs with and without a hashtag (ex: #whitewashed vs. *whitewashed*) through corpus analysis. The paper also

investigates the grammatical and semantic functions of the hashtag with regard to the racial meaning of English *whitewashed*. The study explores #whitewashed as a metacomment on human behavior, as #whitewashed serves to characterize beliefs about what actions are considered socially unacceptable with respect to performing an "authentic" ethnic identity. Based on qualitative analysis, the data suggest that the use of #whitewashed, as opposed to *whitewashed* without a hashtag, carries a meaning predominately informed by internalized racism and works to bind ethnic minorities to racial stereotypes. And while #whitewashed is used to refer to many ethnic minorities, the data also show that the most salient meaning of #whitewashed is one linked to national identity and xenophobia. The study explores how online users understand ethnic identities shaped by internalized racism and how they communicate these views through the grammatical function of the hashtag.

The Impact of Runoffs: Electoral Reform and Duvergerian Factionalism in Metropolitan Atlanta

Cameron Niakan, CURO Research Assistant
Dr. Charles Bullock, Political Science, School of Public & International Affairs

In Part I, I address claims made by City of Duluth, Georgia officials that runoff elections: (i) inflict too high of a cost, (ii) draw too small of a voter turnout, and (iii) produce inequitable results. Drawing data from 48 Metropolitan Atlanta cities, I examine 160 municipal election returns and their corresponding election invoices from 1993-2013. (i) I utilize average price per ballot cast as a metric of electoral cost and find that Duluth enjoys inexpensive runoffs in comparison to those of other Metropolitan Atlanta cities. (ii) I render the ratio of average runoff turnout to average general election turnout as a metric of "turnout efficiency" and find that Duluth indeed has poor turnout efficiency, whereas Metropolitan Atlanta as a whole has a strong turnout efficiency. (iii) I define an instance of an "inequitable electoral result" as an instance of the "leader loses" phenomenon and/or of an anomalous majority and find that runoffs in Duluth and in Metropolitan Atlanta are reasonably equitable. In Part II, I test whether municipal elections in Metropolitan Atlanta align with Bradley Canon's findings that electoral rules decide patterns in factionalism. In Part II, I utilize the same election returns as those used in Part I to determine, by electoral system, the average number of candidates that ran per post. I find that Canon's "primary structure" hypothesis does not apply convincingly to patterns of factionalism in Metropolitan Atlanta. Although plurality-rule municipal elections are, on average, almost perfectly bifactional, majority-rule municipal elections lean toward bifactionalism, not multifactionalism.

Cloning and Constructing of a Complete RNA Polymerase from *Acinetobacter*

Hanna Nune
Dr. Cory Momany, Pharmaceutical & Biomedical Sciences, College of Pharmacy

RNA polymerases are multi-subunit proteins that transcribe DNA to RNA. In prokaryotes, the enzyme has five subunits: a b subunit involved in ribonucleotide chain elongation; a b' subunit that contains the active site for nucleotide chain polymerization; two a subunits involved in regulation and DNA recognition; a w subunit; and the s subunit that directs promoter specificity. Although we know a great deal about RNA polymerases, a major question remains: how does RNA polymerase communicate with transcriptional regulators? The objective of this research is to produce RNA polymerase from *Acinetobacter baylyi* ADP1. The first step of this project was to PCR amplify RNA polymerase genes from ADP1. The PCR-amplified DNAs encoding

the b and b' subunits (the *rpoB* and *rpoC* genes) were introduced into the vector pRARE2, which has chloramphenicol antibiotic resistance. Each has its own T7 RNA polymerase promoter and terminator. The PCR-amplified DNA encoding a, w, and s subunits (*rpoA*, *rpoZ*, and *rpoD)* were introduced into the pet-28b vector, which has kanamycin resistance. In this construct, a single T7 promoter is used. The two vectors, pRARE2 and pET-28b are compatible with one another in *E. coli*, where the proteins will be co-translated. Purified RNA polymerase from ADP1 will allow studies to be performed to examine the communication between RNA polymerase and transcriptional regulators. Ultimately, the enzyme will be used to identify small molecules that prevent transcriptional activation. By blocking essential regulatory networks in microorganisms, the resulting therapeutics would represent a new class of antibiotics.

The Influence of Structural Factors on Mental Health of Young Women in Post-Conflict Liberia

Mary Elizabeth Nuttall, CURO Honors Scholar
Dr. Tamora Callands, Health Promotion & Behavior, College of Public Health

The aim of this qualitative study was to identify what and how structural factors influence mental health among young women in post-conflict Liberia. We conducted five focus groups with 49 young women and 16 in-depth key informant interviews. Our interviews focused on identifying the impact of everyday stressors and struggles young women in Liberia encounter. We focused primarily on sexual health, mental health, gender roles, and exposure to violence. In this study, young women described ways in which structural factors influence adverse mental health outcomes. The major interconnections are the result of shifts in family structure and dynamics, compromised interpersonal relationships, and unaddressed trauma stemming from war-related violence. Understanding how these connections impact mental health outcomes is key to developing culturally relevant intervention to reduce mental health issues among young women in post-conflict Liberia.

The Effects of Incumbent and Challenger Campaign Spending on Election Results

Kasey O'Brien
Dr. Anthony Madonna, Political Science, School of Public & International Affairs

The purpose of this research design is to identify the effects of campaign spending and to evaluate policy proposals for campaign finance reform. This will be determined by comparing the effects of additional spending by two types of candidates – incumbents and challengers. The experiment would be limited to House elections; because more House seats are up for election each year, a wider sample is available for testing. The findings would show that, in conjunction with conventional wisdom, the effects on vote shares by challenger spending far outweigh the effects of incumbent spending. However, the second component of this theory breaks from relevant academic literature in that additional spending by both candidates is negligible beyond a certain point. Challenger campaign spending eventually reaches a level that puts them on an "even playing field" with the incumbent. At this maximum threshold, the challenger's spending has granted them the same name recognition and other built-in advantages enjoyed by an incumbent, and the marginal gains of spending by either candidate are relatively equal. The experiment examines campaigns over the course of the election cycle, comparing spending data to polling data. The maximum threshold will be determined by accounting for the challenger political quality, brand name recognition, and number of terms served by the incumbent.

These findings could have implications for campaign spending limits, which, if set below the maximum threshold, could be detrimental to challenger success.

Ryanodine Channel Protein in Insects: A Novel Pesticide Target

Onyinyechi Ochiobi, CURO Research Assistant
Dr. Michael Adang, Entomology, College of Agricultural & Environmental Sciences

Ryanodine receptor (RyR) proteins are large-sized calcium channel proteins located in the sarcoplasmic/endoplasmic reticulum that regulate calcium signaling between muscle and neural cells in animals. Ryanodine is a compound in a neotropical bush that is a natural insecticide which locks the calcium channel causing irreversible muscle contraction and insect death. Diamides are synthetic forms of ryanodine with high specificity for caterpillars. Diamides have a critical role in managing caterpillar pests in cotton, soybean, and other crops. However, resistance in the diamondback moth has stimulated interest in RyR proteins of field insects that differ in susceptibility to diamides. My thesis is that by cloning a soybean looper RyR, we can model RyR structure and conduct analyses of RyR-diamide interactions. In our present study, the full length cDNA of *Chrysodeixis includens* RyR (CiRyR) was cloned from adult looper thorax mRNA. CiRyR cDNA contains a 15273-bp ORF encoding 5090 amino acids with a predicted molecular weight of 574.9 kDa. CiRyR has up to 99% amino acid identity with other lepidopteran RyRs. All common conserved structures are present in CiRyR, including six transmembrane domains at C-terminal and a consensus calcium-binding site. Other conserved domains such as MIR (Mannosyltransferase, IP3R and RyR) domains, RIH (RyR and IP3R Homology) domains, SPRY (splA and RyR) domains, and RyR domains (RyR repeated domain) were identified in CiRyR. Significantly, three alternative splice sites were identified in the CiRyR gene. These results provide the foundation to analyze and understand the relationship between structure and function of RyR in *C. includens*.

Transcriptional Interference and Regulation of the Hyb Hydrogenase Operon of *Salmonella*

Selin Odman, CURO Research Assistant
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

Bacterial transcription initiation requires a sigma factor to interact with core RNA polymerase for identification of promoters and opening double stranded DNA. Sigma54 interacts with unique promoter sequences and atypically requires the presence of a DNA-bound activator capable of hydrolyzing ATP to initiate transcription. Recent microarray and ChIP-chip (Chromatin Immunoprecipitation linked to microarray analysis) assays in *Salmonella* Typhimurium (SalTy), which detected sigma54-regulated genes and sigma54-holoenzyme DNA binding sites, identified an antisense sigma54-dependent promoter associated with annotated transcription start sites for the hyb hydrogenase operon. Activation of this sigma54-dependent promoter appears to be associated with decreased transcription of the hyb operon. This novel promoter was identified in the presence of a constitutive, promiscuous activator of sigma54-dependent transcription6, so the focus of this work is to define the physiologically-relevant conditions that activate expression of this sigma54-dependent promoter. Two of four SalTy hydrogenase operons are known to have sigma54-dependent promoters in *E. coli* and are controlled by the activator FhlA. FhlA is activated by anaerobic conditions and formate; it stimulates transcription from promoters that have an associated DNA binding site for FhlA. I am currently

evaluating transcrition from the sigma54-independent promoters for the hyb operon and the antisense sigma54-dependent promoter using a plasmid reporter system and quantitative reverse transcriptase polymerase chain reactions (qRT-PCR). This work is predicted to establish the native activation conditions for the antisense sigma54-dependent promoter indicated to interfere with transcription from the hyb operon promoters in assays performed with the constitutive, promiscuous activator.

Efficacy and Effectiveness Study of Instructional Conditions When Using IRIS Modules in Teacher Preparation

Susan Oh, CURO Research Assistant
Dr. Kristin Sayeski, Communication Sciences & Special Education, College of Education

IRIS multimedia modules, created by Vanderbilt University, are a promising avenue for increasing teacher candidates' knowledge and skills, but research was needed to verify the efficacy of the modules and the effectiveness of the modules under different instructional conditions. The following research questions were addressed: to what extent do IRIS modules increase candidate knowledge of special education related content; is there a relation between instructional condition and learning outcomes for select IRIS modules; does instructional condition influence participants' perception of the overall importance of the content addressed by the module and degree to which the content was learned; and when provided with three different instructional conditions, do candidates express a clear preference for one condition? For this research project, we examined the efficacy of three IRIS modules under three different instructional conditions, which were: Independent condition–where participants completed the modules on their own time outside of class; "Flipped classroom" condition–where participants completed the module independently and then participated in a class discussion and an application activity; and Facilitated condition–where module completion was facilitated by an instructor. 115 participants enrolled in an introductory special education course at a large public university participated in this study. The study employed an experimental pretest-posttest-maintenance across three instructional conditions design. Each week, participants engaged in a different instructional condition with a different IRIS module. The following data were collected as a part of the study: (a) a pretest, posttest, and maintenance assessment for each module (b) five Likert-tye questions immediately following completion of each module and (c) a final questionnaire related to participants' overall preferred instructional condition. Results demonstrated the efficacy of the modules across all instructional delivery formats and a preference for the Flipped (n = 52) and Facilitated (n = 35) instructional conditions. There were significant differences across all three instructional conditions from pretest to posttest with significant effect sizes (PALS module = $F(1.94, 203.49) = 378.67$, $p < .001$; Classroom Management module = $F(2) = 55.80$, $p < .001$; Accommodations module = $F(2) = 94.11$, $p < .001$). In addition, a significant effect for instructional condition was found for the PALS module only. As the majority of content learned in the PALS module relates to how to implement this evidence-based approach, it can be inferred that the implementation of the role-play activity for the Flipped condition supported participants' understanding and knowledge of PALS implementation, thus contributing to higher scores. Overall, findings from the study demonstrate that IRIS modules are successful in teaching the content. Future research should explore knowledge associated with planning and skills related to implementation to determine if the Flipped and Facilitated condition produced learning not assessed by the multiple-choice assessment.

Genetic Determination of Obesity Induced Inflammation and Blood Brain Barrier Alterations

Whitney Okie, CURO Research Assistant
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

Obese patients exhibit an increased risk for chronic diseases such as cardiovascular disease, diabetes, and several cancers. The genetic mechanisms that couple obesity and disease are incompletely defined. Mouse studies have addressed this issue by examining the effects of diet-induced obesity in strains exhibiting disparate sensitivities to a high-fat diet. In the present study, we tested whether obesity-induced changes in gene expression are determined by genetic background in three obesity-prone inbred mouse strains: C57BL/6J (B6), DBA/2J (D2), and AKR/J (AKR). Mice from each strain were assigned to either a control (10% fat) or high-fat (60%) diet for 10 weeks, after which tissues were harvested. Expression of genes related to inflammation (IL-6, IL-1β, TNFα) and blood-brain barrier (BBB) integrity (Claudin-5, Occludin) were analyzed by qPCR. Obesity caused a decrease in liver IL-6 ($p = 0.0035$) in B6 mice and an increase in liver IL-1β ($p = 0.005$) in AKR mice. Obesity also caused an increase in the Blood Brain Barrier marker Occludin in AKR ($p = 0.044$). DBA/2J did not show a significant change in expression in any of the three inflammatory markers, and heart tissue was also consistently resistant to obesity-induced changes in gene expression. Our results suggest that obesity-induced changes in gene expression are: 1) dependent upon genetic background and 2) tissue-specific.

Examining the Digestibility of Methionine in Poultry

Ijeoma Okoye, CURO Summer Fellow, CURO Research Assistant
Dr. Sammy Aggrey, Poultry Science, College of Agricultural & Environmental Sciences

L-Methionine is an essential amino acid required for protein synthesis and normal growth of animals. It is also the first limiting amino acid in a typical corn-soy poultry diet. Utilization of protein or amino acids is affected when deficient or excess levels of a limiting amino acid are supplied. Amino acids interact, and amino acid transporters maintain coordination and integrity of metabolic events. Since methionine is the first limiting amino acid in poultry diet, deficiency in or excess of dietary methionine has the potential to affect nutrient availability and molecular transport. We investigated the growth, feed intake, feed conversion ratio, digestibility, and ileal molecular expression of amino acid transporters in a chicken population fed deficient (DEF: 75% of requirement), normal (CONT: 100% requirement) or excess (EXC: 125% of requirement) dietary methionine over an 18 day period. The body weight gains were 1.52, 177 and 1.64 kg in the DEF, CONT and EXC groups, respectively. There were significant differences in feed intake, digestibility and amino acid transporter expression among the groups. Dietary methionine needs to be optimal to support growth. Deficiency or excess in dietary methionine can affect growth through differential digestibility and nutrient transport of methionine and other essential amino acids.

Evaluating the United States Counterterrorism Strategy Regarding Violent Extremism

Matthew Oldham, CURO Research Assistant
Dr. Dan Silk, Political Science, School of Public & International Affairs

Homegrown violent extremism (HVE) has been perceived as a growing problem in the United States, and community policing has been suggested as an approach needed to address this challenge. This paper provides a metadata analysis of the United States' *Empowering Local Partners* strategy, the United Kingdom's *Prevent* strategy, and articles and

policies to identify growing problems that surround today's model of community policing. Building off existing research, this article will contribute to help academics and policymakers alike, understand the growing issues associated with policing in order to build a better understanding of community engagement programs. The primary areas of focus relate to building relationships with affected communities, identifying homegrown violent extremism, and understanding cultural practices in order to build a more informed police unit.

Investigating the Cell Walls of *Arabidopsis thaliana* Organs using Screenings with Glycan-directed Monoclonal Antibodies and Electron Microscopy

Fatai Olorunsola, CURO Research Assistant
Dr. Michael Hahn, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Plant cell walls are primarily composed of polysaccharides, including cellulose, hemicellulose (e.g., xyloglucan, xylan, and mannan), pectin (e.g., homogalacturonan, rhamnogalacturonan, substituted galacturonans) and arabinogalactans [1]. A large and diverse collection of monoclonal antibodies has been generated that bind to various non-cellulosic polysaccharides present in the primary and secondary cell walls of plants [2]. The cell wall structure and composition can now be explored systematically from the whole plant to the sub-cellular levels because of this large collection of antibodies [2]. However, the complexity of the cell wall has made it difficult to observe the composition of the cell wall [3]. Screenings of wall extracts with cell wall glycan directed mAbs allow for the simultaneous comparative examination of cell walls from larger numbers of samples [2]. The results of such screens can further be used to inform the selection of antibodies to be used for more detailed immunohistochemical studies [2]. The studies described in this paper center on growing Arabidopsis wild type plants, isolate organs, preparing cell walls from the harvested tissues, preparation and screening the cell walls extracts against the monoclonal antibody collection. Each reagent used is able to extract specific portions of the plant cell wall. The experimental plan here is to generate cell wall residues from multiple organs that vary in their structure and make up by treating the wall with specific reagents that remove distinct wall components selectively. The final resulting residues will be examined using scanning electron microscopy (SEM) for understanding the net structural changes.

Analysis of P1 Function in *Mycoplasma pneumoniae* Adherence and Gliding

Babajide Oluwadare, CURO Honors Scholar, CURO Summer Fellow, CURO Research Assistant
Dr. Duncan Krause, Microbiology, Franklin College of Arts & Sciences

This study focuses on *Mycoplasma pneumoniae*, a human pathogen causing bronchitis and primary atypical, or "walking" pneumonia. Mycoplasma adherence to respiratory epithelium is mediated by a differentiated terminal organelle. Located on the surface of the terminal organelle is the P1 protein, which functions directly in both cell adherence and motility. There is evidence from recent studies to indicate that P1 repeatedly catches and releases sialic acids, present on airway cell surfaces, to thrust the mycoplasma cell forward. Furthermore, P1 is believed to exist in conformationally distinct subpopulations that shift when mycoplasma cells glide. Little is known about the specific mechanism by which the bacterium exhibits motility via the P1 protein. Learning about this unique form of movement can lead to new strategies for treatment of infections and a greater understanding of bacterial motility. By means of immunofluorescence microscopy with

monoclonal antibodies specific for P1, mAB1 and mAB2, we sought to define quantitatively the location and relative amounts of P1 subpopulations. The antibodies mAB1 and mAB2 consistently yielded distinct labelling patterns, which were not the result of background or "noise." Furthermore, mAB1 appeared to bind only to a subset of P1 proteins and only at specific times, as opposed to mAB2, which appeared to bind to all P1 at all times.

Analysis of the Effects of High-Fat and Low-Fat Diets on Blood Lipid Profiles

Maria Orlando, CURO Research Assistant
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Obesity is the condition of containing excess body fat and is a risk factor for many diseases. It can be induced by various stimuli such as high-fat diet. We used lipidomics to test the hypothesis that fat content in the maternal diet affects the phospholipid profiles of offspring. To determine these changes we extracted phospholipid from whole blood of mothers fed high-fat and low-fat diets and also extracted phospholipid from the blood of their offspring. These samples were analyzed using electrospray ionization-mass spectrometry, followed by multivariate analysis, which allowed us to identify differences in the phospholipid profiles between groups. As expected, mothers fed a high-fat diet for six weeks had significant differences in their blood lipid profiles as compared to those fed a low-fat diet for six weeks. Interestingly, we also observed significant differences in the phospholipid profiles of female offspring of high-fat diet fed dams and low-fat diet fed dams. Statistical analyses will be performed to identify significantly altered lipid species, followed by the tentative identification of these species using mass spectrometry. The current data suggest that diet can affect blood lipids and could serve as a precursor for obesity-related disease states in offspring. These findings will ultimately allow us to better understand the effects of parental diet on offspring's lipidome.

Investigating Macular Pigment Optical Density in Pregnant Mothers during Prenatal and Postnatal Stages

Mallory Osborne, CURO Research Assistant
Kaitlyn Barrow, Selena Soviravong, Kayla Patel, Rosie White, Katelynn Porto, Noopur Luthra
Dr. Janet Frick, Psychology, Franklin College of Arts & Sciences

The carotenoids lutein (L) and zeaxanthin (Z), which are obtained via diet (e.g., green leafy vegetables), accumulate in the central retina where they are referred to as macular pigment. Macular pigment optical density (MPOD), a measurement of L and Z in the retina, has been positively correlated with adult cognition and visual functioning (e.g., processing speed; Bovier et al., 2014). During prenatal development, L and Z are deposited in the fetal retina in high concentrations (Bone et al., 1988), and lutein is the predominant carotenoid in infant brain tissue, despite comparatively low dietary intake from mature breastmilk (Vishwanathan et al., 2011; Hammond, 2012). These discoveries have led to the idea that L and Z are actively transported to fetal and infant neural tissue, perhaps being taken from maternal tissue stores (e.g., macular pigment) to meet the developing infant's nutrient demands when maternal dietary intake is insufficient (Hammond, 2012). The current study examines women's MPOD, measured with a Macular Densitometer™ (Wooten et al., 1999), and dietary intake of foods containing L and Z, during pregnancy and postpartum to see if maternal MPOD changes over the course of pregnancy and early breastfeeding. We predict that MPOD will decrease across pregnancy, with dietary intake of L and Z moderating the slope of the decline. These

findings could have significant implications for prenatal dietary recommendations in order to maintain optimal health for both mother and infant.

The Effects of Lutein and Zeaxanthin on Cognitive Function and Neural Efficiency in Older Adults with and without Cognitive Impairment

Meredith Osborne, CURO Summer Fellow, CURO Research Assistant
Dr. Lisa Renzi, Psychology, Franklin College of Arts & Sciences

Low levels of circulating dietary carotenoids lutein (L) and zeaxanthin (Z) and low macular pigment optical density (MPOD, or L+Z levels in the neural retina) have been associated with increased risk for neurodegenerative diseases such as age-related macular degeneration (AMD) and Alzheimer's disease (AD). L and Z serve a number of functions *in vivo*. For example, L and Z have anti-inflammatory properties and are antioxidants. Consequently, L and Z, in high concentration, might protect metabolically active neural tissue from oxidative stress and inflammation known to cause neurodegenerative disease. L and Z also influence formation of gap junctions and, as a result, might influence neural efficiency. The protective hypothesis has been tested previously, but the neural efficiency hypothesis has not been widely tested. In order to test the neural efficiency hypothesis, 100 adults between 18-92 years of age were tested. Serum L+Z, MPOD, cognitive function, temporal visual function, and neuroimaging measurements were conducted at baseline and, for most measurements, at 4-month intervals over the course of one year. Participants were given either a lutein supplement (12 mg / day) or placebo, and both participants and experimenters were masked to treatment type. Although the study is ongoing, the purpose of the current sub-study is to examine the relationships between processing speed, baseline L+Z levels and speed-based cognition measures in healthy adults. It is predicted that individuals with higher serum L+Z and MPOD will have improved processing speed at baseline relative to other healthy adults with low L+Z levels, indicating improved neural efficiency.

Do Non-Native Apple Snails Feed Preferentially on Non-Native Aquatic Plants in Lake Seminole, Georgia?

Jack Owen
Dr. Alan Covich, Odum School of Ecology

Invasive species are increasingly affecting natural communities and creating novel food webs. The first species to invade Lake Seminole in Georgia was *Hydrilla verticilata,* which dominated the submerged vegetation. More recently, the "giant apple snail", *Pomacea maculata*, was found to be widespread around the lake's shoreline. These large snails, native to South America, are known as voracious herbivores. Their appetite has made them a species of concern to both ecologists who study the lake's ecosystem and recreationists who use the lake for fishing and boating. Many speculate whether the snails will help control the *Hydrilla* problem or if they will consume other less dominant, non-native plants such as water hyacinth (*Eichhornia crassipes*), that float on the lake's surface near shore. To test the hypothesis that the apple snails would not selectively consume one plant species more than another, I fed two sizes of snails three different types of food: romaine lettuce (control), *Hydrilla* and *Eichhornia*. I measured how the snails' body masses and shell sizes responded to the different types of food they ate. While preliminary studies had suggested that snails would grow fastest when fed water hyacinth, other literature suggested that the snails do not prefer water hyacinth. My study found that snails fed *Hydrilla* grew at a faster rate than did snails fed either lettuce or *Eichhornia*.

Abstracts

Using Environmental DNA to Detect and Track Dispersal of the Island Apple Snail Invasion in Lake Seminole, Georgia

Jack Owen
Dr. Alan Covich, Odum School of Ecology

One of the challenges in determining the dispersal of species in an aquatic ecosystem is the need for direct observation. This project seeks to utilize the novel method of environmental DNA (eDNA) analysis to map the dispersal of the island apple snail, *Pomacea maculata*, in Lake Seminole of southwestern Georgia. Typically, the snails' large egg masses are considered an approximation of dispersal. To validate this assumption, water samples were taken at sites containing a range of egg mass abundance. Water samples were then filtered at the lake, preserved, and transported to the University of Georgia for analysis. DNA was extracted from the samples, and then amplified via polymerase chain reaction (PCR). Primers used in PCR ensured that only a 650 base pair strand of the snail's cytochrome c oxidase subunit I, or COI, was amplified. This segment of mitochondrial DNA is the one generally used as a DNA "barcode" when identifying animal species. Gel electrophoresis was then performed on each sample to confirm the identity of source DNA. While we hypothesize that we will find DNA in the samples from areas where apple snails have been observed, we also expect that apple snail DNA will be amplified in at least some of the samples from areas where apple snails were not directly observed. These findings will provide greater information on the range of apple snails in Lake Seminole and help track patterns of dispersal into nearby lakes and wetlands, hopefully serving as a means of "early detection" of an invasion.

Vocal Repertoire and Call Structure of Red-and-Green Macaws (*Ara chloropterus*)

Joel Owen, CURO Summer Fellow
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

The behavioral biology and vocal repertoire of Red-and-green Macaws (*Ara chloropterus*) are virtually unstudied in the wild, with only one known study (Schwob et al., unpublished). Our objectives for this study were three-fold: to document the repertoire of the Red-and-green Macaw and analyze call structure; to match vocalizations with behavioral patterns to gain insight into call function; and to compare calls with those of the Blue-and-gold Macaw (*Ara ararauna*). The study area was in the Cerrado of Brazil on Fazenda Boa Vista (FBV), a privately-owned property. Data collection occurred between May 2014 and July 2014 and involved opportunistic audio recording. A total of 177 recordings were made, yielding 111 processed calls. Vocalizations were processed using Audacity and SoundRuler software. To analyze the calls, several structural and temporal parameters were used: duration, dominant frequency, maximum and minimum fundamental frequency, and frequency band. We categorized vocalizations as *flight* (shorter duration; frequency modulation) or *alarm* (longer duration; no modulation) depending on the parameters. Statistical analysis of the data involved principal component analysis (PCA) and discriminant function analysis (DA). A total of 37 *A. chloropterus* calls and 36 *A. ararauna* calls were tested in the PCA and DA. Preliminary results show that the three temporal components explain 75.4% of the variation of all variables. The DA is currently ongoing to determine which parameter discriminates between the calls of each species. Structurally, *A. chloropterus* vocalizations appear to be noisier and contain less structural bands than those of *A. ararauna*.

Theatrical Imagery in Nabokov's *Invitation to a Beheading*

Meredith Paker, Foundation Fellow, CURO Research Assistant
Dr. Charles Byrd, Germanic & Slavic Studies, Franklin College of Arts & Sciences

The Russian-American author Vladimir Nabokov calls his 1935 work *Invitation to a Beheading* his "dreamiest and most poetical novel" for which he has "the greatest esteem" (*Strong Opinions,* 76, 92). The mysterious Cincinnatus C. has been convicted of "gnostical turpitude" and awaits his execution in torment in an atypical prison setting. To many readers, *Invitation to a Beheading* is an abstract work of art, aesthetically beautiful but thematically abstruse. However, by analyzing the theatrical imagery of the surreal execution scene, the theme of "all the world's a stage" emerges. The imagery Nabokov uses in this scene includes the doubling of two characters, the portrayal of the executioner as a larva, and the falling of two-dimensional trees. When Cincinnatus realizes the unsubstantiality of this theatrical world, he divests himself of it and causes its collapse.

The Welfare Effects of Off-Label Prescriptions

Meredith Paker, Foundation Fellow
Dr. Jonathan Williams, Economics, Terry College of Business

Though the FDA restricts the marketing of a drug to its set of FDA-approved "on-label" uses, physicians can prescribe any prescription drug for any condition. Many prescription drugs are prescribed "off-label" because it is costly for pharmaceutical companies to get new uses of existing drugs FDA-approved. These off-label prescriptions have potentially desirable effects if they allow for the best treatment of a patient's condition or if they permit innovative new uses of safe drugs. However, off-label prescriptions could be undesirable if they become wasteful or if they cause patient harm. Little is known about which populations receive off-label prescriptions and whether the potential benefits to patients from off-label prescriptions outweigh the costs. We find that about thirty percent of prescriptions are for off-label uses, and our results suggest that off-label prescribing may enhance patient welfare, motivating a deeper welfare study. We combine the U.S. government's Medical Expenditure Panel Survey data on doctor visits and prescription records with yearly Physician's Desk Reference data on the conditions each drug is FDA-approved to treat to identify off-label prescriptions. Determining the welfare effects of these prevalent and controversial off-label prescription practices will add an important dimension to the national policy conversation regarding the FDA's regulatory environment.

Reducing the Disparity between Federal Sentencing of Crack and Powder Cocaine

Bailey Palmer, Ramsey Scholar
Mallika Madhusudan, Foundation Fellow
Dr. Linda Renzulli, Sociology, Franklin College of Arts & Sciences

Federal sentencing for crack cocaine has been one of the greatest sources of inequality and racial discrimination in recent years. Though the 2010 Fair Sentencing Act reduced the 100:1 sentencing disparity between the pharmacologically identical crack cocaine (usually found in lower income neighborhoods with large minority populations) and powder cocaine (typically used by affluent Caucasians), there remains continual discrimination within federal sentencing structures. Current FSA policy has changed the sentencing disparity between crack and powder cocaine to 18:1 though the drugs' similarities suggest a 1:1 sentencing ratio would be more appropriate. Furthermore, though reduced crack penalties were made retroactive, alterations to

mandatory minimum legislation were not made retroactive. This means thousands of offenders remain in prison under excessive, outdated sentences. According to Michael Nachmanoff, a federal defender for Virginia, "A person with crack will have to have 28 grams before triggering a mandatory 5 year minimum sentence. But the person with powder cocaine must still have a much larger amount – at least 500 grams." Our policy would implement a 1:1 sentencing ratio for both powder and crack cocaine and second, remove mandatory minimum restrictions that prevent retroactive sentence reductions. Though there have been some proposed policies to fix the residual issues in federal cocaine sentencing such as Rep. Bobby Scott's proposed House Bills and Smarter Sentencing Act as proposed in the 113th Congress, none of these policies have passed. There are currently no sentencing bills introduced in the current 114th Congress.

Democratic Institutions and the Human Right to Health

Eytan Palte, Foundation Fellow
Dr. K. Chad Clay, International Affairs, School of Public & International Affairs

The human right to health is enshrined in various human rights regimes, first appearing in the 1948 Universal Declaration of Human Rights and further elaborated upon in subsequent conventions. Despite these guarantees, there is a disparity between what is enshrined in international law and what is effectuated by governments worldwide. Although this gap can be attributed to various factors, this paper focuses specifically on how differences in democratic institutions affect the enjoyment of this human right. Previous research has demonstrated that certain democratic institutions lead to more representative governments, while other institutions yield more accountable ones. We predict that a nation's healthcare system will be related to the degree of representativeness incentivized by its state's electoral institutions, while the effectiveness of those systems for the covered populations will vary according to the incentive for accountability. We will test these hypotheses using quantitative data sets on healthcare systems and comprehensive indicators of health outcomes in democracies.

Using the Chemical Reporter Strategy to Analyze Glycoproteins in Pompe Disease

Sora Park, CURO Summer Fellow
Dr. Richard Steet, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Lysosomes are organelles within cells that help degrade macromolecules so that precursors such as amino acids and sugars can be recycled and reused by the cell. Lysosomal Storage Diseases (LSDs) have some type of abnormal lysosomal storage, and it is likely that this storage causes altered storage or recycling of glycoproteins. Using a chemical reporter strategy employed previously for Niemann Pick Type C disease, we will test this possibility by studying Pompe disease (PD), an LSD characterized by the storage of glycogen within lysosomes. Our initial experiments will focus on the visualization of glycoprotein storage using microscopy- and biochemistry-based methods. Confirmation of storage would lead to the development of technology that would allow isolation and identification of the glycoproteins that accumulate inside the cell. Discovering the identity of the stored glycoproteins would be greatly insightful to their pathological roles in in LSDs. This work could potentially lead to a clarification of the pathophysiology of not only Pompe disease and Niemann-Pick disease, but of LSDs in general. A better understanding of how storage leads to impaired movement of other molecules in the cell will hopefully lead to the development of more effective therapies.

Tea Polyphenols Inhibit Activity of Pancreatic Lipase

Sungwhan Park, CURO Research Assistant
Xiaoping Yang, Key Laboratory of Horticultural Plant Biology, Huazhong Agricultural University, Wuhan, China
Dr. Fanbin Kong, Food Science & Technology, College of Agricultural & Environmental Sciences

The purpose of this research was to investigate the effect of tea polyphenols, found in green tea, on pancreatic lipase activity under *in vitro* conditions. Porcine Type II pancreatic lipase was dissolved in ultra-pure water to make 0.5 mg/mL solution. The lipase solution (100 μL) was mixed with 450 μL of 0.02% (w/v) pNP laurate substrate, 350 μL of pH 7.2 Tris buffer, and 100 μL tea polyphenol solution with concentration ranging from 0.1 to 1.0 mg/mL. Control was prepared by using the same amount of lipase and substrate but with 450 μL buffer. The control and sample mixtures were incubated in a water bath at 37°C for 2 hours, and the mixtures were then analyzed in a spectrophotometer with wavelength at 400 nm. The result showed that tea polyphenols inhibited the lipase activity. The inhibition increased with tea polyphenol concentration, and reached maximum at concentration 0.5 mg/mL, where pancreatic lipase activity was reduced by 47.83%. The reduction in lipase activity was 2.38%, 15.24%, and 37.77%, for tea polyphenol concentration of 0.1 mg/mL, 0.25 mg/mL, and 1.0 mg/mL, respectively. It has been known that drinking green tea helps reduce the risk of obesity and cardiovascular disease. This study indicated that the enzyme inhibition may be part of the mechanism. The result also confirmed that green tea could be used as a natural medicine to reduce the risk of these diseases.

Rolling the Dice: The Economic Impact of Casinos

Davis Parker, Foundation Fellow, CURO Research Assistant
Dr. David Mustard, Economics, Terry College of Business

Over the past 30 years, the prevalence of casinos and legal gambling has skyrocketed across the United States as state legislatures have begun granting casino licenses to Native American tribes and private corporations in mass. Seen as a means for greater employment, tourism, and development, these new casinos offer a bouquet of gambling opportunities such as blackjack, slots, poker, dog racing, and bingo. Yet, definitive conclusions on the efficacy of casinos in creating economic prosperity have often evaded researchers. Using data from the Bureau of Labor Statistics as well as a homemade dataset of casino start and closing dates, we study the economic impact of casinos. Applying high-level data analytics, we identify the intertemporal effects casinos can have on establishment counts, levels of employment, and wage rates. Additionally, we examine how these effects vary across counties by population size and region. We hope that our research will better inform policy makers at the national and local levels in their deliberations on the consequences, both positive and negative, of licensing casinos.

UGA Employee-Benefit and Retirement Preparedness

Jessica Parks
Dr. Heidi Ewen, Institute of Gerontology, College of Public Health

The purpose of this study is to understand the ways in which UGA employees make decisions regarding their available retirement planning options. Retirement preparedness and the financial confidence of UGA employees has much room for exploration. With changes in social security benefits and employee-based investing plans, the need for

retirement preparedness is even more important for the financial well-being of UGA employees. I am recruiting employees who are eligible for UGA's two retirement options (the Teacher's Retirement System and the Optional Retirement Plan). They will be asked to complete an online survey of questions related to their financial planning and anticipated retirement needs. Their responses will be recorded in a database, coded for security and then analyzed. Data will be analyzed using mixed methods, qualitative and quantitative, testing for relationships among age, employment type, gender, marital status, family size, religious affiliation, political ideation, health, and future plans. Data collection is still in progress.

Understanding Floral Trait Evolution in Wild Sunflowers

Hiral Patel, CURO Summer Fellow
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

To predict crop and wild species' reproductive success and persistence under looming environmental changes, we must understand how floral traits are adapted to specific climates. This project investigates ecological and evolutionary causes of variation in floral traits across the genus *Helianthus*. Thirty species of wild sunflowers were grown using common garden techniques to assess an evolutionary trade-off between investment in pollinator attraction and seed production. The evolutionary strategy adopted by specific species under this trade-off is hypothesized to be affected by differences in life history and environmental factors. It is hypothesized that annuals will invest more in attraction as they get one chance to reproduce, compared to perennials which are expected to invest less in attraction because they have many opportunities to reproduce over their multi-year lifespan. Investment in attraction and flower size will decrease in hotter, drier environments in order to avoid water loss. Investment in attraction and flower size will decrease as soil fertility decreases to conserve resources. Evolutionary statistical analyses such as ancestral state reconstruction and phylogenetically independent contrasts will be performed to determine which traits are evolutionarily conserved and which are labile and potentially adaptive. Understanding trade-offs in floral biomass allocation has ecological consequences. Species adapted to specific environments may be unable to adapt to changing conditions under the short time scales of current climate change and could be threatened by the increasing frequency of droughts due to water loss from investment in large attractive petals, which are not able to control water loss like leaves.

Expression and Purification of PRMT1 and Mutant Variants

Viral Patel, CURO Research Assistant
Dr. Y. George Zheng, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Epigenetics involves cellular and physiological traits that are heritable by conceived generations in a manner that is independent of the core DNA sequence. It has often been observed that many pathological conditions and malignant tumors have an epigenetic basis for disease onset (Yang, Bedford, 2013). In the post-genomic research era, epigenetic processes are proving to be increasingly important as scientific data accumulates. One key epigenetic process involves remodeling of chromatin to regulate gene expression. Post-transcriptional modifications such as methylation, acetylation, or phosphorylation of histone tails change chromatin stability and alter the binding of transcription factors (Zhang et al., 2013). Histone modifying enzymes, such as PRMT1, can methylate residues in histones to either reduce OR sometimes increase its gene expression. PRMT1 specifically methylates guanidine nitrogens of arginine residues in certain histones. Understanding the regulatory factors

of such chromatin remodeling complexes, along with their specificity and functional roles are critical for further understanding of disease association with epigenetics. In order to perform such studies, the enzymes involved themselves must be expressed or generated for further experimentation. Using standard molecular biology techniques, PRMT1 was expressed multiples times, along with mutant variants. The goal was to improve yield and purity of the obtained protein. The model organism *Escherichia coli (E. coli)* was used to conduct the experiments. Specifically, the BL21(DE3) strain was used due to the several biotechnological advantages, such as lower acetate yield and a higher biomass, which are beneficial for protein production, the overall goal of the experiment (Waegeman et al., 2011). The BL21(DE3) *E. coli* were transformed with the pET28b+ plasmid, which contains the genetic code for histidine-6x-human-PRMT1 (his-6x-h-PRMT1), Kanamycin resistance, and the lacl repressor protein. A sample of the *E. coli* were inoculated in Kanamycin and Lysogeny broth (LB) media and further incubated for growth at 37° C until the proper optical density (OD) was reached. Isopropyl β-D-1-thiogalactopyranoside (IPTG) was added to initiate transcription and translation of his-6x-h-PRMT1. After approximately 16 hours of incubation, post-IPTG addition, the BL21 cells were collected from their media using centrifugation. The collected cells were suspended in *Cell Lysis Buffer* and then disrupted. After further centrifugation, the resulting supernatant contained the recombinant protein. Using Nickel (Ni) beads in purification columns, the protein was collected. The isolated PRMT1 was aliquoted and stored at -78° C after it was concentrated using dialysis and centrifugation through a filter membrane. Bradford assay and sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) of the protein and purification column samples were conducted to test for the purity and quality of the expressed protein.

Folic Acid Knowledge and Use among Participants of a Community-Based Intervention Study in Pregnant Women

Meagan Patterson, CURO Research Assistant
Dr. Dorothy Hausman, Foods & Nutrition, College of Family & Consumer Sciences

Periconceptional supplementation with folic acid is an important public health recommendation aimed at reducing the risk of neural tube defects (NTDs). Unfortunately, many women may be unaware of this recommendation or fail to follow it before becoming pregnant. To determine the extent of folic acid knowledge and use and potential factors influencing use, we conducted a secondary analysis of baseline data collected as part of an on-going folic acid supplement intervention study in pregnant women. Select data were extracted from medical records and baseline health behavior questionnaires of study participants (n=31, age range=20-37, 55% White, 16% African American, 29% Hispanic) for which information on age, race, parity, and marital status, prior folic acid knowledge, source of knowledge, and multivitamin use before and in early pregnancy, were available. Chi-square analysis was used to determine prevalence of folic acid knowledge and use by demographic and lifestyle factors and logistic regression was used to estimate predictors for multivitamin use before pregnancy. Results showed that although 87.1% of participants had heard of folic acid, only 45.2% took multivitamin supplements prior to pregnancy. Regression analysis indicated that older age (age≥28, P=0.028) and being married (n=14, P=0.0463) were significant predictors of periconceptional multivitamin use while race, parity, and prior folic acid knowledge were not. All married participants and 28.6% of single participants reported taking multivitamin supplements during early

pregnancy. Although this was a small study, the results indicate that public health recommendations for periconceptional folic acid intake need to be reinforced, particularly among younger, sexually active single women.

Investigating Invertebrate Utilization of Bryophytes in a Mid-Order Piedmont River

Meryom Pattillo
Dr. Mary Freeman, Odum School of Ecology

Over the past few decades anthropogenic effects on stream structure and function have been increasingly studied, particularly concerning in-stream and out-of-stream water needs in relation to flow regulation. Human-driven impacts resulting from abstraction of surface water can drastically alter stream structure and function, especially pertaining to plant assemblages. One such group of plants are the bryophytes consisting of mosses, liverworts, and hornworts. Bryophytes inhabit both terrestrial and aquatic systems but little is known about their function in riverine ecosystems. Bryophytes offer excellent habitat for aquatic macroinvertebrates because they provide food through captured organic matter and offer protection from predation through their chemical defenses. This study focused on assessing aquatic macroinvertebrate utilization of bryophytes on rock outcroppings in a piedmont sand bottomed river. Bryophyte samples were collected from the Middle Oconee River near Athens, GA where submerged samples of the bryophyte *Porella* as well as other bryophytes were collected from rocks and trees trunks. We predicted a higher density of macroinvertebrates in bryophyte mats compared to literature values for other common invertebrate habitats and a significant difference in invertebrate biomass and diversity between different species of bryophytes. This research is important because it provides insight into a poorly understood yet widespread macroinvertebrate habitat. Furthermore this research has implications for riverine management and conservation practices because flow regulations preventing inundation of riverine bryophytes could negatively affect macroinvertebrate habitat availability.

Do You Know Why 6 - - 2 Is the Same as 6 + 2?

Andrew Peake, CURO Research Assistant
Dr. Jessica Bishop, Math & Science Education, College of Education

How do 7th and 11th grade students think about subtracting negative numbers? As a field, we do not know much about students' understanding of integers. When compared with research on rational numbers or place value, the research on students' understanding of integers is relatively sparse (NRC, 2001). We interviewed forty 7th graders and forty 11th graders to better understand how they thought about integer arithmetic. We investigated their success and underlying reasoning when solving integer subtraction problems. We found that although most 7th and 11th graders could correctly solve integer subtraction problems, over 70% of the students could not explain why their procedures worked. The majority of students initially changed subtractions problems like 6 - -2 = __ to an equivalent addition expression using rules or procedures like "keep-change-change" (keep the sign of the first number, change the operation, and change the sign of the second number).

Differential Consumption of *Eurypanopeus depressus* When Infected by *Loxothylacus panopaei*

Sarah Perry
Dr. Jeb Byers, Odum School of Ecology

Populations of the mud crab *Eurypanopeus depressus* are often heavily infected with the parasite *Loxothylacus panopaei*, a castrating barnacle parasite. To determine if the

predators differentially preyed upon infected or healthy mud crabs, we conducted a tethering experiment on Skidaway Island in summer 2014. Healthy mud crabs were paired with infected mud crabs, and the pairs were interspersed on tethers along an oyster reef in the intertidal zone. We deployed the crabs during low tide and collected them during the following low tide (approximately 12 hours of exposure). We conducted a total of five nighttime and three daytime trials. Infected *E. depressus* were consumed at a significantly higher rate than uninfected *E. depressus* during the nighttime trials. There was no significant difference between infected and uninfected *E. depressus* during the daytime trials. We conducted a literature review to determine which nocturnal predators could be driving the observed predation differential and found that the red drum (*S. ocellata*), Chesapeake blue crab (*C. sapidus*), pinfish (*L. rhomboids*), and grey snapper (*L. griseusi*) are likely contributing. Parasitic infection is apparently making *E. depressus* a more enticing prey target, and its consumption could reduce prevalence of *L. panopaei* reducing its spread.

The Impacts of Iron Deficiency Anemia on Mitochondrial Capacity

Kelly-ann Peters, CURO Research Assistant
Joanna Szymonik
Dr. Kevin McCully, Kinesiology, College of Education

Iron deficiency anemia is the most common blood disorder and nutritional deficiency in the United States. General fatigue and weakness often accompany this deficiency and can greatly impair overall work capacity and athletic performance. The primary aim of this study is to determine if iron deficiency impacts the function of skeletal muscle mitochondria, the organelle responsible for producing energy in the cell. Ten participants with a known history of iron deficiency anemia will be observed in this study. Each participant will be matched to a control in order to best compare results (20 participants total). Hematocrit and hemoglobin levels will be measured in each participant in order to determine iron deficiency status and severity. Mitochondrial capacity will be measured with near-infrared spectroscopy using the recovery rate of muscle oxygen consumption after a short bout of exercise of the brachioradialis muscle in the forearm. Metabolic rate will be measured as the slopes of the HHB, HbO2, and HbDiff during short duration arterial occlusions. We hypothesize that iron deficient anemic individuals will show a lower mitochondrial capacity in their skeletal muscles compared to a matched control. The establishment of the relationship between iron deficiency status and mitochondrial function can provide information to guide future studies to improve the health in people with iron deficiency anemia.

Spoken Word Activism in the Age of Social Media

Sonja Petrovic
Dr. Chris Eaket, Theatre & Film Studies, Franklin College of Arts & Sciences

With the rise of social media, there has been an increase in the popularity of spoken word. Spoken word has evolved to mean performance-based poetry that is usually socially-aware and centered around identity politics. Although social media has often been considered "slacktivism," spoken word generally attempts to show and educate the audience about how dominant, oppressive systems function to privilege certain groups over others. It is with the help of YouTube, Twitter, and Facebook that organizations such as Button Poetry (over 300,000 subscribers) as well as individual and group performers are able to reach such large audiences. This presentation explores the history of spoken word, starting in the Harlem Renaissance (within the frame of Black Activism) and moving onward into other identity politics. bell hooks's theory of language as a site of

resistance states that one can choose and vocalize their space in the margins in order to resist; applying this theory, this presentation states that spoken word poetry brings social justice issues and systems of inequality to light and actively resists them. Spoken word plays with and blurs the conventions between the narrator and author by having the speaker adopt a persona and speak either genuinely or ironically. This allows them to critique societal values and power structures by using everyday experiences while simultaneously remaining at a distance. Spoken word has navigated the difficulties of social-media culture and become a form of activism that's accessible. It stands to have an unprecedented impact in the social media era.

Analyzing Persistent Organic Pollutants in the Tissue of Stranded *Tursiops truncatus* along the Coast of Georgia, USA: Effects of State of Decomposition and Stranding Location

Tabitha Phillips, CURO Research Assistant
Dr. Susan Wilde, Warnell School of Forestry & Natural Resources

Tissue samples are collected from stranded bottlenose dolphin (*Tursiops truncatus*) from the Georgia coast annually by the Georgia Department of Natural Resources. Blubber samples from stranded dolphins were analyzed (n=12) for a suite of persistent organic pollutants (POPs) which include: PCBs, PBDEs, and other organochlorine pesticides (OCPs) with the goal of determining the relationship between state of decomposition and stranding location on contaminant load. Skin samples (n=11) were also analyzed for total mercury (THg). No statistically significant differences were found between POP class and the state of decomposition. Significant differences were found between Aroclor 1268 proportion and stranding location. A positive correlation was found between total body length and THg concentration in skin (R2=0.5576).

Closing the Achievement Gap: Elementary Second Language Education in Philadelphia Schools

Laura Pontari
Dr. Gary Green, Warnell School of Forestry & Natural Resources

Research was conducted to formulate a policy proposal for an elementary bilingual education program in the School District of Philadelphia (SDP.) The goal of this policy is to improve the quality of education provided by the SDP without putting additional strain on its already-failing budget. The project outlines a program that establishes a partnership between the SDP and local public universities in Philadelphia to provide qualified college students as assistant teachers for second language education programs in the SDP. To address the rapidly increasing Latino population, the program would provide second language instruction in Spanish to elementary students from Kindergarten through third grade. This program gives college students in local education programs practical experience, and exposes elementary students to Spanish vocabulary and basic grammar to create a basis of knowledge for further fluency.

Controlling Contamination of Algal Grazers Using Nitrogen Sources

Grace Power
Dr. Manjinder Singh, College of Engineering

Microalgae biofuels answer the current need for new and sustainable energy sources. Before algae biofuels can become mainstream, however, production of fuel must become more cost effective. Currently, biomass yields are threatened by algal grazers. Ciliate and rotifer populations are commonly controlled by pesticides, but alternate nitrogen sources may offer a safer and cheaper substitute. This experiment introduced grazer control using Poultry Litter Extract and Ammonium bicarbonate. Two algal strains *Chlorella*

sorokiniana (Cs) and *Chlorella minutissima* (Cm) were grown in 250 mL flasks and inoculated with ciliate and rotifer populations. Three treatments of growth medium supplementation were tested for each strain; Ammonium bicarbonate (100mg/L Nitrogen), 5% Poultry Litter Extract (PLE) and control grown in standard BG11 medium. Algal growth, and Ciliate/ rotifer populations were monitored at regular intervals. The average growth rate in both strains in control treatment was negative. The ciliate growth rate was 1135 and 528 ciliates/d in *Cs* and *Cm* respectively. Ammonium bicarbonate treatment eliminated grazers completely; however, algal growth rate was also lower relative to control. In PLE, grazers' population declined by an average 52 and 86% in *Cm* and *Cs* respectively during five days incubation. However, algal growth was also negatively impacted by 5% PLE. Further studies with longer incubation periods are being carried out to evaluate algae recovery from high nitrogen shock and achieve net positive growth after grazers' elimination.

The Impact of Rest and Game Location on NBA Team Performance

Steven Pugh, Mckenzie Benson, Rebecca Gaines, Mary Catherine Kelley
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

In today's globalized society, travel has become an accepted element of work. However, travel is associated with factors that have the potential to affect performance. Previous research shows a negative relationship between traveling and performance. It has been found that people perform better in familiar environments. Rest has the capacity to counteract the negative effects of traveling. Sports data have been used to analyze these relationships due to the availability of information. For example, the game's home versus away status can be used to measure an unfamiliar environment, point differentials can measure performance, and days rest can objectively measure time between games. For this study, we examined home versus away status and the amount of rest between games using NBA data. We expected that teams playing at an away location would attain less sleep, and therefore away games would amplify the negative impact of lack of rest on performance. Results show that teams performing at away games, who received less rest, performed worse. Teams lost more frequently at away locations than at home. Results support the original prediction of a negative relationship between away game location and performance. Results found from this study can be applied to the work environment by suggesting that managers give employees adequate rest time while traveling. Traveling employees given ample rest time could offset some of the negative effects of travel. Therefore, business managers should allow for recovery time upon arrival at their business trip destination or run the risk of increased exhaustion and decreased performance.

Validation of CRISPR/Cas9 for Genome Editing of Fktn in C2C12 Mouse Myoblast Cell Lines

Vedika Rajasekaran, CURO Research Assistant
Dr. Aaron Beedle, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Dystroglycanopathies are caused by defects in glycosylation of α-dystroglycan. Current *in vivo* research, involving the genes associated with glycosylation, are time consuming, expensive, and do not provide a full understanding of dystroglycanopathy gene functions. Therefore, the purpose of our project is to create genetically modified C2C12 mouse myoblast cell lines, with knockout of dystroglycanopathy gene *Fktn,* using CRISPR/Cas9 technology. C2C12 cells were used because they can be differentiated into rudimentary myotubes in culture to model

skeletal muscle dysfunction *in vitro*. C2C12 cells were transfected with a CRISPR/Cas9 plasmid, including a guide RNA targeting the mouse *Fktn* gene, under different conditions. Transfected cells were selected by Fluorescent Activated Cell Sorting and plated to generate clonal lines. In order to determine if mutations occurred in transfected C2C12 cells, a relevant region of the *Fktn* gene was sequenced. Development of genetically modified cell lines is ongoing. Generation of knockout cell lines in *in vitro* research will enable a better understanding of the genes specific to glycosylation of α-dystroglycan and allow us to discover better therapeutic strategies for dystroglycanopathies treatments.

Surveying *Mycobacterium tuberculosis* Gene Function by Complementation

Ashitha Rajeurs, CURO Research Assistant
Samantha Tucker, Graduate Student
Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Mycobacterium tuberculosis (*M.tb*) is a leading cause of morbidity and mortality in humans. In 2013, *M.tb* caused 9 million new cases of TB disease and 1.5 million deaths. Understanding the physiology and biosynthetic capabilities of *M.tb* bacteria may aid in the development of new drugs and vaccines to fight this global health threat. Coenzyme B12 functions as a cofactor in various metabolic enzymes in a wide range of organisms, but is only made by bacteria and archaea. Coenzyme B12 is a complex molecule requiring over 20 enzymes for its synthesis. The *M.tb* genome has homologs of many B12 synthesis genes; however, coenzyme B12 is not detected in strains grown under standard culture conditions. Either all of these strains have mutations in the B12 synthesis pathway or production of this molecule is only made under specific environmental conditions, such as those found inside a human host. To assay *M.tb* genes predicted to function in B12 synthesis, selected genes were cloned into expression plasmids and introduced into mutants of *Salmonella enterica* (*S.en*) blocked in individual steps of the B12 synthesis pathway. At the submission of this abstract, the first *M.tb* gene assayed has been found to restore B12 production by an *S.en* mutant. This supports that this gene encodes an enzyme with the predicted role in B12 synthesis. Results of all of the genes tested using this type of functional complementation assay will be reported. This work will help elucidate whether *M.tb* encodes functional enzymes for all steps in the B12 synthesis pathway.

Convergent and Divergent Validity of the WISDM-68

Marie Rapoport, CURO Research Assistant
Dr. Lawrence Sweet, Psychology, Franklin College of Arts & Sciences

Despite the well-known dangers, cigarette smoking is still the leading cause of preventable death in the United States. Dependence occurs when an individual is unable to quit or reduce smoking despite adverse consequences. Impulsivity is a key construct in addiction research, but it is multi-faceted and inconsistently measured. Prior research has shown that impulsivity is associated with higher rates of substance abuse and dependence and lower success rates in treatment. However, the association between impulsivity and an individual's motives for substance use has been understudied. In the current study, we will use a battery of behavioral and self-report measure to assess impulsivity (go/no-go, delay discounting, the cigarette purchase task, the UPPS Impulsive behavior scale) and its relationship to nicotine dependence and nicotine dependence motives. To assess dependence and motives we will use the Fagerstrom Test for Nicotine Dependence (FTND), a measure of nicotine dependence, and the Wisconsin Inventory of Smoking Dependence Motives (WISDM-68), a measure

of an individual's motives for smoking. We predict that the motives in the WISDM-68 and FTND will be significantly related to impulsivity with specific motives for nicotine dependence differentially associated with individual measures of impulsivity. These results will help inform understanding of how impulsivity translates into substance use.

Effect of Music on People with Developmental Disabilities during Physical Activity

Caroline Ray, CURO Research Assistant
Dr. Kevin McCully, Kinesiology, College of Education

People with intellectual disabilities (ID) are typically less involved in regular physical activity and unhealthier than people without disabilities. The aim of this study was to investigate the effect of music on the exercise intensity selected by participants with ID. The hypothesis was that participant-requested music would result in higher heart rates during exercise compared to non-specific or no music while walking on a treadmill or while cycling. Six participants with ID enrolled in a wellness program course were recruited and permission of their guardians was gained. Three musical situations were carried out: a control situation with no music, a second general "gym music" situation, and a situation with requested music. Heart rate was recorded while on a treadmill or a stationary bike for each situation in separate trials. Questions were asked after each session regarding enjoyment of the workout. Starting at the same speed each session, participants walked or biked for ten minutes during each trial and were encouraged to control their speed. During the first semester of research, the study proved to be a feasible way for measuring the comparison between exercise intensity and different music conditions. It was determined that 80% of participants were not reaching their individual cardiovascular training zones during physical activity; however, more measurements are needed to complete the study. There appears to be a positive effect of self-selected music on exercise intensity. We feel self-selected music might be an important tool to allow fitness programs to provide health benefits to people with ID.

The Relationship between CEO Risk-Taking Behavior and Employee Attraction and Retention

Shelby Reilly, Adam Lowe
Dr. Brian Hoffman, Psychology, Franklin College of Arts & Sciences

Given the likelihood of today's employees to switch companies frequently throughout their careers, organizations that attract and keep the most talented workers often enjoy a competitive advantage (Ployhart, Weekley, & Baughman, 2006). Additionally, CEO behavior plays an important role in how employees view organizations (Quigley & Hambrick, 2014). Therefore, it is possible that how risky a CEO's behavior is perceived to be can impact employee attraction and retention. However, despite the potential impact of CEO behavior on current and potential employees, the relationship between CEO risk-taking and employee attraction and retention has yet to be examined. To meet this end, this study analyzes the relationship between environmental uncertainty (via risk-taking behaviors) in the workplace and employee recruitment and retention. 155 chief executive officers (CEOs) (N = 155) from various Italian organizations and 493 (N = 493) of their followers completed an online survey of study measures. Study findings show that risk-taking behavior is positively related to employee attraction yet negatively related to employee retention. The differing effects of CEO risk taking on selection and retention can present a challenge to organizations, as the same CEO behaviors are not equally successful in recruiting and maintaining employees. Therefore, these

findings suggest that leader strategies designed to attract workers should differ from strategies designed to retain workers. More specifically, leaders should highlight their risk-taking behaviors when recruiting employees, but downplay them during their day-to-day interactions with current workers.

College Students' Credit Experience and Behavior

Anthony Reyna, CURO Honors Scholar
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

Credit reports provide a very specific window into a person's behavior and experience, and for two and a half years this project has been observing the "windows" of college students. The purpose of this research is to better understand college students' credit experience and their credit behavior based on their credit reports. The credit report data was gathered from University of Georgia students enrolled in the "Money Skills for Life" course (FHCE 3110) from 2008-2013. Credit experience was measured in four ways – whether the student used credit (binary variable measured as 1 if the student's credit report consisted of any accounts attached to their name, zero otherwise), the ownership of the credit (a binary variable measured as 1 if the student had individual ownership of at least one credit account, zero otherwise), the debt-utilization ratio (the ratio of a student's total current balances to his/her total available credit), and a student's total number of open credit accounts. We used Microsoft Excel to build and analyze the dataset and partnered with a graduate STAT course for important findings. A deeper understanding of the relationship college students have with the credit system will help shape course content and effectively present the best practices for credit management to college students.

The Evolution of Quail Hunting Attire in South Georgia and Northern Florida

Lucille Reynolds, CURO Research Assistant
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The story of quail hunting is an important part of Southern heritage that has not been documented in depth. Formalized quail hunting first gained popularity in the region when wealthy northern industrialists migrated south to purchase vast, bankrupt farms to create sporting plantations for winter vacationing. With their arrival, the dress and kit of quail hunters became more practical, suited to the rough, briar-laden environment. The objective of the project was to identify a timeline of the evolution of quail hunting dress, which includes snake-proof boots, briar britches, safety vest with numerous pockets, and a hat with brim to shade the eyes. To collect data field research was conducted through attending quail hunts, visiting historic locations where quail hunting used to be practiced, face-to-face interviews with quail hunters, and the review of available published materials. The traditional plantation hunting culture has influenced contemporary dress practices by borrowing hunting and shooting features, accents, and materials from the traditional quail hunting attire. Prestige brands, such as Barbour and Orvis, are today staples in non-hunters' wardrobes who seek association with the distinct dress of quail hunters. Although changes in agricultural practices depleted the wild quail population in the region, conservation efforts by organizations such as Tall Timbers Research Station & Land Conservancy offer hope for the preservation of the quail hunting tradition and the wild lands that foster it. They will likely keep its dress traditions alive as well because they are associated with status and convey nostalgia for a disappearing lifestyle.

Abstracts

Nostalgia Inverted: The Golden Age Motif in Strepsiades' Pre-Dramatic History

Elizabeth Ridgeway, CURO Research Assistant
Dr. Charles Platter, Classics, Franklin College of Arts & Sciences

K.J. Dover sketches the protagonists of Aristophanic comedy as figures of opposition who jeer against social custom, myth, public figures, and "all those who in one way or another are superior to [them]selves" (Dover, 1974, p.19). My research applies Dover's claim to lines 43-5 of *Clouds*, positing that, on the one hand, Strepsiades' narrative of his own "*ἥδιστος βίος*" (p. 43) reflects the longing for a prehistoric Golden Age manifest in traditional Greek thought. On the other hand, Aristophanes juxtaposes Strepsiades' ridiculous behavior throughout the play with the literary and cultural prestige accorded the legendary Golden Age. Ultimately, Strepsiades' account of his pre-dramatic life mocks both temporal tradition and comedic archetype. This paper proposes to trace extra-narrative allusions in Strepsiades' life prior to *Clouds*. In lines 43-5, contrast creates laughable distance between Strepsiades the buffoon and his former prosperity. Aristophanes draws on a common cultural understanding of the Golden Age to heighten the humor of this juxtaposition. To argue this claim, I'll consider several specific points: first, that structure and contradiction in lines 43-5 serve to mock several elements of Greek culture, including the Golden Age; second, that fragments of Aristophanes' contemporary Eupolis attest to the cultural prevalence of the Golden Age ideal; and finally, that the passage's content finds thematic precedents in Hesiod, Pindar, and what we know of the Kronia festival. For an Athenian audience, these recognizable cultural allusions bring Strepsiades' absurdity into hilarious relief.

State-Driven Development Initiatives under Kenya's Vision 2030 and Perceptions by Project-Affected Persons in the Northern Rangelands

Paola Rivera, CURO Honors Scholar, CURO Summer Fellow
Dr. Laura German, Anthropology, Franklin College of Arts & Sciences

This paper seeks to explore ongoing state-driven development initiatives (SDIs) in the northern rangelands of Kenya under the Government of Kenya's (GoK) *Vision 2030* development plan. Since the *Vision 2030* projects discussed in this paper are still in their early stages, the analysis is meant to explore early outcomes in light of project goals and GoK legal commitments to project-affected persons (PAPs) so as to highlight issues not consistent with the project goals before they are too late to amend or mitigate. The research is situated theoretically in the wider literature and critiques of state-driven "betterment schemes" which highlights the divergence between project aims on the one hand, and outcomes (both intended and unintended) on the other. Reasons behind the failure of projects to live up to expectations, and the generation of unintended effects, may be productively explored through a look at the processes through which these initiatives are carried out. This paper aims to do this through an ethnographic analysis of Koija Group Ranch in Laikipia County during early stages of implementation of *Vision 2030*. Projects include a megadam, an irrigation scheme, a road, and a power line, which are all on schedule and receiving more funding. The GoK has already started work on the power line and transport road and has hired workers and set up a camp for the megadam. Drawing on published information and interviews with PAPs, we document early project activities and evaluate them based on the extent to which they reflect duties of the GoK towards PAPs (as enshrined in relevant policy and legislation). In interviews

conducted with PAPs in the Koija Group Ranch, some attendees expressed dissatisfaction with the consultation and awareness process of some projects.

Regulation of Mitochondrial Dynamics in *C. elegans*

Spencer Robinson, CURO Research Assistant
Dr. Edward Kipreos, Cellular Biology, Franklin College of Arts & Sciences

Mitochondria play a vital role in maintaining the health of most eukaryotic cells by generating ATP, the predominant source of chemical energy for cellular processes. Production of ATP varies in response to the energy needs of a cell, and mitochondrial morphology changes to meet this need; as a deficit of ATP develops, the incidence of mitochondrial fusion increases. Fused mitochondria have been shown to produce ATP more efficiently than their tubular (non-fused) or fragmented counterparts. As such, regulation of mitochondrial morphology is critical to cellular function. Mitochondrial dynamics is regulated by several GTPase proteins. Using the nematode *Caenorhabditis elegans* as a model organism, we can study the regulatory pathways that would signal the mitochondria to adapt to the cellular bioenergetic state. EAT-3 is a conserved GTPase that induces mitochondrial fusion in *C. elegans*. SPG-7 and PPGN-1 are mitochondrial proteases, which can inhibit fusion. We hypothesize that SPG-7 and PPGN-1 inhibit fusion by proteolytically cleaving EAT-3. We aim to fluorescently tag SPG-7, PPGN-1 and EAT-3 to enable us to study their role in regulating mitochondrial fusion in *C. elegans*. These constructs are then integrated into the *C. elegans* genome by microinjection into the gonad, inducing expression of the tagged proteins in subsequent generations. It is expected that expression of SPG-7 and PPGN-1 will result in vastly reduced rates of mitochondrial fusion due to proteolytic cleavage of EAT-3, which can then be visualized under a fluorescence microscope.

Resolving Offensive and Defensive Realism

William Robinson
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

Both offensive realism, as defined by John Mearsheimer, and defensive realism, as defined by Kenneth Waltz, are predicated on the anarchic nature of international affairs. The two theories differ, however, on how states pursue security. In offensive realism, each state is a power maximizer and seeks to become a regional hegemon; a state's security is assured by increasing its share of power at the expense of others. In defensive realism, security is dependent on reaching a balance of power; a state's security is assured by bandwagoning with or balancing against a threatening power. Despite sharing several core assumptions, the two theories remain unreconciled. I argue that by modifying the theories to account for state capacity, the two theories can be merged. Only states with a substantial share of power or potential power would abide by offensive realist thinking because only those states could become a regional hegemon. Minor powers, contrastingly, would be forced to bandwagon with or balance against the more capable, power maximizing state, and would therefore abide by defensive realist thinking. The utility of both theories is their explanatory and predictive powers. As separate theories, each provides useful insight into one segment of states, either minor or great powers. By fusing the two, the joined theory would provide more accurate explanatory and predictive powers in a way that can be applied to all states.

Abstracts

Fetal Outcome of Pregnant C57BL/6 Mice Infected Late Pregnancy with 10^3 *Plasmodium chabaudi chabaudi* AS

Kerryn Roome
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Despite immunity in malaria-endemic regions, pregnant women have an increased susceptibility to a significant infection. In these women, red blood cells infected with malarial parasites can accumulate in the maternal side of the placenta, leading to drastic changes in the placental tissue which hampers fetal intrauterine growth. This leads to low birth weight, stillbirth, and preterm abortion. Due to ethical and anatomical limitations in studying placental malaria in humans, murine models are a common alternative. In this experiment, pregnant C57BL/6 mice, aged 8-12 weeks, were intravenously infected with 10^3 *Plasmodium chabaudi chabaudi* AS on day 6, 8 or 10 of gestation. The courses of infection and pregnancy status were monitored until day 18 of gestation when the mice were sacrificed to have organs and plasmas collected for assessment. Mice that were infected during mid to late pregnancy showed significantly higher parasitemia levels compared to non-pregnant infected females. Mice infected on day 6 and 8 aborted their pregnancies on days 15.5 and 16.5, respectively. The majority of mice infected on gestation day 10 did not abort by day 18, so these mice had their placentae and fetuses weighed to compare against those of uninfected pregnant mice. Although viable, these pups weighed significantly less than the pups from healthy mothers. Activated macrophages and tissue factor expression in the placentae will be analyzed via immunohistochemistry staining. Giemsa staining will then compare the placental and peripheral parasitemia. Finally, Western blot analysis will be used to assess the extent of fibrin deposition in the placentae.

Reflections on the City: Urban Space and Ideology

Lazarus Roth, CURO Research Assistant, CURO Graduation Distinction
Dr. Athanasios Samaras, Philosophy, Franklin College of Arts & Sciences

Ideology is the guiding force in shaping the physical arrangement of urban space, and through that arrangement, ideology is reproduced and reinforced into and through the members of the given society. Drawing on the works of Henri Lefebvre, David Harvey, Antonio Gramsci, and others, this paper will attempt to draw a connection between ideological reproduction and the material production of urban space. Urban space will be presented as a product of the hegemonic nature of ruling class ideology and is arranged in such a manner as to reinforce the power structures and dynamics of the society in which it manifests. To justify a ruling class conception of the normative use-values of urban space, a science like urbanism is necessarily constructed that justifies and directs the ideological formation of urban space and rationalizes the proscriptions and prohibitions for the use of that space. Finally, urban space will be presented as a site of manifestation for the unconscious desires that have been shaped by ideology in material social space.

Investigating the Effects of Removing Genes for DHPS Degradation in *Ruegeria pomeroyi* DSS-3

Selena Roth
Dr. Mary Ann Moran, Marine Sciences, Franklin College of Arts & Sciences

Nutrient cycling between marine bacteria and phytoplankton plays a significant role in carbon and sulfur cycles occurring in the ocean. Studying the interactions between a single population of a marine bacterium of the Roseobacter clade and a diatom, *Thalassiosira pseudonana* CCMP 1335, allows for closer

investigation into compounds that are important in the ecological association and the environment. In the bacterium *Ruegeria pomeroyi* DSS-3, genes key to a metabolic pathway involving the degradation of 2,3-dihydroxypropane-1-sulfonate (DHPS) are up-regulated during co-culture with diatoms. One of the final enzymes in this pathway, *cuyA* allows formation of pyruvate and bisulfite from cysteate. Pyruvate is used in cellular processes while bisulfite is expelled, contributing to the oceanic supply of dissolved sulfur compounds. A genetic knockout was performed specifically targeting *cuyA* in *R. pomeroyi*, investigating the gene's role in the overall function of the bacterium. To study the effects of an inactive *cuyA* gene, both wild type DSS-3 and the mutant Δ*cuyA* strain were grown in media with DHPS as the sole carbon source or sole sulfur source at varying concentrations. In addition, wild type DSS-3 and the Δ*cuyA* strain were each grown in co-culture with diatoms, using flow cytometry analysis to observe the population growth of each organism. In both manipulated media and especially co-culture with diatoms, the mutant strain showed stunted growth. Contributing to our understanding of sulfonate cycles in the ocean, this indicates the bacterium cannot function properly at normal levels without being able to produce pyruvate and bisulfite through DHPS degradation.

Can People with Low Self-Esteem Directly Self-Enhance?

Sahar Sabet, CURO Research Assistant
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

Self-enhancement is the desire to possess and enhance positive aspects of the self-concept. Regardless of their approach, people tend to accentuate the positive in themselves while ignoring the negative. Research consistently finds people with high self-esteem are able to self-enhance more easily than people with low self-esteem; these differences are largest on direct measures of self-enhancement. One possible reason for this disparity is that, when asked to think positively about themselves, people with low self-esteem experience more self-doubt. The purpose of this study was to investigate whether people with low self-esteem could self-enhance directly. When there are no indirect options available, participants are only able to self-enhance directly. We predicted that by alleviating some of the pressure people with low self-esteem experience when asked to directly self-enhance, the opportunity to self-doubt would be minimized. Participants reported their trait self-esteem and self-enhancement. Then participants either circled positive attributes they thought were more descriptive of themselves than their peers or they crossed out positive attributes they thought they possessed to a lesser degree than their peers. After the manipulation, participants reported their state mood, self-esteem, and implicit self-esteem. Our findings indicate that condition (circling versus crossing out) interacted with trait self-esteem to predict state self-esteem. Crossing out attributes tended to improve state self-esteem for low self-esteem participants whereas it lowered state self-esteem for high self-esteem participant. These findings suggest that this opportunity for self-enhancement functioned differently for people with low and high self-esteem.

Evaluation of Novel Antiviral Drug NSC95397 for Treatment of Swine Influenza Infections in Pig Cells

Preston Samowitz
Dr. Ralph Tripp, Infectious Diseases, College of Veterinary Medicine

Discovering countermeasures for the influenza virus has faced many obstacles because the virus incessantly evolves, causing vaccines and antiviral drugs to be ineffective. Targeting host factors instead of the virus is

thought to be an approach to limit resistant, since host targets are stable. A novel drug NSC95397 targets host cell mechanisms to treat influenza virus infections. RNA Interference (RNAi) was utilized to screen for host genes involved in the influenza virus replication and found the host gene cell division cycle 25 B (CDC25B). CDC25B is a phosphatase that dephosphorylates cyclin-dependent kinases (CDKs). An influenza non-structural protein (NS1) has been identified to be phosphorylated by a CDK, CDK1. The phosphorylation of NS1 modulates its nuclear localization and chromatin association. The viral NS1 protein inhibits host antiviral genes such as the interferon (IFN) response. Activation of the IFN response stimulates IFN-stimulated genes (ISGs) to mount an antiviral response. NSC95397 inhibits the CDC25B activity; as a consequence, the phosphorylation of NS1 does not occur causing a modulation of its interferon inhibition activity and nuclear localization. The purpose of my studies is to determine if NSC95397 can be used as an effective treatment for veterinary use in pigs to treat swine influenza infections. My project will evaluate if there is a specific escape mutation that occurs when passaging a clinical isolate of swine influenza A virus in pig kidney epithelial (PK1-LLC) cells treated with increasing drug concentrations. I hypothesize that specific mutation(s) in the influenza virus genome confer resistance to NSC95397.

Functional Consequences of Different CAAX Motifs

Colby Samuelson-Ruiz, CURO Honors Scholar
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Many eukaryotic proteins possess a C-terminal tetrapeptide CAAX motif. This motif is known to drive a trio of post-translational modifications: isoprenylation, endoproteolysis, and carboxylmethylation. These modifications influence CAAX protein interactions with other proteins, membrane association, and can be essential for protein function. A thorough understanding of how CAAX proteins are modified post-translation is important because many CAAX proteins are of significant biomedical relevance. The Ras GTPase is a prime example: mutated Ras is associated with 90% of pancreatic cancers, 50% of lung cancers, and 30% of all cancers in humans. Given the similarities among CAAX motifs, it has been assumed that all CAAX proteins undergo the same post-translational modifications at the C-terminus. This study used the yeast mating pheromone **a**-factor and heat-shock protein chaperone Ydj1p as reporters in the model organism *Saccharomyces cerevisiae* to investigate whether CAAX proteins are processed in a similar manner. Over the course of this study, four distinct CAAX motifs were independently assessed in the context of our two reporters, and the impact on protein function was assessed. We demonstrate that the motifs markedly differ in their ability to support function of the reporters. Moreover, our findings support an unanticipated divergence in the post-translational processing of CAAX proteins that allows some proteins to be isoprenylated but not undergo the proteolysis and carboxylmethylation events that are widely thought to be coupled downstream events. We will discuss the impact of our findings, especially the potential that this noncanonical pathway may be more widespread than anticipated.

Stemflow as a Contributing Source to Early Runoff

Sam Santoso, CURO Graduation Distinction
Dr. John Dowd, Geology, Franklin College of Arts & Sciences

Panola Mountain Research Watershed (PMRW), located near Atlanta, GA, has been studied extensively for over 30 years. Earlier work by Richard Cary used geochemistry to separate storm hydrographs into four component hydrographs. During most storms, water from current rainfall was not a significant component of flow until relatively late in the storm despite bare rock in the upper reaches of the watershed. Water to the stream early in the storm, but with the geochemical signature of soil water is stemflow from trees. To investigate the potential for stemflow to contribute to early storm flow, four Yellow Poplar trees (*Liriodendron tulipifera*) were wrapped and caulked with a collar funneling the water through a tipping bucket measuring device. The tipping buckets were connected to an Arduino to save the time of each tip. A GPS was used to synchronize the high resolution real-time clocks. The timing of stemflow compared to rainfall and stream flow will be used to evaluate stemflow contributions to runoff.

MindPlay Virtual Reading Coach

Lisa Savchenko, CURO Research Assistant
Dr. Jennifer Lindstrom, Communication Sciences & Special Education, College of Education

What are the effects of an online reading intervention on at risk students' reading performance in grades one and two? We are hoping to determine whether there are significant mean differences in decoding, encoding and fluency achievement scores of at-risk students (those that are receiving Tier 2, Tier 3, or Special Education Services.) The MindPlay Virtual Reading Coach online reading intervention will be used in addition to standard English/Language Arts instruction. Participants come from a public primary school in the Southeastern United States. There will be 90 participants. Approximately half of the participants will interact with the MindPlay intervention and the other half will conduct business as usual. Intervention is on-going and results will be calculated in Spring 2015.

Understanding the Role of *Helicobacter pylori acxABC* in an *Escherichia coli* Model System

Scott Schaffer
Dr. Timothy Hoover, Microbiology, Franklin College of Arts & Sciences

Helicobacter pylori is a gram-negative bacterium that is responsible for being one of the leading causes of peptic ulcers and chronic gastritis in humans. Since *H. pylori* colonizes the stomach mucosa, it has a variety of essential genes that facilitate its ability to survive the harsh, nutrient-limited environment of the stomach. One set of genes, HP0695 (*acxA*), HP0696 (*acxB*), and HP0697 (*acxC*) allow *H. pylori* to utilize acetone as a potential carbon source. These set of genes encode for an enzyme that is homologous to acetone carboxylase from *Xanthobacter autotrophicus* and *Rhodobacter capsulatus*. Acetone carboxylase catalyzes the reaction of acetone to acetoacetate, which can then be fed into central metabolism through subsequent enzymatic events. The genes encoding for the three subunits of this acetone carboxylase, *acxA*, *acxB*, and *acxC*, have been shown to be important for the efficient colonization of *H. pylori* in the murine gastric mucosa. In our study, synthetic *acxABC* genes were generated, cloned into the expression vector pLAC22, and transformed into *Escherichia coli*. *E. coli* was chosen as a model organism as it utilizes acetoacetate, but not acetone, as a carbon and energy source. The goal of my research project was to determine if an *E. coli* strain expressing *H. pylori* acetone carboxylase is able to use acetone as a sole carbon source. Such a result would be significant, as it would allow us to use the *E. coli* strain to screen possible inhibitors of acetone carboxylase that may

have therapeutic value in controlling *H. pylori* infections.

Microwave-Assisted and Benzotriazole-Mediated Synthesis of 1,2,4-Triazole-Based Peptidomimetics

Lewis Schendowich, CURO Research Assistant
Dr. Richard Morrison, Chemistry, Franklin College of Arts & Sciences

1,2,4-Triazoles derivatives are dynamic compounds that serve a wide range of biochemical applications, including antifungal drugs, antibacterial activities, CRF1 receptors antagonists, H2 antagonists and contain inhibitory properties on Janus associated kinases. Furthermore, 1,2,4-triazoles can been utilized as a structural peptidomemtic that is highly resistant to hydrolytic cleavage at a wide variety of peptide amide bond angles, including cis and trans. Developing new and efficient techniques to synthesize 1,2,4-triazole moieties are critical for medicinal and pharmaceutical chemists. Microwave organic synthesis provides a fast and high-yielding method of synthesizing a diverse range of chemical compounds. Currently we are employing benzoletriazole chemistry along with traditional and microwave techniques to synthesize a library of single and diamino acid substituted 1H-1,2,4-triazoles. The library will contain amino acids at a variety of positions attached to a triazole core and mimic known peptide bond angles. The microwave not only enables the reaction to occur, but also expedites several reaction times to less than 40 minutes. By combining low-cost starting materials like benzoletriazoles and amino acids with the efficient technology of microwave chemistry, we have produced in good yields a technique for further triazole synthetic chemistry.

Incidence of Anesthesia-Related Fatality in Birds

Amanda Seamon, CURO Graduation Distinction
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

While there is ample research about the anesthesia-related fatality rate for cats, dogs, and humans, there is little research into the rate in birds. The purpose of this study was to determine the fatality rate in birds associated with general anesthesia. Our hypothesis was that birds will have a higher fatality rate due to anesthetics than the rates in dogs, cats, and humans. Data were collected from cases seen between 2004 and 2014. Cases were identified by searching the records for patients designated as "avian" and having any inhalant anesthesia charge on their bill. Patients were organized into four groups: intensive-care unit related death, anesthesia related death, euthanized, and survived to discharge. Data collected includes date of visit, age, species, gender, pet vs. wildlife, weight, body condition score, diagnosis, procedure, American Society of Anesthesiologists status, premedication, induction medicine/anesthesia, maintenance medicine/anesthesia, fluid type, fluid route, crystalloid volume, colloid volume, heart rate nadir/peak, end-tidal CO2 nadir/peak, Inhalant anesthetic nadir/peak, temperature nadir/peak, intraoperative events, estimated blood loss, anesthesia duration, surgery duration, recovery time, recovery notes, survive to discharge, time of death, total bill, and anesthesia bill. Comparisons were made between the birds who did not survive to discharge and birds that did survive to discharge. The outcome for birds was survival to discharge 86%, died during anesthesia 3.4%, died in the intensive care unit 4.3%, or euthanized 6.3%. Overall, none of the variables studied are associated with the likelihood of death due to anesthesia in birds.

Abstracts

Behavioral Testing on Piglets to Assess Cognitive Deficits of a Traumatic Brain Injury

Kathryn Sellman
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Traumatic brain injury (TBI) affects over 150,000 children per year and is a leading cause of neurological disability and death during childhood. There are limited treatments available, but recently induced pluripotent stem cell-derived neural stem cells (iNSCs) have shown potential as a regenerative option. Due to similarities to children in brain formation and development, we have chosen to use a piglet model to 1) develop applicable and quantifiable behavioral tests to assess cognitive function, 2) quantify cognitive deficits after sustaining a TBI and 3) determine the effectiveness of iNSC treatment in reducing cognitive deficits after TBI. To assess cognitive function we will use a spatial plus T-maze test and an object recognition test. The spatial plus T-maze test will access learning and spatial memory. Piglets will start from a north or south arm and can enter both the east and west arms, with only one arm being baited. We expect the piglets to find the reward by using extra-maze visual cues, not motor memory. The object recognition test will test spontaneous trial-unique memory. Piglets will be exposed to two similar objects within an arena for 10 minutes. After a 10-minute delay, piglets will be reintroduced to one familiar and one novel object. Time spent with each object will be measured. We expect the piglets to prefer the novel over the familiar object, based on the piglets' memory of the familiar object. The successful development of these behavioral tests will enhance our ability to assess cognitive function in piglets.

Is Everyone on Twitter Better Than You?: Correlations between Twitter and Exercise Motivation among College Students

Patrick Semanie, CURO Research Assistant
Dr. Juan Meng, Grady College Of Journalism & Mass Communication

Purpose: The purpose of this research is to better understand the effect that Twitter can have on individuals' perceptions on their own personal fitness and exercise habits. Particularly, the researcher is interested in investigating the perceptions of college-aged individuals, as they are generally attracted to a wide variety of social networks. *Research Methods:* A 30-question online survey was distributed to the students at the University of Georgia by using a convenience sampling strategy. In addition, two focus groups (one comprised of males and the other of females) were conducted in order to gather in-depth insights about the participants' perception of Twitter's effects on exercise motivation both on themselves and others. *Results:* Results of the research will show differences amongst various demographics and their perception of Twitter. The results also show that participants believe that Twitter has a greater effect on the fitness and exercise habits of others, as opposed to on their own habits. Prior research showed that Facebook could lead to negative social comparison (Chou, 2012). Findings in this research reveal similar patterns about Twitter as it pertains to exercise. *Practical Implications:* This research will help us understand how Twitter can be used to stimulate the motivations to exercise. More importantly, it will also help better explain how Twitter must be used responsibly in order to promote a positive body image amongst its users.

Mapping the Genetic Basis of Leaf Physical and Chemical Defenses in Sunflower

Rahul Shah, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

Plants are faced with a variety of threats to their survival and reproduction. Such threats include disease from bacterial or fungal pathogens as well as herbivory from pests like insects. Plants have evolved a wide array of physical and chemical defenses to reduce the impact of these factors, and such traits are incredibly diverse among species. This work seeks to understand the genetic basis of variation in leaf defenses in the crop sunflower (*Helianthus annuus*). Using a 288-line association mapping panel that captures ~90% of the genetic diversity across all crop sunflower varieties, we phenotyped key defense traits including thickness, toughness, trichome density, tannin activity, and leaf ash content. Here we map variation in these traits to the sunflower genome using published genotype data for this association mapping panel, including ~5500 single nucleotide polymorphism (SNPs). Based on insights from previous studies of leaf defense evolution across wild *Helianthus*, it is hypothesized that (1) leaf defenses are likely controlled by few regions of large effect, and (2) leaf defenses likely do not share common genetic bases, with the possible exception of leaf thickness and leaf ash content. Identifying the genetic bases of leaf defenses informs breeding efforts and will improve our understanding of pest and disease dynamics in crop sunflower.

Promoting Success for English Learners: Dual-Language Immersion in Georgia

Rahul Shah, CURO Research Assistant
Dr. Linda Harklau, Language & Literacy Education, College of Education

In the last two decades, Georgia experienced unprecedented growth in immigration rates. The resultant enrollment rate of English learners (ELs) in Georgia public schools has increased by 400 percent, with nearly 90,000 new ELs enrolling annually. ELs are severely academically disadvantaged because Georgia schools do not adequately support their English acquisition needs. For example, high school ELs have lower End-of-Course-Test passing rates in all 10 tested subjects compared to their non-ELs peers. Additionally, only 44 percent of Georgia's ELs graduate high school in four years—a rate 26 percent below the state average. Georgia currently utilizes a "pull-out" model, in which ELs students are removed from traditional academic courses for a class period to be instructed in English. This places undue burden on ELs who face the pressure of learning English while simultaneously fulfilling complex high school graduation requirements. Because they lack English proficiency, ELs often cannot enroll in courses they need to graduate. This retention is discouraging, and furthers the tendency of English learners to become high school dropouts. To improve English proficiency rates and educational outcomes of ELs, Georgia should subsidize the implementation of dual-language immersion magnet programs in public schools, in which students take coursework taught in Spanish for part of the day and coursework taught in English for the other.

Formation of Mitochondria-Targeted Blood Brain Barrier Penetrating Biodegradable Nanoparticles for Stroke Treatment

Nivita Sharma, CURO Honors Scholar
Dr. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Stroke is the third leading cause of death in the United States. There are several developing drug treatments for stroke injuries.

However, only one drug, tissue plasminogen activator, has received FDA approval. The critical need for effective treatments for stroke injuries motivated regenerative stem cell therapy aimed at re-stimulating brain activity and protecting brain cells from further injuries. A devastating effect after a stroke event is the loss of blood supply, and thus, death of brain cells. The dying cells trigger secondary immune and inflammatory responses producing a cytotoxic environment and inflammation in the brain. Several current studies are using adult stem cells (ASCs) to renew cell stimuli and inhibit immune and inflammatory responses that cause cytotoxic environments for the cells. Unfortunately, these recent studies show that ASCs cannot survive sufficiently long in cytotoxic environments to effectively integrate and replace lost cells. To protect stroke patients from significant detrimental effects, it is imperative to consider a new source of stem cells for stroke treatment. In this project, we focus on developing a cell therapy using induced pluripotent stem cell derived neural stem cells (iNSCs) that have the same capabilities as ASCs in addition to effectively integrating into damaged neural tissues. However, the functional success of iNSCs varies because of the cytotoxic brain environment. Accordingly, we are developing an efficacious biodegradable nanoparticle to deliver aspirin that can cross the blood brain barrier to reduce inflammation in the brain so that iNSCs are able to differentiate and integrate more successfully.

Body Mass Index and Performance-Based Functional Independence in Older Adults

Shubam Sharma
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

Body mass index (BMI) aids in the classification of individuals as underweight, normal, overweight, and obese, functioning as a tool to determine an individual's risk of developing different problems, including physical health diseases, cognitive dysfunctions, and behavioral issues. One variable BMI has shown a relationship with is functional independence in older adults. Functional independence is characterized by the ability to perform both basic activities of daily living (BADLs) and also more complex, instrumental activities of daily living (IADLs). Previous research has utilized self-report measures to assess functional independence in older adults, yielding inconsistent results. The purpose of the present study was to assess functional ability in 75 older adults using a performance based measure, the Direct Assessment of Functional Status-Revised (DAFS-R). This study hypothesized that BMI level would correlate with an individual's functional ability, specifically IADLs. BMI was calculated according to the World Health Organization's formula: BMI = Weight (in lbs) / Height (in inches) ^ 2. Curvilinear regression analysis was used to analyze the relationship between BMI and functional ability. Results approach significance ($p = 0.084$) suggesting a curvilinear relationship may exist between BMI and functional ability. If borne out, this relationship would suggest that the more extreme an individual's BMI – either higher or lower – the greater the risk for functional disability.

Mitigating the Spatial Mismatch of Social Service Provision and Demand: The Potential of Faith-Based Facilities

Keller Sheppard, CURO Research Assistant
Dr. Sarah Shannon, Sociology, Franklin College of Arts & Sciences

Comparing the concentration of social service programs to the location of neighborhoods with a high potential demand for those services allows for an assessment of the efficiency of the social safety net's geographic coverage. Agencies are not operationally restricted to their own facilities. Indeed, there are a number of means by which agencies can

mitigate the effects of geographic inaccessibility. One such strategy is the utilization of other organizations' facilities. Faith-based facilities such as churches can provide office or meeting space and allow for a more efficient distribution of social services. The current set of social service providers located in Athens-Clarke County and their potential faith-based collaborators will be mapped over the potential demand across the city measured by data from 2009-2013 American Community Survey 5-year estimates. Locations of social services providers are generally clustered in and around the center of the city with geographically underserved areas of high potential demand along the periphery. The potential for faith-based institutions to penetrate these areas both spatially and culturally is examined using a method of qualitative GIS. Faith-based facilities' cultural accessibility and current collaborative behaviors with social service provides are investigated through semi-structured interviews with prominent church parishioners throughout the county. The utilization of faith-based facilities presents an opportunity to more effectively reach underserved and isolated neighborhoods by decreasing the travel costs associated with service uptake.

Role of Glypican-1 in Prostate Cancer Cell Growth

Sheela Sheth, CURO Research Assistant
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College Of Pharmacy

Glypican-1 (GPC-1) is a membrane-bound heparan sulfate proteoglycan involved in intracellular and extracellular signaling, and is suggested to mediate cancer cell proliferation and metastasis. GPC-1 shuffles Group IIA secreted phospholipase A_2 ($sPLA_2$ IIA) between intercellular and extracellular domains. High concentrations of $sPLA_2$ IIA are destructive to the cellular membrane of diseased tissues, such as in arthritis and atherosclerosis; however, prostate cancer cells remain viable under high concentrations of $sPLA_2$ IIA (22-fold increased expression). We hypothesize that GPC-1 mediates prostate cancer cell growth and viability through its interaction with $sPLA_2$ IIA. To initially address this hypothesis we determined the expression of both GPC-1 and Group IIA $sPLA_2$ in non-cancerous (RWPE-1) and cancerous (LNCaP, DU-145 and PC-3) prostate cell lines. Immunoblot analysis demonstrated that prostate cancer cells have increased expression levels of Group IIA $sPLA_2$ compared to RWPE-1. Interestingly, GPC-1 expression was detected in the metastatic prostate cancer cells (DU-145 and PC-3), but was not detected in the non-cancerous (RWPE-1) and moderately metastatic prostate cancer cells (LNCaP). This suggests that GPC-1 may play a role in cancer metastasis and protecting cells from $sPLA_2$ IIA's toxic effect in advanced prostate cancers. We are further testing our hypothesis using lentiviral transfection of shRNA to knock down GPC-1 in PC-3 cells and confirming knock down using immunoblot analysis. These cells will be used in future studies to test their sensitivity to Group IIA $sPLA_2$, as well as their differences in proliferation and migration activities, as compared to control cells.

An Investigation of Anaerobic Methane Oxidation by Consortia of Methanotrophic Archaea and Bacterial Partners Using Process-Based Modeling

Yimeng Shi, CURO Summer Fellow, CURO Research Assistant
Dr. Christof Meile, Marine Sciences, Franklin College of Arts & Sciences

Biological activities, including oxidation of methane in marine sediments, play an important role in the global methane cycle. Methane can be converted to CO2 under anaerobic conditions by microbial consortia

consisting of archaea and bacteria. We used reactive transport models to study the magnitude of methane oxidation. Compared to rates in laboratory incubations, it was shown that reaction kinetics, transport intensities, and energetic considerations all decisively impact the overall rate of methane consumption. We applied the model to different environmental settings and spatial distribution patterns of archaea and bacteria. E.g., in some cases archaea and bacteria separately form their own groups while in some other cases they are well mixed with each other. We also investigated newly proposed potential reaction pathways and studied the effectiveness of various potential chemical species, including acetate, hydrogen, formate, and disulphide between the archaea and bacteria. Moreover, we investigated the effect of hyper diffusion and nanowires, when the potential chemical species diffuses at a higher speed by potential biological vehicles. We concluded that for the six spatial distribution patterns, the well-mixed situation has significant influence on the efficiency of the oxidation of methane, because the vicinity of bacteria and archaea counteracts the build up of products and therefore prevents the thermodynamic shutdown of microbial metabolism. Also, disulphide has the potential to serve as efficient intermediate species. Our simulations with hyperdiffusion or nanowires show that effective electron transport between the point of reduction and oxidation is a critical aspect for efficient anaerobic methane oxidation in microbial consortia.

Asymmetric Functional Movement Screen Scores and Injury Occurrence in Collegiate Female Athletes

Taj Shorter
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

There is limited research discussing the differences in bilateral Functional Movement Screen (FMS) scores and injury occurrences in female collegiate athletes. Increased risk of injury has been observed in athletes with poor FMS scores, but it is unknown if injury occurrence is associated with asymmetric functional movement. The purpose of this study was to determine if injury occurrence is associated with asymmetric FMS scores in the lower extremities of Division I female collegiate athletes. Asymmetry was defined as ≥1 point difference in unilateral tests. The FMS scores of 29 consented female athletes (18 soccer and 11 basketball) were obtained by trained raters prior to the start of the fall semester. Injuries were documented during the season by the teams' sports medicine staff. The injured group contained those who missed ≥1 day of full sport participation due to athletic-related injury. The uninjured group did not miss any time. Nine chi-square tests were performed using variable crosstabulations of the side of lower extremity asymmetry (lower scoring limb) and the side of injury (side variable). No significant results were found for the chi-square tests (Cramer's $V=0.022$, $p=0.904$). Injury occurrence does not appear to be associated with side of lower asymmetry FMS scores in the lower extremities in this preliminary study of female collegiate athletes. Future research should focus on whether an asymmetry in functional movement pattern leads to injury over time.

The Complete Genome of *Diachasmimorpha longicaudata* rhabdovirus: A Symbiont of Parasitoid Wasps

Tyler Simmonds
Dr. Gaelen Burke, Entomology, College of Agricultural & Environmental Sciences

Several lineages of parasitoid wasps employ viral symbionts as a mechanism to deliver immune-suppressing genes to the host to prevent the wasp's eggs from being destroyed during development by the host immune system. These viral symbionts have been acquired at several different points during the

evolution of parasitoid wasps, and show differing degrees of genome re-organization in response to the symbiotic relationship. The Polydnaviruses (PDVs), found in Braconid and Ichneumonid wasps, are the oldest and best characterized parasitoid wasp symbionts and have undergone extensive genome re-organization. In comparison, little is known about the more recent viral symbionts found in other parasitoid wasp lineages. By examining both ancient and recent viral symbionts, we can further understand the process that has allowed these viruses to transition to a beneficial role. We examined one of the more recent viral symbionts acquired by parasitoid wasps, *Diachasmimorpha longicaudata* rhabdovirus (DlRV), via sequencing and phylogenetic analysis. The assembled DlRV genome is 13kb in size and contains a total of 6 open reading frames (ORFs). Three ORFs correspond to the genes for N, G, and L proteins found in other rhabdoviruses. Additionally, a parasitism-specific protein (PSP24) was identified that previously had unknown origin in the fly and wasp system, and may play a key role in mediating successful parasitism. Phylogenetic analysis of the DlRV L amino acid sequence revealed that DlRV is closely related to two recently discovered insect rhabdoviruses, *Spodoptera frugiperda* rhabdovirus (SfRV) and Taastrup virus.

The Role of the Chaperone-Protein Interactions in Driving Protein Trafficking in the Malaria Parasite

Brandon Sims
Dr. Vasant Muralidharan, Cellular Biology, Franklin College of Arts & Sciences

Malaria is a widespread, global disease that causes 225 million cases and hundreds of thousands of deaths every year. *Plasmodium falciparum* is the most deadly cause of human malaria. The goal of my research is to investigate new classes of drug targets in *Plasmodium falciparum*. My lab studies the roles of a family of proteins called chaperones or heat shock proteins (Hsp) in allowing the parasite to establish its habitat within red blood cells. My project is to engineer Hsp expression constructs to generate protein chaperones to test their interactions. I have worked to engineer ten constructs; including five chaperones (Bip, Hsp-660, Hsp70x, Grp-94, and Hsp110) with and without a degradation domain in a pET-28 expression vector. First I amplified the target sequence on the gene of interest via PCR. Next restriction nucleases were utilized to cut both the intended insert and the recipient pET-28 vector. The insert and vector were fused together in a ligation reaction. These reactions were then transformed into *Escherichia coli*. To confirm uptake, DNA from *E. coli* colonies was purified, digested, and run on an agarose gel. Currently Bip, Hsp-660, and Hsp70x in pET-28 and Hsp-660 in pET-28 with the degradation domain have been screened showing successful uptake of the plasmid. The other five are currently being screened. Once all ten constructs have been successfully made I will test protein-chaperone interactions *in vitro* necessary for protein trafficking in *Plasmodium falciparum*.

Will Butterfly Gardens Take Off? Butterfly Dynamics and Recruitment in Response to Planted Gardens

Stuart Sims
Dr. Andy Davis, Odum School of Ecology

Global decline in pollinators poses a threat to ecological communities and processes worldwide. Habitat loss and degradation have led to several efforts to restore habitat area for both plants and their associated pollinators. As a result, butterfly gardens have become an emergent trend in pollinator conservation efforts. Little is known about the recruitment success of pollinator gardens or their most efficient composition. Here, we investigate garden composition, maintenance schedules, and population dynamics of several species in

order Lepidoptera to determine the effectiveness of pollinator gardens for conservation. We also investigated larval survival both inside and outside the garden plots at varying distances. We found that across species, adult abundance, egg counts, and species richness were explained by plant type, month, and number of plants blooming. Maintenance scheme and structural complexity did not have a significant effect. Survival increased outside the gardens, but not strongly with distance from the gardens. Understanding the importance of these variables in pollinator gardens helps optimize their effectiveness in conservation efforts.

Genotype-Phenotype Correlations in POMGNT1 and POMGNT2

Danish Singh, CURO Summer Fellow, CURO Research Assistant
Dr. Lance Wells, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Congenital muscular dystrophies (CMDs) affect the lives of millions of people every year. These genetic disorders are caused by the dysfunction of the dystrophin-dystroglycan complex that helps to coordinate cell movement and are thus appropriately termed dystroglycanopathies. Specifically the protein alpha-dystroglycan is of interest to this project since this protein in heavily glycosylated and the o-linked glycan structures on the protein are important of its function to bind laminin to a transmembrane protein. Dystroglycanopathies occur when these o-linked glycan structures are not glycosylated on to alpha-dystroglycan properly by other enzymes in a process known as post translational modification (PTM). The two enzymes investigated in this project were POMGNT1 and POMGNT2 which extend O-mannose initiated structure of α dystroglycan with a GlcNAc (N-Acetylglucosamine) by producing UDP-GlcNAc. While both these enzymes attach the same sugar they do it in different linkages and the sugar structure is glycosylated differently based on the linkage. Thus if a mutation occurs in one of these enzymes it can result in a glycan not being attached to alpha-dystroglycan which can cause the protein to not to bind to laminin which results in weakened muscle movement, a symptom of congenital muscular dystrophy. The aim of this project was to correlate specific single, nucleotide mutations in POMGNT1 and POMGNT2 to specific changes in enzymatic activity and also to understand how these two enzymes differentiate which one will glycosylate alpha-dystroglycan and when. By doing so this can provide diagnostic information on how to treat specific CMDs.

Profiling the Spatiotemporal Regulation of DNA Methylation in a Social Insect

Daniel Skowronski, CURO Research Assistant
Dr. Brendan Hunt, Entomology, College of Agricultural & Environmental Sciences

DNA methylation plays a role in development through the regulation of gene function in a diverse number of eukaryotes. The methylation is also affected by environmental input and may thus represent a fundamentally important mechanism by which development is influenced by the environment. Evolutionary conserved enzymes known as DNA methyltransferases (DNMTs) are responsible for DNA methylation. *De novo* methyltransferases of the DNMT3 family establish new methylation patterns within an organism's genome. Maintenance methyltransferases of the DNMT1 family maintain previously established methylation patterns across cell generations. In this study we have identified orthologs of DNMT1 and DNMT3 in the genome of *Solenopsis invicta* (red imported fire ant) as well as designed and validated qPCR primers for these genes. We will be profiling patterns of gene expression across seven developmental stages (egg, first through

fourth-instar, pupae, and callow adult) from two nests of the monogyne (single reproductive queen per nest) social form of *S. invicta* in order to provide insight into the timing and levels of activity of mediators of DNA methylation. Our effort represents a novel contribution to the field of insect epigenetics. This research will enable further investigations of the relative roles and temporal patterns of *de novo* and maintenance DNA methylation, which are integral to understanding environmental contributions to social insect development.

A GDOT Case Study for the Beneficial Use of HVFA in Concrete Pavements

Scott Smith, CURO Research Assistant
Dr. Stephan Durham, College of Engineering

The plurality of past academic life-cycle assessments for concrete pavements have shown the beneficial use of high volumes of supplementary fly ash in concrete pavement mixtures. However, because of the overall size and scope of these studies, findings were intangible due to their magnitude. An economic, structural, and environmental study of high volume fly ash (HVFA) in concrete mixtures is detailed in this research, but the scope has been limited to an 11 mile section of pavement located on I-75 in Bogart, GA. Through the use of life cycle assessments, it was found that the total carbon footprint for the pavement section could be reduced 17% by increasing the fly ash content of the concrete mixture from 10% to 20%. Quantitatively, this is enough energy to power roughly 4,500 average American homes for an entire year. This study will provide the quantitative data in areas of structural performance, economic savings, and environmental sustainability that will provide GDOT with the necessary information to modify the current Class I concrete specifications from the current 15% to an increased level. Additionally, a new and innovative metric for communicating the efficiency of a structural material is being developed. The concept is to generate a "nutrition" label, similar to those required by the FDA for food, but for structural materials. This labeling system would provide an understandable metric for contractors, architects, and other consumers to cross-compare service life, cost, and environmental impact.

A De-Demonized Future for the Radical Right in France? Media Framing of Marine Le Pen

Alexandra Snipes, CURO Research Assistant
Dr. Cas Mudde, International Affairs, School of Public & International Affairs

Sharing the core values of authoritarianism, anti-establishment populism, and nativism, populist radical right parties have strengthened their presence and legitimacy across Europe. France's Front National's platform includes an aggressive anti-immigration policy, an emphasis on law and order, a welfare state that privileges French "natives," and a virulent opposition to the European Union. The party traditionally appealed to predominantly male voters with low incomes, low educational levels, and low social statuses. In 2011, party leadership was passed to Marine Le Pen, daughter of party founder Jean-Marie Le Pen, and she has sought to modernize the party's image by declaring a de-demonization strategy for the Front National. This analysis focuses on her and her party, who witnessed a surge in media attention this past summer after their successes in the European Parliament elections. Women in politics are often viewed in the mainstream media as being more liberal than their male counterparts, even if their political opinions are in fact more conservative. Journalists never claimed that the achievements of the Front National under Jean-Marie Le Pen were due to a liberalization of his policy stances, making him more appealing to the mainstream. These claims are

now ever-present in the media stampede surrounding his daughter. To examine whether gendered media bias exists cross-nationally, I analyze articles in two American newspapers, *The Economist* and the *New York Times*, and two French newspapers, *Le Monde* and *Figaro*, focusing on the perception of Marine Le Pen.

Anti-Binge Drinking Public Health Campaigns: Their Effectiveness in Targeting Female College Students

Margaret Sparks, CURO Research Assistant
Dr. Juan Meng, Grady College of Journalism & Mass Communication

Purpose: The purpose of this research is to determine the effectiveness of anti-binge drinking public health campaigns aimed at female college students. In doing so, the research presented in this paper compares different mediums, print and video, used in this particular public health campaign to determine the most effective medium for targeting this particular public. *Research methods*: An online post-test-only experiment was used. Participants were randomly exposed to one of four different conditions (no stimuli, print advertisement, video advertisement, or both the print and the video advertisements), followed by the same questionnaire. Approximately 100 completed responses were collected (approximately 25 responses per experimental condition). A series of focus groups were also conducted in order to obtain insights on the investigated subject. *Findings*: Results suggest that video is the most effective medium for the anti-binge drinking campaign. Participants who watched the video elicited the most negative attitudes toward binge drinking. Results also reveal that increased levels of exposure to anti-binge drinking material will lead to negative attitudes toward binge drinking. *Practical implications*: Public health campaigns targeting female college students should be mindful that video is the most effective medium. Also, it is important to note that increased exposure to anti-binge drinking campaigns will affect audience's attitudes toward the subject. Therefore, future campaigns should integrate such strategies to increase effectiveness.

Development of an Improved Tuberculosis Vaccine

Jaclyn Speer, CURO Research Assistant
Research Professionals: Monica LaGatta, Simon Owino
Dr. Russell Karls & Dr. Frederick Quinn, Infectious Diseases, College of Veterinary Medicine

An experimental tuberculosis (TB) vaccine strain under study in our laboratory features a naturally, cold-adapted *Mycobacterium* species carrying a plasmid encoding the protein Antigen 85B (Ag85B) from the TB-causing bacterium *Mycobacterium tuberculosis* (*M.tb*). The Ag85B protein is known to be secreted to the bacterial surface in both *M.tb* and the vaccine platform strain. While the Ag85B-expressing vaccine yields a strong immune response, our hypothesis is that the vaccine can be enhanced if additional *M.tb* surface or secreted proteins are expressed simultaneously with Ag85B and exported to the surface of the vaccine strain. Genes encoding *M.tb* target proteins were obtained and inserted adjacent to the Ag85B gene, such that the target protein is synthesized as a fusion to the C-terminus of the Ag85B protein. Restriction endonuclease digestion and DNA sequencing was performed to screen for the expected DNA banding patterns and for the absence of mutations in the generated plasmids. A plasmid encoding one of the Ag85B fusion constructs was confirmed free of mutations. It was recently introduced into a fast-growing species (*Mycobacterium smegmatis*) to assess fusion protein synthesis and localization to the bacterial surface. Similar analyses will be performed upon introduction of this plasmid into the vaccine strain. Based on earlier studies with Ag85B, we anticipate that if the

Ag85B fusion protein is surface-localized in *M. smegmatis*, then it is likely to be located similarly in the vaccine strain, which will support future studies to test the efficacy of this new vaccine strain.

Bone Fracture Putty: A Combined Stem Cells and Lentiviral Approach

Karishma Sriram, Foundation Fellow, CURO Research Assistant
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Worldwide, there is a need for effective methods of treating non-healing fractures. Some bone fractures, termed *delayed unions*, which do not heal within 20 weeks, or *nonunions*, which do not heal within six months, are the result of more severe fractures, constituting nearly 10% of the 7.9 million fractures sustained yearly. Bone morphogenetic protein 2 (BMP2) can induce rapid ossification when used to treat bone defects. MSCs can function as a vector to deliver BMP2, while the lentivirus, containing the gene for BMP2, can allow transduced stem cells to confer the BMP2 protein. Thus, lentiviral BMP2-transduced MSCs will generate enough exogenous BMP2 to produce heterotopic ossification in mouse models, and the MSC will release trophic factors, enhancing the effects of BMP2, especially when confined inside a hydrogel matrix—such as glycosaminoglycan (GAG). For the mouse experiments, 3 million cells in phosphate buffer saline (PBS) and 350,000 cells in GAG gel were harvested and injected into the leg muscles of 8 non-obese diabetic/severely-compromised immunodeficient (NOD/SCID) mice. Furthermore, GAG gels were lyophilized and combined with GFP-labeled MSC to increase viability and even distribution of the MSC, as well as the total volume of cells injected. Observations from this experiment suggest the possibility of using a greater number of transduced MSCs in lyophilized GAG to induce more bone production. The observations from the mice indicate that the stem cells transduced with the BMP2 gene were successful in producing bone in mice and that the GAG gel successfully encapsulated the cells and enhanced the BMP2 production—and therefore, bone production.

Retinal Development with IFT122

Romik Srivastava, CURO Research Assistant
Dr. Jonathan Eggenschwiler, Genetics, Franklin College of Arts & Sciences

What are the mechanisms controlling the specification and morphogenesis of the mammalian retina? Several cell-intrinsic factors (e.g. Rx, Six3, Lhx2, Pax6, Pax2, Chx10) and cell-extrinsic signaling pathways (e.g. Hedgehog, Bone Morphogenetic protein, Wnt, retinoic acid) have been shown to participate in this process but how they are coordinated and used to execute retinal development remains unclear. To gain a better understanding, our lab is studying several mutations in mouse genes that disrupt specific aspects of retinal development. In addition to characterizing the mutant phenotypes, it will be important to understand the influence of developmental history and tissue-specific requirements of these genes in retinal formation. A useful way to address this question will depend on the characterization of the developmental potential of mutant cells in different contexts. Our goal is to exploit the *in vitro* and *in vivo* differentiation of mouse embryonic stem cells that harbor mutations in these genes. For this purpose, Mr. Srivastava will work to generate mutant embryonic stem cell lines that carry the mutations and express a GFP marker that will allow us to follow the fates of the mutant cells. Following this, we will conduct two types of experiments. First, wild-type and mutant ES cells will be subjected to *in vitro* differentiation protocols to form retinas and optic cups in the culture

dish. We will determine whether the mutant cells, in a heterologous environment, retain an inherent potential to give rise to retinal cell fates and retinal tissue morphogenesis. Second, the mutant and control ES cells will be microinjected into wild-type blastocysts to generate mosaic embryos composed of both types of cells. We will then determine whether, in a largely wild-type environment, the mutant cells are rescued in their ability to give rise to retinal cell fates.

The Effects of a Fucosyltransferase 3 (FUT3) Gene Knockout in *Arabidopsis thaliana*

Heather Steckenrider, CURO Graduation Distinction
Dr. Michael Hahn, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The Fucosyltransferase (*FUT*) family of genes is currently being characterized in *Arabidopsis thaliana*. However, only *FUT1*, *FUT4,* and *FUT6* have been characterized successfully. It has been found that *FUT1* encodes a fucosyltransferase that fucosylates xyloglucan while *FUT4* and *FUT6* encode fucosyltransferases that appear to fucosylate arabinogalactan proteins. The fucosylation of xyloglucan by *FUT1* has been shown in the leaves of *Arabidopsis thaliana,* and the fucosylation of arabinogalactan proteins by *FUT4* has also been shown in the leaves of *A. thaliana*. The pronounced expression of all three of these *FUT* genes has been shown in the roots of *A. thaliana*. The expression pattern of the *FUT3* gene in Arabidopsis, as well as the subcellular localization of the FUT3 protein remain unknown. The Arabidopsis Information Resource predicts that FUT3 is involved in fucosylation based on its similarity to FUT1, but it predicts that the specific functionality is different. So far, two plant lines carrying homozygous mutations in the *FUT3* gene have been identified (*fut3* mutants). These *fut3* mutant plant lines will be compared through polymerase chain reaction and gel electrophoresis with the wild type *A. thaliana* plants in order to obtain information about the function(s) of FUT3. I have isolated homozygous mutants through these methods to compare with the wild type *A. thaliana*.

The Effectiveness of Counseling and Psychiatric Services at the University of Georgia: An Empirical Investigation

Mara Steine, CURO Research Assistant
Dr. Juan Meng, Grady College of Journalism & Mass Communication

Purpose: The purpose of this research is to identify the effectiveness of mental health programs on the University of Georgia campus by particularly examining the Counseling and Psychiatric Services (CAPS) provided by the University Health Center. The research aims at determining the general knowledge of the CAPS program on campus as well as the success of the CAPS program in its mission to help students.
Design/methodology/approach: The researcher used three research methods in this study to investigate the subject: (1) an online survey of UGA undergraduate and graduate students; (2) two focus groups—one with five participants and the other with four participants—with UGA students; and (3) in-depth interviews with mental health professionals at the University of Georgia.
Findings: Results suggest that students at the University of Georgia are generally not aware of the services CAPS provides to students. Mental health is also an issue on campus since many students struggle with depression and stress stemming from their academic endeavors. *Practical implications*: CAPS needs to find effective ways to reach out to students so that they are aware of the resources and help available on campus. CAPS needs to put emphasis on reaching out to freshmen, since being new to campus can pose many challenges to maintaining mental health. Speaking at new student orientation or

freshmen programs can be a great way to reach those target groups. *Originality/value*: The study provides insights into the effectiveness of CAPS programming and the issues that surround mental health on the college campus. It is important that students receive the help they need in order to be successful in college and beyond.

Understanding and Preserving the Practice of Medicinal Plant Cultivation and Use in San Luis, Costa Rica

Olivia Stockert, CURO Research Assistant
Dr. Jon Calabria, College of Environment & Design

San Luis is a small community in the Monteverde region of Costa Rica with a rich history of medicinal plant use, although few studies have documented this tradition in a way that makes information accessible for other researchers and for the local community. The use of medicinal plants is an important way for members of the community to share culture, and some residents of San Luis have observed that this generational transfer of traditional knowledge is in decline as modern pharmaceuticals become more prevalent. This study was conducted in order to determine residents' attitudes about the use of medicinal plants and the environment where they are found or cultivated. Upon the recommendation of University of Georgia Costa Rica Campus staff, selected residents of San Luis were interviewed in the summer of 2014. Open ended interviews were conducted in Spanish and the interviewer asked about environmental knowledge and ideology, medicinal plant use, and relevance of medicinal plant use to younger generations. Several themes emerged from the interviews indicating that older residents are more likely to use medicinal plants and have concerns about ineffective conservation strategies and limited adoption of medicinal plants by younger generations. Respondents indicated that educating others about traditional medicinal plant practice is an important part of the community's history and identity, which can also foster conservation. These findings reveal the critical role of medicinal plants in the San Luis community and their waning cultivation and use in recent years. Survey respondents suggested solutions to reverse this trend that included direct education of the younger generation and assistance from UGA Costa Rica to preserve this tradition. One way to address this perceived decline in interest and use of medicinal plants is to establish a community of practice. Traditional knowledge of medicinal plant cultivation and use could potentially be preserved while simultaneously strengthening cross-generational bonds within the community, educating younger generations, and encouraging conservation. Further research could implement a formalized community of practice and assess its effectiveness in preserving this important facet of San Luis's culture.

Leaf Litter Quality, Not Local Adaptation of Macroinvertebrate Communities, Drives Leaf Decomposition in Forested Headwater Streams

David Stoker, CURO Research Assistant
Dr. Catherine Pringle, Odum School of Ecology

Resource subsidies from terrestrial ecosystems can be important for stream ecosystem structure and function. Subsidy dynamics between terrestrial and aquatic ecosystems are dependent on the amount, timing, and identity of the resource, and consumer interactions within recipient systems. Forested headwater streams depend on leaf litter inputs, and intra- and inter-specific variation in leaf litter quality affects leaf decomposition and macroinvertebrate community assemblage. Here, we evaluated the relative importance to leaf litter decomposition of (1) local adaptation of macroinvertebrates; and

(2) leaf litter quality. We conducted a full reciprocal transplant experiment between two low- and two high-elevation streams within the Coweeta Hydrologic Laboratory, Otto, NC. Leaf input data were used to create leaf packs characteristic of riparian zones for each elevation, and leaf packs were deployed in home and away sites. We observed greater decomposition of higher quality leaf packs, irrespective of deployment site ($P = 0.001$). There were non-significant differences between leaf packs deployed in home or away sites ($P = 0.406$). Our results suggest litter quality, not local adaptation, drives leaf decomposition in these forested headwater streams.

Design and Analysis of Reactive Red Dye 120 Absorption by Nanocellulose Gel

Zack Stokes
Dr. Abhyuday Mandal & Dr. T. N. Sriram, Statistics, Franklin College of Arts & Sciences
Dr. Suraj Sharma, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The reduction or elimination of water usage in dyeing fabrics is an important concern to many who participate in the activity on an industrial scale. One way of addressing this issue is to make the dyeing agent more responsive to the material it is being applied to. Research has shown that the nanocellulose gel obtained from wood pulp, when combined with certain dyes, such as Reactive Red 120, can permanently bind to the cotton textile surface as a uniform thin film. The extent to which the dye is absorbed by the nanocellulose is thought to be influenced by several factors, such as the volume and concentration of the dye used, the amount of time for which the gel solution is heated, and the temperature at which this heating is done. We have determined levels for these factors and used a fractional factorial design. Analyzing the data from this experiment, we are investigating the combination of factor levels which maximizes the absorption. Additionally, as a follow up to this process we can quantitatively determine the change in the dye color and use both pieces of information to create a measure for the overall dye performance. Our statistical analysis has the potential to reduce the amount of water needed to complete the coloring process while allowing the dye to maintain much of its original intensity. This could lead scientists to create a more environmentally-friendly process, which has broader social benefits.

The Influence of Caregiver Emotional Functioning on Perceived Barriers and Adherence in Adolescent Solid Organ Transplant Patients

Tyler Stollman, Charlotte Goldman, Kelsie Flanigan
Graduate Students: Cyd Eaton, Ana Gutierrez-Colina, Julia LaMotte
Dr. Ronald Blount, Psychology, Franklin College of Arts & Sciences

Previous studies have shown significant relationships between patient emotional functioning (EF), medication adherence, and barriers to adherence in adolescent solid organ transplant recipients. However, little is known about the role of caregivers' EF on patients' barriers and adherence. This study investigated the influence of caregiver EF (i.e., anxiety and depression symptoms) on barriers and medication adherence, beyond that explained by patient EF, in adolescent transplant recipients. Forty adolescent patients (*M* age= 16.03) and caregivers (*M* age= 44.85) completed self-report measures of their own EF and adolescents' medication adherence and barriers to adherence. Transplant types included 10 kidney, 11 liver, and 19 heart. Correlational analyses demonstrated higher levels of caregiver depression and anxiety symptoms were associated with more patient barriers and lower adherence. Multiple regression analyses showed caregiver EF accounted for significant variance (+

association), beyond that accounted by patient EF, in predicting barriers related to medication ingestion issues (depression model: $R^2 = .552$, $p < .01$; anxiety model: $R^2 = .515$, $p < .01$) and regimen adaptation issues (depression model: $R^2 = .38$, $p < .05$; anxiety model: $R^2 = .234$, $p < .05$). Caregiver EF accounted for significant additional variance (-association), beyond that accounted by adolescent EF, in predicting adherence (depression model: $R^2 = .147$, $p < .05$; anxiety model: $R^2 = .169$, $p < .05$). These results suggest that intervention to reduce caregiver anxiety and depression levels may help lower adolescents' barriers to adherence and increase medication adherence.

Properties of the Monkey Saddle

John Stroud, Foundation Fellow
Dr. David Gay, Mathematics, Franklin College of Arts & Sciences

In mathematics, a critical point of a function is a specific point where the function is level or unchanging. A monkey saddle graph is a three-dimensional surface, often studied in multivariable calculus courses, with an unusual type of critical point. The monkey saddle itself is similar to a normal saddle graph, but with three depressions instead of two. The interesting feature of this saddle is that its critical point is always an inflection point and never a local minimum or maximum regardless of the intersecting plane. We wish to study the monkey saddle to better understand its unusual fixed point and its formation of bifurcations as we perturb the surface. My research concerns creating a short movie using Sage, an open-source Python-based mathematics software, to generate three-dimensional pictures of the monkey saddle changing as its parameters change, as well as mathematically understanding how perturbations of the surface affect its fixed points. Other methods include using the Tachyon ray-tracing system that operates on top of Sage to create more realistic images.

Cryptosporidiosis: New Methods for Combating an Important Disease

Caleb Studstill, CURO Research Assistant
Dr. Boris Striepen, Cellular Biology, Franklin College of Arts & Sciences

Diarrheal diseases are responsible for nearly ten percent of early childhood mortality around the world. *Cryptosporidium*, a unicellular, eukaryotic parasite is among the most important causes of diarrhea in infants. In the United States, *Cryptosporidium* is a threat to people who are immunocompromised due to HIV/AIDS infections or organ transplants. To prevent and cure this disease, better tools for studying the parasite are essential. Recently, we have developed technology that enables us to genetically modify *Cryptosporidium parvum* parasites. I constructed the DNA transformation vectors necessary to accomplish this breakthrough. This included the cloning of plasmids for utilizing the CRISPR/Cas9 system in *C. parvum*. Now, we can detect parasitic infection with great sensitivity and precision. In addition, we can now isolate mutants of the parasite as well as determine gene function within *C. parvum*. In the research presented here, I use cloning and molecular biology techniques to make constructs containing different genetic reporters and drug markers. This will allow us to further develop methods for studying the parasite's cellular biology. I will report on the use of the CRISPR/Cas9 method for modifying *Cryptosporidium parvum* and the effectiveness of these new constructs in the parasite.

Investigating Student Satisfaction and Social Ties in a Biology Research Network

Zoheb Sulaiman, CURO Research Assistant
Dr. Jennifer Jo Thompson, Crop and Soil Sciences, College of Agricultural & Environmental Sciences

This ongoing longitudinal study investigates an interdisciplinary biology research collaboration across several institutions to examine the impact of networked research participation on undergraduates. We have adopted a mixed-methods approach—conducting observation and interviews with undergraduate researchers, and collecting survey data about their network interactions and outcomes. We are conducting a multiyear network analysis to examine the relationship between students' position in the network and their outcomes. For example, preliminary analyses of these data indicate a correlation between research satisfaction and students' total number of ties the following year. In Spring 2015, to further investigate the significance of these preliminary network results, we conducted observations and interviews with undergraduates currently in the research network (N=7). We are analyzing qualitative data to investigate how students characterize research satisfaction, and how satisfaction relates to their formation of social ties to students and faculty. To further investigate the impact of networked research in particular, we are continuing to explore the relationship between student outcomes and ties to individuals outside their home institution. This research contributes to the development of hypotheses of how participation in collaborative science influences undergraduate researchers and their persistence in scientific careers.

Capabilities of Detecting Atmospheric Cosmic Ray Induced Muon Showers by the NOvA Far Detector

Mehreen Sultana, CURO Research Assistant
Dr. Craig Wiegert, Physics & Astronomy, Franklin College of Arts & Sciences

The research goals of Fermilab's NuMi Off-Axis Electron Neutrino Appearance (NOvA) are to observe muon neutrino to electron neutrino oscillations, determine the ordering of neutrino masses, and explain violation of matter/anti-matter symmetry. However, NOvA can also be used to study cosmic ray induced high energy extensive air showers. This presentation describes the initial characterization of NOvA as a cosmic ray detector. The detector has a combination of large size and high spatial resolution that will allow future studies of the hadronic cores of cosmic ray air showers. A large component of these showers are muons. Multiple parallel muon tracks seen in a single event with the NOvA detectors result from the same primary cosmic ray collision in the upper atmosphere. In order to use these muon bundles to probe the cosmic ray physics involved, we determine event characteristics such as the multiplicity of observed multiple muons, the effective area of the detector, the angular resolution of the detector, the scattering of individual muons, and the effectiveness of identifying and isolating these parallel muon shower events from background and noise.

The Evolution of Presidential Unilateral Powers and Congressional Reaction Mechanisms

Rachel Surminsky, CURO Research Assistant
Dr. Michael Lynch, Political Science, School of Public & International Affairs

Congress is actively seeking a means to thwart the expansion of presidential powers by barring unilateral action. President Obama's adjustments to the implementation timeline of the Affordable Care Act rollout in regards to employer mandate waivers catalyzed Speaker John Boehner to purpose a House Resolution authorizing a lawsuit against Obama. We explore the following question: can the federal courts impede presidential executive actions? Assessing factors derived through the analysis of precedent setting legal decisions, we outline the necessary components for a successful lawsuit against the president through the context of Speaker Boehner's pending lawsuit. Through our research, we have found that suing the president is not a productive means

of blocking executive expansion; federal courts will avoid ruling on inter-branch conflict unless all other efforts for resolution have been exhausted.

Assembly of a Dual-Selection Cassette for Gene-Specific Targeting by CRISPR/Cas9 to Recapitulate Dystroglycanopathies

Noreen Syed, CURO Research Assistant
Dr. Aaron Beedle, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Secondary dystroglycanopathies are a class of muscular dystrophies in which the glycosylation of α-dystroglycan is aberrant. Fukutin is necessary for functional glycosylation of α-dystroglycan; however, its specific activity is unknown. Mutations in the *FKTN* gene lead to a secondary dystroglycanopathy called Fukuyama Congenital Muscular Dystrophy. In order to further the research on secondary dystroglycanopathies, we seek to develop a *Fktn*-knockout skeletal muscle cell line for *in vitro* work to complement *in vivo* studies. To increase the flexibility and utility of the cell line, we designed a strategy using homolog-directed repair to modify the *Fktn* locus using CRISPR/Cas9 technology. Therefore, the purpose of our current work is to create a dual-selection cassette plasmid for genome editing. The completed targeting plasmid will be used to promote homologous recombination to disrupt the *Fktn* gene of C2C12 cells using CRISPR/Cas9 technology.

The Relationships between Dietary Protein Intakes and Cortical Bone in Prepubertal Black and White Boys and Girls

Jordan Sylvester, CURO Research Assistant
Dr. Richard Lewis, Foods & Nutrition, College of Family & Consumer Sciences

Understanding the nutritional determinants of bone mass and strength during growth is essential since the majority of bone mass is accumulated by late adolescence. While calcium and vitamin D have been the primary nutrients studied, little is known about protein intake and bone in children. The purpose of this study was to determine relationships between dietary protein and bone measures in black and white boys and girls in the early stages of puberty (9-13 years of age; N=323) who participated in a vitamin D supplementation trial. Dietary protein (g/day) was determined using three-day diet records (Food Processor v.9.7.3). Tibia and radius cortical bone was measured at 66% from the distal growth plate via peripheral quantitative computed tomography (Stratec XCT 2000). There were no significant correlations between dietary protein and skeletal measures when accounting for race, sex, maturation, and energy intake. Using a cutoff of 1.2 g/kg body weight (bw)/day, high (HP; >1.2g/kg/bw) and low (LP; < 1.2g/kg/bw) protein intake groups were created. Protein intake in the LP group was correlated with cortical bone mineral content and cortical bone area at the tibia, and with total bone area, periosteal circumference, endosteal circumference, and strength strain index at the tibia and radius ($r=0.413$-0.271, all $p<0.05$). Protein intake in the HP group correlated with radial cortical thickness ($r=0.155$, $p=0.037$) only. These results indicate that dietary protein intakes between 0.8-1.2 g/kg bw/day, but not higher intakes, may be advantageous for cortical bone strength; however, dose-response intervention studies are needed to confirm this.

The Effects of Interval versus Continuous Conditioning on Physiological and Kinematic Parameters of Equine Fitness

Lindsey Taylor, CURO Research Assistant
Dr. Kylee Duberstein, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Interval conditioning is a method of training which alternates between varying degrees of effort and is frequently used to train elite human athletes. The objective of this study was to determine kinematic and physiological changes of equines in response to either interval or continuous conditioning. Nine unconditioned horses were randomly divided into either a continuous conditioning (CC) or interval conditioning (IC) group. Both groups underwent a conditioning program of increasing workloads 3 times a week for 8 weeks. Horses were evaluated before and after conditioning to establish fitness levels for comparison. Both groups showed improved fitness following 8 weeks of training as measured by a decrease in peak blood lactate post SET. The IC group had a significant decrease in peak blood lactate levels post SET as compared to the CC group ($P<0.05$). Resting hematocrit levels increased for both groups following 8 weeks of conditioning; however, IC horses showed a significantly lower increase in hematocrit levels post SET as compared to CC horses ($P<0.05$). Kinematic analysis of horses at the trot showed shorter hind stance times post training for IC horses only ($P<0.05$) with no significant change in swing time for either the front or hind limbs. IC horses also had a longer period of suspension at the trot post training as compared to CC horses ($P<0.05$). Results from this study suggest that interval conditioning may be more effective as compared to continuous conditioning, indicated by improved physiological response to exercise as well as improved muscular propulsion.

Role of tRNA Nucleotidyl Transferase and 3' Exonucleases in the Biogenesis of Functional tRNAs in *Escherichia coli*

Fahim Thawer, CURO Research Assistant
Bijoy Mohanty, Research Scientist
Dr. Sidney Kushner, Genetics, Franklin College of Arts & Sciences

All mature tRNAs in both the eukaryotes and prokaryotes contain the CCA trinucleotide at their 3' termini, which is required for aminoacylation so that they can function in protein synthesis. In *E. coli*, all of the 86 tRNAs have the CCA determinant encoded in the genome. Accordingly, the gene (*cca*) encoding the tRNA nucleotidyl transferase, the enzyme responsible for adding CCA, is not essential in *E. coli*. It is thought that the enzyme works to repair tRNAs that have been processed incorrectly by the 3'→5' exoribonucleases such as RNase T (*rnt*) and RNase PH (*rph*) so that the CCA determinant is no longer intact. The data in this report show that *E. coli* lacking the CCA adding enzyme grows more slowly compared to a wild type control strain. The growth rate improved significantly in a *cca Δrnt* double mutant compared to a *cca rph-1* double mutant. Additionally, the growth rate of a *cca rph-1 Δrnt* triple mutant was not better than the *cca Δrnt* double mutant. These data suggested that RNase T may be responsible for overprocessing the tRNA 3' ends in the absence of the CCA adding enzyme. Northern analysis will be carried out to identify tRNAs with shorter 3' ends. In addition, the 3' and 5' ends of these tRNAs will be cloned and sequenced to confirm potential defects in their processing. This work was supported in part by a grant from the National Institutes of Health (GM081554) to S.R. K.

The Effects of Travel on Team-Based Performance

Parker Thomas, Rebekah Trotti, Christopher Morgan, Kyle Ledesma
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

We examined the relationship between distance traveled to work and job performance. As teams in the workforce are required to go on longer trips, the impact of travel is becoming more relevant. Current research indicates that travel induces stress,

but there has been little to no research on how travel influences job performance. Using team-based sports data, we examined the relationship between distance traveled and job performance. In addition, we evaluated how the total accumulated miles that teams travel impacts the relationship between travel and performance. Similarly, we looked at how a team's average job experience affects the relationship between travel and performance. Our study shows that the further that teams travel for their job, the worse they perform. However, our research indicates that employees are less sensitive to trips the more miles they have traveled. The findings of our study are important because there are tangible consequences of travel for one's job. Based on our findings, employers should seek alternative methods for long distance work. However, if travel is inevitable, organizations should be aware that with more trips the negative effects of traveling are weakened. Organizations can further reduce these adverse effects by selecting teams with more average job experience.

American Film's Portrayal of CEOs: An Increase in Complex and Confusing Personalities from the 1930s

Erin Todd
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

In Industrial/Organizational Psychology, great strides are being made to help companies derive an equation for the perfect CEO, but one variable is rarely discussed in the literature: the media. Although a CEO may possess all the qualities for success, without media support her company's success may be capricious. This study seeks to uncover media's portrayal of CEOs as a means to educate both CEOs and the public about the effects media has on leaders. In order to examine media's effects, popular films containing CEOs were analyzed. A standardized method was used to select each film: the top-grossing films of each decade (starting in the 1930s) that contained a CEO as a lead character were selected; then, each CEO was analyzed based on physical characteristics, personality traits, actions, decision-making skills, and various other qualities. Results suggest that CEOs in popular films have become more complex and enigmatic. Older films portrayed CEOs as strictly "good" or "bad," whereas current films characterize CEOs as morally ambiguous, a mixture of good and bad. Taking these results into account, it appears that CEOs should make themselves more available and open to the public regarding their companies and their personal lives. Implications of this study may be used to provide CEOs with feedback of how to establish a positive image with their companies and with the public.

Pretreatment of Cellulose Powder and Nanocellulose Gel Production

Lauren Tolbert, CURO Research Assistant
Dr. Suraj Sharma, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

Cellulose, the most abundant natural polymer, is found in lignocellulosic raw materials like wood or fibrous plants, having applications including biomedical films that relieve burn victims' pain and car parts made from cellulose-based composites. Although cellulose is naturally easily accessible, extracting its fibrils from wood, cotton, and other natural forms and separation from hemicellulose, lignin, and other components is difficult. Once extracted, size reduction through mechanical and/or chemical processing to a nano-level produces nanocellulose in microfibrillatd (MFC) or nanocrystalline (NCC) form. MFC is mechanically produced using high pressure and shear force from homogenizers or microfluidizers, resulting in lateral dimensions of 5-20 nanometers. Pretreating cellulose pulp

by carboxymethylation, refinement, or addition of specific salts allows mechanical processing of nanocellulose to produce uniform, engineered nanofibril structures. Processing includes knife milling wood pulp sheets in three cycles to form hydrophilic powder. Thermogravimetric analysis determines weight loss due to bound water under a temperature scan (room temperature to 500 deg. C), and scanning electron microscopy (SEM) reveals morphological changes and particle sizes. Pulp cellulose powder is combined with water and carboxymethylcellulose (CMC) to form slurry, which is heated, then cooled to specific temperatures before homogenization, which transforms pulp powder cellulose dispersion to nanocellulose gel. High-energy consumption and harsh chemicals during processing and pretreatment could have substantial economic and environmental impact. Therefore, this research seeks to discover processing and pretreatment methods that optimize gel ratios and characterize nano-gel properties (rheology, morphology and adhesion). Future studies involve structure-property relations and economical and efficient nanocellulose gel production.

Truth & Testimony

Margaret Touchton, CURO Research Assistant
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

Truth and Reconciliation Commissions (TRCs) are a form of transitional justice that are meant to be a method of healing for divided nations that have endured civil wars, internal strife, and human rights abuses. TRCs usually focus on creating a dialogue among victims, perpetrators, bystanders, and all those in between in the hopes of reconciling the nation's differences. In these dialogues, an emphasis is placed on obtaining a whole and complete truth from all involved in the conflict or abuses so that a better understanding of the issues can be formed and past grievances can be addressed. TRCs became internationally renowned after the post-apartheid government in South Africa created a TRC to examine human rights abuses that occurred during apartheid. The South African TRC has been widely celebrated as a success and has become a model for transitional justice. Despite the popularity of TRCs, there is still debate over their effectiveness. This paper will explore how well TRCs engaged a specific segment of the population, women. If a TRC's goal is to achieve reconciliation amongst the entire population by establishing a greater truth, then it is important to include the entire nation in the process, which means creating a space for women to tell their stories. Thus my research will attempt to answer the following question: Does the mandate of a TRC affect the subject of women's testimony? I plan to determine this by examining the mandate and testimonies from three TRCs (South Africa, Sierra Leone, and Liberia).

Fostering Peaceful Nuclear Infrastructure Sharing in Southeast Asia

Thomas Trahan, CURO Research Assistant
Dr. Sara Kutchesfahani, International Affairs, School of Public & International Affairs

Recent history has generally been favorable towards Southeast Asian economies, and expansion is expected to continue. As Southeast Asian GDPs rise, so too will regional energy consumption, and states will need to examine new strategies for meeting the rising demand. Peaceful nuclear energy is one such strategy, but only three Southeast Asian states include it in current official policy: Indonesia, Malaysia, and Vietnam. This study investigates how the ten member states of the Association of Southeast Asian Nations (ASEAN) could use their regional intergovernmental organization to promote development of peaceful nuclear energy

throughout the region by means of nuclear infrastructure sharing. It first examines case studies of peaceful regional nuclear cooperation through EURATOM in Europe and ABACC in South America. It will then provide an overview of the current status of nuclear energy in all ten ASEAN states, revealing wide disparities not only in nuclear energy policy but also states' respective histories with non-energy-related nuclear infrastructure. Finally, it will provide recommendations for how ASEAN can grow ASEANTOM, its organ of nuclear safeguards cooperation, in order to address these infrastructure disparities. These recommendations draw on enduring lessons found in the aforementioned case studies, mainly: 1) the effectiveness of a simple, narrowly-defined institutional mandate as demonstrated by EURATOM, and 2) the importance of groups of experts and sustained dialogue as demonstrated by ABACC. Although economic factors are also at play, implementing a collective, infrastructure-focused approach could contribute towards a more equitable nuclear energy future for Southeast Asia.

The Src Homology 3 Binding Domain is required for Lysophosphatidic Acid 3 Receptor-Mediated Cellular Viability in Melanoma Cells

Sterling Tran, CURO Research Assistant
Dr. Mandi Murph, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The LPA3 receptor is a G protein-coupled receptor that binds extracellular lysophosphatidic acid and mediates intracellular signaling cascades. Although we previously reported that receptor inhibition using siRNA or chemical inhibition obliterates the viability of melanoma cells, the mechanism was unclear. Herein we hypothesized that amino acids comprising the Src homology 3 (SH3) ligand binding motif, R/K-X-X-V/P-X-X-P or (216)-KTNVLSP-(222), within the third intracellular loop of LPA3 were critical in mediating this outcome. Therefore, we performed site-directed mutagenesis of the lysine, valine and proline, replacing these amino acids with alanines, and evaluated the changes in viability, proliferation, ERK1/2 signaling and calcium in response to lysophosphatidic acid. Our results show that enforced LPA3expression in SK-MEL-2 cells enhanced their resiliency by allowing these cells to oppose any loss of viability during growth in serum-free medium for up to 96 h, in contrast to parental SK-MEL-2 cells, which show a significant decline in viability. Similarly, site-directed alanine substitutions of valine and proline, V219A/P222A or 2aa-SK-MEL-2 cells, did not significantly alter viability, but adding a further alanine to replace the lysine, K216A/V219A/P222A or 3aa-SK-MEL-2 cells, obliterated this function. In addition, an inhibitor of the LPA3 receptor had no impact on the parental SK-MEL-2, 2aa-SK-MEL-2 or 3aa-SK-MEL-2 cells, but significantly reduced viability among wt-LPA3-SK-MEL-2 cells. Taken together, the data suggest that the SH3 ligand binding domain of LPA3 is required to mediate viability in melanoma cells.

Modeling a Baseline of Forest Energetics: A Method for the Evaluation of Sustainable Practices and Technologies

Mathieu Trunnell, CURO Research Assistant
Dr. John Schramski, College of Engineering

Sustainability metrics most often quantify biogeochemical flows such as nitrogen, carbon, and water. However, energy is also a finite resource. In order to consider acceptable energy consumption limits, appropriate ecosystem-based benchmarks must be derived. Can reasonable energy balance models be created from existing ecosystem data to appropriately develop a balanced thermodynamic model of a typical ecosystem? To test this question, I propose to develop an input-output energy model of

UGA's Driftmier Woods. This study uses data from peer-reviewed literature as well as those gathered by a team of student researchers from UGA's School of Ecology, the College of the Environment and Design, and the College of Engineering to propose a baseline energy input-output computational model describing natural energy flows into and out of these woods, including but not limited to the yearly insolation, biomass accumulation (i.e., spring and summer), biomass loss (i.e., fall and winter), and eventual heat degradation. Driftmier Woods is an old-growth forest with little to no new ongoing year-to-year increase in biomass storage and as such, we model the woods as a steady-state system where the energy inputs are equal to the outputs over a one-year cycle. If successful, this benchmark study of expected energy flows can be used to evaluate prescribed grazing methods currently being proposed to eradicate invasive species and ultimately determine if this is an energetically sustainable practice. This represents an entirely novel means to compare the sustainability of a manmade process or technology to the balanced ecosystem energetics of the biosphere.

The Effects of TNFR1 and TNFR2 on Low Birth Weight as Seen in Malaria-Infected Mice Models

Ha Truong, CURO Research Assistant
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Placental malaria is a condition where malaria-infected erythrocytes and mononuclear cells, namely macrophages, sequester within the intervillous spaces of a pregnant woman's placenta. In the malaria endemic regions of Sub-Saharan Africa, women experiencing placenta malaria often give birth to babies of low birth weight (LBW), a condition that greatly increases the mortality of these babies as compared to normal weight babies. Poor pregnancy outcomes such as LBW correlate with high levels of inflammation and Tissue Necrosis Factor (TNF), a pro-inflammatory cytokine produced mostly by macrophages. In the Moore laboratory, I am assisting in a project that will observe effects of Tissue Necrosis Factor (TNF) on pregnancies experiencing placental malaria and observe how TNFR1 and TNFR2, receptors 1 and 2 for TNF, are activated in this relationship. We will establish a mice model where pregnant C57BL/6J mice infected with *Plasmodium chabaudi* on day 0 of pregnancy. Up to the tenth day of gestation for the C57BL/6J mice, daily clinical measurements of weight, hematocrit, and parasitemia will be taken. On the tenth day, the mice will be sacrificed and their placentas preserved by fresh frozen in liquid nitrogen for RNA and protein isolation and in neutral buffered formalin for histology. By observing how TNFR1 and TNFR2 affect mice pregnancy, we can evaluate if TNF will be a valuable detector of malaria during pregnancy.

Health Care Policy Evaluation: A Case Study Examination of Workplace Wellness

Abby Tyre, CURO Research Assistant
Dr. Marisa Pagnattaro, Director, Legal Studies Certificate Program, Terry College of Business

The health care industry is one that touches the lives of all individuals as health is a universal principal, encompassing all humans. Currently the US spends approximately 17.9% of its GDP on health care expenditures, translating into $2.9 trillion dollars each year. Yet as health care expenditures are exponentially increasing, quality nor quantity of care is improving. This disparity creates a societal need for drastic health care policy reform. Reform came on March 23, 2010, when the Patient Protection and Affordable Care Act (ACA) was passed into law. The ACA is the policy reform designed to expand health care coverage and health insurance for

all Americans. One component of this legislation includes a $10 billion dollar budget for workplace wellness. The ACA defines wellness as "a program offered by an employer that is designed to promote health or prevent disease." The design of this present study is to produce a policy evaluation of the ACA's expansion of workplace wellness using a thorough review of cost-benefit analysis. Evaluation will occur by comparing and examining several case studies of workplace wellness: small businesses, large businesses, as well as at the University of Georgia. By examining several direct examples of workplace wellness, a conclusion can be made about both financial benefit as well as health benefits including improvement to community health, reduction of health disparities, and reduction of health costs. It is predicted that the ACA's workplace wellness impact will have positive long term health impacts but few financial benefits.

Response of Stream Biofilms across an Urbanization Gradient

Rachel Usher, CURO Research Assistant
James Wood, Graduate Student
Dr. Amy Rosemond & Dr. Seth Weger, Odum School of Ecology

This study examined 30 sites from 2010-14 investigating stream biofilms response to urbanization in Athens-Clarke County, GA. Urbanization initiates cascading environmental stressors impacting stream systems altering abiotic factors including hydrology and water chemistry. Biofilm, the active biological surface on stream bottoms comprised of algae, bacteria, fungi and organic matter, integrates the effects of multiple stressors. Thus, biofilm characteristics including its biomass and nutrient content can indicate the effects of watershed land use on stream condition. We determined watershed land cover and used physical/chemical data provided by Athens-Clarke County to examine biofilm response. We found a positive correlation between impervious surface cover (%ISC) and total nitrogen (TN), dissolved inorganic N, and temperature of stream water. An isotope of N, 15N is typically found in higher quantities in streams with wastewater inputs. Total phosphorus was positively correlated with δ15N, suggesting sewage or wastewater input but surprisingly, there was a negative relationship between biofilm δ15N and %ISC. The δ15N response to forest cover yielded expected values (3-4) in heavily forested areas (>60%), increased values (4 – 9) in moderately forested areas (30-60%), and decreased values (>2.5) in reduced forest area (>15%). These findings suggest that land uses can differentially affect inputs and cycling of N in biofilms, resulting in non-linear relationships between potential source indicators (e.g., δ15N) with single types of land cover change.

Using Model-Based Analysis to Develop a More Robust Measure of Flow-Mediated Dilation

Charles Van Brackle
Dr. K. Melissa Hallow, College of Engineering

Cardiovascular Disease (CVD) is the leading cause of death in the United States. The endothelium is responsible for controlling the dilation and contraction of arteries through control of smooth muscle tone in response to shear stresses. Endothelium dysfunction is an early indicator of atherosclerosis and can predict CVD before it becomes more seriously developed. Ultrasonic assessment of brachial artery flow is used to non-invasively study flow-mediated dilation (FMD) and the function of the endothelium. Currently, FMD is unable to explain variability in the dilatory response due to differences in shear response and other physiological factors in different subjects. We are developing a mathematical model to characterize the relationship between shear stress and the flow-mediated dilatory response, and also account for

varying physiological factors among subjects. This is done in two parts: by modeling the velocity profile observed via ultrasound, and then modeling the blood vessel's dilatory response to that velocity/shear profile. The diameter is modeled as a function of the shear stress on the interior of the brachial artery by an exposure-response relationship. The model seeks to establish parameters that describe the underlying physiological response to shear and that account for physiological variability between subjects. This will remove confounding effects and enable the FMD test to more accurately identify physiological markers that indicate the subject's risk for CVD, improving the clinical utility of this measurement.

Visual Brand Identity on Pinterest

Haley Vann, CURO Research Assistant
Dr. Jhih-Syuan Lin, Grady College of Journalism & Mass Communication

In response to the growing popularity of Pinterest among consumers, global brands have expanded their marketing efforts into the visual wonderland, aiming to build visual brand identity and create a deeper engagement with their consumers. Pinterest is considered an essential social media outlet because consumers on Pinterest are actively seeking and including brands in their possible selves and selecting brands that appear to advance their evolving taste regimes. Considering this, the current research project aims to explore global brands' visual brand identity presentations on Pinterest. As the literature suggests, brand identity is a unique set of associations that a brand aspires to create or maintain. It is the holistic look, feel and style of a brand. The essentials of a brand's visual brand identity include its logo, shapes, colors, typography, location, character and styles. These elements must be cohesive across all platforms to unify the brand and should correlate with the brand's identity so that it emphasizes the brand's core values and philosophies. In order to answer our overarching research question—does brand identity helps facilitate the development of consumer-brand relationships? — we first develop a comprehensive conceptual framework of visual brand identity based upon literature on visual representations in advertising. We then collect data from top 100 global brands' Pinterest official accounts and conduct a content analysis. Specifically, we systematically code samples into categories that deal with brand, board, pin and image level. It is our belief that this research project will provide important insights into visual brand identity development and image-based content strategies useful to advertisers and marketers.

Gender as a Moderator of Work-Family Conflict Coping Strategies

Juhi Varshney, CURO Research Assistant
Dr. Malissa Clark, Psychology, Franklin College of Arts & Sciences

Work-family conflict is pervasive among both men and women (e.g., Gutek et al., 1991). Accordingly, the use of coping strategies in alleviating this conflict has been well documented (e.g., Clark et al., 2014). Prior research shows that gender may affect an individual's work-family conflict (e.g., Gutek et al., 1991), but little research has examined how gender influences the type and the frequency of coping strategies that individuals use. The purpose of this study is to explore the role gender plays in coping with work-family conflict, by specifically examining gender differences in the use of coping strategies. Furthermore, it examines gender as a moderator in the relationship between coping strategies and work-family conflict, as well as whether gender influences the relative importance of these coping strategies. This study collected data from 301 individuals who worked at least 35 hours per week. Multiple regression results showed gender differences

in the use of several coping strategies, with women using certain coping strategies more than men. Specifically, gender moderated the relationship between the coping strategy of exercise and work-family conflict, and the relationship between exercise and burnout. These strategies appeared to be more beneficial for women compared to men. However, relative importance analyses indicated that the relative importance of the coping strategies in relation to work-family conflict did not vary by gender. This research helps advance our understanding of the relationship between gender and work-family conflict coping strategies and has the potential to help men and women better cope with work-family conflict.

Analysis of Heparan Sulfate Fragments by NMR Spectroscopy

Rachel Vecchione
Dr. James Prestegard, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Heparan sulfate (HS) is a glycosaminoglycan (GAG) composed of repeating dissacharide units of glucuronic acid (GlcA) or iduronic acid (IdoA) and N-acetylglucosamine. These sugar (or glycan) reisdues are attached through an α1-4 glycosidic linkage from GlcNAc to the uronic acid and a b1-4 linkage from the uronic acid to the next GlcNAc. Sulfation can occur at the 2 position on the uronic acid, the 4 position on the N-acetylglucosamine and the N position on the N-acetylglucosamine. Heparan sulfate is attached to proteoglycans like glypican in the extra cellular matrix of cells where it has an important role in cell to cell interactions. Understanding how heparan sulfate binds to its substrates may increase the ability of pharmaceutical science to capitalize on the regulatory function of heparan sulfate and manipulate it to control certain interactions that may have an effect on biological processes which cause disease. To begin my studies, heparan sulfate was isolated from 15N labeled glypican through digestion with Heparinase II. The oligosaccharides produced from the digestion were separated using size-exclusion chromatography. The fractions (from the size-exclusion column) were then checked for UV absorbance at wavelengths of 194nm, 203nm and 214nm. The fractions showing high absorbance were consolidated and characterized using NMR spectroscopy. 15N is an NMR active nucleus normally found at a very low natural abundance. An ability to isolate HS fragments enriched in this isotope facilitates future observation of HS interactions in biological systems.

The Mini-FLOTAC: An Analysis of a Novel Fecal Egg Counting Technique

Emily Vermillion, CURO Honors Scholar
Dr. Ray Kaplan, Infectious Diseases, College of Veterinary Medicine

Measuring the numbers of worm eggs per gram of feces is important for estimating levels of parasite infections and for assessing anthelmintic drug efficacy. There are several different methods for performing fecal egg counts (FEC), with each having certain advantages and disadvantages. The Mini-FLOTAC is a recently developed novel device used to perform FECs that is designed for both ease of use and higher sensitivity than the commonly used McMaster FEC technique. There are two primary goals of this study: (1) to assess the accuracy, precision, and sensitivity of the Mini-FLOTAC compared to the two other most commonly used FEC techniques, the modified McMaster and the modified Wisconsin; and (2) to assess the overall ease of use and efficiency of the device. To assess the precision and accuracy of the three methods, a simulated fecal egg count reduction test was performed using fecal samples from horses, cattle, and goats. Overall ease of use was assessed by evaluating the ability to see the eggs under the microscope with clarity, and measuring the

amount of time needed to perform the three different methods. Though Mini-FLOTAC is designed for ease of use, we found a decreased sample clarity with the mini-FLOTAC causing an increase in the time required to count the eggs. This was especially a problem when analyzing feces from goats. Experiments investigating the accuracy, precision, and sensitivity are still in progress.

The Influence of Appeal on Overconsumption

Kelsie Walker
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

Overconsumption is a form of low self-control; we aimed to discover what factors might predict this behavior. To analyze this question, we asked participants to eat a sample of four types of cookies (sugar, chocolate chip, mint chocolate, and pumpkins spice). They were told that while they needed to eat at least some of each cookie, they were welcome to eat as much as they would like. Each participant was given a plate with 24 cookies (6 of each type). We manipulated the appeal of the cookies by heightening the cookies' aroma and freshness. We did this by randomly splitting the participants into one of two conditions. In the baking condition, experimenters freshly prepared cookies using a portable oven in the same room as the participants completed all study tasks. In the non-baking condition participants tasted day-old cookies. Once the participants were brought to the study room, they completed a questionnaire while they ate the cookies. The questions asked the participants about their current mood, their feelings toward the cookies, how many cookies they felt they should eat, and demographics. A *t* test revealed that overconsumption was higher on the baking versus non-baking days. The results indicate that while appeal does not cause overconsumption, it does have a positive effect on enhancing overconsumption. Implications for reducing overconsumption will be discussed.

The Prevalence of Hemoparasites in Seabird Populations on Middleton Island, Alaska

Morgan Walker, CURO Research Assistant, CURO Graduation Distinction
Dr. Michael Yabsley, Warnell School of Forestry & Natural Resources

In recent years, the nesting seabirds of Middleton Island, Alaska have experienced severe population declines. Since blood parasites have previously been shown to negatively impact the survival and reproductive success of their avian hosts, hemoparasitism may be a factor contributing to these population declines. The purpose of this research was to determine the prevalence of hemosporidian parasites in the seabird community of Middleton Island, with an emphasis on the relative prevalence of parasites of the three genera *Plasmodium*, *Haemoproteus*, and *Leucocytozoon*. From June to August 2014, we collected 290 blood samples from adult Black-legged Kittiwakes, Pelagic Cormorants, Rhinoceros Auklets, Common Murres, and Tufted Puffins. Presence–absence and parasitemia values of hemoparasites were determined through microscopic evaluation of peripheral blood smears. Of the 70 Black-legged Kittiwake and 50 Pelagic Cormorant smears analyzed thus far, no hemoparasites have been identified. The absence of hematozoa in seabirds is unusual, but not unprecedented. There could be several explanations for this absence, including the displacement of potential dipteran vectors by ectoparasites, low hemoparasite prevalence in the area, or protective immunity of the hosts. Since blood smear analysis is presently ongoing, a pattern may still emerge that could provide more explanation into the apparent lack of hemoparasites in the Middleton Island seabird community.

Using Artificial Neural Networks to Predict Solar Radiation in Georgia

Emily Wall, CURO Research Assistant
Dr. Walter Potter, Computer Science, Franklin College of Arts & Sciences

The Georgia Power Advanced Solar Initiative set a target for Georgia Power to obtain 210 megawatts of contracted solar capacity within two years. We implemented an Artificial Neural Network (ANN) on behalf of Georgia Power to predict solar radiation at various locations across the state. We utilized weather data collected from the Georgia Automated Environmental Monitoring Network (AEMN) including temperature, humidity, wind speed, and past values of solar radiation. We then analyzed the prediction error produced from various combinations of input fields in order to produce the most accurate predictions and optimize the performance of our model. We found that input fields day, time, and previous values of solar radiation were the most significant in predicting solar radiation. We ultimately obtained a model with mean-squared error (MSE) of 0.004382. The resulting model will be used to make decisions regarding the optimal placement of solar collection facilities in order to reach the goal of 210 megawatts of contracted solar capacity.

High-Fat Diet Consumption and Behavioral Dysfunction: What Are the Roles of Maternal vs. Post-Weaning High-Fat Intakes?

Matthew Weber
Saritha Krishna, Graduate Student
Dr. Nick Filipov, Physiology & Pharmacology, College of Veterinary Medicine
Dr. Donald Harn, Infectious Diseases, College of Veterinary Medicine
Dr. Claire de La Serre, Foods & Nutrition, College of Family & Consumer Sciences

Obesity, caused in part by high-fat diet consumption, is a major public health concern associated with metabolic and neurological dysregulations. Obesity is growing rapidly amongst the youth. Since children may be affected by the maternal and/or their own diet, we conducted a study where female mice were fed low-fat (LFD) or high-fat (HFD) diets beginning six weeks prior to conception through weaning (postnatal day [PND] 21). To determine pre- vs. post-weaning dietary effects, pups were gender-separated and weaned onto a LFD or HFD. The offspring then went through a series of behavioral tests beginning on PND70. In a forced swim test we found that males with post-weaning HFD swam significantly more, suggesting increased anxiety; only female mice on HFD both pre and post-weaning exhibited a trend towards increased swimming. Additionally, novel object recognition test was used to assess recognition memory. Females that were on HFD pre or post-weaning, but not both, did not show novel object preference. The preference for the novel object in all dietary treatments was not affected in the male offspring, suggesting a gender-specific offspring susceptibility to HFD. In a marble burying test another gender-bias arose. Males on HFD post-weaning exhibited higher burying activity. In contrast, the pre-weaning HFD significantly increased the marble burying by female offspring. While still under analysis, some thought-provoking relationships are emerging from these data. When it comes to anxiety-like behavioral aberrations, maternal diet may be of greater importance to female offspring whereas the postnatal diet may be more important for males.

Molecular and Genetic Analysis of the Ab10 Meiotic Drive Haplotype in Maize and Teosinte

Amy Webster, CURO Graduation Distinction
Dr. Kelly Dawe, Genetics, Franklin College of Arts & Sciences

In *Zea mays*, abnormal chromosome 10 (Ab10) exhibits meiotic drive by segregating into 65-80% of progeny instead of the Mendelian 50%. Ab10 differs significantly from normal chromosome 10 (N10) primarily due to the presence of a distal tip of unknown origin and heterochromatic regions called knobs. Three haplotype variants of Ab10 have been found across subspecies of *Zea mays* called teosinte, the wild progenitor of domesticated maize. They are denoted types I, II, and III and vary in knob content, but all exhibit meiotic drive in maize. The three main goals of this study were to determine genes that could be important for causing meiotic drive, to analyze Ab10 variants in teosinte, and to show that Ab10 exhibits meiotic drive in teosinte. To do this, I first utilized gene conservation principles and expression level analyses to determine three genes that may be important for causing meiotic drive to occur. One of these, a kinesin, is of particular interest and studies of this gene are ongoing. To analyze Ab10 in teosinte subspecies, I first identified plants positive for Ab10 in four teosinte subspecies. I then followed up with one of these, *Zea mays parviglumis*, and used fluorescent *in situ* hybridization (FISH) to identify Ab10 type II in this plant. Then, since Ab10 has only been shown to exhibit meiotic drive in maize and not teosinte, I showed that meiotic drive occurs in *Zea mays parviglumis*.

Does Georgia's Voter Identification Law Disproportionately Affect African American Voter Turnout in Georgia?

Hannah Weiss
Dr. Anthony Madonna, Political Science, School of Public & International Affairs

There is presently a great deal of controversy surrounding voter identification laws throughout the United States. These laws require voters to present some form of identification at a polling place in order to vote. Opponents point to a disproportionate negative impact on voter turnout among minorities, and liken these laws to Jim Crow-era disenfranchisement tactics. Supporters cite examples of voter fraud to justify their necessity. Claims that minority voters are disproportionately affected by voter identification laws may have serious implications for the integrity of the political process in the United States. I expected my study, however, to find that Georgia's voter ID law has inconsequential disproportionate effects on minority voters. I examine the current state of voter identification laws throughout the nation and then turn specifically to Georgia and its voter ID law for a more comprehensive study. Georgia is an appropriate case to study due to its 'strict' voter ID law, the Secretary of State's compilation of turnout data based on race in Georgia, and Georgia's sizable minority population, which should make the results of the study generalizable to other states. Georgia's voter ID law was implemented in 2007, so the study examines white and African American voter turnout in the 2004, 2008, and 2012 presidential elections as well as the 2006 and 2010 midterm elections in order to examine the impact of the implementation of the voter ID law on African American voter turnout relative to white voter turnout in Georgia.

Antioxidant Potential of Anthocyanins in Micronized Tart Cherry Puree

Maddison Wenzel, CURO Research Assistant
Dr. Rakesh Singh, Food Science & Technology, College of Agricultural & Environmental Sciences

Antioxidants are defined as substances that prevent destructive chemical reactions involving the combination of oxygen and other materials in many processes foods. These substances help reduce free radicals, or by-products, that can lead to heart disease, diabetes and cancer. Fruits and vegetables are known to have a high content of antioxidant potential and when they are processed their

phytochemical and nutrient content is generally improved (Ou, 2012). Tart cherries are known to possess different chemical compounds that aid in increasing the overall biotic activities they perform. As far as concerns cherry anthocyanins, studies have demonstrated that they are able to reduce proliferation of human colon cancer cells in culture (Ferretti, 2010). Tart cherry products also possess *in vitro* anti-inflammatory activity and antioxidant capacity against diverse forms of oxidative and nitrosative stress (Ou, 2012). Based on theories such as this, the purpose of this study is to understand the different antioxidant potentials associated with tart cherry puree in relation to particle size. The overall experimental nature of this study was to evaluate the overall color, viscosity and total phenolic content. While comparatively testing the original sample in relation to the micronized sample to determine overall antioxidant potential changes. This information was recorded and analyzed to determine the following applicable results.

Identifying Leadership Qualities of Classroom Teachers for the Purpose of Guiding Pre-Service Teachers

Jane Whatley, CURO Research Assistant
Dr. Amy Heath, Language & Literacy Education, College of Education

In the education system, leadership roles were traditionally considered part of the administrative level, despite a disconnect between the policy and decision makers and the ones most effected – students. However, research has begun to change its focus on teacher leadership by examining how it pertains to those individuals communicating daily with learners – classroom teachers (Boyd-Dimock & McGree, 1995). Research has been used to collaboratively determine definitions and qualifications of a "teacher leader," but the findings do not communicate which specific leadership qualities those leaders possess. Therefore, the overall goal of this study was to identify which common *leadership qualities* are considered most important to teaching instruction in high school English Language Arts (ELA) classrooms. The research method consisted of a five-question electronic survey that asked current ELA certified educators about the leadership qualities they considered most valuable to teaching, the challenges that follow implementation of those qualities, and their professional experiences regarding teacher leadership. Collected data was analyzed by comparing individual selections of leadership qualities and challenges with years of teaching experience and the presence of any official or unofficial teacher leadership positions. A correlation between amount of teaching experience and preferred leadership qualities was expected, as well as a correlation between a presence of official or unofficial leadership positions and preferred leadership qualities. The data gathered from these surveys provided a better understanding of which leadership qualities allow teachers to be most successful in the school environment. Research findings will be presented to the UGA community to educate future educators about developing important leadership qualities in the classroom.

The Enigmatic Country: Analysis of Russian Expansionism in the Modern Age

Patrick Wheat, CURO Research Assistant, CURO Graduation Distinction
Dr. Sara Kutchesfahani, International Affairs, School of Public & International Affairs

Since the fall of the Soviet Union, the Russian Federation has held the international community in a state of almost constant confusion, with the Russian government's actions growing increasingly aggressive towards her neighbor nations over the past several years. A marked change that differentiates this growth from pervious Russian government actions towards their neighbors is an increased tendency to use

military force in engagements with their neighbor nations. To assist with international understanding of the indication factors which make a state more likely to be a target of Russian expansionism, analysis of past actions involving Russia and her neighbors were used to anticipate the key circumstances in which Russia is more or less likely to commit to military expansionism. After analysis of the case studies of Russia's individual relationship with the Republic of Georgia, the Republic of Poland and the Republic of Estonia, the primary indicators towards aggressive action by Russia are the existence of a Russian ethnic minority that claims to be oppressed and an active presence of Russia as an energy provider to that nation. The absence of one or both of these factors markedly reduces the likelihood of Russian expansionism in that country, giving a strong analysis towards the potential indicators of Russian aggression towards her neighbor states in the future.

The Relationship between CH, CO, and Dust in MBM 12

James White, CURO Research Assistant
Dr. Loris Magnani, Physics & Astronomy, Franklin College of Arts & Sciences

The high-latitude molecular cloud, MBM12, is a small, opaque, interstellar cloud below the Galactic plane, which harbors a small association of newly-formed stars. As one of the only high-latitude clouds that are currently forming stars, it is important to characterize its molecular gas and dust properties. We present for the first time a map of the 3.3 GHz emission line from the CH molecule. This molecular species is an excellent tracer of the low-density molecular gas in the cloud. We compare the CH emission to existing infrared maps of MBM 12, which trace the dust distribution. In this way, a comparison of the gas-to-dust ratio between MBM 12 and other small molecular clouds can be made. In addition, a comparison of the CH emission is made with the J=1-0 emission line of the CO molecule. We find that the correlation between CH and dust is excellent, while the correlation between CH and CO is not as robust. Our findings establish that MBM 12 has a lower gas-to-dust ratio than comparable, non-star forming interstellar clouds

An Examination of Two Different Instructional Approaches for Teaching Preservice Teachers Common Phoneme-Grapheme Relations

Jessy Whitenton, CURO Research Assistant
Dr. Kristin Sayeski, Communication Sciences & Special Education, College of Education

Matching phonemes (letter sounds) to graphemes (letters) is an important aspect of the alphabetic principle. Preservice teachers are typically not prepared in how to correctly produce letter sounds (Gormley & Ruhl, 2007). Lack of skill in the production of letter sounds makes it difficult for teachers to (a) identify student errors and (b) serve as a model for students when teaching beginning reading. The purpose of the study is to examine the effects of massed versus distributed practice on teacher candidates' (n = 49) learning of letter sounds. Specifically, the study will explore the concept of mastery learning posited by Benjamin Bloom (Bloom, 1971, 1976). Bloom's theory of learning was based upon the belief that all students can make learning gains when provided with the *necessary time* and *appropriate learning conditions*. Although the principle of mastery learning is not new and has been echoed in the recommendations of other instructional scholars (see Bransford, Brown, & Cocking, 2000; Rosenshine & Stephens, 1986), very few applications of this principle exist in teacher education. To establish appropriate learning conditions, the constant time delay in conjunction with electronic flashcards will be used for instruction. Specific research questions to be answered are: 1) Are there differences in learning outcomes associated with massed versus distributed practice for

teacher candidates learning concepts associated with the alphabetic principle and the correct pronunciation of phoneme-grapheme pairs in isolation? 2) Do conditions for learning, specifically, massed versus distributed practice, result in differences in maintenance of knowledge and skills? For the study, participants (n = 28) in the distributed condition will receive initial instruction (1.5 hours) plus weekly practice sessions (20 min in duration) over a period of 4 weeks for a total of 2.5 hours of instruction. Participants (n = 21) in the massed practice condition will receive a total of 2.5 hours in one session. Pretest, posttest, and maintenance data will be collected.

Quantifying Replicating and Latent CFPHV in Symptomatic and Asymptomatic Infected Turtles

Jordyn Whitfield, CURO Research Assistant
Annie Page-Karjian, Graduate Student
Dr. Nicole Gottdenker, Pathology, College of Veterinary Medicine

Fibropapillomatosis (FP) is a panzootic, neoplastic disease of marine turtles that is associated with an alphaherpesvirus called chelonid fibropapillomatosis-associated herpes virus (CFPHV). An open reading frame with sequence similarity to a latency-associated nuclear antigen (LANA) gene of Kaposi's sarcoma-associated herpesvirus was recently identified within the CFPHV genome. Here, we use necropsy findings and quantitative PCR (qPCR) data to identify and compare the presence, location, and quantities of CFPHV LANA (F-LANA) and DNA polymerase (*pol*) gene sequences in samples that were aseptically collected from 10 green turtle (*Chelonia mydas*) carcasses from Florida (5 with FP, 5 FP-free). Using genomic DNA extracted from 109 (current sample number) biological samples of various types including FP tumors, normal skin, heart, thymus, lungs, kidneys, spleen, liver, urinary bladder, blood, urine, and neurological tissues, including brain and spinal, optic, and peripheral nerves, quantities of each gene target will be evaluated via qPCR to determine whether certain tissue types are associated with relatively higher quantities of *pol* or F-LANA in symptomatic and asymptomatic green turtles. The DNA assay is ongoing; however, we expect to find a correlation between certain tissue types and stage of CFPHV infection (tumored versus infected turtles without tumors) as displayed by relative concentrations of *pol* versus F-LANA in each type. The results from this study are expected to provide valuable insight regarding the CFPHV life cycle including replication, viral loads and cell type infected, and potential sites of latency in turtles with and without FP tumors.

Influence of Maternal Diet on the Offspring Gut Microbiota

Brittany Whitlock, CURO Research Assistant
Dr. Claire de La Serre, Foods & Nutrition, College of Family & Consumer Sciences

An obesity epidemic currently plagues the U.S. and other western nations, threatening the health of millions across the globe. Research efforts over the last decade have pointed towards the gastrointestinal (GI) microflora having a potential role in the development and persistence of obesity and other metabolic disorders. The following study focuses on the inheritance of obesity from mother to child, and asks whether the inheritance of unhealthy GI microbiota could be the vehicle that increases offspring propensity towards metabolic disease. Female C57BL/6 mice were fed either high-fat (HF) or control low-fat (LF) diets for 6 weeks prior to mating and remained on their respective diets throughout pregnancy and lactation. Pups were weaned onto a control LF diet. Microbiota composition and gastrointestinal (GI) health were determined at different time points. This study focuses on the health of pups at post-natal date (PND) 21, who were weaning off of their mother's

milk. It was found that, at weaning, offspring of HF fed, obese dams displayed significant alterations in gut microbiota composition associated with impaired GI epithelial permeability. This microbial profile has previously been associated with obesity and could increase their propensity toward metabolic disorder later in life.

Reviving Our Roots: Reconnecting Teens to Agriculture

Elizabeth Wilkes, Foundation Fellow
Dr. Susannah Chapman, Anthropology, Franklin College of Arts & Sciences

The American farmer is growing older, the American agricultural system is unsustainable, and the American teenager is not interested in farming. The Green Revolution has led to increasingly industrialized and consolidated farms, leaving farmers and consumers starkly disconnected. A new generation of farmers is the key to building a sustainable food system in today's agricultural environment. While the latest Farm Bill promises to invest millions of dollars in beginning farmers, it fails to consider who and from where these new farmers are likely to come. High school students - the majority of whom live in urbanized areas - grow up with no cultural attachment to farming and are agriculturally illiterate. Following a literature review and discussions with community stakeholders, I propose that high schools at the rural-urban interface should implement farmer development programs to address the lack of new farmers. The rural-urban interface (RUI) presents a confluence of ideas, people, and spaces, which offers an opportunity to reimagine farming landscapes. Studies suggest that developing policy to support agriculture at the RUI is warranted, and the "metropolitan farmer" is a growing reality. Farmer development programs can restore intergenerational relationships, encourage transfer of knowledge, and foster more sustainable forms of agriculture, in addition to providing practical skills to teenagers who face an increasingly competitive job market. A model Young Urban Farmer development program in Athens, GA, demonstrates this potential. Further research, evaluation, and engagement should reveal additional insight and inform the creation of pilot programs and related policies in Athens and beyond.

Development of a Chimeric Chick Neural Tube Injury Model incorporating 3D, mESC-Derived Neural Aggregates

Elizabeth Wilkins, CURO Honors Scholar
Catherine Callaway, Foundation Fellow
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Due to low cost, availability, and *ex utero* development, the chicken embryo serves as the oldest vertebrate developmental model. During development, the primitive spinal cord, termed the neural tube, is patterned caudally by retinoid signaling, and ventrally by a gradient of Sonic Hedgehog (Shh), yielding five specific progenitor domains. The pMN domain gives rise to motor neurons (MN), which synapse on muscles. The other domains yield interneurons, which compose the premotor control circuit. This neural network is cumulatively responsible for controlling all muscle actuation.We generated three-dimensional aggregates of mouse embryonic stem cells (mESC) from a cell line expressing a green fluorescent protein behind a MN-specific promoter. The aggregates were patterned with retinoic acid and a Shh pathway agonist to mimic organotypic ventral neural tube development. The line also expresses channel rhodopsin-2, a light-gated cation channel, which triggers depolarization in neurons when exposed to blue light. We hypothesize that embryos will survive 72 hours post-injection, and that the aggregates, including optically active motor neurons, will integrate into the injured spinal cord. A portion of the neural tube of developing

chicks was removed *in ovo*, followed by microinjection of neural aggregates. After three days, embryos were inspected for survival and integration. Ultimately, we expect a light stimulus to MN will result in a visible motor response within the embryo. As seen in paralytic injuries, adult spinal tissue has limited regenerative properties, making cell replacement an attractive therapy. Here we provide the first steps towards making that a reality.

Physical Activity Effects on Social Physique Anxiety

John Williams, CURO Research Assistant
Dr. Ellen Evans, Kinesiology, College of Education

Social physique anxiety (SPA) is anxiousness and concern with the evaluation of an individual's own physique by others. Relationships have been seen between SPA and physical activity (PA). A negative correlation has been seen between SPA and CDC PA guideline fulfillments. This study measured pre and post SPA levels with the Social Physique Anxiety Scale 12 item questionnaire. Each participant engaged in a 6-week moderate aerobic or high intensity interval training exercise regiment. The primary aim of this study is to examine a possible reduction of SPA with exercise. This study's hypothesis is exercise will reduce SPA notably in a sample of overweight, college-aged females who were previously sedentary. This study will help educate individuals about how physical activity could positively impact their lives, specifically with regards to social physique anxiety.

Simultaneous Vibration Isolation and Energy Harvesting

Nolan Williamson, CURO Research Assistant
Dr. Benjamin Davis, College of Engineering

Vibration isolators are employed in a wide variety of everyday applications to minimize the force or motion transmitted to a device from a known source of vibration. Recently, researchers have studied vibration isolators that use buckled beams in place of traditional linear springs. A buckled beam exhibits nonlinear stiffness characteristics, a property which is valuable in vibration isolation as it allows for a wider range of isolation frequencies with less static displacement of the test mass. For this experiment, a prototype isolator was fabricated and tested to determine its performance characteristics. Then, piezoelectric patches were added to the buckled beams to allow useful electric power to be harvested from the otherwise wasted vibrational energy of the buckled beams. Performance with respect to vibration isolation and energy harvesting is investigated experimentally by measuring the power produced by the piezoelectric elements and the transmissibility between the applied vibration and the motion of the test mass. This device could be used in a number of applications, as it would allow for the protection of sensitive devices from harmful vibration, while also generating useful electric that can be used to power other equipment.

Characterization of the Inositol Hexakisphosphate Kinase (IP6K) of *Trypanosoma brucei*

Brian Windle
Ciro Cordeiro, Graduate Student
Dr. Roberto Docampo, Cellular Biology, Franklin College of Arts & Sciences

Trypanosoma brucei causes human African trypanosomiasis (HAT), one of the most neglected diseases in the world. The parasite alters its morphology between an insect and mammalian host and different functional stages. The adaptation to these diverse environments requires rapid changes and the involvement of signaling pathways. We are currently studying a signaling pathway that results in the synthesis of inositol pyrophosphates (InsPPs). InsPPs are present

in all eukaryotes studied and have a variety of functions. The first enzyme involved in their synthesis is the inositol hexakisphosphate kinase (IP6K) that converts inositol hexakisphosphate (IP_6) into diphosphoinositol pentakisphosphate (5PP-IP_5, or IP_7), which has a PP_i group at carbon 5. In this work the *T. brucei* IP_6K was cloned, sequenced, and expressed in *Escherichia coli*. For kinetic studies we measured ATP consumption using a Kinase-Glo Max luminescence kit. Furthermore, $TbIP_6K$ reaction products were identified by electrophoresis in 35% polyacrylamide gels. We determined that the optimal pH for protein function was between pH 6.5 and 7.0. We confirmed that $TbIP_6K$ transfers a phosphate from ATP to inositol hexakisphosphate (IP_6) to form IP_7 and ADP. $TbIP_6K$ also has a phosphatase activity, transferring a phosphate from IP_6 to ADP to form ATP and inositol IP_5. Characterizing this pathway not only will provide a better understanding of trypanosoma biology but of the biology of other eukaryotes.

Nutrient Relations of a Sexually Dimorphic Plant Species

Mavis Wolf, CURO Research Assistant
Dr. Shu-Mei Chang, Plant Biology, Franklin College of Arts & Sciences

Geranium maculatum is a perennial herbaceous understory plant that grows along the Eastern side of North America; ranging from Ontario, Canada to Alabama and west to Missouri. *G. maculatum* is a gynodioecious species with female plants coexisting with their hermaphroditic conspecific individuals in some populations. In these gynodioecious populations, the establishment of females in a population of hermaphrodites has been suggested to depend on the habitat and the phenotypic plasticity of sex allocation in the hermaphrodites. Though reports show that abiotic environmental conditions such as soil moisture and precipitation are critical for explaining the lability in hermaphrodite phenotype and success of female reproduction, the effect of environmental nutrient limitation on sex distribution of gynodioecious species remains unclear. In this experiment, we seek to experimentally determine the optimal nitrogen:phosphorus (N:P) ratio for *G. maculatum* by administering nutrient treatments of varying N:P ratios to individuals over a growing season of three months. We will measure vegetative growth rate, reproductive output, and tissue nutrient content during the growing season. Using these data, we will be able to generate the baseline information regarding plant's interaction with their local soil nutrient levels. By comparing such baseline data and those we obtained from natural populations, we aim to achieve the following goals: (1) to better understand how sex distribution of *G. maculatum* in the wild might be related to their abiotic environments in their natural habitat and (2) to identify how and whether levels of nitrogen and phosphorus are limiting to growth for this native plant.

Investigating Interest in Ingesting Insects

Audrey Wright, CURO Research Assistant, CURO Graduation Distinction
Dr. Marianne Shockley, Entomology, College of Agricultural & Environmental Sciences

With a human population projected to reach nearly 10 billion people by 2050, current food production will need to double in order to sustain our species. Because expansion of existing agricultural land is neither likely nor realistically feasible, current farming practices must be reevaluated. Increasing livestock production, though seemingly necessary to supply enough edible protein to the world's population, will also exponentially increase already-high greenhouse gas emissions and exacerbate climate change. A more sustainable solution exists. Since invertebrates make up a majority of the biomass on the Earth, insects—the largest subgroup of

invertebrates—provide the most encouraging and sustainable solution for providing protein to a growing population. While some cultures have been eating insects for ages, a popular taboo exists in the Westernized world that condemns this practice. This study examined the effects of education and exposure on the attitudes towards insects and willingness to consume them as food. We surveyed 50 college students before and after five weeks of entomology and entomophagy education and consistent contact with live insect specimens. Our study supports the notion that increased education and exposure not only increases positivity towards insects, but also the inclination to consume them as food.

The Severity of Cases Admitted into a Small Animal Hospital and the Phase of the Full Moon

Alyssa Wuellner
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

A correlation between the moon phases and human/animal behavior has long been a belief among people. Previous studies have suggested an increase in the number of cases seen or admitted into small animal hospitals during a full moon. However, other studies have shown no significant effect of the full moon. All previous studies have looked only at numbers of cases, not severity of cases. The purpose of this study was to determine if the severity of the cases (as determined by the cost and duration of treatment) admitted into a small animal hospital is correlated with the phase of the full moon. The hypothesis was that there is no correlation between the full moon phase and the severity of cases admitted into a small animal hospital. All data were obtained from the University of Georgia Veterinary Hospital's Medical Records. Cases were admitted to the hospital between 2009 and 2014. A full moon was defined as the date of the occurrence of the actual full moon plus and minus one day. Variables collected included cost of treatment and duration of stay in the hospital. A total of 82,455 cases were analyzed with approximately 9,935 being on dates classified as full moons. Of the cases analyzed so far, the cost of treatment is 17.9% higher on dates of the full moon versus dates of non-full moons, and the duration of hospitalization is 19.7% higher on dates of the full moon versus dates of non-full moons.

Prevalence of Pain in Dogs with Cancer

Alyssa Wuellner, Kayla Hargrove
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Cancer is painful in people, but the effect of cancer on pain in dogs is unknown. Knowing the prevalence of pain in dogs with cancer could help us to prevent and treat the pain. The purpose of this study was to determine the prevalence of pain in dogs diagnosed with cancer. The hypothesis was that dogs with cancer will have a substantial prevalence of clinically significant pain. Dogs that have been diagnosed with cancer that have no interfering pre-existing medical conditions presenting to the University of Georgia's Veterinary Teaching Hospital were considered for inclusion. After client consent was obtained, data on age, breed, type of cancer the patient has, length of time since diagnosis, and treatments the patient is receiving were recorded. Clients were presented with a survey asking about behavioral traits and the client's impression of their pet's pain level. Pain scoring was done by one of two researchers using a ranking system of either none, mild, moderate, severe, very severe, or worst possible. The average pain level reported on the cases was a level of "none", with no instances of the pain being reported as "severe", "very severe", or "worst possible." Dogs with cancer seem to have a lower prevalence of clinically significant pain than people.

Effects of Bisphenol A on Macrophages when Controlled with Genistein

Shibo Xu
Dr. Tai Guo, Anatomy & Radiology, College of Veterinary Medicine

Bisphenol A (BPA) is a convenient and affordable compound that is used to make clear plastics and epoxy resins, and is therefore used in a mass array of products. However, there have been numerous reports citing its adverse endocrine-disrupting effects on the human body, most relating to immune dysregulation. The objective of this study was to determine the effects of BPA on macrophages, which play a critical role in various diseases including diabetes and autism, by studying its interaction with the isoflavone genistein (GEN), a phytoestrogen found at high levels in soy products that possess many beneficial properties. It is hypothesized that GEN can reduce the detrimental effects of BPA on macrophages. In this study, PMA (phorbol 12-myristate 13-acetate; 10 nM) differentiated U937 macrophages, a widely used cell line for primary human macrophages, were exposed to different concentrations of BPA (0, 0.1, 1, and 10 μM) ± GEN (0,1, and 10 μM) and incubated over a period of 24 and 96 hours. Proliferation was then determined using Alamar blue dye. BPA at 1 and 10 μM significantly suppressed the proliferation of macrophages following 96 hour of exposure, which could be attenuated by GEN at 1 and 10 μM with more effects observed at 10 μM. The proliferation of macrophages was not significantly affected by BPA at 24 h, while it was increased by GEN at 10 μM. Taken together, the results indicate that GEN can attenuate the inhibitory effect of BPA on macrophage proliferation in a long-term cell culture.

Influence of Genetic Background on Anthocyanin-Mediated Antioxidant Mechanisms

Sarah Yoo, CURO Research Assistant
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

Glutathione (GSH) is an important cellular antioxidant that mitigates the harmful effects of oxidative stress in diseases such as diabetes. A recent 2014 study by Zhou, et al., identified novel candidate genes that regulate GSH, but the effects of diet on this process remain unclear. Anthocyanins, a class of pigments found in plant tissues, demonstrate many potential health benefits, including protection against oxidative stress. The anthocyanin cyanidin-3-0-beta-glucoside (C3G) stimulates synthesis of GSH, which ultimately reduces oxidative stress (Zhu et al., 2011). We predict that genetic background regulates GSH responses to C3G, and we also hypothesize that C3G-induced GSH synthesis is tissue-specific. To test our hypotheses, mice representing five genetically-diverse mouse strains (A/J, 129s1/SvlmJ, CAST/EiJ, C57BL/6J, and NOD/ShiLtJ) will be fed either a control or high-C3G (100 mg/kg C3G) diet. After six weeks, on their respective diets, mice will be euthanized and several tissues will be harvested, including liver, kidney, and heart; GSH will be quantified in these tissues. This study will serve as the foundation for future efforts to identify candidate genes that determine C3G-mediated antioxidant mechanisms.

The Effect of Anesthetic Variables on Patient Outcome

Courtni Young, CURO Honors Scholar
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Many patient variables may affect outcome during a medical procedure. Most of the variables examined in the past have been related to the patient's status before the procedure. Events which arise under anesthesia may have a predictive relationship with outcome. The purpose of this study was to compare the correlation between anesthetic

variables and outcome variables. The hypothesis was that the anesthetic variables would have a direct though not proportional correlation to the outcome variables. We defined anesthetic variables as the events that take place before and during anesthesia. Some variables collected included drugs administered, incidents of hypotension, body temperature nadir, and duration of anesthesia. The outcome variables included the time in hospital, the amount of time in the intensive care unit, and the overall financial cost of hospitalization. Data was collected through the records of current and previous patients admitted to the University of Georgia's Small Animal Teaching Hospital. Based on our results, among other things we have concluded that longer time under anesthesia tends to lead to greater chances of having either hypothermia or hyperthermia at some point during the operation, that breed has minimal influence over the amount of anesthesia needed, and that patients under anesthesia longer are more likely to need post operational oxygen after the operation.

Seeing Danger?: How Weapon Priming Changes Beliefs that the World is Threatening

Jacob Young
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

Previous research has investigated the effects of seeing weapons on aggressive behaviors but little research has investigated how weapons affect cognition. The purpose of this study was to determine if seeing handguns leads to an increase in how threatening people perceive the world to be. Participants in the study played a computer-based sorting game and were randomly assigned either to a game sorting pictures of handguns and tools or a game sorting pictures of sporting equipment and tools. The participants then reported how threatening they perceived the world to be. Additionally, they read several ambiguous social scenarios in which they rated how hostile a person's actions were and how hostile their response would be if they were in the scenario. Finally, participants completed a personality inventory and demographic information. Though we did not find that seeing handguns increased beliefs that the world is threatening overall, we did find an interaction between political beliefs and condition. Participants who were politically conservative viewed the world as less threatening when exposed to guns compared to when they were not exposed to guns. Participants who were politically liberal, however, viewed the world as being more threatening when they were exposed to guns than when they were not exposed to guns. The results suggest that liberals and conservatives may disagree about gun control in policy in part because they have different cognitive reactions to seeing guns.

Estuarine Flow Rates in Coastal Georgia

Kathryn Youngblood, CURO Research Assistant
Dr. Brock Woodson, College of Engineering

This research project involves identifying flow rates into and out of a small estuary on the Georgia Coast near the Skidaway Institute of Oceanography (SKIO) as part of a larger project to quantify nutrient fluxes and anthropogenic effects in the marshland. The student collaborated with her mentor to develop a sampling design and program the Acoustic Doppler current profiler (ADCP), and then traveled with her mentor to Skidaway to execute a field deployment of the instrument at the mouth of Grove's Creek with members of SKIO faculty. After retrieval of the instrument in two weeks, the student will work with her mentor and use MATLAB to analyze the data for currents and turbulence of the water. They will work with a larger group at SKIO and contribute their findings to nutrient and oxygen data from Coastal Georgia.

Abstracts

The Effects of Preferred Listening on Anxiety, Nausea, and Claustrophobia of Cancer Patients during Radiation Treatment

Pomi Yun, CURO Research Assistant
Dr. Roy Kennedy, Hugh Hodgson School of Music

Purpose: The purpose of this study was to investigate the effects of cancer patients listening to their preferred music on claustrophobia, anxiety, and nausea during radiation treatments. Patients with head and/or neck cancer may experience claustrophobia as a result of having to wear a mask during their radiation treatments. *Method:* This quasi-experimental study included an experimental group who were exposed to music and a control group who were not exposed to music. The two groups were followed from their first treatment to their last day of radiation therapy. Data was collected via paper and pencil questionnaires for the dependent variables: anxiety, claustrophobia, and nausea. Since the treatment room was very small, the patients' preferred music was played on an Ipod connected to speakers through the application, Pandora, by the radiation therapist during each patient's treatments. *Results:* The results indicate that more than half of patients who listened to music during their radiation treatments showed lower levels of anxiety and claustrophobia than the control group. The researchers recorded qualitative comments that the patients made before and after treatments, which provided additional information concerning their experience. *Conclusion:* The results of this study may be of use to music therapy professionals that work with cancer patients undergoing radiation. In addition, no music therapy studies were found that specifically investigate the effects of patient preferred listening on the claustrophobia of cancer patients.

Multiple Muscle Stimulation to Enhance Health

Zoe Yurchuck, CURO Research Assistant
Rebecca Baltenberger
Dr. Kevin McCully, Kinesiology, College of Education

Introduction: Cardiovascular disease is the leading cause of death for patients with spinal cord injury (SCI) and other neurological diseases such as multiple sclerosis which can be attributed to the lack of physical activity. Neuromuscular electrical stimulation (NMES) could provide a cost-effective method of reducing the health risks associated with SCI and MS as it has been shown to increase skeletal muscle mass and improve mitochondrial capacity in these populations. *Methods:* Eight healthy individuals aged 19-21 completed a single 30 minute session of NMES. Electrical stimulation was applied to eight lower extremity muscles at a constant intensity during the protocol. Additionally, two participants also completed a second session which applied electrical stimulation at incremental increases of intensity to the same muscle groups throughout the duration of the protocol. Oxygen consumption, metabolic equivalents, ventilation, respiratory exchange ratio, heart rate, RPE, and pain were obtained during the duration of both protocols. *Results:* Oxygen consumption (VO2) and ventilation increased an average of 33% ($P<0.001$) during the 30 minutes session of NMES. Heart rate increased an average of 13% ($P=0.006$) and was highly variable. RER was inconsistent among subjects ($P=0.43$). *Conclusion:* Although an increase in oxygen consumption was observed during each session, the magnitude of the metabolic response was not enough to provide physiological benefits that could increase health. Therefore, future studies could use a treatment consisting of progressive intensities or different electrode placement in order to achieve the desired benefits while maintaining an acceptable level of comfort.

Time to Extinction in Deteriorating Environments

Katherine Zarada, CURO Research Assistant, CURO Graduation Distinction
Dr. John Drake, Odum School of Ecology

Theoretical models have failed to examine the effects of environmental deterioration on the distribution and delay of extinction times for populations despite the fact that environmental deterioration is currently a major threat to population persistence. We used computer models and simulations in the program R to show that the effects of deterioration on population dynamics affect both the changes in distribution and the delay between deterministic and realized extinction. We created three models to represent a decrease in birth rate, an increase in death rate, and a change in both rates due to deterioration. Each model ran for 1000 simulations with starting parameters representing the life histories of two organisms and initial carrying capacities of either 500 or 2000. While the distribution changes between carrying capacities and organisms were not significant, the differences between the models indicate the possibility for a large variation in extinction predictions if the differing effects of deterioration on the birth and death rates are not taken into consideration. The discrepancy in distributional changes is enhanced through the delay in extinction time, which varied from 10 to 80 years depending on the model. These delay and distribution variations allow for inexactitudes to be present in time to extinction predictions. Knowledge of the effects of deterioration and the inclusion of delay can help prevent such inaccuracies in future predictions of time to extinction for populations.

Analysis of Cortex and Pith Size Contribution to Fruit Size in Different Apple Cultivars

Mark Zenoble, CURO Research Assistant
Dr. Anish Malladi, Horticulture, College of Agricultural & Environmental Sciences

Apple fruit consists of the economically important fleshy cortex and a generally inedible pith/core, which can constitute a significant volume of the fruit. The relationship between core and cortex size among different cultivars is unknown. This study's objective is to determine the variation in core to cortex size ratios across apple cultivars. This knowledge could be applied to develop cultivars with more edible flesh. Thirty cultivars were used in this study. Fruit weight, length and diameter were measured using approximately 16 fruit from each cultivar. Half of the fruit from each cultivar were sliced longitudinally and the rest vertically to obtain sections of the core and cortex areas. These sections were scanned using a high resolution flatbed scanner. ImageJ software was used to determine the core and cortex sizes across the cultivars. Although the exterior area of the fruit section could be readily measured from the images, inversing the image was required to better visualize the vascular tissues that form the core boundary. Precise measurement of the dimensions of each of the components within the fruit is currently being performed. It is expected that significant variation in the core to cortex size ratios will be observed across the 30 cultivars. This would suggest that the growth of the core and the cortex tissues of the fruit are independently regulated. Such information can be applied to increase the size of the cortex region of the fruit, resulting in more of the edible part of the fruit.

CURO

April 4, 2016

Dear Students, Faculty, and Guests,

Welcome to the 16th annual CURO Symposium, UGA's celebration of undergraduate research across the disciplines. Many individuals—administrators, faculty members, staff, graduate students, and, of course, undergraduate students—have collaborated to make the CURO Symposium the premier undergraduate academic event at UGA.

Each year, the Symposium has grown larger, and the 2016 Symposium is the largest to date with 408 undergraduate researchers communicating their substantial accomplishments to their peers, mentors, and the public at large.

From its inception, the CURO Symposium has showcased research and scholarship in all disciplines. The 2016 Symposium continues that commitment, featuring presenters pursuing 85 different majors from 14 schools and colleges who are conducting research with 248 faculty members from 69 departments. This two-day event displays UGA's broad and substantial support of research and the invaluable commitment of UGA's administration and faculty to providing exceptional learning opportunities for our undergraduates.

Thank you for your continued support of undergraduate research and CURO.

Sincerely,

Dr. David S. Williams, '79, '82
Associate Provost and Director

Dr. Martin P. Rogers, '01, '11
Associate Director

Oral Session IX **3:30-4:45 p.m.**
Athena Breakout Rooms A, B, C, D, G

CURO Research Mentoring Awards

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the CURO Research Mentoring Awards, formerly the EURM awards, in 2001.

These awards recognize outstanding faculty who consistently engage undergraduate researchers through CURO Programming (courses, the symposium, summer fellows, JURO, theses, et al.) and enhance the learning experience of undergraduate researchers at the University of Georgia. Award recipients have provided superior research opportunities and mentoring and have collaborated with undergraduate researchers on publications and presentations at professional conferences.

Before 2014, awards were designated as "Early Career" and "Master Level" and were granted to corresponding faculty ranks.

2016

Dr. Mable Fok, Assistant Professor, Division of Electrical and Electronics Engineering, College Of Engineering

Dr. Richard Lewis, R.D., FACSM, Department of Foods and Nutrition, UGA Foundation Professor in Family and Consumer Sciences

2015

Dr. Jeb Byers, Professor, Odum School of Ecology

Dr. Erik Hofmeister, DVM, DACVAA, DECVAA, MA (Anesthesia), Associate Professor of Anesthesiology, Chief of Small Animal Surgery and Anesthesia, College of Veterinary Medicine

2014

Dr. Carl Bergmann, Associate Vice President for Research-Facilities; Associate Director, Complex Carbohydrate Research Center; Executive Director, Animal Health Research Center; Senior Research Scientist

Dr. Andrew Owsiak, Department of International Affairs, School of Public & International Affairs

2013

Master Level Faculty Award

Dr. Jennifer McDowell, Department of Psychology, Franklin College of Arts & Sciences

Early Career Faculty Award

Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

2012

Master Level Faculty Award

Dr. Lawrence Shimkets, Department of Microbiology, Franklin College of Arts & Sciences

Early Career Faculty Award

Dr. Michael Yabsley, Warnell School of Forestry & Natural Resources

2011

CURO Symposium Best Paper Awards

Since 2001, CURO Symposium Best Paper Awards have recognized excellence in papers developed from work being presented at that year's Symposium.

Each recipient is recognized at the Symposium's Award and Keynote Session, and each award carries $100 in financial support, generously provided by the UGA Alumni Association. Winners from the 2016 CURO Symposium are listed below.

Arts, Humanities, and Media:

Katherine Opacity	Tolstoy's Second Epilogue: On Page and Screen

Life Sciences:

Michelle Sequeira	Susceptibility to Chronic Social Defeat Stress Increases Ethanol Consumption in Mice

Physical and Environmental Sciences:

Dessa Dun	Ecosystem Services and Restoration Efforts of Campus Forests: Tanyard Creek and Driftmier Woods

Public and International Affairs:

Emily Maloney	Reducing Teacher Turnover in Georgia Public Schools

Social Sciences:

Megan Murphy	White Matter Structure Differs Between Schizophrenia and Healthy Comparison Groups as a Function of Cognitive Control and Age

Business:

John-Jordan Nunnery	How the Market Responds to Changes in Firm Health Policy

Program: Monday, April 4, 2016

Oral Session I: 11:15 a.m.-12:05 p.m.
Athena Breakout Rooms A, B, C, D, G

Room A	**Urmi Patel**	The Role of Dual Oxidase 1 in Tracheal Immunological Functions
	Madison Miracle	Investigating miRNA-195-Mediated Regulation of Cell Cycle Gene CHEK1 in Respiratory Syncytial Virus (RSV) Replication
	Chip Chambers	The Role of Cas4-2 in the CRISPR Adaptation Stage of *Pyroccocus furiosus*
Room B	**Joshua Willis**	Comparison of Oconee and Ocmulgee River Basins for Water Management Improvement
	Grace Power	Approaches to Reducing the Cost of Algal Biomass Production
	Lucas Montouchet	The Spatial Interaction between Cordgrass and Oysters across an Estuarine Gradient
Room C	**Emily Ivey, Olivia Carlson, Colleen Keeler**	The Influence of Psychosocial Functioning on Tic Severity in Children with Tourette Syndrome
	Kodiak Sauer	Cognitive Control as Assessed by Multiple Eye Tracking Paradigms
	Megan Murphy	White Matter Structure Differs between Schizophrenia and Healthy Comparison Groups as a Function of Cognitive Control and Age
Room D	**Catherine Braun**	The Hijab as a Feminist Tool of Agency
	Molly Mastin	Cooling Fabric: The Future of Keeping Cool
	Melissa Cousins	Optimizing Plique-à-Jour Enameling
Room G	**Ali Anderson**	Hookworm Egg Production in a Virulent Hookworm-Fur Seal System
	Caitlin Harris	*In-Vitro* and *In-Vivo* Assessment of a Yeast By-Product on the Inhibition of *Histomonas meleagridis*
	Mary Mehegan	Longitudinal Assessment of a Porcine Traumatic Brain Injury Model Utilizing Immunohistochemistry

Program: Monday, April 4, 2016

Oral Session II: 12:20-1:10 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Meili Swanson**	Issue Framing and Beliefs about the Importance of Climate Change Policy
	Ashka Patel	The Implications of International Intellectual Property Law on Global Access to Medicines
	Samuel Dickinson	The Influence of Social Conversation Case Study: Iran Nuclear Deal
Room B	**Mallika Madhusudan**	Eradicating Food Insecurity in Metro Atlanta
	Laura Pontari	Standardized Public Education Funding Formulas: A Best-Practice Evaluation
	Emily Maloney	Reducing Teacher Turnover in Georgia Public Schools
Room C	**Nivita Sharma**	Variation of Nanoparticle Surface Lipophilicity for Blood Brain Barrier Penetration
	Kodiak Sauer, Jacob Beckham	The Relationship between Central Nervous System Xanthophyll Status and Brain Activation in Healthy Older Adults
	Evan Knox	Effects of Cognitive Reserve and MPOD Levels on Personality in Older Adults
Room D	**Manisha Banga**	The Narrative Retelling of Marginalized Ancient Greek Mythological Characters by Contemporary Female Authors
	Sydney Wilson	Copy-Cats: Aphra Behn's *The History of the Nun* and Its Adaptations
	Joy Peltier	Functions of the Discourse Marker *"Bon"* in Spoken French
Room G	**Nikita Vantsev**	The Role of Cas1, Cas2, Csn2, and Cas9 in the Type II CRISPR-Cas Adaptation
	Bryan Grommersch	Metallothermic Reductions and Conductive Coatings for Lithium-Ion Battery Anode Materials
	Melissa Jennings	Regulation of Base J Synthesis in Trypanosomes
Room H	**David Reagan**	A Bright and Budding Future for Sunflowers: Understanding the Predictive Properties of *Helianthus annuus* Seedlings for Improving Adult-Stage Crop Yield

	Hayley Schroeder	The Effects of Migration and Infection on Resting and Flight Metabolism in Monarchs
	Jessica Story	Detritus Preferences in a Mangrove-Saltmarsh Ecotone

Oral Session III: 1:25-2:15 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Rebekah Worick**	Soldiers of Fortune: The Incidence of Mercenary Usage in Civil Conflict
	Sarah Sammons	How the Recruitment of Female Fighters for Islam Has Changed Transnational Terrorist Organizations and What the Long-Term Implications of This Trend Will Be for Interstate Conflicts
	Kimberlee John-Williams	The Effect of the Colonial Past on Women's Representation in the Caribbean
Room B	**Emily Maloney**	Correspondence between Family Needs and Family Goals: Implications for Early Childhood Interventions for Low-Income Families
	Hailey Clark	Addressing Teenage Pregnancy in Athens-Clarke County, Georgia
	Jenny Alpaugh	Examining Diversity in High School Publication Staffs
Room C	**Caroline Shearer**	Parasite Infection and Host Behavioral Complexity
	Martinique Edwards	Abundance of *Vibrio* Bacteria Associated with White Pox Disease in Elkhorn Corals
	Isabel Ott	Investigating a Potentially Novel Cache Valley Virus Variant in a Clinical Case in Missouri
Room D	**Insiyaa Ahmed**	Trait Variation in Sunflower Cultivars Grown Under Nutrient Stress Conditions
	Thomas Gottilla	Evolutionary Analysis of Mating-Type Genes in *Stagonosporopsis* Species Causing Gummy Stem Blight of Cucurbits
	Sabrina Park	Genetic Analysis of *Exobasidium maculosum* Using Microsatellites
Room G	**Patric Campbell**	Geographic Distribution of Adult Body Mass in Muridae

	Elizabeth Wilkes, Julia Connell	Fracking Governance and Resistance in Western North Carolina
	Shannon Burns	Spatial and Temporal Iron Isotope Fractionation in Hawaiian Soils
Room H	**Garrison West, Markus Cleveland, Alan Bosworth, Alexandria Lushaj**	Forensically Influential Beetle Fauna in the Spring
	John Roquet	Predictable Variation in Temporal Transmission Potential: West Nile Virus as a Case Study
	Onyinyechi Ochiobi	Investigations of How *Lysinibacillus sphaericus* Bin Toxin Kills a Cell Line Derived from the Malarial Mosquito *Anopheles gambiae*

Oral Session IV: 2:30-3:20 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Joshua Reynolds**	Lutein and Zeaxanthin Are Unrelated to Performance on the Short Physical Performance Battery
	Morgan Gibbs	Methadone and Loperamide Interactions with the Multidrug Transporter P-Glycoprotein
	Caroline Langley	Examining the Antioxidant Properties of Hops
Room B	**Allison Fialkowski**	Best Practice for Informing Parents of their Newborn's Disability
	Vineet Raman	Eliminating Cultural and Linguistic Boundaries in Healthcare: Creating Standards and Funding for Medical Interpreters
	Sara Johnson	Parentification as a Predictor of Emotion Dysregulation in Young Adults
Room C	**Catriona Geddes**	Personality Judgment Accuracy: Personality and Social Context Influence the Way People See Each Other
	Benjamin Shepard	IO Variables in Gaming: When Work is Play
	Lauren Locklear, Ian Armstrong	Third Party Reactions to Mistreatment: A Meta-Analysis

Program: Monday, April 4, 2016

Room D	**Marrissa Blackwell**	The Effect of Form and Source on Bioavailability of Vitamin E Supplementation in Mature Horses
	Adrea Mueller	Expression Analysis of Immune Genes in the Liver and Ceca of Blackhead Infected Turkeys
	Kathryn Sellman	Use of Social Recognition Test and Open Field Test to Assess Piglet Cognition
Room G	**Chelsea Thorpe**	Has *Laïcité* Transformed into a Law of Islamophobia?
	Taylor Martin, Rachael Andrews	A Policy Proposal for the Reduction of Violence in Georgia's State Prisons
	Hanna Han	Examination of Supply-Side Incentives and Motivations That Perpetuate the Skill Mismatch of Cambodian University Graduates
Room H	**Shannon Hochschild**	Dressing with a Disability
	Grace Donnelly	Seeing the Future: Interactive Data Visualization and Behavioral Intentions
	John-Jordan Nunnery	How the Market Responds to Changes in Firm Health Policy

Awards and Keynote Session: 3:30-4:30 p.m.
Athena Room E

Welcome and Introductions	David S. Williams, Associate Provost and Director of Honors and CURO
Remarks	Jere W. Morehead, President
	Pamela Whitten, Senior Vice President for Academic Affairs and Provost
Introduction to Awards	Martin Rogers, Associate Director of CURO and Honors
CURO Research Mentoring Awards	David C. Lee, Vice President for Research
2016 Symposium Best Paper Awards	Rahul Shrivastav, Vice President for Instruction
	Meredith Johnson, Executive Director of Alumni Association
UGA Libraries' Research Awards	Caroline Barratt, UGA Libraries

Program: Monday, April 4, 2016

Introduction of Keynote Speaker	Ms. Nivita Sharma, Class of 2018, Biochemistry & Molecular Biology
Keynote Address	Dr. Alan Darvill, Director of the Complex Carbohydrate Research Center (CCRC) and Regents Professor of Biochemistry & Molecular Biology, "Lessons Learned Studying Carbohydrates"
Closing Comments	David S. Williams

Poster Session and Reception: 4:30-6:30 p.m.

Poster # 148	**Camille Bauer**	Development of Immunologic Reagents for the Ferret Animal Model
Poster # 149	**Preston Samowitz**	Evaluation of Novel Antiviral Drug NS95397 for

		Treatment of Swine Influenza Infections in Pig Cells
Poster # 150	**Nicole Gilreath**	Serum Levels of Circulating and Exosomal MicroRNA Regulate Transformed Cell Growth
Poster # 151	**Christian Cullen**	The Role of Flagellar Motility in *Pseudomonas aeruginosa*-induced NET Formation
Poster # 152	**Nirali Patel**	Investigating the Antiparasitic Activity of Cry5B Protein against Fourth-Stage Nematode Parasites
Poster # 153	**Sahl Hakim**	Examining a Potential Role for *Mycobacterium tuberculosis* CtpB in Copper Transport
Poster # 154	**Ashitha Rajeurs**	Examining *Mycobacterium tuberculosis* Genes for Roles in B12 Synthesis
Poster # 155	**Kerryn Roome**	Malaria in the Late Stages of Pregnancy and the Significance of Tissue Factor
Poster # 156	**Ann Gore**	Improving Efficacy of HIV Vaccines for Immune-Suppressed Recipient
Poster # 157	**Hammad Khalid**	O-Linked Glycosylation Patterns of Cervical Mucins in HIV Infection
Poster # 158	**Elyssa Cohen**	Polysialic Acid Expression in AICAR Treated Mouse Neuroblastoma Cells
Poster # 159	**Lauren Dennison**	Extracellular Vesicle Dependent Transfer of a Virulence Factor Confers Human Infectivity to *Trypanosoma brucei brucei*
Poster # 160	**Jason Kwak**	The Impact of Blood Circulation on Cancer Metastasis Patterns
Poster # 161	**Anjali Kumar**	Analysis of Pancreatic Cancer Biomarkers
Poster # 162	**Sarah Hatton**	Identifying the Monoclonal Antibody Epitope Peptide Expressed on Pancreatic Adenocarcinoma
Poster # 163	**Christopher Whitlock**	How Does Mutagenesis of N-Linked Glycosylation Sites of C6f1 Fragment affect MAb109 Binding?
Poster # 164	**Juhi Varshney**	DARC Expression in Triple-Negative Breast Cancer
Poster # 165	**Kathryn Vollum**	Regulation of DARC Isoforms among Ancestry Groups and Associations with Aggressive Breast Cancer Subtypes

Poster # 166	**Andrea Brown**	Distinct Transcript Isoforms of the Atypical Chemokine Receptor 1 (ACKR1)/Duffy Antigen Receptor for Chemokines (DARC) Gene are Expressed in Lymphoblasts and Altered Isoform Levels are Associated with Genetic Ancestry and the Duffy-Null Allele
Poster # 167	**Isha Dabke**	Pharmacological Inhibitors of Epigenetic Mechanisms Alter Liposome Uptake
Poster # 168	**Thao Le**	Effects of Mitochondrial-Targeted (MitoQ) Antioxidants on the Lipidome of a Transgenic Mouse Model of Alzheimer's Disease
Poster # 169	**Marshall Kastens**	Age Related Metabolism of Pyrethroids in Rat Brain Microsomes
Poster # 170	**Paige Lane**	Efficient Cloning By Temperature Upshift
Poster # 171	**Kikachukwu Okolo**	Structural Characterization of an LTTR in *Acinetobacter baumannii*
Poster # 172	**Vincent Way**	Large-Scale Plasmid DNA Purification for Gene Therapy of Hemophilia B in Dogs
Poster # 173	**Julian Selano**	Development of a Non-Radioactive High Throughput Assay to Detect Thyroid Hormone Uptake in Cryopreserved Hepatocytes in Suspension
Poster # 174	**Kyle Brown**	Examining the Effects of Astrocytes on Chlorpyrifos Metabolism
Poster # 175	**Kyle Mott**	Trace Level Determination of Trichloroethylene in Plasma by Headspace Solid-Phase Microextraction Gas Chromatography/Negative Chemical Ionization Mass Spectrometry
Poster # 176	**Oluwasegun Olorunyolemi**	Sensitive Liquid Chromatography/Mass Spectrometry Method for the Determination of the Lipophilic Anticancer Drug in Rat Plasma
Poster # 177	**Kirsten Allen**	The Effects of Grape and Muscadine Juice on Protein Glycation
Poster # 178	**Kaylyn Bell**	Engineering the Active Site of Histone Acetyltransferase 1
Poster # 179	**John Lee**	Fractionation and Analysis of Wild Type and Galacturonosyltransferase 14 (GAUT14) Knockdown

		Switchgrass Cell Walls to Determine the Structure Synthesized by GAUT14
Poster # 180	**Olivia Mendel**	Proteome and Glycome Profiling of Medaka Exposed to Chronic, Low Level Ionization Radiation
Poster # 181	**Jerin Varghese, Jason Moraczewski, Brittany Tummings**	Proteomic Profiling of a Model Species (Medaka Fish) to Study the Physiological Response to Chronic, Low Level Ionizing Radiation in the Environment
Poster # 182	**Kyle Bowler**	The Enzymatic Characterization of Three Nucleotide-Sugar Aminotransferases in Pathogenic *Bacillus*
Poster # 183	**Lauren Davis**	Regulatory Pathway of X-Polymer Formation in *Bacillus* Species
Poster # 184	**Michael Cheng**	Post Translational Modifications of CaaX-Box Proteins Are Dependent on Specific CaaX Motifs
Poster # 185	**Haeun Kim**	Investigating the Post Translational Modification of CaaX Proteins
Poster # 186	**Rohit Munagala**	Investigation and Structural Inhibition of Rce1 and Ste24 Activity in a Prokaryotic System
Poster # 187	**Justin Dumrongkulraksa**	Identification of CRISPR Adaptation Complexes and Associated Nucleic Acids in *Pyrococcus furiosus*
Poster # 188	**Jesse Hu**	Evaluation of Cas4 Function in CRISPR-Cas Adaptation
Poster # 189	**Jessica Dinsmore**	A Study of Transposon Movement in *C. bescii*
Poster # 190	**Cynthia Ponir**	Yield Improvement of *Pyrococcus furiosus* Soluble Hydrogenase I by Overexpression of Accessory Proteins
Poster # 191	**Monisha Narayanan**	Examining Intercellular Heme Transport via Freixenet Transgenic Zebrafish
Poster # 192	**Adam Aston**	Transcriptional Activity of MGA and Mutation in Zebrafish
Poster # 193	**Bryanna Thomas**	Biological Function of an AAK1-Like Protein Kinase in *Trypanosoma brucei*
Poster # 194	**Haley Vale**	Localization of Casein Kinase 1.2 in *Trypanosoma brucei*
Poster # 195	**James Kraus**	Identifying Genetic Suppressors of ZYG-11

Poster # 196	**Rachel Vaizer**	The Role of Intraflagellar Transport in Ciliary Gliding
Poster # 197	**Leanna Harbor**	*Agrobacterium tumefaciens* Mediated Transformation of *Mimulus nasutus* via the Floral Dip Method
Poster # 198	**David Cowan**	Heterologous Expression of Carbohydrate Utilization Genes from *Acidothermus cellulolyticus* in *Caldicellulosiruptor bescii*
Poster # 199	**Grace Johnson, Mary Abkemeier, Catherine Waldron, Daniel Blumenthal, Vivian Vu**	Knockdown of IFT Proteins Phenotypically Affects Primary Cilia
Poster # 200	**Thomas Layman**	Experimental Evolution and Sperm Precedence in *D. recens* and *D. subquinaria*
Poster # 201	**Dhairya Shukla**	Small Molecule Inhibition of CARM1 in Adipocytes to Control the Epigenome-Induced Risks of Obesity
Poster # 202	**Kitra Cates**	*In Vitro* DNA-Protein Interaction Analyses of *Zea mays* Transcription Factors
Poster # 203	**Madeline Steffensen**	Using Mutants to Understand Mechanisms of DNA Methylation in *Brachypodium distachyon*
Poster # 204	**Zehneel Jiwani**	Feeding Choice Characterization of *Euptoieta claudia* and Oviposition Choice Analyses of *Agraulis vanilla* in Relation to Cyanide Production of *Passiflora incarnata*
Poster # 205	**Atul Lodh**	Investigating the Role of Cyanogenic Glycosides in *Passiflora incarnata* (Maypop)
Poster # 206	**Michael Lopez**	Regulation of Intracellular Membrane Fusion by V-ATPase Subunits
Poster # 207	**Samuel Macfie**	Exploring Alternative Mechanisms of RidA-Independent 2AA Stress Relief
Poster # 208	**William Moxley**	Characterization of murI, racD and racR of *Acinetobacter baylyi*
Poster # 209	**Hirel Patel, Lucas Bougang, Rebecca Buchanan, John Buchanan**	Genetic and Metabolic Modeling the Methanogenic Archaeon *Methanococcus maripaludis*

Poster # 210	**Isabella Tondi Resta**	Determining Gene Products Interacting with RtcB of the rsr-rtcBA RNA Repair Operon via a Synthetic Lethal Screen
Poster # 211	**David Rink**	Synthesis and Surface Engineering of Fe5C2 Nanoparticles for Superior r2 Relaxivity in Liver-Specific MR Imaging
Poster # 212	**Sang Min Lee**	Investigations of Chromium Photocatalyzed Cycloadditions
Poster # 213	**Alexander Winkles**	Theoretical Investigation of the Combustion Chemistry of Acetaldehyde and Ethenol
Poster # 214	**Brett Askins**	Synthetic Iron Oxide Containing HDL Nanoparticles for Atherosclerosis
Poster # 215	**Noah Newman**	Alpha-Tocopheryl Succinate Encapsulated Nanoparticles for the Enhancement of Mitochondrial ATP Production

Program: Tuesday, April 5, 2016

Oral Session V: 9:30-10:45 a.m.
Athena Breakout Rooms A, B, C, D

Room A	**Kayla Alward**	Correlation between Teat End Scores and Presence of Mastitis in the UGA Dairy Herd
	Kendall Lee	The Effect of Supplemental Vitamin E Form on Blood Oxidative Stress Parameters Measured in Exercising Horses
	Joseph Elengickal	Deficiencies and Improvements to Mental Health Institutions in Georgia
	Kayla Hargrove	Assessment of Adult Pig Cognition Utilizing an Open Field and Object Recognition Test
Room B	**Andrew Jarnagin**	When Coca-Cola Grows Citrus on the Nile, Who Wins? Revisiting the Arab Boycott in Egypt
	Jazmine Griffin	Corporate Inversion: Companies Leaving the American Tax System
	Jennifer Hardister	Conference Calls and Tax Forecasting
	Melody Alam	Short Selling Pressure and the Information Disclosure of Corporate Innovation: Evidence from a Policy Experiment
Room C	**Camily Williams**	Love, Lust, and Loyalty: Female Sexuality in the Auchinleck Romances
	Leah Scott	"Brave Little Belgium": The British Home Front Response to Belgian Refugees, 1914-1918
	Aaron Conley	The Effect of Shield Laws on Journalists Acting as Investigators, Specifically at Public Universities
	Kinsey Brooke	The Mythical Realm of Faerie: Dragon-Lore Symbolism and the Literary Elements of Faerie
Room D	**Jackson Hopper**	Digitally Delicate Primes
	Lindsey Spreen	Acceleration of Human Transportation and Its Impacts on Energy Consumption
	George Barron	Quantum Fourier Transform in the Single-Excitation Subspace Method of Quantum Computation
	Joseph Skehan	Designing Chiral Metasurfaces and Understanding their

Optical Properties

Oral Session VI: 11:00 a.m.-12:15 p.m.
Athena Breakout Rooms A, B, C, D

Room A	**Johnathan Mayfield**	An Investigation into the Complex Viral Interactions between *Microplitis demolitor* Bracovirus and TnAV-2a, an Ascovirus
	Alyssa Wuellner	Severity of Cases Admitted into a Small Animal Hospital and the Phase of the Moon
	Kayla Hargrove	Effect of Preoperative Laboratory Testing on Anesthesia-Related Decision Making in Apparently Healthy Dogs
	Lauren Dempsey	A Systematic Review of Adverse Effects Resulting from Administration of Propofol in Domestic Dogs and Cats
Room B	**Xueying Li**	Conjugated Polymers
	Shreya Ganeshan	What Good is a Low-Carbon City if No One Can Afford to Live There?
	Megan Douglass	Caveolae in 3D Neuronal Cell Cultures
	Garrett Steck	An Environmental Engineering Challenge: Improving the Energy Balance of Global Food Production
Room C	**Casey Grippando**	Procedural Polarization: Examining Changes in the Roll Call Voting Record (1877-2012) and their Effects on Political Polarization
	Bryson Culver	Lesbian, Gay, and Bisexual Employment Protection: An LGB-Inclusive Argument for Title VII Sex Discrimination
	Robert Oldham	Coalitional Stability: Apportioning the Legislature at the U.S. Constitutional Convention
	Bert Thompson	The Doctrinal Development of Sea-Launched Nuclear Capabilities
Room D	**Brennan Ninesling**	Role of Human Intelectin-1 in the Innate Immune System
	Ashley Lall	Super-Resolution Microscopy vs. Epifluorescent Microscopy of Aurora Kinase C and SYCP3 Localization in Mouse Oocytes and Spermatocytes

	Tiffany Jenkinson	Expression of Inflammatory and Coagulation Factors in Syncytiotrophoblast BeWo Cells Exposed to *Plasmodium falciparum* Derived Hemozoin
	Andrew Webster	Regulation of Ovarian Cancer by RGS10 and BIN1

Oral Session VII: 12:30-1:45 p.m.
Athena Breakout Rooms A, B, C, D, G

Room A	**Caroline Harvey**	Need of the "Other": Paradox in Gordon Parks' *Airline Terminal* and *American Gothic*
	Christian Lisa	A Romance: A Creative Writing Project
	Katherine Opacity	Tolstoy's Second Epilogue: On Page and Screen
	Jessie Blaeser	Literature and Art: How One Creates the Other
Room B	**Benjamin Leigh**	Foreign Aid: Helping or Hurting Democracy?
	Zoe Condon	The Gendered Risorgimento: How Wealthy British Ladies Ended Up Campaigning for Italian Unification
	William Robinson	Offensive Realism in a World of Hegemons
	Andrew Jarnagin	Understanding the Rise of the Sadrist Movement in Iraq
Room C	**Shannon Griffiths, Brittany Talkin**	Women, Welfare, and Borrowing
	Madison Turner	Blackout, the New Binge: A Case Study on Underage Drinking Patterns at the University of Georgia
	Ana Duron-Fleck	Financial Education in Georgia Public Schools and its Impact on Students' Financial Behaviors
	Duncan Lord	An Analysis of Trends in Difficulties Faced by Beginning Music Educators, with Discussion and Implementation of Effective Classroom Solutions
Room D	**Syed Tahmid**	Administration of Varying Carbon and Nitrogen Sources into a Defined Growth Media for Polysaccharide Secretion in *Bacillus cereus*
	Elizabeth Wilkins, Catherine Callaway	Optogenetic Control of a Neuromuscular Junction Model on a Chip
	Emily Myers	The Role of Trehalose-6-Phosphate Synthase in the

		Development and Transmission of *Cryptosporidium parvum* Oocysts
	Nikhil Gangasani	Enzymatically Preparing Carbohydrates for Development of an Effective Treatment against a Bacterial Pathogen
Room G	**Sarah Cunningham**	The Genetic Network of Circadian Rhythms in *Neurospora crassa*
	Alyssa Wuellner, Kayla Hargrove	Prevalence of Pain in Dogs with Cancer
	Caroline Langley	A Retrospective Study Analyzing the Relationship between Blood Coagulation and Liver Shunts

Oral Session VIII: 2:00-3:15 p.m.
Athena Breakout Rooms A, B, C, D, G

Room A	**Theresa Young**	Poverty and Shame: Implications for Social Work
	Laura Courchesne	Psycho-Social Impact of Drone Strikes on Non-Combatant Populations: The Cognitive Mechanism Underlying Pro-Group Endorsement of Extremist Violence
	Rachel Schwartz	Nazi vs. "Soup Nazi": The Double-Talk of Holocaust Rhetoric
	Chandler Johnston	Silencing in Chicana Literature: How Chicana Women Writers Navigate Marginalization in the Borderlands
Room B	**Kip Lacy**	Xenophobic Ants: Social Form Discrimination in the Tropical Fire Ant
	Katherine Russell	Investigating the Influence of Geospatial Attributes on Spider Species Richness and Diversity
	Jack Owen	Exploring Uncertainty in Models of Mosquito Vector-Borne Disease
	Caroline Spohn	Population Dynamics and the Ecology of the Common Bottlenose Dolphin of the Central Georgia Coast
Room C	**James Tyson**	Testing for a Correlation between History of Shoulder Injury and Functional Movement Screen Score
	Katherine Miller	Results of Gender and Personality Interactions on

		Mobility in a Sample of Older Adults
	Fatima Kamal	The Effects of Two Different High-Fat Diets on Appetite
	Emma Auger	The Effects of Predictable Targets on Saccade Behavior
Room D	**Allie Harbert**	Microwave Synthesis of MOF-5
	Erin Smith	Ecosystem Decomposition Using Fluxes
	Wesley Brown	An Improved Synthesis of a Fundamental MOF Precursor
	Emma Meehan, Doyle Wallace	Implementation of picoSpin(TM) NMRs into Organic Chemistry Teaching Laboratories through Spectral Analysis of Fischer Esterification Products
Room G	**Ruth Schade**	The Effect of Maternal Diet on Gastrointestinal Health of Offspring
	Zack Flagel	Injury Risk of Major League Foul Balls
	Kharine Jean	Education Level May Differentially Buffer Cognitive Decline in Older Adults Based on Race

Oral Session IX: 3:30-4:45 p.m.
Athena Breakout Rooms A, B, C, D, G

Room A	**Laura Courchesne**	The Psychology of Nazism and Genocide: The Role of Religion and Symbolism
	Katherine Nichols	"I Just Wanted a Roof over My Head": Possible Housing Solutions for Asylum-Seekers in Germany
	Kelsey Lowrey	Motherhood, War and Ownership in Bertolt Brecht's "Mother Courage and Her Children" and "The Caucasian Chalk Circle"
	Iva Dimitrova	Oral Histories of the Vazov Machine Works
Room B	**Jordan Berne**	Short-Run Economic Mobility in the Wake of the Great Recession
	Meredith Paker	Psychiatric Drug Use and the Business Cycle
	Andrew Teal	Effects of Campaign Finance on Legislator Polarization
	Ian Van Giesen,	Green Power Solutions for Georgia

	Haidi Al-Shabrawey	
Room C	**Lawrence Towe**	Recycle or Landfill? Assessing the Efficacy of a Green-Themed Intervention
	Danei Ting	Financial Knowledge amongst College Freshmen
	Sarah Williams	New Challenges: ADHD Goes to College
	Rutvik Dmello	The Effects of Inclement Weather on Dining Hall Usage

Trait Variation in Sunflower Cultivars Grown Under Nutrient Stress Conditions
Insiyaa Ahmed
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

A growing global population has put a strain on the limited arable land and natural resources available to meet crop demand. Starting in the early 1900s, high yield has been achieved through the use of inorganic fertilizers. This high input, high output system has led to environmental and soil degradation while providing no long-term solutions to increase production. Breeding more stress tolerant plants could be key to maintaining high yield while saving resources, preventing further ecological damage, and allowing farmers to use less fertile land for agriculture. This greenhouse study looks at variation in stress resistant traits in 12 sunflower cultivars grown at different nutrient treatments. Variation is necessary for breeding because it allows us to select for traits in the cultivars that coincide with increased tolerance. For the experiment, plants were grown to either the seedling or adult stage and traits relating to growth, physiology, and phenology were measured. Analysis of seedling data shows that there is indeed a high variation in response to different nutrient levels among the 12 lines. There was also variation in beneficial stress tolerant traits within the cultivars; for example, certain lines took fewer days to get to the harvest stage but also had lower whole plant leaf area. Adult plant data is currently being analyzed, but it is expected that there will be similar levels of variation in traits.

Short Selling Pressure and the Information Disclosure of Corporate Innovation: Evidence from a Policy Experiment
Melody Alam, CURO Research Assistant
Prof. Jie He, Banking & Finance, Terry College of Business

This study seeks to analyze shifts in information disclosure about a company's innovations when it is subjected to increased short selling pressure. Short selling is a technique that traders use to profit when they expect a company's share price to decrease. It is regulated in many countries. In 2004 a Securities and Exchange Commission policy experiment tested the effects of relaxing these regulations on 1,000 companies listed on the Russell 3000 index. This move increased short selling pressure on the affected 1,000 companies, which in turn incentivized managers to convince traders that future stock price would not decrease. One result of this policy change was an increase in the company's innovation as measured by the number and quality of patents it produced. I will collect data from the Factiva database on media coverage of the 3,000 companies on the Russell 3000 index for years 2001-2010. Then I will filter to find the proportion of those articles related to a company's innovation. This includes key words like patents, research and development, and intellectual property. We hypothesize that the proportion of articles related to innovation will increase for the affected 1,000 companies after the SEC policy experiment. Information dissemination is the basis of efficient markets—buyers and sellers need to know what a company is doing for its stock price to be accurate. In order for potential short sellers to be convinced of a company's long-term price growth, managers should theoretically ensure increased media coverage of their innovations.

The Effects of Grape and Muscadine Juice on Protein Glycation
Kirsten Allen, CURO Research Assistant
Dr. Phillip Greenspan, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Protein glycation results in the production of advanced glycation end products that contribute to inflammation and have been

linked to diabetic complications and many other aging conditions like Alzheimer's disease. The experiment we conducted tested whether grape or muscadine juice inhibits protein glycation. The formation of glycated protein was performed in incubations containing 50 mg albumin/ml and 250 mM fructose in 200mM potassium phosphate buffer, pH 7.4. The formation of a glycation product, in the presence and absence of 2.5 μL/mL of grape (Welch's Red Grape) and muscadine (Paulk's Pride Muscadine) juices, was measured using a spectrofluorometer set at the wavelength pair, 370/440 nm. After three days of incubation at 37ºC, the samples containing only albumin and buffer averaged a fluorescence of 45 units, and this is considered background fluorescence. When fructose was added to the samples, fluorescence increased to a level of 180 units, an indication of the formation of a fluorescent glycation product. Both grape and muscadine juice inhibited fluorescence, with 2.5 uL juice/mL inhibiting glycation by 27% and 88%, respectively. Both juice samples did produce substantial diminishing of the fluorescence; however, muscadine juice was more effective in inhibiting protein glycation than grape juice. The presence of ellagic acid, a phenolic compound with antioxidant activity, in the muscadine juice is thought to be responsible for this difference.

Examining Diversity in High School Publication Staffs

Jenny Alpaugh, Ramsey Scholar, CURO Research Assistant
Prof. Joseph Dennis, Grady College of Journalism & Mass Communication

As the United States continues to deal with racial tensions, it is important that the media continues to increase diversity in order to properly cover these events from a variety of perspectives. However, diversity remains a problem in the media, with the American Society of News Editors reporting in their 2015 census that the percentage of minority journalists working in daily-newspaper newsrooms falls at 12.76 percent. When the demographics of a nation's journalists fail to represent the demographics of the nation, problems arise in obtaining fair and balanced coverage. This study aimed to discover if problems with minority representation were also present in high school publication staffs. Members of the Journalism Education Association were invited to participate in a 10-question survey which asked advisors to self-report both school and staff demographics. These demographics were then compared to determine if diversity in a school is represented in the school's publication staff with initial analysis suggesting that a school's diversity is not always represented within its publication staff. This lack of representation at the high school level illustrates a problem with diversity that exists in all levels of media.

Correlation between Teat End Scores and Presence of Mastitis in the UGA Dairy Herd

Kayla Alward
Dr. Stephen Nickerson, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Mastitis is an inflammation of the mammary gland caused by bacteria that affects 1 in every 3 cows and costs the producer an average of $180/cow/year. Penetration of bacteria into the teat canal causing mastitic infections may be enhanced by hyperkeratosis, a thickening of the teat canal keratin, which provides a breeding ground for bacteria. The goal of this research project was to determine if a correlation existed between elevated teat end scores (degree of hyperkeratosis) and presence of mastitis and elevated somatic cell counts (SCC). For this study, 30 purebred Holstein cows in early lactation were sampled. Their teat ends were scored on a scale of 1 to 4 according to level of severity, and teat canal

swabs as well as milk samples were collected aseptically from each quarter for microbiological examination. Additionally, milk samples were evaluated for SCC using a DeLaval Cell Counter. The association of teat end score, infection status, and SCC was analyzed using the CORR procedure of SAS. Preliminary analysis of data suggested a relationship between mammary quarter infection status and teat score. Uninfected quarters exhibited an average score of 2.00, whereas the overall average score for infected quarters was 2.42. Among infected quarters, teat scores were CNS – 1.9, streptococcus – 2.0, prototheca – 2.0, *S. aureus* – 2.6, mold 3.0, and *E. coli* – 3.0. Results suggest that teat end hyperkeratosis is associated with the presence of mastitis, and that management practices should be in place to prevent this condition and to promote healthy teat ends.

Hookworm Egg Production in a Virulent Hookworm-Fur Seal System

Ali Anderson, CURO Honors Scholar
Dr. Nicole Gottdenker, Pathology, College of Veterinary Medicine

The South American Fur Seal (SAFS, *Arctocephalus australis*) is a marine mammal that inhabits the southern coasts of South America. While this species is one of the most widely distributed otariids in the world, the populations in the Pacific Ocean have experienced an alarming decline (57%) over the last 20 years. Although the cause of this decline is unknown, hookworm disease plays a significant role in the population dynamics of SAFS. Via necropsies conducted at Guafo Island, or Chilean Patagonia, hookworms were collected from SAFS pups with the aim of studying this host-parasite system, in which the parasite, the hookworm, causes significant damage to the host (high virulence). Since the virulence of this parasite is related to the extraction of host resources (blood), we hypothesize that high virulence correlates with a greater chance of transmission for the parasite. Additionally, we hypothesize that these populations will select for individuals with higher virulence over concurrent generations. In order to determine the effective transmission of this system, we measured the egg production of hookworm females collected from fur seal pups found dead due to trauma or hookworm disease. While results are pending, it is expected that there will be larger numbers of eggs in hookworm females collected from pups that died due to hookworm disease compared to hookworms collected from pups that died due to causes unrelated to hookworm infection (trauma).

Lung Abnormality Detection from Laser Projection Modeling

Sommer Anjum, CURO Research Assistant
Dr. Ramana Pidaparti, College of Engineering

Many respiratory diseases like asthma, chronic obstructive pulmonary disease (COPD), and pneumonia require the estimation of lung parameters that are very crucial in analyzing the health condition of a patient. Most of the available devices in the market perform these measurements invasively, and the non-invasive kinds like laser-based 3D monitoring of the chest wall are subject to issues involving maintenance, portability, and resolution. In addition, these instruments are not capable of performing localized measurements. We are in the process of developing a laser-based portable device capable of measuring respiration dynamics and heart rate non-invasively. The device primarily projects a laser grid onto an area of interest, and the displacement of the grid with time is monitored with an integrated CCD camera. These displacements can be measured precisely to a micrometer level and hence very minute changes in functional residual capacity of lungs can be monitored. Experiments were carried out to see how the respiratory rate can be predicted from well-defined surfaces

mimicking the patient chest. These results are presented in the poster.

Synthetic Iron Oxide Containing HDL Nanoparticles for Atherosclerosis

Brett Askins
Prof. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Atherosclerosis is one of the world's most aggressive diseases, claiming over 17.5 million lives per year. This disease is often caused by high amounts of lipoproteins circulating in the blood stream, which leads to plaque formation. Ultimately these plaques can undergo thrombosis and cause heart damage. A major contributor to these vulnerable plaques is macrophage apoptosis. Development of subcellular vehicles that carry contrast and therapeutic agents to the mitochondria within these apoptotic macrophages is attractive for the treatment of atherosclerosis. Previously, our lab reported construction of a biodegradable, synthetic HDL nanoparticle (NP) system that is capable of detecting vulnerable plaques by mitochondrial membrane potential collapse, which occurs during apoptosis. This platform contains a core of poly(lactic-co-glycolic acid) and cholesteryl oleate, with similar hydrophobicity as found in natural HDL. Surrounding this core is a phospholipid layer comprised of 1,2-distearoyl-sn-glycero-3-phosphoethanolamine, along with stearyl-triphenylphosphonium (TPP) cations for detection of mitochondrial membrane potential collapse. On the surface of this lipid layer is an apoA-I mimetic 4F peptide capable of binding cholesterol and participating in reverse cholesterol transport (RCT). A Magnetic Resonance Imaging (MRI) iron oxide-based probe, mito-magneto, was encapsulated within the HDL NPs for potential use in therapeutic monitoring of atherosclerosis by MRI. This platform displays excellent composition, stability, and physiochemical properties required for encapsulation inside the core of the HDL-NPs. Characterization of the potential therapeutic and imaging abilities of these IONP-based HDL-NPs in atherosclerosis can be completed upon conduction of studies to further understand bioimaging, biocompatibility, toxicity, cholesterol efflux properties, and immunogenicity.

Transcriptional Activity of MGA and Mutation in Zebrafish

Adam Aston
Dr. Scott Dougan, Cellular Biology, Franklin College of Arts & Sciences

This study focuses on the normal function of MAX Gene Associated (MGA) transcription factor during zebrafish development as well as its involvement in tumorigenesis. The MGA gene is known to regulate the cell cycle and differentiation not only in zebrafish but also in mice and humans. In order to study the transcriptional activity of MGA in zebrafish, the CRISPR/Cas9 system is utilized to generate a targeted mutation in the T-Box DNA binding site. CRISPR/Cas9 is a genome editing method that utilizes the endonuclease activity of the Cas9 protein guided by the gRNA to cut at the target sequence of interest. Co-injection of the Cas9 mRNA and the T-Box gRNA in embryos can yield mutant phenotypes: a wide array of defects in the heart, tail, and eye development. The embryos are examined at both 24 hours and 48 hours post-fertilization; zebrafish exhibiting mutant phenotypes are documented and photographed. The gRNA injected F0 generation is raised to adulthood. The potential mutants are identified by outcrossing the F0 generation to wild-type zebrafish. DNA from the F1 larvae is extracted, PCR amplified, and T7E1 digested. Once the potential mutants are identified, their progeny are raised for further screening. Homozygous mutant MGA zebrafish are recovered by in-crossing two heterozygous F1. Crossing two homozygous

recessive F2 zebrafish will yield a maternal-zygotic mutant F3 generation. By analyzing the gene expression pattern and morphological defects of mutant fish, the results should allow for a better understanding of MGA regulation and involvement in embryonic development and human cancer.

The Effects of Predictable Targets on Saccade Behavior

Emma Auger
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

The ability to see patterns and alter behavior based on those patterns allows individuals to respond efficiently in predictable environments. Saccades, also known as rapid eye movements, are used when studying the influence of cognitive processes such as detection of timing patterns on sensory-motor function. This study investigated subjects' ability to adapt behavior to a predictable, patterned sequence of events by comparing saccade latency on a visually-guided pro-saccade task with random target locations to a predictive saccade task with alternating target locations. In the predictive task, subjects (n=40) performed blocks of trials with different rates of target alternation: 0.1, 0.2, 0.4, or 0.8 Hz. It was hypothesized that the faster the speed of the predictable targets the lower the latency would be, as subjects learned the timing pattern and generated anticipatory saccades. The preliminary analysis shows that at 0.1 Hz latency does not differ significantly compared to the visually-guided saccades. As the target movements get faster, however, the latency in the predictive task decreases. At 0.4 and 0.8 Hz subjects have faster latencies as the block progresses, ultimately having negative latencies as they learn to predict the target motion before it occurs. In conclusion, faster alternations in the predictive task allow subjects to construct internal representations of target timing patterns and to react more quickly to the change in target location than in a visually-guided pro-saccade task. This information supports the notion that cognition, in this case prediction of patterns, influences motor function and causes adaptive behavior.

Practice Makes Perfect: A Capuchin Monkey Becomes Skillful at Nut Cracking with an Unfamiliar Stone

Rhianna Baldree, Emily Unholz, Margaret Bergmann
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Skill is defined as fluid and effective performance of a specific action, or set of actions, under varying circumstances. Wild bearded capuchin monkeys typically crack tough palm nuts by placing them on a log or stone anvil, and striking them with stone hammers that weigh a considerable portion of a monkey's body mass. To evaluate nut-cracking skill, we videotaped an adult male using an unfamiliar stone hammer of an average weight and size. We documented the monkey's behavior with the stone during nut cracking in slow-motion playback. We coded three exploratory actions with the stone (preparatory lifts, spins, and flips), the position of the monkey's hands on the stone each time it moved the stone, the angle of the strike, and outcome (stone dropped, nut cracked). We determined the frequency of actions and outcomes for the first 100 strikes of this monkey and reported that the monkey cracked 31 nuts in 100 strikes and produced between exploratory actions. Proportions of the three exploratory actions were also recorded, with .73 in spins per strike, .36 in flips per strike, and .38 in preparatory lifts per strike. The monkey rarely performed unskillful actions. As more strikes occurred, the number of exploratory actions decreased. We interpret the decrease in these actions across practice as an indication that the monkey became more familiar with the stone and therefore more skilled at using it,

increasing the efficiency. We also determined that exploratory actions may help with positioning the stone for an effective strike.

Quantifying Muscle Function in a Previously Fatigued Muscle

Rebecca Baltenberger
Dr. Kevin McCully, Kinesiology, College of Education

A clinically relevant muscle endurance test using electrical twitch stimulation and accelerometry has been developed. Our aim was to characterize the endurance index (EI) of an endurance test in a previously fatigued muscle. We hypothesized that a supermaximal electrical current for muscle twitch accelerometry could be identified, and that maximal acceleration and the endurance of the muscle after a 5-minute test would be altered in a previously fatigued muscle. *Methods:* We tested males and females. Acceleration was measured using an accelerometer placed over the trapezius muscle. Supermaximal current was measured using electrical stimulation on the trapezius at 4Hz for 1-second intervals at progressively increasing current. Fatigue was produced with 5-minutes of 6Hz stimulation. EI was calculated as the difference between the start and the end values. Fatigue was induced using shoulder shrugs with weights to exhaustion. The EI was measured both after exercise and during a rested state and compared. *Results:* Acceleration leveled off with tolerable current levels. After shrugs, the initial acceleration at the start of the test was only 21% of the non-fatigued acceleration ($p < 0.05$). The EI was 39% +/- 17% in the rested and 190% +/- 154% in fatigued muscle ($p = 0.033$). *Conclusions:* We produced a supermaximal stimulus that may allow us to identify previously fatigued muscle. The decline in initial acceleration observed following exercise influenced the EI, which could potentially confound tests of clinical populations. Future studies need to address the impact of fatigue if we are to use the EI on clinical populations.

The Narrative Retelling of Marginalized Ancient Greek Mythological Characters by Contemporary Female Authors

Manisha Banga
Dr. Benjamin Wolkow, Classics, Franklin College of Arts & Sciences

This research examines marginalized characters from ancient Greek mythology in the context of work by contemporary female authors. Specifically, it examines the phenomenon in which contemporary female authors retell the stories of ancient Greek characters who were sidelined in their myths—usually without agency and often without personality or complexity. When female authors reimagine these characters, they provide new character depth which the ancient mythology does not present. The texts examined will include Anne Carson's *Autobiography of Red*, Sarah Ruhl's *Eurydice*, and Cherríe Moraga's *The Hungry Woman: A Mexican Medea*. These texts reinvent the ancient characters of Geryon, Eurydice, and Medea by delving into their characters on a deeper narrative level by virtue of a defined three-part pattern in which modern authors villainize the ancient heroes, humanize marginalized characters, and finally reveal a corruption of the marginalized character by the hero. This research will employ classical, literary, and feminist analyses both on the ancient mythology and on contemporary work in order to understand the connection between the works in context of their relation to both time period and gender. The researcher argues that female authors retell stories of marginalized characters due to a sympathy derived from the general marginalization of female characters in contemporary art, literature, and culture.

Abstracts

Comparing Meiotic Spindle Structure and Chromosome Attachment in Control and Pericentrin-Depleted Mouse Oocytes

Wendi Bao
Dr. Maria Viveiros, Physiology & Pharmacology, College of Veterinary Medicine

Errors in meiotic division in oocytes can lead to aneuploidy, a major cause of genetic disorders such as Down syndrome and pregnancy loss in women. While accurate chromosome segregation depends on stable spindle formation and correct chromosome-microtubule interactions, the regulation of these critical processes is not well defined. In previous studies, we identified an important role for pericentrin (Pcnt) in meiotic spindle stability and developed a unique transgenic mouse model in which *Pcnt* is knocked down exclusively in oocytes to test its function *in vivo*. Pericentrin is a key scaffolding protein that associates with microtubule organizing centers (MTOCs). The objective of this experiment was to compare the spindle structure and chromosome configurations between control and Pcnt-depleted ovulated (Metaphase II-stage) oocytes collected from control and transgenic (Tg) females. The oocytes were simultaneously immunostained with anti-pericentrin and anti-acetylated a-tubulin antibodies, then counterstained with DAPI to assess Pcnt expression as well as the spindle microtubules and chromosomes, respectively. Specific measurements of spindle pole diameter and inter-pole length revealed differences in the Pcnt-depleted group. Notably, the meiotic spindles in Pcnt-depleted oocytes were significantly shorter with relatively broader, less focused spindle poles. Spindle organization was also disrupted in a significant percentage of the oocytes. Moreover, Pcnt-depleted oocytes exhibited a high incidence of lagging chromosomes, indicative of chromosome-microtubule attachment defects. These meiotic errors can potentially lead to aneuploidy. Hence, our data support an important role for pericentrin in the regulation of stable spindle formation and chromosome attachment, necessary for accurate meiotic division.

Quantum Fourier Transform in the Single-Excitation Subspace Method of Quantum Computation

George Barron, CURO Research Assistant
Dr. Michael Geller, Physics & Astronomy, Franklin College of Arts & Sciences

The primary question of our research is "What does the Hamiltonian for the unitary operator associated with quantum Fourier transform look like?" The primary result of the paper is that we determined an analytical expression for the Hamiltonian and present possible applications, including applications to quantum chaos. To accomplish this, we apply results in linear algebra. The significance of this development is that it allows the quantum Fourier transform to be applied in one step in the single-excitation subspace method of quantum computation.

Development of Immunologic Reagents for the Ferret Animal Model

Camille Bauer
Prof. S. Mark Tompkins, Infectious Diseases, College of Veterinary Medicine

The study of influenza disease and immunity in humans is complicated by the multitude and variety of encounters during a lifetime. Accordingly, influenza researchers have developed animal models of influenza infection and immunity, including mice and ferrets. While the mouse model benefits from precise genetics and many immunological reagents, it is widely recognized that mice do not adequately model infection or transmission of influenza. The ferret is a superior model for transmission and pathogenicity and offers major advantages for understanding, preventing, and modulating the course of influenza. Despite the utility of

the ferret, it is underutilized. One recent review noted that "the major drawback to the more widespread use of the ferret as a model for influenza has been the lack of immunological reagents." The objective of this research is to develop validated reagents and protocols to study ferret cellular and immunological responses to influenza infection. Specifically, recombinant ferret proteins are being used to generate novel monoclonal antibody (mAb) reagents. Candidate mAbs will be tested for reactivity to recombinant ferret proteins expressed in the laboratory or provided by collaborators. Leading mAb candidates will be validated for reactivity using ferrets cells and tissues. We have generated plasmids encoding cDNAs for a panel of recombinant ferret proteins and included a 6x Histidine tag (6xHis), enabling detection and purification of the ferret proteins. The cDNAs have been confirmed by sequencing and we are now transfecting HEK293 cells for stable expression of the ferret proteins. Protein expression will be confirmed by multiple assays, including Western blot and immunohistochemistry (IHC), using 6xHis-specific antibodies, and then purified using the 6xHis tag, as well. These proteins and proteins from collaborators are being used to generate mAb, which will be screened for specificity using the recombinant proteins and validated using native antigens from ferret cells and tissues. The long-term goal is to develop ferret-specific mAbs for use in flow cytometry, ELISA, Western blot and other antibody-based assays, which in turn will be used for infectious disease and vaccine studies in the ferret model.

The Effect of Social Comparison on College Students' Attitudes toward Debt and Their Ability to Delay Gratification

Elliott Beale
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

The research question I will answer is: "how does social comparison/peer pressure affect college students' attitudes toward debt and their ability to delay gratification?" I hypothesize that the students who compare themselves more to their peers and give in to peer pressure easily will be more accepting of debt and will not be able to delay gratification as well as students who do not compare themselves to others and do not give into peer pressure. I will research this question using data collected by Dr. Cude from college seniors in her classes since 2008. I will control for gender, financial knowledge, current financial situation, involvement of parents in financial education, confidence in financial knowledge, and previous financial education. I will use a scale used by Ray and Najman to measure delay of gratification, a scale used by Davies and Lea to measure attitudes toward debt, a scale used by Norvilitis and Maclean to measure parental involvement in financial education, a scale used by Norvilitis and Mao to measure confidence in financial knowledge, and a scale used by Gibbons and Buunk to measure social comparison. Financial knowledge and all other variables will be measured by student self-assessment and/or response to a survey question. By discovering the answer to this question, we will be better able to understand which college students are more at risk to make bad financial decisions.

Engineering the Active Site of Histone Acetyltransferase 1

Kaylyn Bell
Dr. Y. George Zheng, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Histone acetyltransferase (HAT) enzymes regulate gene expression by transferring the acetyl group from acetyl-CoA to specific lysine residues of histones. However, recent studies provide evidence that HATs may provide for the intimate connection between epigenetics and metabolism, acting upon thousands of substrates exclusive of histones.

These proteins play key roles in posttranslational modification, cellular metabolism, and a multitude of other pathways in cell physiology, as well. My objective is to engineer the active site of histone acetyltransferase 1 (HAT1) via site-directed mutagenesis, in order to ultimately identify some of the enzyme's many substrates by conducting enzymatic activity assays. This will provide molecular insights into the biological functions of HAT enzymes and may lead to the development of novel bioorthogonal probes for further investigation.

Thinking Geographically in Regards to Power Dynamics of the Social Environment: Its Effect on Health

Catherine Bernard
Dr. Andy Herod, Geography, Franklin College of Arts & Sciences

Behavior, as it relates to health outcomes, is best predicted through socio-historical interactions, weighted by scale, which provide context to current interactions and seemingly intangible power dynamics that make up the social environment. Through a stance that is dialectical and non-judgmental, making use of critical reflection, successful and functional solutions that address the maladaptive appropriation of stimuli by the individual may be created. Health is correlative with the degrees of power of individuals. The nature of these power dynamics is that they are internalized and constantly re-established through habitual behaviors, reaffirming geographically contingent social constructions. Behavior is geographically contingent, meaning people at specific spaces and times have certain avenues and resources available to them for behavior to be enacted based on a myriad of environmental, socio-historical, and biological factors. This lens provides a more holistic approach to the understanding of behavior, particularly maladaptive behavior that can result in physical health problems. The purpose of this paper is to argue the interpretive value geographers provide in regards to behavior and health is both warranted and necessary in health studies and policies.

Short-Run Economic Mobility in the Wake of the Great Recession

Jordan Berne, CURO Research Assistant
Dr. Robert Nielsen, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

The goal of this research is to identify short-run correlates of upward and downward wealth mobility in the aftermath of the Great Recession. The paper investigates individual components of wealth that are relevant to the causes and consequences of the recession (i.e. housing wealth and stock market holdings), along with a composite indicator of a household's net worth. Using panel data from the 2008 Survey of Income and Program Participation (SIPP), a series of two-period conditional logistic regressions is constructed to understand the correlates of household wealth mobility. This research fills a gap in the literature on wealth mobility since the recession and will inform the policy debate on how to increase upward mobility and decrease downward mobility. The results suggest that household upward mobility was greatest among those that weren't poor, lived in the South, lived in metropolitan areas, and were employed full time. Increasing educational attainment, improving outcomes for single-parent households, and helping households navigate housing markets may reduce downward mobility.

Androgynous Dress: A Sign of a New American Social Landscape

Ashley Biscan
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

Gender was at the forefront of discussion in 2015, both inside and outside of the fashion industry. Political, social, and retail actions have all been instrumental in breaking down the gender binary in the United States. Recently, fashion's culturally intuitive industry has turned androgynous dress into more than an avenue of personal expression; it created a national (and global) trend, affecting both the LGBT community and heterosexuals. To analyze this occurrence I studied a variety of sources. First, to examine the historical development of the rise of androgyny in today's culture I reviewed numerous academic texts. Next, I looked for proof for the expansion of the new trend in periodicals and by examining current designer collections. My aim was to curate evidence from a combination of sources to understand that the increasing mass acceptance of androgynous dress practices is reflective of dramatic social changes in the United States. I have grouped my findings into sections based on how they relate to fashion cycles, social reform, marketing, and celebrity endorsements. After analyzing my data, I arrived at the conclusion that the simultaneous progress of LGBT freedoms of the 21st century and the rise of androgynous dress as a style trend is more than coincidental. Together, they push and pull each other to help construct a more egalitarian culture. Today, androgyny is truly in fashion in America both literally and politically.

The Role of Chondroitin Sulfate Glycosaminoglycans in Glioma Cell Progression

Nicole Bisel, CURO Graduation Distinction, CURO Research Assistant
Dr. Lohitash Karumbaiah, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Glioblastoma multiforme (GBM) is an aggressive, devastating type of brain tumor characterized by a highly invasive nature. Chondroitin sulfate proteoglycans (CSPGs) and their glycosaminoglycan (GAG) side chains are important elements in the brain extracellular matrix (ECM) and have been implicated in promoting tumor invasion. However, conclusive evidence to suggest CSPGs or the associated CS-GAGs induce brain tumor invasion is currently lacking. We aim to provide evidence suggesting that tumor cell invasion can be influenced by the level of sulfation of CS-GAGs in the tumor ECM. This was tested *in vitro* by encapsulating the glioblastoma cell line U87MG-EGFP into CS-A (4-sulfated), composite CS-A/E (4,6-sulfated), hyaluronic acid, and agarose hydrogels. We hypothesize that the sulfation of CS-GAGs influences tumor cell migration, potentially through a chemokine-mediated mechanism. Choice assays using microfluidics devices showed preferential cell migration into composite hydrogels ($p<0.05$). Immunohistochemistry for the cytoskeletal components FAK and vinculin demonstrated that cells encapsulated in CS-GAG gels show significantly more colocalization than control treatments ($p<0.05$). Chemotaxis assays with the chemokine SDF-1α suggest that, after three hours, GBM cells migrate further into composite gels containing SDF-1α than those without, displaying potential for chemokine-GAG affinity ($p<0.05$). Sandwich ELISA assays to determine SDF-1α binding affinity and qRT-PCR assays are ongoing to establish a molecular basis for SDF-1α mediated migration of U87MG cells in CS-GAG matrices. If glioma malignancy is influenced by the level of sulfation of CS-GAGs, this work could contribute to development of novel therapies for brain cancer and lead to improved patient prognoses in clinical medicine.

The Effect of Form and Source on Bioavailability of Vitamin E Supplementation in Mature Horses

Marrissa Blackwell

Dr. Kylee Duberstein, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Vitamin E (alpha-tocopherol) is an essential nutrient for all horses that has an integral role in preventing excessive production of free radicals that can cause major damage to cell structures. Uncontrolled oxidative stress can inhibit the horse's ability to combat the imbalance between production and removal of free radicals, resulting in tissue damage and, most recently discovered, degenerative disease. Since alpha-tocopherol is not synthesized by the horse, it is a crucial nutrient for all types of equine diets. Vitamin E can be found in natural sources through green pastures, alfalfa, and other quality roughages, as well as in synthetic forms, such as liquid or powder supplementation. However, due to structural differences, absorption rates and effectiveness of alpha-tocopherol can vary. The objective of this study was to compare the bioavailability of natural and synthetic forms of Vitamin E. In this study, we utilized sixteen mature horses, previously housed on pasture. Horses were confined to stalls with minimal turnout to a dry lot (2-4 hrs/day) for a two-week washout period prior to the start of the trial. Horses were then randomly assigned to one of four treatment groups (Group 1 = synthetic acetate powder, Group 2 = natural acetate powder, Group 3 = Emcelle Powder, Group 4 = Emcelle Liquid), and then placed on a two-week feeding trial. Plasma was collected pre-feeding on days one, seven, and fourteen and four hours post-feeding on days one and fourteen to measure vitamin E levels.

Literature and Art: How One Creates the Other

Jessie Blaeser
Dr. Simon Gatrell, English, Franklin College of Arts & Sciences

For this research project, I will answer the following question: what relationships exist between painting and literature? Specifically, I am studying literature and art in England between 1820 and 1920 with works ranging from the paintings of J.M.W. Tuner to the Modernist movement. The purpose of this study includes three key elements: to develop a holistic understanding of literature that has been influenced by artistic movements, to discover how and why artistic movements influence literature, and to gain an understanding for how works of literature can influence and inspire works of art. Writing is meant to create images within a reader's mind's eye; therefore, I am investigating how literature is influenced by images themselves, and conversely, how images fuel pieces of literature. Although some research has been done on this topic, I will bring my own experience as a student of English and art to analyze individual paintings, novels, plays, and poems. My method of study will involve closely reading the poems, plays, and novels that have been tied to specific artists or artistic movements. Then, I will study the paintings that I believe have inspired or influenced these works of literature. After studying each, I will form my own conclusions on how one form of expression has influenced the other. For this presentation, I will be looking specifically at the paintings and poetry of William Blake and Dante Gabriel Rossetti.

Mineralogy and Petrology of Huerfano Butte: A Tertiary Intrusion on the Great Plains, Colorado

Joe Booth
Dr. Michael Roden, Geology, Franklin College of Arts & Sciences

Huerfano Butte, an alkali gabbro igneous intrusion located in the Great Plains of eastern Colorado, has been dated by K-Ar methods to be 25.2 million years old making this one of the most recent magmatic events in the Great Plains and placing it in the same

time frame as the famous dikes and plutons of Spanish Peaks, CO. Most likely, Huerfano Butte is a satellite intrusion of Spanish Peaks. It is composed of felsic and mafic rocks. The mafic rocks contain small felsic segregation veins representing the last portion of the melt to crystallize. Huerfano Butte likely formed by mantle melting related to the Rio Grande continental rift as recently inferred for some dikes in Spanish Peaks. The purpose of this study is to determine mineral compositions in both felsic and mafic rocks in order to understand crystallization history, and to place Huerfano Butte in the context of Tertiary magmatism in the western U.S.A. Compared to the dikes at Spanish Peaks, the rocks from Huerfano Butte are coarser-grained and fresh, allowing a more complete study of crystallization history. Samples were collected during the UGA/USC geology field school course in 2015 and analyzed using the JEOL electron microprobe housed in the Department of Geology at UGA. Olivine compositions range from Fo 71 to Fo 80 confirming a mantle origin, whereas other minerals track the evolution of the magma as it crystallized. Most intriguingly, apatite, amphibole, and mica contain significant H2O, indicating a hydrous magma consistent with a link to Spanish Peaks.

Assessing the Costs of Investments in Immunocompetence on the Fitness of *Hemigrapsus sanguineus*

Sydney Alyce Bourget, CURO Honors Scholar
Dr. Jeb Byers, Odum School of Ecology

Hemigrapsus sanguineus, commonly known as the Asian shore crab, is a highly invasive species that is native to the island of Japan and other coastlines in Asia. Found in Asian shore crabs' environment are rhizocephalan parasites, which often infect and castrate the crabs. This elicits an immune response in the crabs in which they attempt to phagocytize the foreign bodies through encapsulation. This study seeks to determine how infection impacts the fitness of the crab, specifically its metabolic rate. Crabs were infected with an immune response inducing bacteria for a span of 48 hours and then their metabolic rates were measured. The metabolic rates were measured before and after infection. The number of circulating blood cells and the effectiveness of the crabs' immune response were also measured after the infection process. Although data collection is still underway, increases in metabolic rates after infection are expected to be observed. Additionally, we also predict that there will be a positive correlation between the number of circulating bloods cells and the effectiveness of the immune response. This research is significant because the Asian shore crab's invasive range is the northeastern coast of the United States. These crabs are decreasing the biodiversity of these coastal ecosystems and are feeding upon commercially important species like the larvae of lobsters and blue shellfish. Thus, gaining a better understanding about this organism is extremely important in order to ultimately eradicate it from these areas.

The Enzymatic Characterization of Three Nucleotide-Sugar Aminotransferases in Pathogenic *Bacillus*

Kyle Bowler
Dr. Maor Bar-Peled, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Sugar-conjugated macromolecules, or glycans, play significant roles in cell-to-cell recognition, binding to the extracellular matrix, and pathogenicity. Glycobiology has become an increasingly popular and medicinally relevant field of study, as there are more than 100 known human diseases related to glycan metabolism. Glycan synthesis requires the formation of diverse nucleotide-sugars. This work describes the formation of amino-nucleotide-sugars in the gram-positive

endospore forming bacterium *Bacillus cereus*. I have identified and characterized three NDP-4-keto-4-aminotransferases in *Bacillus* to gain insight on their levels of catalytic interplay and promiscuity. The aminotransferase genes, RBTH_04255, Bc5273, and Bc1944, were cloned into *E. coli*-compatible plasmids. Transformed *E. coli* were induced to express recombinant protein, which was harvested and purified. Assays were developed to characterize enzymatic activity in terms of substrate/cofactor specificity, buffer/pH specificity, optimal temperature, ideal nitrogen donor source, and ideal pyridoxal and redox groups. Enzymatic products were analyzed via liquid chromatography coupled to mass spectrometry and were confirmed by the fragmentation of nucleotide-mono-phosphate. Enzymatic "% Conversion" was calculated by dividing the integral of eluted product by the sum of the integral product and integral substrate. Bc5273 and Bc1944 were able to convert RBTH_04255's established substrate, UDP-4-keto-6-deoxy-L-AltNAc, to UDP-4-amino-6-deoxy-L-AltNAc at approximately 20% catalytic efficiency. Each aminotransferase was able to convert UDP-4-keto-6-deoxy-D-glucose to UDP-4-amino-6-deoxy-D-glucose. These results indicate an exciting amount of interplay in NDP-sugar metabolism *in vitro*, which demonstrates that proteins are capable of having broad and promiscuous catalytic activities. Future studies are required to better understand the regulation and biological role of these three aminotransferases in *Bacillus*.

Marijuana Use, Nutritional Behaviors, and Educational Attainment in U.S. School-Aged Youth

Ashley Bradford, CURO Research Assistant
Dr. Grace Bagwell Adams, Health Policy & Management, College of Public Health

Over the past decade as state laws regulating the sale and possession of marijuana have undergone significant changes, concern has increased over the impact of liberalization on youth marijuana use. Simultaneously, rates of youth obesity have increased substantially over time. Further, substance use, body image, and nutrition are individually known to be inputs into health and educational production functions for high school youth. However, relatively little is known about the interaction between these factors in health and educational achievement. In this paper we will use data from the Youth Risk Behavior Survey (YRBS) from 1995 to 2013 to study the interaction between marijuana use and nutritional inputs (including healthy eating and exercise) on BMI and on self-reported grade point averages. The underlying conceptual model assumes youth maximize utility across health (proxied by BMI) and school performance (proxied by GPA), where BMI and grades are the outputs of a household production function that has marijuana use, healthy foods, and exercise as inputs. The analysis data contains a representative sample of over 800,000 high school youth from 39 states over the 1995 to 2013 time period. Our models will control for potential endogeneity of the input demand decisions in the BMI and grade production functions using standard instrumental variables methods. Finally, we will discuss the potential policy interventions available to mitigate the adverse consequences of risky youth behaviors and nutritional deficits, and how those policies may differentially affect minority populations.

The Hijab as a Feminist Tool of Agency

Catherine Braun
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The hijab and the practice of veiling within Islamic culture have been subject to ongoing negative criticism, shaped mostly by exclusionist Eurocentric viewpoints. In the wake of 9/11, many Americans began to view

the hijab as a symbol of an oppressive part of the world. Although the hijab is enforced by many fundamentalist regimes, it is forbidden and penalized by others. Whatever the case may be, wearing the hijab can be a highly personal choice for Muslim women, shaped by political ideology, cultural identity, and modesty. This paper identifies the shifting global trends of hijab wearers and discusses disparate meanings of this dress item for different wearers. In Turkey, for example, Muslim women have often covered themselves to distinguish themselves from the ideological viewpoints of different family members. To better understand the hijab as a tool of empowerment, I have reviewed academic articles and memoirs of hijab wearers. My objective was to identify the positive aspects of veiling. Although it is difficult to measure the exact potential of the hijab as a feminist tool, attempts for the normalization of veiling practices can be detected in social media platforms among millennials and Generation Z members. While women will likely continue to be judged for their appearance, alternative social media representations of veiled women appear to have the potential to jumpstart a dialogue in which such a controversial sartorial phenomenon may find new interpretations.

The Mythical Realm of Faerie: Dragon-Lore Symbolism and the Literary Elements of Faerie

Kinsey Brooke
Dr. Jonathan Evans, English, Franklin College of Arts & Sciences

Characters of the dragon and the dragon-slayer are important symbols in popular themes found in medieval myths and fantasy literature. This project purposes to answer the question, "What are the literary elements of Faerie, and how do they relate to the evolution of dragon-lore and J.R.R. Tolkien's adaptation of these themes?" An inquiry reveals Tolkien's interpretation of what constitutes a fairy story and what defines the broader realm of Faerie. It further contributes to the body of research investigating the symbolic importance of the dragon and dragon-slayer legends and the fantasy worlds in which those tales take place. The focus of the research includes exploration of dragon myths, the historical influences of medieval social customs, the adaptation of dragons in fantasy literature, and the expansion of their portrayals in the works of Tolkien. Additionally, it elaborates on the attributes of dragons from their first conception. I examined the way in which Tolkien used these subjects and adapted them into his stories through survey of his essay "On Fairy Stories" and other literary works. Scholarly articles from other sources were also consulted. In conclusion, the features of dragons are not static but have morphed over time, varying depending on the author's imagination, and the realm of Faerie is given very few literary limits thus adding to the author's flexibility when composing a fairy story.

Distinct Transcript Isoforms of the Atypical Chemokine Receptor 1 (ACKR1)/Duffy Antigen Receptor for Chemokines (DARC) Gene are Expressed in Lymphoblasts and Altered Isoform Levels are Associated with Genetic Ancestry and the Duffy-Null Allele

Andrea Brown
Dr. Melissa Davis, Genetics, Franklin College of Arts & Sciences

The Atypical ChemoKine Receptor 1 (ACKR1) gene, better known as Duffy Antigen Receptor for Chemokines (DARC or Duffy), is responsible for the Duffy Blood Group and plays a major role in regulating the circulating homeostatic levels of pro-inflammatory chemokines. Previous studies have shown that one common variant, the Duffy Null (Fy-) allele that is specific to African Ancestry groups, completely removes expression of the gene on erythrocytes;

however, these individuals retain endothelial expression. Additional alleles are associated with a myriad of clinical outcomes related to immune responses and inflammation. In addition to allele variants, there are two distinct transcript isoforms of DARC which are expressed from separate promoters, and very little is known about the distinct transcriptional regulation or the distinct functionality of these protein isoforms. Our objective was to determine if the African specific Fy- allele alters the expression pattern of DARC isoforms and therefore could potentially result in a unique signature of the gene products, commonly referred to as antigens. Our work is the first to establish that there is expression of DARC on lymphoblasts. Our data indicates that people of African ancestry have distinct relative levels of DARC isoforms expressed in these cells. We conclude that the expression of both isoforms in combination with alternate alleles yields multiple Duffy antigens in ancestry groups, depending upon the haplotypes across the gene. Importantly, we hypothesize that DARC isoform expression patterns will translate into ancestry-specific inflammatory responses that are correlated with the axis of pro-inflammatory chemokine levels and distinct isoform-specific interactions with these chemokines. Ultimately, this work will increase knowledge of biological mechanisms underlying disparate clinical outcomes of inflammatory-related diseases among ethnic and geographic ancestry groups.

Examining the Effects of Astrocytes on Chlorpyrifos Metabolism

Kyle Brown, CURO Research Assistant
Dr. Michael Bartlett, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Chlorpyrifos (O,O-diethyl O-[3,5,6,-trichloro-2-pyridyl] phosphorothionate, CPF) is a widely used organophosphate insecticide. CPF is utilized as an insecticide, and its activity and toxicity is due to the irreversible inhibition of acetylcholinesterase. Chlorpyrifos is metabolized by Cytochrome P-450 (CYP) into chlorpyrifos-oxon (O,Odiethyl-O[3,5,6,trichloro-2-pyridinly]phosphate, CPO) and 3,5,6,-trichloro-2-pyrinidol (TCP). CPO is approximately 3,000 times more potent than CPF and leads to neurotoxicity. TCP is nontoxic and is eliminated in the kidneys. Methods have been developed to quantify chlorpyrifos and its two metabolites by column liquid chromatography/electrospray ionization tandem mass spectrometry (LC/ESI-MS/MS). Preliminary data showed the detoxification of CPF into TCP in the presence of astrocytes. An increase in TCP levels was observed in cell culture medium in the presence of astrocytes, but was inhibited in the presence of CYP inhibitor SKF525A. This suggested that astrocytes have the ability to metabolize and detoxify chlorpyrifos, and the metabolism could be inhibited by the CYP inhibitor. This poster will discuss quantitative data obtained from the co-culturing of neurons with astrocytes in the presence of CPF and how astrocytes affect the metabolism of CPF into CPO and TCP.

An Improved Synthesis of a Fundamental MOF Precursor

Wesley Brown, CURO Research Assistant
Dr. Douglas Jackson, Chemistry, Franklin College of Arts & Sciences

As the first step in a multi-step synthetic project, the synthesis of methyl 10-nitro-9-anthracenecarboxylate is critical to the foundation of the organic linker needed to complete the construction of a hybrid molecular switch to metal-organic framework, or MOF. To synthesize this methyl ester, esterification of 9-anthracene carboxylic acid was implemented in methanol and sulfuric acid, and the reactions completed to various yields. However, rather than pursuing conventional synthetic routes for this reaction, such as oil-bath reflux, microwave irradiation was implemented to greatly reduce

the time table of this reaction. A more successful esterification was achieved by first converting 9-anthracene carboxylic acid to the acyl chloride, and then immediately converted to the desired methyl 9-antrhacenecarboxylate with the addition of methanol in acidic conditions. Following the successful esterification, methyl 9-anthracenecarboxylate was nitrated to methyl 10-nitro-9-anthracenecarboxylate by way of the creation of the nitronium ion in sulfuric acid and an acetic acid/acetic anhydride solution. Current methods improve upon the literature in terms of reduced reaction time, improved yield, and purity.

Characterization of *Bacillus thuringiensis* Cry51Aa Toxicity to *Lygus*

Darcie Bruce, CURO Summer Fellow, CURO Research Assistant
Prof. Michael Adang, Entomology, College of Agricultural & Environmental Sciences

Tarnished Plant Bugs, *Lygus lineolaris*, have emerged as major global crop pests. This group of bugs in the Order Hemiptera has piercing-sucking mouth parts, stylets that puncture plant cells and remove cellular contents. These species are cosmopolitan pests of high value crops. During the early bud and bloom stage, feeding by these insects causes bud and flower loss, reducing yield on stone fruits such as peaches, and a number of agricultural row crops including cotton. Recently, the structure of Cry51Aa was solved by collaboration with the Adang laboratory. Based on the discovery by Baum et al. (2012) that a Cry51A-typetoxin has toxicity to *Lygus*, I tested Cry51Aa for *Lygus* activity in the 2015 Summer and Fall semesters. This involved developing an effective bioassay method and then using bioassays to determine Cry51Aa toxicity to *L. lineolaris*. My goals for this semester are: 1) determine the Lethal Concentration50 (LC50) value for Cry51Aa against *Lygus*, 2) conduct a *Lygus* bioassay with activated Cry51Aa toxin, 3) using fluorescently labeled Cry51Aa toxin, image toxin binding and damage to gut tissue in *Lygus* nymphs by confocal microscopy. The data will provide basic information on toxin interaction with the *Lygus* gut, and will guide the optimization of Bt Cry51Aa toxin for enhanced activity against *Lygus* and other hemipteran pests.

Diabetes Self-Education App

Ben Burgh
Dr. Kyle Johnsen, College of Engineering

Diabetes mellitus is a metabolic disorder affecting almost 400 million people worldwide. In order to help these people understand how their actions (i.e. adhering to their medication, diet, and exercise regimes) can affect their health, we constructed a mobile application to promote patient knowledge and keep track of their well-being. The primary means of accomplishing this is a "What If" simulation which visually demonstrates to users how different behaviors would hypothetically improve or degrade their health. Users would be encouraged, both by the application and their doctors, to live a healthier lifestyle. Our question is, are patients willing, or even able, to educate themselves through this application?

Spatial and Temporal Iron Isotope Fractionation in Hawaiian Soils

Shannon Burns, CURO Graduation Distinction, CURO Research Assistant
Dr. Aaron Thompson, Crop & Soil Sciences, College of Agricultural & Environmental Sciences

In the future, iron isotope fractionation patterns can serve as tracers for redox conditions in past climates, particularly when coupled with fractionation patterns for other metal isotopes. Given that microbes play a role in iron reduction, these redox conditions might elucidate microbial composition in ancient soils. Hawaiian soils have undergone

controlled soil formation, or pedogenesis, as a result of their formation from volcanic hot spot activity. We sought to determine differences in the iron (Fe) isotopic ratio of 56Fe/54Fe in soils of varying age and climate from Hawaii. Our sampling sites varied in mean annual precipitation. We hypothesize that elevated weathering from increased precipitation and/or age of soils will yield a greater 56Fe/54Fe ratio. Samples were digested for Fe isotope analysis. For Fe purification, a double-spike of 58Fe-54Fe was added to each purified sample to account for mass bias in Inductively Coupled Plasma Mass Spectrometry (ICP-MS) measurements of 56Fe and 54Fe. Isotopic compositions will be compared across soils with temporal and spatial climate variation to elucidate redox patterns in the soils.

The Influence of Formal and Informal Sources of Support on Foster Parents' Couple and Co-parenting Relationship Quality

Avery Campbell, CURO Research Assistant
Dr. Ted Futris, Child & Family Development, College of Family & Consumer Sciences

Nearly 7,500 of Georgia's children are placed in foster care each year. Having had experience with maltreatment, poor parenting, and high-conflict homes, foster children benefit the most from foster homes that include both high-quality parenting and healthy couple relationships. However, foster parents experience many unique stressors (e.g., traumatic experiences of foster youth, challenges with both foster and birth children, financial strain, legal processes, increase on time demands, lack of permanency) that increase their risk of experiencing marital and co-parenting challenges, which may jeopardize placement quality and stability. Couples who have meaningful social connections they can turn to during challenging times typically do better managing their concerns. The current study examines the influence of formal and informal sources of support on married foster parents' couple and co-parenting relationship quality. From an initial pool of 4,346 active foster parents in Georgia shared by the Division of Family and Children Services, 2,465 were identified as married (62.4% Caucasian) and 300 couples were randomly selected and mailed a survey (50% Caucasian). A total of 100 foster parents responded (69.0% Caucasian; 59.0% female), representing a total of 60 married couples (63.3% with data from both partners). Preliminary results show that foster parents identified support from friends, their family or child's doctor, and other foster parents as most helpful. Additionally, foster parent support was associated with greater commitment to the couple relationship and higher relationship quality. This presentation will share the results of this study and implications for enhancing support services for foster parents across Georgia.

Geographic Distribution of Adult Body Mass in Muridae

Patric Campbell
Dr. John Gittleman, Odum School of Ecology

Geographic range size and body mass have been well studied in mammalian species. However, the studies overlook the fact that geographic distribution may correlate with body mass. We used various museum rodent specimens to estimate body mass using an allometric relationship between adult body mass and skull length. The reason we are using rodent specimens is that we have a lot of information on many rodent species; yet, we are still missing data from a few rodent species. In order to find out more information on their geographic distribution, we can use patterns of information that is analyzed to provide correlations to the data we are missing for the few rodent species. Using the location data for where each museum specimen was collected, we will analyze global

patterns of body mass across a map of biogeographic realms. The main goal in mind is to predict patterns of geographic distribution in rodent species to help aid with conservation measures, due to the fact that environmental changes are expected to alter geographic distribution and can put many of these species at risk for extinction.

Synthetic Estrogen Disrupts Spindle Organization and Meiotic Division in Oocytes

Madison Canning, CURO Research Assistant
Dr. Maria Viveiros, Physiology & Pharmacology, College of Veterinary Medicine

Aneuploidy, the presence of an abnormal chromosome number, in embryos is a leading cause of birth defects such as Down syndrome and pregnancy loss. This condition is primarily attributed to meiotic division errors in female oocytes before fertilization. Studies indicate that environmental toxins, such as estrogenic compounds, can disrupt oocyte development and meiosis. This investigation tested the effect of short-term exposure to the synthetic estrogen, Diethylstilbestrol (DES), on mouse oocytes in culture. To determine whether DES impairs the resumption and progression of meiotic division, GV-stage oocytes with surrounding granulosa cells were collected from pre-ovulatory follicles and cultured with increasing concentrations of DES (0, 5, 15 and 30 uM) for 17 h. Additionally, we tested whether a brief 4h exposure to DES disrupts mature MII oocytes post-ovulation. Following culture, the oocytes were fixed for immunofluorescence analysis of chromosome and meiotic spindle configurations. The distribution of key MTOC associated proteins, pericentrin and g-tubulin, was also analyzed. DES exposure during 17h culture disrupted the progression of meiosis, with higher concentrations of DES leading to MI-arrest. The oocytes showed significant chromosome-microtubule attachment errors as well as disrupted meiotic spindle organization. In addition, both pericentrin and g-tubulin showed atypical distribution in numerous smaller foci throughout the cytoplasm. Interestingly, similar errors were observed in ovulated MII eggs following short exposure to DES. These data indicate that DES exposure significantly disrupts oocyte microtubule organization, causing meiotic spindle structure defects and chromosome attachments errors. These deformities can result in aneuploidy, which adversely effects embryonic development post fertilization.

Corporate Social Responsibility and Stock Prices: The Environmental Responsibility of Shareholders

Katie Cannon, CURO Research Assistant
Dr. Christopher Pope, Banking & Finance, Terry College of Business

Over the past few decades, the American population has taken an increased interest in the environmental and social problems that directly result from corporate decisions. Multiple studies have found that consumers, investors, and financing organizations have become sensitive to corporate environmental responsibility, and especially their irresponsibility. Decision makers need dependable information to help them balance their responsibilities to the shareholders and to show the company as environmentally responsible. The objective of this study is to measure the impact that eco-friendly and eco-harmful events have on stock prices, as a measure of corporate performance. To examine the impact that sustainable initiatives (or lack thereof) have on stock prices in modern times, a series of event studies was performed. Relevant events between 2010 and 2015 were identified using Wall Street Journal articles, found through Factiva. Focusing on the environmental responsibility portion of CSR, appropriate events were determined using applicable

keywords. Each event was then categorized into one of two groupings: eco-friendly or eco-harmful. A three-day event window [-1,1] was used to observe any abnormal returns surrounding the events. Based on previous research, it is likely that this study will find a causative relationship between eco-harmful and eco-friendly events and a change in the company's stock price. Specifically, past studies have indicated that stock prices will rise after the announcement of an eco-friendly event, while stock prices will fall after the announcement of an eco-harmful event. The results of this study should give decision makers a clearer path to follow.

Investigating the Plasmonic Property of Ag-Cu Alloy Nanostructures

Daniel Carlson
Dr. Yiping Zhao, Physics & Astronomy, Franklin College of Arts & Sciences

When a photon hits the interface between a noble metal and a dielectric (such as air), it causes electrons to oscillate at that interface. When the size of the metal becomes much smaller than the wavelength of the incident light, at certain frequencies photons will excite a strongest oscillation, which is known as surface plasmon resonance (SPR). At the SPR frequency, the electric field around the metal surface will be greatly enhanced, which can be used in a wealth of applications such as food safety, medical diagnostics, microscopy beyond the diffraction limit, or even disease treatment. For different applications, it is very important to tune the SPR frequency. This project focuses on manipulating the SPR frequency using the silver-copper composite nanostructures. The Ag-Cu composite nanostructures are fabricated using shadow nanosphere lithography with a two-source electron beam deposition system. Glass substrates are coated with a hexagonal close-packed colloid monolayer of polystyrene beads (500 nm and 750 nm in diameter) and act as a mask during physical vapor deposition. By controlling the deposition rate of the two metals, their relative composition can be tuned. The resulting materials are characterized by UV-Vis spectrometer, scanning electron microscopy, transmission electron microscopy, atomic force microscopy, and energy dispersive x-ray spectroscopy. We find that the SPR frequency decreases with the Cu composition, which is consistent with the theoretical prediction. We will establish the relationship between the optical properties and the morphology and composition of the Ag-Cu nanostructures.

Pre-to-Post Transplantation Changes in Caregiver Emotional Functioning

Olivia Carlson
Emily Ivey, Colleen Keeler
Dr. Ronald Blount, Psychology, Franklin College of Arts & Sciences

Objective: Caregivers and families of children awaiting solid organ transplantation often experience significant stress. Less research has examined how caregiver and family distress changes from before to after transplantation. This study investigated how caregiver and family psychosocial functioning changed from before (T1) to 6 months after transplantation (T2). It was hypothesized that caregiver and family distress would decrease from T1 to T2. *Methods*: The sample included 46 caregivers of pediatric transplant recipients (T1 *M* child age = 8.08 years; T2 *M* child age = 9.11 years). T1 data was collected at the pre-transplant evaluation and T2 data was collected 6 months post-transplantation. Caregivers completed questionnaires of their own emotional functioning and the impact of the child's illness on the family. *Results*: From T1 to T2 (*M* time passed = 11.92 months), caregivers demonstrated significant decreases in somatization symptoms ($d = .31$, $p = .04$), overall emotional distress ($d = .40$, $p = .02$), and post-traumatic stress symptoms ($d = .45$, $p = .01$). There were no differences from T1 to T2 for caregiver depression, anxiety, or the

impact of the child's illness on the family. *Conclusions*: Symptoms likely decreased in response to having the burden of awaiting transplantation removed. Anxiety and depression symptoms and the impact of the child's illness on the family may require intervention to decrease post-transplant. Providers may inform caregivers that aspects of emotional distress will likely decrease post-transplantation, and provide support for current symptoms. *Significance*: Results inform evidence-based practices for the content of psychoeducation provided to families before transplantation.

Effects of Maternal Immune Stimulation by a Viral Mimic on Autistic and Other Behaviors of Juvenile and Adult Mouse Offspring

Annika Carter, CURO Summer Fellow
Dr. Nick Filipov, Physiology & Pharmacology, College of Veterinary Medicine

In line with epidemiological data, maternal immune stimulation of mice leads to neurobehavioral deficits of autistic nature in the offspring. While other studies focused on the effects of maternal immune activation (MIA) early in development predominantly on male offspring, this study investigated the degree and nature of behavioral deficits caused by MIA in juvenile (postnatal day [PND] 35) and adult (PND70) offspring of both sexes. A viral mimic, Poly I:C, was administered at mid-gestation to dams. Offspring were left unperturbed until behavioral testing. Male and female offspring were subjected to behavioral tests at PND35 or PND 70 designed to detect motor, emotional and cognitive behavioral deficits, including some of autistic nature. From data analyzed thus far, sex differences are apparent: the juvenile females swam longer and climbed more in the forced swim test, and both juvenile and adult females had decreased grip strength compared to age-matched males in a grip strength test. In the marble-burying test, a measure of anxiety, there was a trend for increased marble burying by juvenile male offspring of dams treated with Poly I:C; this trend was significant at PND70. These results indicate that male and female mice, while performing differently in tests for depression and muscle strength, are not affected by MIA in these two domains. Alternatively, male mice born to MIA dams exhibit increased anxiety, which is more pronounced in adult offspring. These data suggest that key autistic behaviors in offspring of MIA dams are maintained in adulthood and have a male bias, similar to children with autism.

***In Vitro* DNA-Protein Interaction Analyses of *Zea mays* Transcription Factors**

Kitra Cates, CURO Research Assistant
Dr. Robert Schmitz, Genetics, Franklin College of Arts & Sciences

Corn (*Zea mays*) serves as an integral world crop used for oil production, livestock feed, and nutrient sources in the human diet. Corn is a cereal crop grown for the palatable grains it produces, which are primarily composed of endosperm. Research concerning regulatory pathways associated with transcription in endosperm is necessary to study the factors involved in early seed development and the regulatory influences on hypomethylation observed in corn endosperm. In addition, this study serves to develop a novel *in vitro* DNA-protein interaction protocol. Transcription factors PBF-1, Opaque2, abi3/ZmAFL4, OHP1, and OHP2 were chosen due to their activity during endosperm development. Each transcription factor gene was artificially synthesized in a Gateway entry vector plasmid and transformed into *Escherichia coli*. Sequential cloning into the destination vector pIX-HALO added a HALO motif sequence to the gene sequences and placed the genes under an inducible promoter. Cloned genes were expressed and translated using an

established *in vitro* protocol. HALO hybrid proteins were utilized to isolate DNA targets of our transcription factors. Purification with an anti-HALO antibody coupled with high throughput sequencing identified the targets of our transcription factors, providing novel data on the role of these transcription factors in regulation of endosperm development**.** The protocol parallels the widely used, but extremely costly, chromatin immunoprecipitation sequencing protocol. It provides an efficient, scalable production of transcription factors and the potential to manipulate regulatory networks of interest.

Possibility of Attitude Change towards Edible Insects When Prepared by Top Chefs

Gillian Caudill
Dr. Marianne Shockley, Entomology, College of Agricultural & Environmental Sciences

In 2012, a previous student studied attitudes and behaviors of individuals before and after eating an insect infused product. The student wanted to determine if choice was based upon attitudes towards their health. Since their findings showed that focusing on health has little impact on changing attitudes, it would be beneficial to study a change in attitude based on appearance of the food. Instead of promoting insects as a healthy choice, we chose to promote insects as an exotic and aesthetic food chefs can prepare at an event this past September of 2015 at the Science Cafe Bug Banquet. This event featured renowned chefs from various restaurants in Athens, GA. We predicted that there will be a more dramatic change in attitudes based upon appealing to people's desire to eat a food that is exotic, mostly unavailable in the States, and that is made by acclaimed chefs.

University Professors with Disabilities

Maria Ceron, CURO Honors Scholar
Dr. Edward Delgado-Romero, Counseling & Human Development Services, College of Education

This project presents preliminary results on the first phase of a qualitative study focused on exploring and comprehending the concept of "inclusive" higher education. The analyzed sample consists of six university professors of education from Bogota, Colombia who have lived almost their entire lives experiencing some form of disability. These professors have lived with a disability during the vital period of adolescence, professional training and development, and today serve as trainers in higher education in various subject areas. This project takes into account the fact that people with disabilities are increasingly able to participate in social processes, and are therefore able to contribute to the construction of an inclusive society for all. The study was conducted in three phases. First, each professor's teaching style was illustrated through video recordings of his/her class. The videos were then analyzed according to an established protocol. Then, instrument inventories were utilized to analyze the effectiveness of each professor's teaching style. Finally, in-depth interviews were conducted, transcribed verbatim, and analyzed in order to understand participants' construction of meaning in terms of the relationship between disability, experience, and teaching. Ultimately, the purpose of this study is to determine the effects in which people with disabilities in professional positions influence society. As professors, they hold positions of influence over students in education who will be responsible for implementing the concept of inclusivity into their own classrooms in the future, thereby aiding to the construction of an inclusive society for all.

Novel Nitric Oxide Releasing Materials for Prevention of Infection in Vascular Catheters

Sarah Chaji
Dr. Hitesh Handa, College of Engineering

Clotting and infection are two common problems associated with vascular catheters. Catheters are used in hospitals in thousands of patients every day and are highly prone to infection. The proteins in blood plasma such a fibrinogen and albumin attach to the catheters allowing bacteria to bind to the catheter surface leading to biofilm formation and infection. Frequent use of antibiotics has shown to create resistant strains of bacteria, increasing the risk of infection, thus making them an expensive approach for hospitals due to longer duration of infection recovery time. Nitric oxide (NO) is known to be a potent antibacterial and anti-thrombotic agent. Endothelial cells that line the inner walls of all blood vessels exhibit a NO flux of 0.5–4 × 10−10 mol cm−2 min−1 that helps prevent thrombosis. This research examines the potential of incorporating NO donor, SNAP (*S*-nitroso-*N*-acetylpenicillamine) within Elast-eon E2As catheters (medical grade polymer). This research study consists of a bacterial adhesion assay on protein-exposed catheters made of SNAP and E2As against gram positive and negative bacteria. The results suggest that the SNAP/E2As catheters have the potential to improve the bactericidal activity of intravascular catheters, as well as other blood-contacting medical devices (e.g., vascular grafts, stents).

The Role of Cas4-2 in the CRISPR Adaptation Stage of *Pyroccocus furiosus*

Chip Chambers, CURO Honors Scholar
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

CRISPR (Clustered Regularly Interspaced Short Palindromic Repeats) Cas (CRISPR-Associated) proteins are revolutionizing the field of modern biology, research, and medicine. With most research occuring within the last 5-10 years, CRISPR is rapidly becoming one of the most hot-button issues in biology, prompting coverage from the New York Times, Wall Street Journal, and NPR. CRISPR-Cas is an adaptive immune system in prokaryotic systems made up of several "Cas" (CRISPR-Associated) proteins. My research focuses on evaluating the role of one protein, Cas 4-2, in the CRISPR system of *Pyroccocus furiosus*. This protein has been implicated in the adaptation stage of CRISPR, possibly associating with Cas 1 and Cas 2, which are known to form complexes in the adaptation phase of the process. This presentation will appeal to a broad audience with an introduction to CRISPR while simultaneously conveying the technical aspects of the research.

Can Virtual Reality Lead Us to Learn More about Empathy?

Bleak Chandler, CURO Research Assistant
Dr. Sun Joo Ahn, Grady College of Journalism & Mass Communication

Can virtual reality lead us to learn more about empathy? The dark triad is a group composed of three personality traits: psychopathy, Machiavellianism, and narcissism. With the use of Samsung Gear VR virtual reality, we want to discover whether or not we can discover a link between the dark triad and an individual's empathic response. Each study will involve two individuals who will enter a room. Before entering, Individual A will take a test that determines their "dark triad" personality. Individual A will then enter the room and be set up with a virtual reality headset. Individual B, a confederate, will be set up with a device that can "measure" their heart palpitations. Individual A will read a prompt from a script to individual B that will "trigger" their heart rate. Individual A will then, using the virtual headset, "walk" inside a 3D virtual representation of individual B's heart and experience their heartbeat and palpitations; this heartbeat is simulated. A test will be given after to Individual A to help

determine a link between the dark triad and empathy. Through this test, we want to discover whether or not Individual A's responses and reactions to Individual B's simulated heartbeat are connected to their dark triad.

Corporate Environmental Responsibility Recognition and Firm Value

Mary Chastain
Dr. Christopher Pope, Banking & Finance, Terry College of Business

This paper investigates the relationship between corporate environmental responsibility recognition and firm value. The purpose of the paper is to answer the following question: does external acknowledgement of a firm's sustainability position affect firm value? Answering this question could provide empirical data encouraging companies to adopt sustainable initiatives. The Corporate Knights' "Global 100 Most Sustainable Corporations" is the acknowledgement considered in this study. A firm's placement on, removal from, or new ranking are evaluated to capture any impact of recognition on firm value. The study might be limited by the importance in which the accolade holds. Results pending.

Post Translational Modifications of CaaX-Box Proteins Are Dependent on Specific CaaX Motifs

Michael Cheng, CURO Graduation Distinction
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The modifications occurring to *CaaX* proteins have largely been established using few reporter molecules (e.g. Ras, the yeast a-factor mating pheromone). These proteins undergo three coordinated COOH-terminal modifications: isoprenylation of the motif's cysteine, proteolysis to remove the *aaX* portion, and carboxylmethylation of the COOH-terminus. Here, we investigated the coupling of all three modifications in the context of the yeast Ydj1p Hsp40 chaperone. We provide genetic, biochemical, and biophysical evidence that the Ydj1p *CaaX* motif is isoprenylated but not cleaved and carboxylmethylated. Moreover, we demonstrate that Ydj1p-dependent phenotypes and Ydj1p localization are altered when *CaaX* motifs from yeast Ste18p or a-factor are transplanted onto Ydj1p. The abnormal phenotypes and localization patterns revert to normal when post-isoprenylation events are genetically interrupted. Our findings promote a general model in which proper Ydj1p function and localization require an isoprenylatable *CaaX* motif that is resistant to post-isoprenylation events. These results expand on the complexity of protein isoprenylation and revise the impact of post-isoprenylation events in regulating the function of Ydj1p and perhaps other *CaaX* proteins.

Yohimbine-Induced Reinstatement in Alcohol-Preferring and Wistar Rats

Scott Chimberoff, CURO Research Assistant
Dr. Jesse Schank, Physiology & Pharmacology, College of Veterinary Medicine

Animal models are frequently utilized to develop treatments for a variety of human medical disorders and have been developed to assess critical adaptations within the brain involved in the development of tolerance to, and physical dependence on, alcohol. To better understand the 50% genetic component to the risk for developing alcoholism, alcohol-preferring (P) rats have been selected for high alcohol preference and bidirectionally bred from outbred Wistar rats. Many studies have shown that P rats will self-administer more alcohol than Wistar rats; however, few have studied relapse-like behavior using the reinstatement model. One study demonstrated

that P rats will reinstate, or relapse, to alcohol-seeking behavior after being injected with the pharmacological stressor yohimbine. However, the P rat's sensitivity to yohimbine was not measured using a dose-response analysis. In this study, we explored yohimbine-induced alcohol seeking using the reinstatement model and neuronal activation in the nucleus accumbens shell, a region involved in drug-reward and positive reinforcement, using immunohistochemistry between P and Wistar rats. Neuronal activation was investigated by staining for the Fos protein, whose presence is indicative of neuronal activation. Consistent with previous studies, we found P rats will self-administer more alcohol than Wistar rats. We also found P rats to have greater sensitivity to the reinstatement effects of yohimbine and show greater neuronal activation in the nucleus accumbens shell. This study is one of few addressing relapse-like behavior using the reinstatement model, and possibly the first to compare the reinstatement effects of different doses of yohimbine between P and Wistar rats.

Analysis of the Relationship between Patient Satisfaction Scores and Patient Health Outcomes

Taylor Chishom, CURO Honors Scholar, CURO Graduation Distinction, CURO Research Assistant
Dr. Amanda Abraham, Health Policy & Management, College of Public Health

The Centers for Medicaid and Medicare Services (CMS) now requires hospitals to report and submit their patient satisfaction ratings, which are known as Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS) scores. These patient satisfaction scores are tied to a portion of the hospital's reimbursement as a part of CMS's new value-based purchasing initiative. The scores are also published on CMS's hospital compare website, and consumers are able to compare hospitals based on the hospital's HCAHPS scores. Consumers can also compare hospitals based on outcomes such as value of care, timeliness of care, and readmission rates. The purpose of CMS's hospital compare website and value-based purchasing initiative are to incentivize hospital providers to increase the quality of their services while also reducing costs. The purpose of this analysis is to determine if CMS's use of HCAHPS scores in determining a portion of the hospital's reimbursement is tied to better healthcare service quality and better patient health outcomes, or if hospitals are simply investing in processes and environments that result in better HCAHPS scores but not necessarily better healthcare service quality or better patient health outcomes. The hospitals being studied in this analysis are Athens Regional Medical Center and St. Mary's Hospital, which are located in Athens, Georgia. Using these hospitals' patient satisfaction scores, general patient readmission rates, and hospital deaths among patients with treatable complications, a determination will be made as to whether higher HCAHPS scores are linked to better patient outcomes and improved healthcare quality.

Addressing Teenage Pregnancy in Athens-Clarke County, Georgia

Hailey Clark
Dr. W. David Bradford, Public Administration & Policy, School of Public & International Affairs

Since reaching an all-time high in 1990, the teenage pregnancy rate in the United States has steadily decreased. This is in large part due to public health programs designed to increase access to preventative care and to decrease risky sexual behavior. Nevertheless, Athens-Clarke County has a teenage pregnancy rate of 59 pregnancies per 1,000 teenage females, which is higher relative to Georgia (41.3) and the United States (34).

Teen pregnancy has consequences for both teenage parents and the children of teenage parents in terms of educational, employment, and financial outcomes. These consequences are passed on to all citizens in the forms of decreased social well-being and fiscal costs to fund support programs. A systematic review of three policy alternatives and the status quo was conducted on the basis of economic viability, medical effectiveness, and political feasibility. Based on the results of a policy matrix, Athens-Clarke County officials should implement an educational program in the local high schools that promotes youth development in addition to providing sexual education, rather than accept such consequences and allow the teenage birth rate to decrease gradually. Increased connection to one's community and preparation for future aspirations lessens the incidence of risky sexual behavior and resulting pregnancy. Further investigation into the public sentiment of Athens-Clarke County citizens and the Clarke County School District's ability to administer the program is necessary going forward.

Effects of Fire in a Riparian Zone on Aquatic Fungi

Sarah Clement, CURO Research Assistant
Dr. Amy Rosemond, Odum School of Ecology

Fires are an important structuring element of forest ecosystems, both naturally occurring and those used for forest management, and can vary in their severity and impact. Nutrient release in the form of nitrogen is one of the known short-term effects of forest fires, both in terrestrial and aquatic ecosystems. Stream nutrient enrichment studies have been shown to cause an increase in aquatic fungal reproductive output, in the form of conidia production, as well as an increase in aquatic fungal abundance and species richness. There are few studies on the effects of fire on stream fungi. This study aims to test if nutrient release from fires causes a similar effect on stream fungi as artificial nutrient enrichment. By comparing a severe burn and a mild burn, this study will provide evidence as to how these effects could change with global climate change, as severity and prevalence of fires increases. I predict that increased nutrients will cause an increase in fungal biomass, production, and conidia production. I predict the increase in conidia production to be more drastic than the increase in biomass, as more production will be devoted to reproduction. I predict there will be a shift in fungal species richness and relative species abundance. I predict the magnitude of these changes to be greater for the severe burn. I will measure fungal biomass via ergosterol extraction, and conidia will be stained in water samples, counted, and identified. Biomass versus reproductive output will be compared pre-burn and post-burn.

The Effects of Lutein and Zeaxanthin Supplementation on Sensory Function in Healthy Adults

Harrison Cloud
Dr. Lisa Renzi, Psychology, Franklin College of Arts & Sciences

Xanthophyll catotenoids lutein (L) and zeaxanthin (Z) are the only carotenoids found in the neural retina and are the dominant caotenoids in the brain. Previous research has shown that supplementation with L+Z can improve visual function under conditions that cause light stress. These effects are largely optical in nature, but additional past research has shown that L+Z may also improve visual function via improving processing speed of visual stimuli in younger adults. The purpose of this study was to determine whether or not supplementation can improve visual processing in older adults. A total of 51 adults over the age of 65 (M = 73.74 +/- 8.2 years) completed a one-year randomized, double-masked, placebo controlled L+Z supplementation study. In addition to a

number of basic cognitive measures, temporal visual processing speeds, visual reaction time and coincidence anticipation ability were tested at baseline, 4-month, 8-month and 12-month time points. Temporal visual processing speed was measured via a custom-built desktop optical device, and visual reaction time was measured using a wall-mounted, custom-built Beyseian timer. In addition to visual function testing, other markers of visual health, such as incidence of age-related cataract, smoking status, and dietary intakes, were collected. Preliminary analyses suggest that nutritional supplementation with L+Z improved visual reaction time in older adults. Analyses are ongoing, but preliminary results suggest that L+Z can improve visual function via both optical (as shown previously) and neural mechanisms.

Natural Killer Cell Maturation is Controlled by Genetic Background in Aging Mice

Erica Coe
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

Natural killer (NK) cells are a key component of innate immune responses. Using granules containing perforin and granzymes, NK cells destroy cancerous and virus-infected cells within the body. Recent studies show that as organisms age, NK cell maturation becomes dysfunctional. NK cells increasingly arrest in the early stages of development and fail to become fully mature. These defects ultimately increase susceptibility to cancer and viral infections later in life. We predicted that age-associated declines in mature NK cells are heritable. To test our hypothesis, we assessed the development of splenic NK cells isolated from old mice representing 19 genetically-diverse inbred strains. We measured the number of NK cells as a percent of total splenocytes, and we quantified the percentage of NK cells in each of the following stages: mature, transitional, immature, and double negative. Our results show that NK cell maturity is highly heritable in old mice. Our future studies will identify novel genes and pathways that drive NK maturation during aging, and we predict that these pathways will serve as targets for innovative cancer therapies.

Polysialic Acid Expression in AICAR Treated Mouse Neuroblastoma Cells

Elyssa Cohen
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Polysialic acid (PSA) is an N-linked glycan decoration found on the Neural Cell Adhesion Molecule (NCAM), which is expressed in Neuro-2A cells, a mouse neuroblastoma cell line. AICAR is a pharmacological activator of AMP-activated protein kinase (AMPK) - mammamlian target of rapamycin (mTOR) signal transduction pathway. AICAR activates AMPK, leading to increased phosphorylation of TSC2, which produces GDP-bound Rheb. GDP-Rheb inhibits mTORC1 activity, and mTORC1 inhibition causes tumor suppression. Therefore, mTORC1 inhibition is currently of great interest as a clinical approach for cancer treatment. Insight into how AICAR might affect glycosylation could lead to an understanding of the roles that specific glycans, such as PSA, might play in the AMPK-mTORC1 pathway. In the Neuro-2A cell line, I hypothesized that treatment with AICAR would increase PSA expression, thereby implicating a novel role for mTOR signaling in the regulation of glycoprotein glycosylation. My experimental results demonstrate that treatment of Neuro-2A cells with 500μM AICAR for twenty-four hours induces cells to increase PSA expression. Western blot analysis demonstrates that the amount of NCAM protein does not change in treated Neuro-2As. Rather, AICAR affects the

glycosylation of NCAM. Furthermore, by lectin blot analysis, AICAR does not appear to impact the ability of Neuro-2A cells to glycosylate proteins; the expression of high-mannose glycans indicates that core N-glycosylation levels are not altered. Thus, alterations of AMPK-mTORC1 signaling affects processing of glycoproteins in neuronal tumor cell lines, suggesting dynamic modulatory mechanisms for regulating cell-surface glycan expression.

Use of a Spatial T-Maze Test and an Object Recognition Test to Assess Learning and Memory in a Piglet Model

Caroline Coleman, Foundation Fellow
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Due to similarities between piglet and human toddler brains in structure, composition, and development, piglets have become increasingly relevant subjects in varying aspects of cognition in a piglet model. The spatial T-maze test assesses learning and spatial memories, and the object recognition test assesses object memory. In the spatial T-maze test, piglets will learn to locate a milk reward within a plus-shaped maze. This will test allocentric memory as piglets will have to use extra-visual cues to locate the milk reward, despite starting at alternating north and south start arms. We will measure latency to choice and proportion of trials correct. We expect that piglets will acquire the ability to use extra-visual cues to locate the milk reward, demonstrated by decreased latency to choice and increased proportion trials correct. In the object recognition test, piglets will be exposed to two similar objects, wait for a ten-minute interphase interval, and then be exposed to one familiar and one novel object. Time spent interacting with each of the objects will be measured, and memory involved in distinguishing between familiar and novel objects will be tested. We expect that piglets will spend more time with the novel object over the familiar object. Together with the social recognition test and the open field test, these two behavioral tests will contribute to further understanding piglet learning, memory, and overall cognitive abilities.

The Gendered Risorgimento: How Wealthy British Ladies Ended Up Campaigning for Italian Unification

Zoe Condon
Prof. Steven Soper, History, Franklin College of Arts & Sciences

This project analyzes the varied political involvement of aristocratic British women in Italian unification efforts during the Victorian reformist era. The goal is to show that women did not simply hold back from the political arena, but they were, for the most part, not on the front line of debate either. Instead, women had a variety of political experiences in their efforts with the Italian campaign, spanning from pamphlet writing and public speaking endeavors to more traditional concepts of female political participation like hosting charitable events. The research was done by examining and analyzing letters and correspondence between wealthy women and members of liberal pro-unification entities, which demonstrate women played a major role in publicizing and contributing to the British efforts in the Risorgimento. This paper argues that British women played a critical role in political reform campaigns.

The Effect of Shield Laws on Journalists Acting as Investigators, Specifically at Public Universities

Aaron Conley, CURO Honors Scholar, CURO Summer Fellow
Dr. Barry Hollander, Grady College of Journalism & Mass Communication

In recent years, there has been much debate about the right of journalists to refuse to testify as to the identity of confidential

sources or confidential information collected in the process of newsgathering. Recently, this protection has been brought into the attention of the general public as the result of the case surrounding James Holmes, the now-convicted shooter from the movie theatre in Aurora, Colorado. In the course of the investigation and trial, a copy of Holmes' diary was leaked to Fox News reporter Jana Winter, who published its contents. The State of Colorado attempted to force Winter to reveal the source who leaked the diary, but the courts ruled that Winter was protected by New York's state shield law. One major question that has been prevalent in the debate over shield laws centers on who specifically is protected by these statutes, especially in the case of student journalists. While the United States Supreme Court addressed many questions about the rights of high school student journalists in its decision for *Hazelwood School District v. Kuhlmeier*, there has been no effort to address the rights and protections that should be afforded to journalists at public universities. By examining the various state shield statutes that have already been established, the proposed Free Flow of Information Act of 2013, as well as other academic sources and court precedents, it can be seen that in many cases collegiate journalists are not afforded the protection under the law that they should rightfully receive.

Fracking Governance and Resistance in Western North Carolina

Julia Connell, CURO Research Assistant
Elizabeth Wilkes
Dr. Jennifer Rice, Geography, Franklin College of Arts & Sciences

Hydraulic fracturing (fracking) is largely unregulated at the federal level and is exempt from nearly all federal environmental laws, leaving individual states and localities to regulate the industry. This fragmented landscape of regulatory responsibility has resulted in limited spaces to contest whether or not fracking should be permitted. Our research attempts to determine the spaces and practices of opposition that are possible under neoliberal forms of fracking governance. Using theoretical insights on the nature of democracy, we examine an anti-fracking movement in western North Carolina, one of the only such movements in the United States to coalesce before drilling had started. We argue that contemporary forms of democracy under neoliberalism limit resistance and activism to what we call "micro sites" of contestation. These include: letters to the editors in local newspapers; landowner rights workshops on fracking; local government resolutions against fracking; and the Mining and Energy Commission (MEC) hearing on the rules that permit hydraulic fracturing. This research contributes literature on state theory and environmental governance by showing the ways in which resistance is focused into narrow spaces of dissent under neoliberal governance.

Psycho-Social Impact of Drone Strikes on Non-Combatant Populations: The Cognitive Mechanism Underlying Pro-Group Endorsement of Extremist Violence

Laura Courchesne, Foundation Fellow
Dr. Jeff Berejikian, International Affairs, School of Public & International Affairs

This research examines the impact of drone strikes in influencing the perceptions and decision-making processes of civilian populations. It presents a critique of the traditional view that drones help protect soldiers by reducing the need for on-the-ground action in a conflict. By contrast, it contends that drones help produce a communal identity as well as a preference towards group ideology and extremism among previously non-militant actors. This argument relies on a neurological, psychological, and anthropological understanding of trauma and

anxiety, modeled around the theory of modes of religiosity, to illustrate the potential harm drone strikes can have in aiding militant recruitment efforts. As a result of the trauma they create, drone strikes are able to alter the behavior of population members, who might not normally endorse or join a violent organization, towards pro-group behavior. This can take the form of a shift in moral values and/or the promotion of extreme actions in protection of the group. The emotional response drones elicit and the subsequent psychological changes which occur lead to improved recruitment and support of militant efforts. To support this causal relationship, the paper will present a cognitive mechanism, based on the trauma's successive influence on mental functioning, sense of group identity, and capacity for moral decision-making. This research utilizes case studies on collective experiences of violence and trauma, including disasters, terrorist attacks, religious rituals, and gang initiations, to illustrate the explanatory power of this mechanism.

The Psychology of Nazism and Genocide: The Role of Religion and Symbolism
Laura Courchesne, Foundation Fellow
Dr. David Williams, Religion, Franklin College of Arts & Sciences

The Holocaust is a widely studied historical example of the consequences of uninhibited intergroup aggression and explicit targeting of a particular community on the basis of a shared characteristic. This research provides a review of relevant literature examining the Holocaust as a case study in understanding the psychological, economic, cultural, and religious factors which contribute to group aggression. It places particular emphasis on what leads an individual to accept the violent and discriminatory ideologies of a group, with an interest in applying a psychological understanding of in-group/out-group biases as well as investigating the role of religion and ideology in fostering pro-group sentiments. It offers an understanding of the factors which instigate intergroup violence and genocide as well as the psychology of individuals involved in genocides. This research explicitly focuses on how religion and cultural mythology within German society acted as a structure which inspired the promotional and ideological tactics of the Nazi party in promoting antisemitism. It provides an overview of the theoretical basis of ethnic conflict and genocide while highlighting the importance of evoking certain emotions in a populace through the use of symbolism, mythos, and religion.

Optimizing Plique-à-Jour Enameling
Melissa Cousins, Ramsey Scholar, CURO Summer Fellow
Prof. Mary Pearse, Lamar Dodd School of Art

My research examines the current methods of plique-à-jour enameling and looks at what is actually beneficial to the final piece of enamel. The modern techniques for many styles of enameling are counterintuitive and contradictory, and the long-winded process and delicacy required by these methods tends to turn people away from this style of enamel. I am looking at each step of the process and determining which are helpful, which do nothing, and which are detrimental. My hopes are to come up with a more streamlined method of plique-à-jour to make it more accessible and less difficult to produce. The methods I am using include visual comparisons between samples made using washed, sifted, washed and sifted, and unwashed and unsifted enamels; experimenting with different firing temperatures, firing times, and framework constructions; trying out mosaic work, mica inclusions, and painting for creating shading or pattern; testing if wet firing produces subpar results in comparison to dry firing; and figuring out the maximum size of a cell when using the surface-tension technique for

making a piece of plique-à-jour. All tests are done with unleaded enamels and do not necessarily reflect the properties of leaded enamel. My results have shown that unwashed, sifted enamel works best; a gradual increase in firing times will produce good results without harming a soldered framework; wet firing works just as well as dry and saves time. Tests on pattern making and cell size are still being conducted.

Heterologous Expression of Carbohydrate Utilization Genes from *Acidothermus cellulolyticus* in *Caldicellulosiruptor bescii*

David Cowan, CURO Graduation Distinction
Dr. Janet Westpheling, Genetics, Franklin College of Arts & Sciences

Current energy sources are unsustainable in the long term as well as being very detrimental to the environment; therefore, our future energy production will need to be both sustainable for the long term as well as being environmentally friendly. Lignocellulosic biomass including corn stover, sugar cane, wood, straw, and waste residues from agriculture and forestry is a promising resource for producing fuels and chemicals. Dr. Jan Westpheling's lab has introduced two xylanases (Acel_0180 and Acel_0372) from *Acidothermus cellulolyticus* into *Caldicellulosiruptor bescii*'s secretome in order to increase the species' ability to degrade plant biomass, particularly xylan. The effects of these introductions were determined by comparing growth on cellobiose and xylan substrates, and conducting xylanase activity assay. The results from these experiments showed a modest increase in the activity of the secretome but a dramatic increase in growth on xylan. The most striking result was the viable cell numbers obtained when growing cells on complex xylan substrates. *C. bescii* strains overexpressing Acel_0180 or Acel_0372 xylanases were viable after 36 h cultivation on oat spelts xylan, while neither control strain could. In addition, both strains with xylanase exhibited 32.7 and 15.5 folds higher viable cell numbers on birchwood xylan than that of the control strain. These results show an important step in biofuel research, as cells from the end of one batch are used as inoculum for the next batch to reduce cost and also xylose is one of the most abundant sugars in lignocellulosic biomass.

The Effects of Serum Dietary Carotenoid Levels on Cognitive Function in Healthy Adults

David Cromer, CURO Research Assistant
Eli Chlan
Dr. Lisa Renzi, Psychology, Franklin College of Arts & Sciences

Past research suggests that dietary carotenoids such as lutein (L) and its isomer zeaxanthin (Z) are capable of improving cognitive function in a wide variety of participants across the lifespan (e.g. Renzi et al, 2013). L and Z are known antioxidants that have been cited previously for their ability to reduce risk for central nervous system (CNS) degenerative diseases such as age-related macular degeneration (e.g. AREDS-2 Research Group, 2013), which has been linked to other CNS diseases, such as Alzheimer's disease (e.g., Sivak, 2013). These carotenoids are not the only carotenoids that cross the blood-brain barrier, nor are they the only antioxidants frequently consumed in the human diet. Whether or not these other carotenoids are as impactful as L and Z in cognitive function is currently unknown. The purpose of this thesis is to relate serum concentrations of alpha-tocopherol, retinol, beta-cryptoxanthin, and alpha-carotene to cognitive function in adults between ages of 18-90 years. Cognitive function was measured through a computerized cognitive inventory that includes measures such as processing speed, cognitive flexibilty, and other related factors. In order to measure serum carotenoids, 5 mm of whole blood was collected via venipuncture. Serum was

separated via centrifugation and was frozen at -80-deg C until it could be analzed via high-performance liquid chromatography (HPLC). Analysis is currently ongoing, and final results will be presented at the symposium.

The Role of Flagellar Motility in *Pseudomonas aeruginosa*-induced NET Formation

Christian Cullen
Dr. Balazs Rada, Infectious Diseases, College of Veterinary Medicine

Cystic fibrosis (CF) is a disease caused by a mutation in the cystic fibrosis transmembrane conductance regulator (CFTR) anion channel, resulting in severely impaired mucociliary clearance in the airways leading to chronic bacterial infections. *Pseudomonas aeruginosa* is the main CF respiratory pathogen responsible for large-scale neutrophil recruitment in the airways. Neutrophils fail to clear *P. aeruginosa*. Instead, they release granule cargo and DNA into the airway lumen causing tissue damage. The mechanism of neutrophil dysfunction in CF airways is unknown and of high clinical relevance. Neutrophil extracellular traps (NETs) represent a novel antibacterial mechanism of neutrophils when they release DNA associated with histones and granule components. *P. aeruginosa*-induced NET formation occurs in CF airways and offers a likely mechanism for neutrophil-mediated lung damage. Therefore, understanding its details is of potential clinical relevance for CF. Previously we had shown that bacterial flagellum is essential to induce maximal NET release in neutrophils. Recently, we found that bacteria with motile flagellum trigger significantly more NET release than *P. aeruginosa* with immotile flagella. To reveal the mechanism of this unexpected finding, we measured *P. aeruginosa* phagocytosis by neutrophils and found that immotile bacteria are not getting phagocytosed as efficiently as their motile counterparts. From our work, we propose that bacterial motility is the primary virulence determinant responsible for triggering NET formation by enabling *P. aeruginosa* and neutrophil encounters. Our work adds to current literature by distinguishing bacterial motility from the presence of flagellin protein, and proposes to target proteins driving flagellar motility as CF therapeutics.

Lesbian, Gay, and Bisexual Employment Protection: An LGB-Inclusive Argument for Title VII Sex Discrimination

Bryson Culver, CURO Honors Scholar
Prof. Alex Reed, Insurance, Legal Studies, and Real Estate, Terry College of Business

The 1964 Civil Rights Act provided various protections for millions of Americans based on their race, color, national origin, religion, and sex. In Title VII of the act, this action takes the form of employment protection. While the language of the legislation is very short and simple, the application of the law has grown to cover a wide range of sex-related aspects. As our understanding of sex and gender grow, so does the protection provided to it. Since 1989, this law has been interpreted to include protection against the many aspects of sex beyond a simple gender difference. Initially, the Supreme Court decision Price Waterhouse v. Hopkins added protection against the stereotypes employers may have about sex. A decade later, another Supreme Court decision protected against sexual harassment from someone of the same gender. These two ideas laid a foundation so that other atypical gender expressions could be protected. Transgenders, lesbians, gays, and bisexuals have had success in Federal Appellate and District courts by claiming their non-conforming sexual orientation should be protected under Title VII. In 2015, the Equal Employment Opportunity Commission endorsed these expanded uses of Title VII in its investigations into employment conduct.

Abstracts

The Genetic Network of Circadian Rhythms in *Neurospora crassa*

Sarah Cunningham, CURO Graduation Distinction
Dr. Jonathan Arnold, Genetics, Franklin College of Arts & Sciences

Many genes of *Neurospora crassa* are under the control of the biological clock in the cell. The clock consists of a closed network loop of the genes, *white collar-1 (wc-1)*, *white collar-2 (wc-2)*, *frequency (frq)*, and *clock controlled genes (ccg)* and their RNA and protein products. A model has been proposed for the network regulating these interactions that improves upon published models by differentiating between reactions in the cytoplasm and nucleus of the cell. Markov Chain Monte Carlo runs were used to test theseis models with published RNA and protein accumulation data and refine the model's parameters. The model ensemble created was found to fit experimental data collected from *Neurospora* statistically similarly to previously published models. This model was also expanded upon to include genes regulating the clock's ability to entrain to light and tested against other light entrainment models. A better model could improve research done on all areas of the clock and further our understanding of circadian rhythms in *Neurospora* and all other organisms with a circadian clock.

Pharmacological Inhibitors of Epigenetic Mechanisms Alter Liposome Uptake

Isha Dabke, CURO Research Assistant
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

In recent years, there have been rapid advances in the understanding of epigenetic mechanisms, which include histone modifications and DNA methylation. These mechanisms, in addition to other transcriptional regulatory events, ultimately affect gene activity and phenotypic expression without physically altering the nucleotide sequence of the DNA itself. Similarly, the potential of liposomes as drug deliverer devices has also gained significant attention in the scientific sphere. Liposomes are amphipathic molecules and have proven to show an improvement in the therapeutic index of new or established drugs by modifying drug absorption, reducing metabolism, prolonging their own biological half-life, and reducing unwanted side-toxicity. The goal of this study is to determine the effects of epigenetic drugs (DNA methylation inhibitor *5-aza-2'-deoxycitidine* and histone deacetylation inhibitor *Trichostatin A*) on liposome uptake in an *in-vitro* cell culture. The hypothesis of this project is that reversing epigenetic changes in cancer cells will enhance the drug-encapsulated liposome uptake in prostate cancer cells. The first step of this two-part liposomal drug delivery project is presented here: cell culture techniques, selection of the drugs used, and MTT analysis of the treated cells at 24-hour and 48-hour time periods. After quantification of cells and compilation of the data from the trials presented in this paper, it was determined that higher concentrations of the selected drugs show a decrease in cell proliferation at the given time periods. Consequently, the experiments presented here in Part I will be built upon next semester in Part II—the actual formulation and encapsulation of the liposomes.

Neural Network Formation and Response to Pharmacological Stimulation

Tarun Daniel, Foundation Fellow
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Recently, efficient testing platforms for developmental neurotoxicant (DNT) screenings have been increasingly achieved through the use of the micro-electrode array (MEA) system, which is a tool that allows researchers to monitor complex spatial and

temporal patterns of neural network firing. Electrophysiological monitoring with the MEA provides the opportunity to observe the organization and response of an entire neural network to pharmacological reagents or neurotoxicants. MEAs provide a cost and time-efficient alternative to *in vivo* DNT testing. The electrophysiological activity recorded can be used to monitor the changes caused by dosage of pharmacological reagents, as different pharmacological reagents will produce a characteristic effect on the pattern of activity such as changes in mean firing rate and other burst parameters. This work will examine the response of stem cell derived mouse motor neurons to bicuculline and lindane, providing a foundation for future testing of many different reagents and solidifying a new model for DNT screenings.

Regulatory Pathway of X-Polymer Formation in *Bacillus* Species

Lauren Davis
Dr. Maor Bar-Peled, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

We recently identified a polysaccharide, named X-polymer that is made when certain *Bacillus* species are grown in a defined medium. While clarification of the chemical structure of the glyco-polymer is ongoing, I am investigating potential genes that are involved in the regulation and production of X-polymer in my research. To do this, I am examining wild type and mutant strains of *Bacillus* species known to produce this polysaccharide that are impaired in signaling, phosphorylation, or stress responses. The detection of the polysaccharide in these strains is carried out in several steps. First, the crude X-polymer is isolated from the cells and hydrolyzed to monosaccharides. Then, the sugars are reduced and alditol-acetate derivatized to volatile compounds. These sugar-derived compounds are separated by gas-chromatography and analyzed by mass spectrometry (GC-MS). This method allows us to quantify the relative amount of sugars that are composed of the X-polymer and determine if none, normal, or higher amount of the X-polymer is made in the various mutant lines. In my poster I will provide examples of genes involved in the regulation of this metabolic pathway.

A Systematic Review of Adverse Effects Resulting from Administration of Propofol in Domestic Dogs and Cats

Lauren Dempsey, CURO Research Assistant
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Propofol, a sedative-hypnotic akyl phenol, is widely used in both induction and maintenance of veterinary anesthesia. It is known for being helpful for its ability to produce unconsciousness in a patient within as little as 30 seconds while also decreasing incidence of postoperative nausea and vomiting when administered with any anesthetic drug. However, when used for induction and administration, anesthetic-related adverse effects can appear. The objective of this systematic review was to identify the most common adverse effects when propofol was administered and the amount of propofol administered, compare the adverse effects with other factors regarding the anesthetic procedure such as its rate and if it was co-induced with another agent, and observe the difference in the occurrence of specific adverse effects between dogs and cats. This study can be used by anesthesiologists as a reference for the potential adverse effects that could occur with the administration of propofol. A comprehensive search of research literature was performed using Pubmed, CAB Abstracts, and the University of Georgia's library system from September 2015 to December 2015. The most common adverse effect observed with the administration of propofol was apnea. Other fairly common

adverse effects observed were bradycardia, hypotension, pain on injection, tachycardia, and increased motor activity. It is anticipated that there is a correlation between the administration of propofol in cats and dogs and the number of adverse effects that occur.

Extracellular Vesicle Dependent Transfer of a Virulence Factor Confers Human Infectivity to *Trypanosoma brucei brucei*

Lauren Dennison, Foundation Fellow, CURO Research Assistant
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosoma brucei rhodesiense is the causative agent of human African sleeping sickness. The related subspecies *Trypanosoma brucei brucei* is able to establish infection in cattle, but is highly susceptible to lysis by a subclass of human high-density lipoproteins called trypanosome lytic factor (TLF) and therefore unable to cause human African trypanosomiasis. *T. b. rhodesiense* is resistant to TLF due to the serum resistance-associated (SRA) protein, a virulence factor localized to the parasite endosome that binds and inhibits TLF following endocytosis. Recently our lab has shown that African trypanosomes produce nanotubes that arise from initial budding of the flagellar membrane and vesicularize into heterologous 80 nm extracellular vesicles (EVs). Mass spectrometry analysis showed these EVs are enriched in flagellar proteins that contribute to virulence, and western blot analysis showed that *T. b. rhodesiense* EVs contain SRA protein necessary for human infectivity. Additionally, co-cultivation of *T. b. brucei* and SRA expressing *T. b. rhodesiense* in a trans-well chamber which blocked direct cell-cell contact but allowed EV diffusion conferred TLF resistance to *T. b. brucei* suggesting EVs play a role in disease pathology. In an effort to understand the function of EV mediated secretion during host infection, we show that upon incubating SRA expressing cells with TLF, EVs purified from the cells now contain TLF proteins. The detection of TLF proteins in EVs is cell dependent, as TLF could not be detected in EVs incubated with TLF alone. This suggests vesicle mediated secretion provides a mechanism of protein efflux, which may play an important role in trypanosome survival in the host.

Influence of Intelligence on Correlation between Personality and Recreational Marijuana Use

Ketki Desai, Luvika Gupta
Dr. Lawrence Sweet, Psychology, Franklin College of Arts & Sciences

Recreational marijuana use prevention and cessation programs emphasize identification of personality traits and cognitive factors that increase the individual's risk for use. Previous research indicates that initiation and frequency of marijuana use are associated with specific personality traits and intelligence. A better understanding of how these risk factors influence use behavior would enhance personalized treatments. The aim of this study is to examine the premise that certain personality traits correlate with marijuana use while controlling nicotine dependence severity, and to determine if intelligence moderates this relationship. Data was collected from 90 rural nicotine dependent cigarette smokers who completed personality and intelligence assessments. Personality traits of interest include neuroticism, conscientiousness, and openness from the Neuroticism-Extraversion-Openness Five-Factor Inventory (NEO-FFI). The Wechsler Test of Adult Reading (WTAR) was utilized to assess intelligence. Self-report measures were administered to assess recreational marijuana use frequency and nicotine dependence severity. Based on prior literature, it is predicted that high frequency of marijuana use will correlate with high neuroticism, low conscientiousness, and high

openness. It is further predicted that intelligence will moderate these relationships. The results are expected to increase understanding of the psychological processes involved in marijuana use initiation and maintenance, which may allow prevention and cessation programs to tailor interventions based on a patient's individual personality and cognitive function.

Addressing Severe Mental Illness of Atlanta's Chronically Homeless
Kaley Desher, CURO Research Assistant
Dr. Nathan Hansen, Health Promotion & Behavior, College of Public Health

The widespread prevalence of severe mental illness among the chronically homeless in Atlanta, Georgia is high; there are 1,322 individuals suffering from chronic homeless as of 2014. An expected 60% of these people are predicted to have a severe accompanying mental illness such as schizophrenia, depressive disorder, bipolar disorder, and/or post-traumatic stress disorder. Most of these individuals are not receiving any treatment. The social and economic consequences of this problem are dire. The debilitating symptoms associated with these disorders drastically diminish these individuals' quality of life and potential to contribute to society. Furthermore, the government incurs significant costs by the overuse of services, such as emergency room visits, hospitalizations, shelter stays, and incarcerations that is characteristic of this demographic. In order to mitigate these negative effects, the City of Atlanta should form a contract with a coalition of local nonprofit organizations working on mental illness and chronic homelessness in the city in an attempt to maximize their impact.

The Influence of Social Conversation Case Study: Iran Nuclear Deal
Samuel Dickinson
Dr. Itai Himelboim, Grady College of Journalism & Mass Communication

When it comes to international public opinion, influence takes the form of a trifecta: governments and non-governmental organizations, traditional media coverage, and grassroots activity. Social media, a relative newcomer, has only recently enjoyed the power to influence public opinion as a result of the widespread and strategic social network involvement of all three actors. The increasing relevance of this new media warrants a case study analysis measuring the scope of its sway and the interplay among key stakeholders. The Iran Nuclear Deal, a highly visible and politically-charged agreement, is proposed here as a case study, examining the role of each trifecta segment in sparking and sustaining conversation using Crimson Hexagon—a social listening tool. In doing so, we will outline the relationship between social media commentary and more cemented information outlets, providing an outline of observed trends that will serve as a comparison for future research.

Oral Histories of the Vazov Machine Works
Iva Dimitrova, CURO Summer Fellow
Prof. Callie Holmes, Richard B. Russell Library for Political Research and Studies

I researched the history of the Vazov Machine Works (VMZ, in Bulgarian) in the city of Sopot, Bulgaria using oral history methodology. I conducted a series of interviews with previous workers to better understand the defense plant's social and economic role in varying scopes, extending from the local to the regional and national. Interviews were recorded using a Zoom H5 recorder and were structured as one-on-one conversations where I acted as the interviewer. Questions pertained to the participants' early life, their work at the plant, and other personal experiences and

reflections. While the workers described the plant through their personal experiences, their work life was directly affected by the larger trends of the economy and the government of Bulgaria, especially after the democratic transition starting in 1990. By comparing responses across interviews, I was thus able to draw larger conclusions about the effect of notable events, trends, and perceptions on local history, as experienced by individual people. While these interviews highlighted VMZ's historical significance, they also raised the concern of anonymity. As a response to this concern, the original scope of my project changed to exclude the photographic and visual materials I had initially recorded, and only include audio interviews, edited to remove personally-identifying information. In addition, I have worked to transcribe the transcripts into Bulgarian and translate them into English to be accessible to multiple audiences.

A Study of Transposon Movement in *C. bescii*

Jessica Dinsmore, CURO Graduation Distinction
Dr. Mike Adams, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

As our oil reserves are depleting, scientists are searching for alternative fuel sources. A promising renewable fuel source is cellulosic biofuels. Consolidated bioprocessing (CBP) is a potential strategy of generating these biofuels in an economically feasible way. CBP involves using genetically engineered organisms to convert biomass into ethanol in a single step. *Caldicellulosiruptor bescii* is an excellent candidate for CBP as it is the most thermophilic cellulolytic microbe known. While *C. bescii* does not natively produce ethanol, previous studies have demonstrated that *C. bescii* can be engineered for ethanol production. As with any organism used for industrial purposes, *C. bescii* must have a stable phenotype. Recently, transposon activity has been observed within strains of *C. bescii*. Because these transpositions could compromise the integrity of the desired phenotype, we are interested in determining whether this high rate of transposon activity is a native phenomenon in *C. bescii* or whether it has arisen due to the procedures used to isolate certain strains. The purpose of this study is to monitor the activity of transposons within *C. bescii* as well as to determine the parent strain responsible for this high rate of transposon activity. We will use southern blots to observe and compare the locations of the transposons within various strains, including those with documented transposon movement, wild type *C. bescii*, and strains isolated in a different manner. We will also grow wild type *C. bescii* under a variety of stressors to determine if high transposon movement is native to *C. bescii*.

Engineering Soybean Mosaic Virus Resistance Utilizing tasiRNA

Andrew Disharoon, CURO Research Assistant
Dr. Wayne Parrott, Crop & Soil Sciences, College of Agricultural & Environmental Sciences

Soybeans, as one of the largest crops in cultivation, are constantly under attack by diseases. One of the most common diseases affecting soybeans internationally is the soybean mosaic virus. Food supply safety is a growing concern that must be addressed through new solutions as old techniques falter in the face of evolving diseases and increasing demand. Gene silencing is a powerful tool that many plants use to regulate their own gene expression. In this case, if gene-silencing could turn off the genes of the invading virus, the plant would be resistant. Even before the causal mechanism was known, genetic engineers have used gene silencing to combat viral disease. With a greater understanding of these silencing mechanisms, genetic engineers can create more efficient ways to induce gene

silencing. One such method is using a specific type of miRNA pathway known as tasiRNA, which is found within crop plants, and using it to induce the desired silencing. By placing a tasiRNA 22 DNA recognition site in the front part of the viral DNA, resistance to soybean mosaic virus should be achievable. Accordingly, vectors for silencing the positive sense, negative sense, and a combination of the two strands of the virus were constructed. These events were introduced into Jack soybean tissue to generate transgenic lines for each vector. Events will be phenotyped for disease resistance upon reaching 20 cm in height. It is expected that not only can this approach impart viral resistance to soybean mosaic virus, but also to all other related viruses.

Creating a Pseudo-Random Number Generator Using the Spectral Analysis Test and Genetic Algorithms

Steve Dixon, CURO Honors Scholar, CURO Research Assistant
Dr. Walter Potter, Computer Science, Franklin College of Arts & Sciences

Pseudo-random number generators use pre-calculated mathematical formulas to produce sequences of numbers that appear random. The need for pseudo-random numbers arises for many purposes. The two most important are data security such as ATM cards, computer passwords, and electronic commerce, and the other is modeling and simulation applications such as the programs that predicate the path of cataclysmic weather events. A genetic algorithm is a problem-solving formula that mimics the process of natural selection. Our genetic algorithm generates each individual with its own "genetic makeup". "Chromosomes" are swapped through crossover and/or mutated to breed a new generation of individuals. Individuals with a higher fitness level will "breed" more often. For our experiment, we used the spectral test as fitness criteria. The spectral test returns a number called a P-value between zero and one, with zero being completely non-random and one being completely random. The spectral test works by finding patterns. The harder it is to find the pattern, the more random the sequence is and the higher its p-value. We use this value as the fitness criteria for the genetic algorithm. The purpose of this experiment is to determine if this combination of algorithms would produce a statistically superior psuedo-random number generator.

The Effects of Inclement Weather on Dining Hall Usage

Rutvik Dmello
Dr. Nikhil Srinivasan, Management Information Systems, Terry College of Business

One of the most important things in running any business smoothly is being able to predict the volume with which customers arrive. This is even truer in the service industry, where staffing and resource allocation directly respond to how busy the business expects to be. For the University of Georgia, this problem is best recognized in the dining hall facilities. While there are many factors that obviously impact dining hall usage, one potentially important variable is the weather. Using regression analysis, my research aims to analyze the impact of precipitation on dining hall attendance. The weather information was attained through the website of the Weather Channel. I gathered contemporary dining hall capacity data through a Java program that I created especially for parsing usage information. Historical data were available through the Information Technology Auxiliary Services. After cleaning the collected data through Microsoft Excel, I utilized the R programming language in order to perform regression analyses. In addition to using simple ordinary least squares regressions, I applied the statistical approach of indicator variables. Both of these methods aim to

elucidate the relationship between precipitation and the utilization of dining hall facilities. Beyond analyzing usage in the aggregate, I was able to stratify the data into the individual attendances of the food service locations. I believe after robust statistical scrutiny, my results could be of significant value to the Department of Food Services. This benefit extends additionally to understanding the mechanics behind service industry utilization.

Seeing the Future: Interactive Data Visualization and Behavioral Intentions
Grace Donnelly
Dr. Bartosz Wojdynski, Grady College of Journalism & Mass Communication

This research project seeks to contribute knowledge to our understanding of how design decisions related to the graphical depiction of data and deployment of interactivity influence news consumers' ability to accurately understand health information and make decisions about their behavior. Specifically, a 2 (data presentation: text-only, text and graphics) x 2 (future self-reference: yes/no) between subject experiment was designed to test the effects of using an interactive online life-expectancy calculator on recall, perceived risks, and behavioral intent. An online calculator page was built and developed for this project that allowed users to input their age, gender, and race and receive average life expectancy information based on U.S. data. Participants were then allowed to input indicators of their exercise per week and smoking behavior to gauge the impact of their actions on their future selves. Conditions varied in how participants' life expectancy was communicated to them, and the degree to which the effects of their present-day choices on future outcomes were made explicit. In the experiment, participants (N =100) were randomly assigned to one of four conditions and asked to use an online life expectancy calculator and then answer a series of dependent measures, including recall of information presented, perceived risk perceptions, and behavior intent measures. Data collection is planned for March 2016. The results of the study have implications for best practices in visually communicating quantitative information to audiences in a way that has both affective and cognitive impact.

Caveolae in 3D Neuronal Cell Cultures
Megan Douglass, CURO Research Assistant
Dr. William Kisaalita, College of Engineering

Traditionally, 2D cell-based assays have shown to be unreliable for drug discovery, as they are not predictive of the *in vivo* response. Therefore, significant importance is being given to providing the cells with a 3D microenvironment that more closely mimics *in vivo* conditions. Cells grown in a 3D microenvironment (microtissue) can be characterized by structural and functional biomarkers that are different from their 2D counterparts. The presence of caveolae, which are 60 – 80 nm, cup-shaped invaginations in the plasma membrane, has been well established in many cell types but has not yet been confirmed in cells of neuronal origin. In this study, the presence and functionality of caveolae in neuroblastoma (SH-SY5Y) cells were examined. Transmission Electron Microscopy (TEM) imaging confirmed the presence of invaginated structures in the cells, closely resembling the physical descriptions of caveolae. Subsequently, the functionality of the caveolae was examined by measuring calcium oscillation frequency, which was found to be similar to *in vivo*, in 3D compared to 2D. These findings present a structural and functional biomarker that may be used to confirm the 3D characteristics of neuronal cells and subsequently establish more predictive 3D cell-based assays for drug discovery.

Abstracts

Identification of CRISPR Adaptation Complexes and Associated Nucleic Acids in *Pyrococcus furiosus*

Justin Dumrongkulraksa, CURO Honors Scholar, CURO Summer Fellow
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

CRISPR (Clustered, Regularly Interspaced, Short Palindromic Repeats) loci and their associated genes (Cas) comprise an adaptive defense system in bacteria and archaea. This immune system protects the organism against phages and other foreign genetic elements. Immunity is conferred via the acquisition and incorporation of invader DNA into the CRISPR locus. The locus is then transcribed to produce an RNA complement (crRNA), which guides Cas nucleases in targeted invader DNA or RNA destruction. In the archaeon *Pyrococcus furiosus*, our lab has recently obtained genetic evidence linking four Cas proteins (Cas 1, Cas 2, and Cas4-1 and 4-2) to the function of integration of new invader sequences in a process called CRISPR adaptation. However, the individual roles of each protein in the process are unknown and will be an area of exploration in my research. To examine how each of these proteins functions in the cell, a number of experiments will be performed in order to test whether or not each protein is a member of a larger functional complex. Additionally, the ability of each protein to bind, recognize, or capture CRISPR and invader DNA will be tested. A CRISPR locus sequence called the leader is required for adaptation. As Cas 1, Cas 2, Cas 4-1, and Cas 4-2 are believed to have some role in adaptation, the leader along with invader DNA is expected to be found when these proteins are immunoprecipitated. This finding would provide substantial insight into this relatively new system.

Ecosystem Services and Restoration Efforts of Campus Forests: Tanyard Creek and Driftmier Woods

Dessa Dunn
Dr. Elizabeth King, Odum School of Ecology

Driftmier Woods is a small forest on UGA's campus overgrown with invasive plant species. There are plans to use prescribed grazing by the Chew Crew goats to reduce invasive plants, but they may affect other parts of the ecosystem. The Chew Crew project can therefore provide a living laboratory to study the interactions between land management and ecosystem services, which are benefits provided by the forest. I first compiled a portfolio of potential ecosystem services and hypothesized goat impacts. Then I focused on ecological roles of leaf litter and English ivy, an invasive plant that covers the ground in parts of Driftmier Woods. While goats consume English ivy, their hooves can disturb soil and leaf litter, lowering soil stability and risking water erosion. To study goat impacts on leaf litter, I first studied the Chew Crew's current site, Tanyard Creek, by comparing quantity and size distribution of leaf litter particles inside and outside goat exclosures. I then assessed potential impacts of goats versus hand removal of ivy at Driftmier Woods. In a non-grazing area, I set up plots in which I removed ivy manually, simulated goat browsing by plucking leaves, or left the ivy as a control. I measured litter, soil moisture, and litter decomposition rates in each plot. Goat impacts on leaf litter at Tanyard Creek proved statistically insignificant, and results from Driftmier Woods are forthcoming. Combined, these studies help assess the Chew Crew's impacts and provide a base for future students to study forest ecosystem services on campus.

What is a Sticking Event in Classical Molecular Dynamics? A Study of Hydrogen Sticking to Amorphous Water-Ice

John Dupuy
Dr. Phillip Stancil, Physics & Astronomy, Franklin College of Arts & Sciences

Gas-grain and gas-phase reactions dominate the formation of molecules in the interstellar medium (ISM). Gas-grain reactions require a substrate on which the reaction is able to occur. The formation of molecular hydrogen in the ISM is a prime example of a gas-grain reaction. In these reactions, an atom of hydrogen will strike a surface, stick to the surface, interact with the molecular structure of the substrate (in this case water), find another H atom, form molecular hydrogen, and then be ejected from the surface. We perform classical molecular dynamics (MD) simulations of hydrogen atoms sticking to an amorphous water-ice surface. This study examines the first step in the process, the sticking of the hydrogen atom to the substrate. We present here possible criteria for sticking and detail on how we arrived at those criteria.

Financial Education in Georgia Public Schools and its Impact on Students' Financial Behaviors

Ana Duron-Fleck, CURO Honors Scholar
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

In the state of Georgia, public high school students are required to take an economics course with a personal finance section in it in order to graduate from high school. In this project we are focusing on whether or not the class taken in high school had any significant impact on the students' financial behaviors. Two data sets are used in this study. The surveys were conducted online and consisted of 463 students, 111 of which were seniors and 352 of which were freshman. Questions were asked about their financial education in high school and whether or not they benefited from the experience. In addition, the surveys were intended to gather information about the students' current financial behaviors. An example of this is whether or not the student owns a credit card they are responsible for or if they are responsible for any loans. It will be interesting to see whether or not the students' experiences in the high school course have a significant impact on students' monetary habits and whether or not they even recall the information they learned while taking the course. We hope to see that the course has had an impact in students' financial lives. However, in the senior data set, we expect to see that the students no longer recall the content learned in their personal finance course.

Abundance of *Vibrio* Bacteria Associated with White Pox Disease in Elkhorn Corals

Martinique Edwards, CURO Research Assistant
Dr. Erin Lipp, ENVIRONMENTAL HLTH SCI -- Public Health

Caribbean coral reefs have declined by 80% over the past decade in part due to the spread of marine diseases. Corals host a mutualistic bacterial community in their surface mucus that serves as protection against pathogenic microbes. This bacterial community may be altered in favor of pathogens when the coral becomes stressed, for example by elevated temperature. Of particular interest are the *Vibrio* bacteria, which are ubiquitous in coastal waters and are implicated in six of twenty coral diseases described. We are studying the critically threatened Caribbean elkhorn coral, *Acropora palmata*, the only species known to succumb to white pox disease. We hypothesize that there is an increased relative abundance of *Vibrio* bacteria on disease lesions compared to the surface mucus of healthy corals. To investigate, we extracted the total bacterial DNA from 4-ml samples (n=5-6) of coral mucus and surrounding water. We then performed quantitative PCR (qPCR) on the bacterial DNA with *Vibrio*-specific primers and non-specific bacterial primers to enumerate both the *Vibrio* population and the entire bacterial community throughout all samples. We will calculate the

ratio of *Vibrio* cells to the total number of bacterial cells and expect a higher ratio of *Vibrio* to total bacteria in samples taken from disease lesions. Researching the population dynamics of *Vibrio* on diseased corals will help elucidate the driving force behind coral disease and decline. If diseased corals are found to be a reservoir for *Vibrio* bacteria, then the biochemical interactions between *Vibrio* cells and coral mucus should be investigated.

Comparative Analysis of Soil Organic Matter Fractionation in Ultisols

Rachel Ehlinger
Dr. Alexander Cherkinsky, Geology, Franklin College of Arts & Sciences

Soil organic matter is one of the largest reservoirs of carbon on earth, containing more carbon than the atmosphere itself. Fractionation and accelerator mass spectrometry are used to study the turnover of soil organic matter carbon from its initial state in the biosphere to its decay in the atmosphere. In this study, we separated microaggregates from Ultisol soils collected in the Calhoun Critical Zone of South Carolina. These microaggregates were separated into heavy and light fractions through physical fractionation methods. The heavy fraction is depleted of organics, while the light fraction is enriched with organics. We then took these samples for AMS radiocarbon dating in order to analyze the turnover rate of each fraction. With this analysis, we are able to interpret the turnover rate of carbon for each fraction. Our results allow us to conclude that the heavier organically depleted fraction has a slower turnover rate and is therefore better preserved in the environment.

Deficiencies and Improvements to Mental Health Institutions in Georgia

Joseph Elengickal
Dr. Leonard Martin, Psychology, Franklin College of Arts & Sciences

A major issue with inpatient mental health institutions is that patient visits can be traumatic. This is because mental health institutions do well at their intended function, keeping suicidal patients alive until their doctors find a sustainable medication type and dose, but inpatient programs do very little past that. Many inpatient programs do not have legitimate methods for coping therapy and rely solely on preliminary therapy. In addition, the relationship between nurses and patients is tense due to the hierarchal structure of the hospital as well as the lack of oversight. While inpatient programs fulfill the status quo, policy change is necessary because many patients do not attend other therapy programs after their inpatient stay, thus making their limited time valuable. In order to examine this situation, the laws related to mental health institutions on the local, state, and national level will be analyzed. Furthermore, research into how other states and countries run their mental health institutions may lead to useful insight into how to improve Georgia's institutions. Also, data collected from past patient visits will reveal trends that may lead to viable solutions to the problem. This research hopes to attain multiple policy solutions that strive to solve problems related to mental health institutions.

Evaluation of Yield and Essential Oil Content of Holy Basil Varieties

Nicole Encardes, CURO Research Assistant
Prof. David Berle, Horticulture, College of Agricultural & Environmental Sciences

Holy basil (*Ocimum tenuiflorum*) is an important medicinal plant that has been associated with decrease in stress, regulation of metabolism, and reduction of inflammation. In many cultures it is used as a tea. The study evaluated yield and essential oil content of *O. tenuiflorum* varieties to determine the best for commercial production. Plants from 14 holy basil varieties were selected from commercial catalogs and the USDA Germplasm systems. Plants were

grown in the field, harvested, and biomass recorded before and after drying. Essential oils were extracted from each sample by hydrodistillation. Varieties were ranked using an index score that was a combination of yield and essential oil content per plant. The top five yielders included both USDA and commercial varieties, including PI288779, Amrita, PI652059, PI652057, and Kapoor. Results indicate an inverse relationship between biomass yield and essential oil content, suggesting that growers should not use biomass as the sole characteristic for variety selection.

Analysis of Hybridization in Chattahoochee Bass (*Micropterus chattahoochae*) Populations below Lake Lanier

Guy Eroh, Foundation Fellow
Dr. Byron Freeman, Odum School of Ecology

Maintenance of fish species diversity is intrinsically and ecologically valuable, but challenging in areas where cross-stocking of ecologically similar species occurs. The Chattahoochee bass (*Micropterus chattahoochae*) is a cryptic species that is difficult to distinguish visually from other closely related species of the genus *Micropterus* (black basses). *M chattahoochae* is endemic to the Chattahoochee watershed in Northwest Georgia where several other black bass species have been stocked. These introduced species pose threats to the Chattahoochee bass through competition and interbreeding. In order to determine if pure populations of *M. chattahoochae* remain in tributaries of the Chatahoochee River below Buford Dam, this study analyzed the genetic identities of several populations of bass below Lake Lanier. Bass samples were taken by electrofishing or rod and reel angling from the Chattahoochee River and tributaries including Hillabahatchee, Snake, and Whooping Creeks. Specimens were also collected from the Maricao River in Puerto Rico, where a population has been established. DNA was extracted from fin tissue and amplified using polymerase chain reaction. To evaluate hybridization in the *M. chattahoochae* populations, a nuclear (ITS2) and a mitochondrial (CO1) gene were sequenced and compared to known *Micropterus* species sequences. Additionally, six microsatellite loci (known to cross amplify and discriminate between related species) were amplified and analyzed. Analysis of microsatellites and nuclear and mitochondrial DNA will identify fish hybridization and backcrossing in these Chattahoochee bass populations.

MGMT Expression in Canine Glial Tumors

Erika Evanoff, CURO Research Assistant
Dr. Elizabeth Howerth, Pathology, College of Veterinary Medicine

This study is being conducted in order to investigate whether or not canine glial tumors express the MGMT protein and if these tumors have hypermethylation within their MGMT promoter region, as these may be indicators of a positive response to cancer treatment with temozolomide. Formalin fixed paraffin embedded tissue from canine glial tumor tissues (oligodendrogliomas and astrocytomas) submitted to the College of Veterinary Medicine Department of Pathology and Athens Veterinary Diagnostic Laboratory from 2005-present were evaluated. Twenty-two glial tumor tissues were tested for MGMT protein expression by immunohistochemistry (IHC). In order to prepare for the methylation-specific PCR portion of this study (to be performed in Spring 2016), genomic DNA from the tissues was isolated and bisulfite conversion of the DNA was performed. Findings from IHC reveal that high-grade glial tumors had the greatest amount of MGMT protein expression with 5 out of 11 (45.5%) having positive staining. In contrast, low- grade oligodendrogliomas and astrocytomas all had

negative staining results. In Spring 2016, methylation-specific PCR will be performed in order to determine if there is a correlation between MGMT protein expression and MGMT promoter region methylation.

Best Practice for Informing Parents of their Newborn's Disability

Allison Fialkowski, CURO Honors Scholar, CURO Summer Fellow
Dr. David Gast, Communication Sciences & Special Education, College of Education

Bad news is news that "drastically and negatively" changes a person's perception of his or her future providing "a feeling of no hope... a risk of upsetting an established lifestyle" (Buckman, 1992; Bor, Miller, Goldman, & Scher, 1993, p.70). This research studies the disclosure of what most families perceive to be devastating news - a disability of their newborn. Because physicians are the primary messengers of this challenging news, medical schools and continuing education services must train physicians in the central considerations that lead to the most positive disclosure process when informing parents of their newborn's disability (Harnett, 2007, p.92). After reading literature concerning best practice for informing individuals, analyzing a physician's training, and understanding the specific concerns and circumstances of families with a newborn with a congenital disability, I identified the central considerations that physicians must make throughout this disclosure process. By addressing these concerns, physicians can ensure a positive experience that prevents parents' distress and anxiety, fosters a strong relationship between the parents and professionals, and assists in attachment between the parents and child.

Characterization of a Muconic Acid Biosensor-Reporter System in *E. coli*

Tyler Fischer, CURO Research Assistant
Dr. Yajun Yan, College of Engineering

Over the past decades, metabolic engineering has proven its superiority on the microbial production of valuable chemicals such as biofuels, pharmaceuticals, nutraceuticals, and materials. To build microbial cell factories that efficiently convert a feedstock into a desired product, metabolic engineers have developed several strategies to direct the intracellular metabolites into the exogenously introduced pathways, including overexpressing rate-limiting enzymes, blocking competing pathways, and bypassing native regulations. However, the directed metabolite fluxes generally resulted in metabolism imbalance which would inhibit cell growth and decrease production in heterologous pathways when the engineered enzymes or intermediates accumulated toxic levels. To monitor the metabolic status of the engineered pathway in real time, Dr. Yajun Yan's laboratory is focusing on creating a transcription factor-based biosensor to alleviate the imbalance metabolism. Transcriptional factors (TFs) are natural sensory proteins that regulate gene expression in response to environmental changes or key intracellular signals which need tight control. They bind to specific DNA sequences in a promoter region to either activate or repress transcription. The DNA-binding activity of TFs can be affected by binding to metabolites. Recently, Dr. Yan's group is exploiting an exogenous TF to monitor the product of muconic acid (a renewable precursor to polyethylene terephthalate and nylon with global sales of $51 billion) in *Escherichia. coli*. However, native TFs always suffer from poor orthogonality and background noise due to uncharacterized interactions between candidate TFs and operator sites in native promoters. Thus, Dr. Yajun Yan's group is focusing on designing hybrid promoters to improve the specificity and sensitivity of TF-based biosensors in response to the concentration of muconic acid. To simplify the screening process, a sensor-reporter system is designed to evaluate the strength of hybrid promoters by monitoring the fluorescence intensity of green

fluorescence protein. In this project, I deeply understand the mechanism of the muconic acid sensor-reporter system and have received systematical training on the basic experimental skills of molecular biology and the design of biochemical experiments. During this process, my critical thinking abilities have greatly enhanced by discussing the experiment with the graduate students.

Optimization of Biogas to Electricity Plant

Carter Fitzgerald, CURO Research Assistant
Dr. Sudhagar Mani, College of Engineering

Recently, much has been made of the increase in the price and reduction of quantity of fossil fuels such as oil, coal, and natural gas. It is widely accepted that biogas, which is a mixture of carbon dioxide and methane, can be produced via anaerobic digestion. Anaerobic digestion is the series of biological processes where organic material is broken down by microorganisms, particularly methanogenic bacteria, in the absence of oxygen. This biogas can be burned to produce electricity, compressed to make compressed natural gas, or compressed even further to form liquid natural gas. The leftover organic material can be used as compost bedding or as fertilizer. The starting organic material that is fed into the anaerobic digestion process can range from cellulose to municipal solid wastes. This versatility is a huge reason for the advantages of biogas, because while it may not be as energy dense as its fossil fuel counterpart, it has other advantages: the source of the energy is renewable and, in the case of cellulose, the net carbon production is zero. After biogas is produced in the digestion tank or chamber it is a mixture of about 60% methane and 40% carbon dioxide. The gas is then scrubbed to increase the purity of the gas to 98% methane which is then sent to be compressed. The hot, high-pressure gas leaves the burner and enters an expansion turbine which turns a generator and produces electricity. Using process modeling software, multiple process variables can be manipulated in order to find the optimal composition, flowrate, and process unit sizes based on economic feasibility. The purpose of this research is to optimize the production of electricity from biogas and run cost analysis on the entire process to find a range of biogas prices where production is profitable.

Injury Risk of Major League Foul Balls

Zack Flagel, CURO Research Assistant
Prof. Nathaniel Grow, Insurance, Legal Studies, and Real Estate, Terry College of Business

Currently, Major League Baseball does not have a standardized policy that requires stadiums to have netting to protect fans from foul balls and broken bats flying into the stands. In other words, fans sitting above the dugouts or down the foul lines often do not have such protection and are at risk to injury. This research paper attempts to ascertain the extent to which fans attending Major League Baseball games are at risk of being injured by foul balls leaving the field of play. Specifically, this paper attempts to quantify the extent to which injury risk and injury severity have increased over time. It identifies several factors that increase spectator risk. Perhaps most notably, new major league ballparks that have opened over the last few decades have been designed with smaller areas of foul territory, thus putting fans closer to the field. Moreover, average pitch velocity has steadily increased over the last decade, helping to cause balls hit off the bat to travel even faster. These prominent factors, along with a multitude of other distractions, have caused the fans' reaction time to decrease. Through statistical analysis documenting the actual changes of stadiums' foul territories and pitchers' pitch velocities, this paper concludes that the injury risk for fans sitting in unprotected seats close to the field of play has increased significantly in the last few decades.

Abstracts

Design of Mass Concrete Specimens and Test Procedures
Rashaan Fowles
Dr. Mi Geum Chorzepa, College of Engineering

The goal of this research is to design specimens to quantify temperature loss and gain in mass concrete structures and develop test procedures for mass concrete specimens for a Georgia Department of Transportation project. There are two important parameters that need to be quantified in mass concrete specimens: (1) maximum internal temperature; and (2) gradient temperature. Current GDOT specification for mass concrete (special provision to the Section 500) includes the maximum allowable internal temperature of 158 °F and temperature differential of 35 °F between interior and exterior portions of the designated mass concrete element. The need to quantify and understand these two parameters and structural behavior is pertinent. This research will focus on understanding the underlying thermal behavior of mass concrete structures through the review of available literature on the subject of mass concrete mix designs and crack width measurement. As it is essential to study temperatures and temperature differences in several common types of mass concrete elements or placement configurations, simple thermal analysis models will be created to validate test procedures and specimens configurations developed during this study.

What Good is a Low-Carbon City if No One Can Afford to Live There?
Shreya Ganeshan, Foundation Fellow, CURO Summer Fellow, CURO Research Assistant
Dr. Jennifer Rice, Geography, Franklin College of Arts & Sciences

Cities increasingly embrace "climate friendly" policies that encourage alternative forms of transportation, incentivize green building and urban infill, and provide environmental services to residents, such as recycling and composting. Meanwhile, corporate investment attracts skilled labor into the technology spheres and specialized industries and significant capital inflows into these cities. Tensions between population growth and "green innovation" pull urban landscapes in opposite directions. The "Emerald City" of Seattle, WA is lauded for its high percentages of walking and biking work commuters and pristine air quality. Census and municipal survey data, however, reveal a different narrative. Median housing values in Seattle have surpassed the $500,000 mark for the first time ever. Energy efficient skyscrapers and "apodment"-style housing have become the built environment norm. In a pattern of carbon gentrification, an influx of high-earning individuals, who can afford to live in the city center and utilize the low-carbon modes of work commute, has crowded out lower-income families. As a result, Seattle faces a new political challenge: providing affordable housing and low carbon lifestyles simultaneously. We argue that conventional production-based representations of urban greenhouse gas (GHG) inventory data fail to display individual consumer contributions to emissions, which hinders the development of targeted public policies. This research disaggregates road passenger transport emissions to provide insight into individual responsibilities for emissions. We identify a need for policy that not only attempts to curb GHG output from transportation, the highest emitting civilian activity, but also the social and economic changes to urban design and governance.

Enzymatically Preparing Carbohydrates for Development of an Effective Treatment against a Bacterial Pathogen
Nikhil Gangasani, CURO Honors Scholar, CURO Summer Fellow
Dr. Fikri Avci, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Pneumococcal diseases like pneumonia are currently a major global health issue. Caused by *Streptococcus pneumoniae* bacteria, these diseases are responsible for up to 1.6 million annual deaths globally, according to the World Health Organization. In particular, *S. pneumoniae serotype III* (Pn3) has increasingly victimized children under the age of five, who represent more than half of global victims. The worldwide proliferation of microbial resistance to antibiotics accentuates the need for more effective pneumococcal vaccines. Glycoconjugate vaccines, composed of carbohydrates covalently linked to carrier proteins, alleviate this issue. The Pn3 bacterium expresses a carbohydrate coating on its microbial surface called a capsular polysaccharide (CPS). Breaking down the Pn3 CPS into fragments of suitable size and composition provides a carbohydrate source for creating a glycoconjugate vaccine against the Pn3 bacterium. In 1931, another bacterium called *Bacillus circulans* was found to secrete an enzyme that degrades the CPS of Pn3. Through a series of experiments, the *B. Circulans* enzyme has been purified and its size has been determined. Furthermore, the interactions between the enzyme and the Pn3 CPS have been studied and the means of CPS degradation are now understood. Ideal conditions for the enzymatic degradation of the Pn3 CPS have been established, and the size of the main degradation products themselves have been determined. Utilizing what is now known about the Pn3 CPS and the *B. Circulans* enzyme that degrades it, future research efforts will work towards creating an effective treatment against the harmful Pn3 bacterial pathogen.

Diet-Induced Obesity is Associated with a Change in Intestinal Innervation and Disruption of Gut-Brain Communication

Brent Gawey
Dr. Krzysztof Czaja, Veterinary Biosciences & Diagnostic Imaging, College of Veterinary Medicine

Obesity has become an important topic in modern healthcare, as obesity rates continue to rise at an alarming rate. In the past thirty years, obesity rates have nearly doubled, with adolescent obesity rates reaching levels almost quadruple their previous levels thirty years ago (Ogden 2014). As obesity becomes more widespread, efforts to understand the consequences of an unhealthy diet and the effects of being overweight are of utmost importance as obesity-related health problems rack up a total of $190.2 billion dollars annually (Teuner 2013). Current studies focus their investigations on body weight in regards to obesity; however, body weight is not an accurate measure of adiposity. In our study, we wanted to understand if caloric value of the diet was the only factor inducing obesity. To test our question, we obtained a sample of twelve rats and randomly assigned rats in groups of four to three different diet groups (low fat, high fat, regular diet). The rats were maintained on a regular diet for nine days and then were fed their designated diet for twenty-eight days. Over the course of the experiment, we measured each rat's body composition using a Minispec LF110. The Minispec LF110 is a machine that uses TD-NMR to measure body composition (fat, lean, free and total body water). This machine allowed us to analyze the living rats without having to use anesthesia to prevent animal movement, as the TD-NMR technology allows for accurate measurements even with little movements from the animal during analysis. Following euthanasia on the twenty-ninth day of the experiment, we measured the liver fat percentage using the Minispec LF110. Additionally, we used neuroanatomical methods and immunohistochemical techniques to measure inflammation in the hindbrain by staining microglia with IBA1 and to check for neural reorganization in the hindbrain by staining non-myelinated fibers with IB4. We found that rats maintained on low fat and high fat diets had body fat compositions that were significantly greater than the regular diet. We did not find any

significant changes in microglia activation (inflammation) in the hindbrain at the given fat levels of the diets. However, we did find neural reorganization of the hindbrain in both the high fat and low fat diets. Our results suggest that a balanced diet of macronutrients is key for optimal health. Consuming high-fat, greasy foods or low-fat diet products can both lead to interrupted satiety signaling between the gut and the brain. Therefore, in effective diet strategies, the caloric density should not be the main focus, but rather a focus on consuming a balanced diet of macronutrients, avoiding any high or low extremes of any given nutrient.

Personality Judgment Accuracy: Personality and Social Context Influence the Way People See Each Other

Catriona Geddes, CURO Honors Scholar
Dr. Brian Haas, Psychology, Franklin College of Arts & Sciences

Effective social interactions often depend on people making quick judgments about one another. The purpose of the study is to investigate how people differ in their ability to determine other people's personality traits and how social context affects the accuracy of personality judgments. In the current study, we characterized individual differences in personality recognition at two time points: during first impressions and following an interpersonal task. In addition, we tested whether social context—interpersonal closeness, competition, or cooperation—had an impact on personality judgment accuracy. We hypothesize that people who score higher in extraversion will be more accurate in reading their partner's traits and those who participate in the interpersonal closeness condition, compared to the other conditions, will be more accurate in reading the personality traits of others. The participants first come in individually and complete a personality inventory (NEO) and a ten-item personality inventory (TIPI). Then as a pair, participants complete a three-minute arbitrary question session, allowing for superficial interaction, and then a forty-five minute activity of one of the interpersonal conditions. The participants complete a TIPI survey for their partners after both activities, allowing us to characterize how well the participants read their partners' traits based on first impression and again after more time. We can then test for an association between a person's personality traits and judgment accuracy. This study holds the potential to identify traits that render a person to be a good judge of character.

Functions of HAN in *Arabidopsis* Embryo Development

Julian Gendreau, CURO Research Assistant
Dr. Wolfgang Lukowitz, Plant Biology, Franklin College of Arts & Sciences

The GATA transcription factor HANABA TARANU (HAN) regulates embryonic patterning in *Arabidopsis thaliana*. We have previously shown that two closely related GATA factors, HAN LIKE 1 (HANL1) and HAN LIKE 2 (HANL2), can substitute for HAN function when expressed with the HAN promoter in mutant embryos. HAN, HANL1, and HANL2 share two recognizable structural motifs: a central B-class GATA zinc-finger domain shared with seven other *Arabidopsis* genes; and a short, N-terminal sequence specific to the HAN clade and called HAN domain. The HAN domain is required for HAN function and deeply conserved in HAN orthologs of all flowering plants, but its molecular function has not been uncovered. My research aims at investigating the function of the two structural motifs of HAN genes by systematic gene and motif swapping experiments. I have expressed the remaining seven members of the B-type GATA factors of *Arabidopsis* under the control of the HAN promoter in mutant embryos and found that only one of them, GATA29, can substitute for HAN. GATA29 lacks a HAN domain;

however, a closer inspection of the GATA29 protein sequence revealed the presence of an N-terminal EAR motif. EAR motifs have been shown to promote transcriptional repression by binding co-repressors of the TOPLESS family. I have hypothesized that the HAN domain may serve a similar function and also constitute a transcriptional repressor domain. Consistent with this view, the EAR motif of GATA29 can be replaced with a HAN motif, and the HAN motif with the well-studied EAR motif of the *Arabidopsis* IAA17 protein. In addition, adding either an IAA17 EAR motif or a HAN domain to the N-terminus of GATA16, which contains a B-class zinc finger but fails to rescue mutant embryos in swap experiments, creates a mosaic protein with HAN function. I conclude that the HAN domain is a repressor domain and biochemically equivalent to an EAR motif. In addition, I have replaced the B-class zinc finger of HAN with A-, C-, and D-class zinc fingers. While mosaic proteins with an A- or D-class zinc finger are inactive, HAN variants with a C-type zinc finger, surprisingly, can complement mutant embryos. This result would suggest that B-class and C-class zinc fingers have similar properties. I am now examining T-DNA constructs in which the three C-class zinc finger genes of *Arabidopsis* are expressed with the HAN promoter, to explore possible functional redundancies.

Passive Drug Delivery for Intraocular Applications

Alyssa Ghuman, CURO Research Assistant
Dr. Hitesh Handa, College of Engineering

The current treatments available for patients who suffer from ocular diseases such as glaucoma, diabetic retinopathy, and age-related macular degeneration include daily eye drops and monthly intraocular injections. In order to avoid blindness, treatment for these diseases must be administered on a regular basis, with some treatments requiring lifelong administration. This work studies a refillable, implantable ocular drug delivery device as a long-term solution to patients who undergo the inconvenience and discomfort of frequent doctor visits and monthly injections. In this study, three different micro-channel designs, along with the modification of the channel surfaces, are tested for the diffusion of various dyes as a model for drug delivery. A refillable device with a three-year time span reduces the number of required doctor visits and prevents frequent replacements of the device, greatly improving patient life.

A Faulty System: An Empirical Analysis on Student Loan Default

Connor Gibbs
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

This study expands student loan policy literature, focusing on shifting from a grant and merit-based financial aid system to one based on repayable student loans. While this policy change provides educational opportunities to individuals who otherwise could not go to college, it also had led to an increase in the student loan default rate. Given associated negative macroeconomic outcomes such as postponed household formation, decreased homeownership, and decreased consumption, this study attempts to empirically evaluate default through a multiple regression model to predict one's own probability of default. This methodology was driven by evidence that for-profit institutions may enroll non-traditional students who qualify for federal student loans but inadequately prepare them for the workforce. The model utilizes four predictor variables: institution type, degree completion status, salary after completion of school, and time after school completion to employment. The results could inform policymakers' choice to lobby for more federal oversight of for-profit universities or even adjusting state funding

formulas to make public universities more attractive for nontraditional students. The research could assist policymakers as they sort an array of policy solutions to lower the growing default rate, improve the welfare of student borrowers, and mitigate the negative economic outcomes of default.

Methadone and Loperamide Interactions with the Multidrug Transporter P-Glycoprotein

Morgan Gibbs, CURO Research Assistant
Dr. Arthur Roberts, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The multidrug transporter P-glycoprotein (Pgp) serves as gatekeeper of the blood brain barrier by effluxing toxins away from the brain, but in doing so, it also prevents the entry of beneficial drugs. Despite similarities in their molecular structures, the opioid agonist loperamide has essentially no brain penetration compared with the opioid agonist methadone. This is because loperamide is effluxed at 4 times the rate of methadone by Pgp. Despite several studies with these drugs and Pgp, the molecular reason for these differences is not well understood. To unravel the molecular basis of loperamide and methadone transport by Pgp, these drugs were investigated using ATP hydrolysis assays, fluorescence and NMR. Pgp-mediated ATP hydrolysis with methadone and loperamide suggests that they have one and two binding sites, respectively, and that methadone competes with one of the loperamide binding sites on Pgp. The interactions of loperamide and methadone with Pgp were also investigated by NMR and found to be consistent with the Pgp-mediated ATP hydrolysis results. These drugs also showed large differences in their ability to induce global conformational changes of Pgp by fluorescence spectroscopy. From these results, a conformationally gated model of opioid agonist transport is proposed to explain the molecular basis of their transport.

Serum Levels of Circulating and Exosomal MicroRNA Regulate Transformed Cell Growth

Nicole Gilreath
Dr. Ralph Tripp, Infectious Diseases, College of Veterinary Medicine

Serum is an essential component of cell culture media and provides the necessary growth factors and biomolecules for efficient cell growth. Fetal bovine serum (FBS) is the most common source of serum, but has several drawbacks including cost, lot to lot variation, and ethical concerns related to its procurement. Various types of chemically defined media are also available but often are more expensive, and in some cases unable to support cell growth as efficiently as FBS. This study examines if variations in pattern or type of serum microRNA expression influence the growth rate of Madine-Darby Canine Kidney (MDCK) cells. We hypothesized that FBS samples contain specific exosome-associated microRNA(s) that impact cell growth parameters. Serum samples from several commercial sources were evaluated for miRNAs from exosomes and within the serum. RT-qPCR was used to identify specific serum microRNAs, and the serum samples were assessed for their ability to support the growth rate of MDCK cells using both manual and automated cell counting methods. Several miRNAs were found to be highly upregulated in serum samples that yielded higher MDCK cell growth rates. The miRNAs that yielded higher growth yields will be validated by testing miRNA mimics and inhibitors for their potential to alter cellular and viral growth kinetics.

Measuring Muscle Fatigue in Men vs Women Using Mechanomyography

Shaun Goh
Dr. Kevin McCully, Kinesiology, College of Education

Previous studies have suggested that women have greater skeletal muscle endurance than men. The purpose of this study was to test this hypothesis using mechanomyography to measure the endurance of the forearm muscles in men and women. Twitch electrical stimulation was used to produce muscle contractions in the forearm muscle of subjects at frequencies of 2, 4, and 6 Hz while a tri-axial accelerometer measured the acceleration of each contraction. Fatigue was estimated with an endurance index (EI), which was final acceleration divided by initial acceleration. Peak acceleration was greater in men than that of women (PA=3.3G +/- 0.9 and 2.2G +/- 0.2 respectively). Women had a greater average endurance index than men (EI=84.1% +/- 3.7% and 77.4% +/- 2.1% respectively). A T-test between the two groups for endurance yielded a P value of 0.11. The study results are underpowered, and additional participants will be tested. However, the magnitude of different between men and women are consistent with previous studies. The mechanism explaining differences between men and women in muscle fatigue needs to be evaluated in future studies.

Neutrophil and Granulocyte Methylation in Normal Weight and Obese Individuals

Jenissa Gordon, CURO Summer Fellow
Dr. Hea-Jin Park, Foods & Nutrition, College of Family & Consumer Sciences

Folate acts as a one-carbon methyl donor, modulating epigenetic activity. Blood contains mixed populations of white blood cells of varying DNA methylation status, and may be responsible for inconclusive reports of variable DNA methylation responses to folic acid (FA) supplementation. A single cell type may serve as a more reliable epigenetic reporter to determine DNA methylation changes due to FA supplementation. Obesity influences folate status and increases risk for neural tube defects, but the impact of obesity on epigenetic responses following FA supplementation has not been investigated. FA was provided (800 μg/d) to normal weight (NW; BMI 21.6+ 1.4 kg/m2; n=12) and obese (OB; BMI 37.5+ 2.3 kg/m2; n=6) women of childbearing age for 8 weeks. Genome-wide DNA methylation changes in CD4+ T cells (CD4) and CD16+ neutrophils (CD16) were determined using Infinium HumanMethylation 450BeadChips. Increased folate status was observed, but OB women at baseline had lower serum folate concentration than NW women; this trend was maintained after supplementation. Methylation changes in response to supplementation were more abundant in CD4 than CD16 in both OB (12.4% vs. 3.1%) and NW (4.6% vs. 1.7%) women. A small number of CpG sites responded in both cell types (0.1% and 0.6% of total CpG sites in NW and OB, respectively). Our results indicate that DNA methylation response following FA supplementation is distinctive in each cell type and obesity affects the epigenetic regulation in response to folate status. Findings provide preliminary evidence to develop cell-type specific biomarkers of folate status unique to obesity.

Improving Efficacy of HIV Vaccines for Immune-Suppressed Recipient

Ann Gore, CURO Research Assistant
Dr. Lisa Shollenberger McEwen, Infectious Diseases, College of Veterinary Medicine

HIV affects millions worldwide, and vaccines have not previously been effective. The Harn lab developed VacSIM, a novel vaccine delivery method in which a liquid forms a gel matrix upon entry into the recipient. Previous studies have proved this delivery method more efficacious than CpG, alum, and Fruend's adjuvant. The delivery method has been tested in the flu vaccine model as well and found it to work well for viral clearance in mice. We decided to then test the efficacy of VacSIM in an Envelope-based HIV vaccine.

To do this, we combined an HIV Envelope protein and VacSIM and administered it to mice via subcutaneous vaccination. We then used ELISAs to determine endpoint titers of HIV-specific antibodies in the blood of vaccinated animals. This experiment showed that VacSIM was by far the best for humoral response, with or without CpG adjuvant. This semester, we are continuing the experiment to study the efficacy of VacSIM-delivered HIV vaccines in mice chronically infected with *Schistosoma mansoin,* which causes immunosuppression. We will vaccinate either infected or uninfected mice with the HIV proteins Envelope and Gag in VacSIM and test humoral responses to Envelope via ELISAs and cellular responses to Gag via ELISpots.

Credit Usage and Financial Literacy among University Students

Theodore Gorman
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

We know the general criteria for good credit use. We know what distinguishes a solid credit score from a weak one, and we know which actions can lead to a particular score. But in all this research, information about a crucial demographic is left largely unexplored: college students, and in particular those who are working to improve their ability to manage their own finances. With a data set compiling information from almost a thousand UGA students' credit reports, we can look more closely at the foundations of strong credit use among students, as well as examine instances where problems arose. Given the continual rise of both college tuition and competition in the US job market, college students have to be thriftier than ever, and having a good credit history has never mattered more. Our data show the effects of authorized versus individual user account ownership, and we can now compare the credit standing of students who have had help from their parents and those who have not. With all this in mind, we've worked to organize and analyze this data set with the intention of producing a provable hypothesis in the form of a research paper.

Evolutionary Analysis of Mating-Type Genes in *Stagonosporopsis* Species Causing Gummy Stem Blight of Cucurbits

Thomas Gottilla, CURO Research Assistant
Dr. Marin Talbot Brewer, Plant Pathology, College of Agricultural & Environmental Sciences

Gummy stem blight of cucurbits has recently been discovered to be caused by three genetically distinct but morphologically indistinguishable fungal species: *Stagonosporopsis cucurbitacearum*, *Stagonosporopsis citrulli*, and *Stagonosporopsis caricae*. A key biological difference among these species may be their mating systems, and specifically the presence and structure of the *MAT1-1-1* and *MAT1-2-1* genes, which together compose the *MAT1* locus. Genes associated with reproduction tend to diverge rapidly, so our objectives were to identify the genes and determine if the genes are rapidly evolving. This would include analyses for both positive and purifying selection. Genomes of the three species were searched for homologs, and tests for positive and purifying selection were conducted primarily in the form of dn/ds analyses. The results of these analyses show that the dn/ds ratio for the three species is less than one, suggesting that the three fungal species are undergoing purifying selection. However, the evolutionary constraints on the three species were significantly different than those affecting the outgroups; although both ratios were less than one, the two ratios were significantly different. Concrete evidence of positive selection in mating-type genes may provide evidence that distinct speciation among *S. caricae, S. citrulli*, and *S. cucurbitacearum* is occurring. Because the

MAT1-1-1 and *MAT1-2-1* genes contained in the mating-type locus are associated with several functions ranging from host recognition to the formation of reproductive structures, understanding the evolutionary factors acting on the *MAT1* locus could be critical in understanding the emergence of new fungal species.

Effect of Multiple Ankle Sprains on Functional Performance Tests in Adolescents

Morgan Green, CURO Honors Scholar
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Ankle sprains are the most common sports injury among athletes and the initial sprain often occurs during adolescence. Functional performance tests are commonly used in injury screens, but it is unclear if adolescents with a history of sprain demonstrate deficits. The purpose of this study was to determine if a significant difference in functional performance ability was present between adolescent athletes with a history of a single ankle sprain versus multiple sprains in the star excursion balance test (SEBT) and single leg hop test (SLHT). We hypothesized the athletes with a history of multiple ankle sprains would perform significantly worse on a SEBT and SLHT than the single ankle sprain athletes. Adolescent soccer players (8 male, 13 female, 15.6±1.3 yrs.) completed surveys to report the number of previous ankle sprains. Each participant performed three trials of the SEBT and two trials of the SLHT to measure functional performance of the ankle. Overall, the subjects with a history of multiple ankle sprains performed significantly worse on the SEBT (69.1±9.3, $p < .001$) and SLHT (18.0±4.1, $p < .001$) than the single ankle sprain athletes (SEBT-99.8±4.9, SLHT-7.2±.7). A history of multiple ankle sprains negatively affects ankle joint function in an adolescent population. Future research may include prospectively tracking ankle sprains over a competitive season to determine the clinical utility of specific cut-off scores for determining those at risk for ankle sprain.

Corporate Inversion: Companies Leaving the American Tax System

Jazmine Griffin, CURO Honors Scholar
Dr. Jeff Netter, Banking & Finance, Terry College of Business

The current Pfizer-Allergan merger is an example of a particular trend in United States mergers and acquisitions, corporate inversions. In corporate inversion, an American corporation may merge with another foreign corporation and move to overseas headquarters. This allows the originally American corporation to escape taxes on income earned abroad. In the case of Pfizer, one of the largest pharmaceutical companies in the United States, merging with Allergan will allow them to move their headquarters to Ireland. Many companies seek tax havens, countries with less stringent tax laws and lower rates, to escape foreign income tax in America. Currently, America taxes foreign income at 35% upon returning to U.S. soil. This tax falls on top of the income taxes corporations already pay in the location income is earned. To avoid the tax burden American companies keep approximately 2.6 trillion abroad. The president, congress, and even some politicians are trying to find solutions to this problem. In the following presentation, we will discover the strategies companies use to avoid U.S. foreign taxation, and the potential income America is losing. To examine the mechanics of corporate inversion we will analyze current corporate inversion deals including, Pfizer-Allergan, Tyco-Johnson, and Applied Materials. From there, we will discuss the pros and cons in America's tax systems and the strategies politicians and congress have devised to keep U.S. corporations from exiting.

Abstracts

Women, Welfare, and Borrowing
Shannon Griffiths, CURO Research Assistant
Brittany Talkin
Dr. Mary Caplan, School of Social Work

The U.S. credit market is awash in credit products for all economic strata of society, and many are marketed toward credit-constrained people. 62% of low-income families have a credit card, and 32% of people who qualify for the Supplemental Nutrition Program (SNAP) have consumer debt. At the same time, approximately 34% of Americans receive some form of means-tested social assistance. The purpose of this study is to examine how and to what extent welfare recipients utilize these consumer borrowing opportunities. This study employs grounded theory design using semi-structured interviews with women over the age of 18 currently receiving means-tested social assistance and using some sort of borrowing, like payday loans, pawn shop loans, revolving credit cards, title loans, and other informal loans. The social process of borrowing is examined using Charmez's constructivist grounded theory approach, including systematic coding, memo writing, and theory development. The research team has conceptualized the study, created and refined interview questions, recruited informants, conducted participant and non-participant observations, conducted interviews, and analyzed data. Informants were recruited through professional networks as well as posting flyers throughout the community, and snowball sampling was used. The main research question is, "What are the borrowing attitudes and behavior of women who receive public means-tested social assistance?" The nascent framework contains three interconnected concepts: 1) complicated methods of borrowing affects and is affected by complex life circumstances; 2) access to credit provides hope, but increases economic vulnerability and self-doubt; and 3) balance between personal responsibility and social pressures.

Procedural Polarization: Examining Changes in the Roll Call Voting Record (1877-2012) and their Effects on Political Polarization
Casey Grippando, CURO Summer Fellow
Dr. Anthony Madonna, Political Science, School of Public & International Affairs

Recently, much attention has been given to the role of partisan politics within the American Congress; namely, how the polarization of American political parties appears more pronounced than ever. The question to be answered then is why modern times have produced the appearance of a polarized political system and whether this problem is as extreme as it appears. We believe that an increase in requests for roll call votes has contributed to this polarized image of Congress. Using the *Congressional Record*, roll call voting data on amendments from 1877 – 2012 was coded in Microsoft Excel and amassed with existing research on previous sessions of Congress to statistically uncover partisan voting and procedural patterns. Variables coded included various Congressional procedural tactics, member party, and type of vote, amongst others. Votes on measures of little importance (more specifically, votes on measures not considered "landmark legislation") were largely ignored. The results so far are as expected: amending activity on legislation has largely increased within both parties, and more amendments have received roll call votes. This in turn creates more party line votes and thus the polarized image of Congress we see today. Given the large range and depth of data, we believe the results are extremely important and applicable when judging the polarization of the current and future Congresses. It is also important in demonstrating that a volume of votes rather than a pure shift in ideology could be at fault for increased polarization.

Metallothermic Reductions and Conductive Coatings for Lithium-Ion Battery Anode Materials

Bryan Grommersch, CURO Summer Fellow
Dr. Ramaraja Ramasamy, College of Engineering

The chemical technology inherent in lithium-ion batteries has not kept pace with the portable electronics and automobiles that depend on them. Fossilized silica (SiO2) frustules, or shells, of the fresh-water diatom *Aulacoseira* feature intricate pores and shapes which make them a promising template for a lithium battery anode. It is believed that retaining these intricacies after a magnesiothermic reduction to Mg2Si and silicon will yield batteries of superior capacity and cyclability. Subsequently coating these microparticles with a conductive polymer promises to improve their electrochemical properties even further. Metallothermic reductions of Al2O3 and GeO2 were also explored in this project, as was the creation of silicon microparticles via an alternative SiCl4 synthesis.

Lunchroom Table Talkers Talk Students into Eating Fruits and Vegetables

Taylor Gutwillig
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

Changes to the National School Lunch Program require schools to provide students receiving a school lunch with two fruit and vegetable servings, but this change has produced high plate waste. In the present study, we draw on principles of behavioral economics to try to nudge students to choose and consume more fruits and vegetables. We developed a low cost intervention using brightly colored, age appropriate table talkers to introduce students to eight fruits and vegetables. Each side of the table talker shows a fun fact rather than health information, as previous research has shown highlighting health related information can decrease consumption. A baseline data collection of fruit and vegetable waste was performed in each school through observing students (kindergarten to fifth grade) in the lunchroom. During an intervention period, half of the schools (chosen by random assignment) received table talkers to place on lunchroom tables. Preliminary results showed that in the control schools, which were not exposed to the table talkers, fruit and vegetable consumption decreased. However, fruit and vegetable consumption remained the same in intervention schools (i.e., did not decrease). An explanation of these findings and their implications for understanding the decisions made by students in the lunchroom and how school programs can promote healthy eating while decreasing the waste and increasing the consumption of fruit and vegetables will be discussed.

Examining a Potential Role for *Mycobacterium tuberculosis* CtpB in Copper Transport

Sahl Hakim
Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Mycobacterium tuberculosis is the cause of human tuberculosis, a chronic and sometimes fatal respiratory infection. The *ctpB* gene in *M. tuberculosis* is annotated to encode Cation Transport Protein B (CtpB) predicted to function as a copper-transporting ATPase. Copper is an essential mineral for many biological processes, but when present in excess can be toxic. The overall goal of this project is to examine the function of *ctpB* when expressed in nonpathogenic *Mycobacterium smegmatis*. The *ctpB* gene will be cloned with a c-myc tag into a mycobacterial expression vector downstream from a tetracycline-inducible promoter. The plasmid will be introduced into *M. smegmatis*. The transformed cells will be induced with varying tetracycline concentrations alone and in the

presence of copper ions. If CtpB is a copper efflux pump, then the expression of the gene is predicted to render the bacteria more resistant to the excess copper compared to the wildtype bacteria. If the CtpB is a copper influx pump, then the expression of the gene is expected to render the bacteria more sensitive to elevated levels of copper. To determine if the protein is made, western blotting will be performed to detect the presence of the myc-tagged CtpB protein. Results of this project will be presented.

Examination of Supply-Side Incentives and Motivations That Perpetuate the Skill Mismatch of Cambodian University Graduates

Hanna Han
Dr. Audrey Haynes, Political Science, School of Public & International Affairs

In Cambodia, the increased enrollment in higher education has not significantly led to a more robust economy as many university graduates remain un- or underemployed. This unusual phenomenon can be ascribed to the graduates' skill mismatch, or the disparity between the labor supply of universities and the labor demand of employers. This study attempts to understand the supply-side incentives and motivations that contribute to the skills mismatch. In short, why university students decide upon the majors and career paths they do. The study makes use of six hour-long semi-structured focus groups with current Cambodian university students stratified according to major and university type (public or private). Coding analysis of qualitative data reveals the major supply-side problem to be the lack of accurate career information and exposure to a diversity of career options, misguided conclusions about labor demand based on economic observations, and societal and familial pressures. This study is significant in that it will inform Cambodian educators, employers, and policymakers about the incentives and motivations encouraging the current skill mismatch, which will then allow them to craft policy solutions to alter incentives. The study also will inform USAID, the World Bank, and other international organizations that implement education development programs within Cambodia about the skill mismatch, which will allow them to alter existing programs or create new ones in order to address the issue and prevent its exacerbation.

Microwave Synthesis of MOF-5

Allie Harbert, CURO Research Assistant
Dr. Douglas Jackson, Chemistry, Franklin College of Arts & Sciences

Metal organic frameworks are an area of research of increasing interest. Organic linkers of various complexities and potentials for activity can be linked together with metal centers to form a porous crystal. Their porous nature combined with their very large surface area allows for MOFs to be ideal substances to store gases as well as capture them. These crystals have great potential for application in different areas including gas storage and capture for environmental and energy uses as well as for delivering drugs, since essentially any linker with at least two reactive sites can be used. This experiment focused on simplifying the process of forming a known MOF, MOF-5, which is formed using Zinc Nitrate and Terephthalic Acid, and has been previously formed using reflux over a period of 48 hours. MOF 5 has previously been analyzed using x-ray powder diffraction. The goal of this experiment was to devise a new reaction scheme to cut down reaction time and maximize yield in order to expand upon the new methodology to more efficiently synthesize more complex MOFs that have applications of interest. This reaction time has been successfully cut down to 50 minutes using microwave chemistry and DMF as the solvent. The MOF was able to be crystallized out and analyzed using X-ray crystallography.

Agrobacterium tumefaciens Mediated Transformation of _Mimulus nasutus_ via the Floral Dip Method

Leanna Harbor
Dr. Andrea Sweigart, Genetics, Franklin College of Arts & Sciences

Agrobacterium tumefaciens mediated transformation is a powerful genetic tool and both floral dip and vacuum infiltration methods have been incredibly successful in the model plant *Arabidopsis thaliana*. *Mimulus* is an emerging model plant genus studied by ecologists and evolutionary geneticists. The study of *Mimulus* species would greatly benefit from genetic transformation and, in fact, the floral dip vacuum infiltration method has been previously successful in transforming the self-pollinating *Mimulus nasutus* species. Stable germ-line transformation was confirmed in the T3 generation through BASTA resistance screening and PCR analysis conducted on the surviving T3 seedlings. However, successful transformation has not been repeatable, highlighting the need for an optimized protocol. In this study, the goal was to optimize *Agrobacterium* mediated transformation of *Mimulus nasutus* by testing a variety of controlled conditions to determine which treatment yields successful transformation. The conditions tested were varying concentrations of Silwet L-77, inoculation technique of either floral dip or floral dip and vacuum infiltration, and repetition of the inoculation treatment. Mature seeds from the inoculated plants were collected and planted to undergo BASTA resistance screening. The number of seeds produced by plants in each condition group greatly differed between the treatment conditions, with some conditions resulting in the production of much fewer seeds. The BASTA resistance screening is ongoing, but available results of plants that have completed resistance screening show no successful transformation events. The transformation process will be repeated on additional *Mimulus nasutus* plants, with altered treatment conditions in addition to a greatly increased sample size.

Hurricane Forecasting and Healthcare Facility Evacuations

Elizabeth Hardister, CURO Honors Scholar
Dr. Curtis Harris, Institute for Disaster Management, College of Public Health

Hurricanes have the potential to produce mega mass casualty and mass fatality events in addition to catastrophic structural damage. The state of Georgia is located in an area vulnerable to hurricanes originating in both the Atlantic Ocean and the Gulf of Mexico; however, Georgia's response to a major hurricane has not yet been tested. While forecasting and emergency planning have greatly improved over the past few decades, recent history demonstrates that hurricanes still have the potential to result in catastrophic loss of life. The successful evacuation of coastal healthcare facilities in response to an impending hurricane requires advanced notice, timely decision making, and an unprecedented coordination effort between coastal and inland facilities. However, government planning assumptions do not accommodate the additional challenges faced by coastal healthcare facilities during severe weather evacuations, specifically, the advanced timelines needed, and the limitations of early hurricane forecasting models.

Conference Calls and Tax Forecasting

Jennifer Hardister, CURO Honors Scholar
Dr. Erin Towery, J.M. Tull School of Accounting, Terry College of Business

Conference calls are one medium from which analysts obtain financial information from company management. Companies typically divide these calls into scripted and discussion sections. In the scripted portion, company managers present analysts with information

about the financial performance of the firm. During the following discussion portion, analysts are able to question managers. Financial analysts then use information gathered from these calls to prepare estimates of financial measures such as net income. This paper analyzes mentions of tax in quarterly conference calls of public companies and their relation to changes in analysts' forecast properties. This analysis provides evidence of the utility of these calls for analyst tax forecasting. Preliminary results suggest management mention of taxes in the scripted portion correlate with improved analyst forecasts.

Effect of Preoperative Laboratory Testing on Anesthesia-Related Decision Making in Apparently Healthy Dogs

Kayla Hargrove
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

The objective of this retrospective study was to determine if the results of pre-operative laboratory testing in otherwise healthy dogs influence anesthesia-related decision making. These decisions include additional non-diagnostic procedures, cancellation/postponement of surgery, intravenous fluid rates, repetition of laboratory tests, monitoring and management techniques, further tests conducted, change in ASA risk status, changes to client communication, and avoidance of NSAIDs. It was hypothesized that few surgeries would be cancelled, but that other anesthetic decisions would be altered on the basis of laboratory results. One hundred dogs that underwent elective orthopedic surgeries and had a complete blood cell count, serum chemistry, and urinalysis performed were selected. All cases were reviewed by 5 veterinary anesthesiologists. Out of 100 dogs, 0% would have additional surgeries or procedures, 6% would have their procedure cancelled or postponed, 38% would have fluid therapy altered, 32% would have laboratory tests repeated, 9% would have changes made to monitoring while anesthetized, 15% would have management techniques altered, 12% would have further tests conducted, 13% would have their risk status changed, 20% would have changes in client communication, and 59% would have NSAIDs eliminated from treatment. It is recommended that routine pre-operative laboratory testing be conducted in healthy dogs presenting for elective orthopedic procedures.

Assessment of Adult Pig Cognition Utilizing an Open Field and Object Recognition Test

Kayla Hargrove
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Behavioral testing allows for the evaluation of learning and memory, and is an integral component for assessing functional deficits in current models of neural injury and disease. Pigs have become a model of interest for neurobehavioral research based on morphologic similarities to the human brain. Studies assessing neurodevelopment in pigs have revealed that they possess sophisticated cognitive abilities; however, further optimization to assess learning and memory capabilities are needed. The present study utilized object recognition testing and open field testing as a means of assessing spontaneous trial-unique memory, and normal/abnormal behaviors, respectively. We hypothesized that object recognition testing would reveal more time spent investigating novel objects than familiar ones, and that when placed in an open field, pigs would demonstrate exploratory behavior. Four male pigs, approximately 5-6 months of age were used. For the open field test, pigs were placed in the arena for 10 minutes and their behavior recorded. At the start of the object recognition test, two similar objects were

fixed to opposite corners in the arena, and the pigs were allowed to investigate them for 10 minutes, followed by a 10 minute inter-phase interval, and a 10 minute test trial in which one of the previous objects was replaced with a novel object. All open field and object recognition trials were recorded via overhead camera and analyzed with Ethovision software. These tests provide valuable insight on pig cognition, and will allow efficacy assessments for treatments targeting the improvement of learning, memory, and behavior.

In-Vitro and *In-Vivo* Assessment of a Yeast By-Product on the Inhibition of *Histomonas meleagridis*

Caitlin Harris, CURO Research Assistant
Dr. Robert Beckstead, Poultry Science, College of Agricultural & Environmental Sciences

Histomonas meleagridis is an anaerobic protozoan and the causative agent of Blackhead disease. This disease can cause up to 100% mortality in turkeys because the innate immune is not able to identify the parasite as foreign. The objective was to determine if a yeast by-product known to upregulate the innate immune system could inhibit *H. meleagridis in-vitro* and *in-vivo*. For the *in-vitro* trial, *H. meleagridis* cells were incubated in Dwyer's media for 24h at 42oC then flasks containing fresh media were inoculated with 100,000 cells per flask. Cells were treated with several concentrations of yeast by-product and counts were performed after 8 and 48 h. For the direct and indirect *in-vivo* trials, 1 day old poults were obtained and had *ad libitum* access to treatment diets and water. Treatments consisted of varying yeast by-product concentrations. At 18 days old, poults were challenged with *H. meleagridis* cells. For the direct trial, all poults were challenged, and for the indirect trial, 5 out of the 30 poults per treatment were challenged. Mortalities were necropsied for liver and cecal lesions. The direct trial was terminated at 10 days post-infection and the indirect trial was terminated when 80% of the inoculated control birds exhibited Blackhead signs. The results of the *in-vitro* trial determined that the treatments did not inhibit *H. meleagridis* cell growth ($P<0.05$). There were also no significant differences between treatments for the direct trial ($P<0.05$). Lastly, the indirect trial determined that the treatments did not inhibit lateral transmission of Blackhead ($P<0.05$).

Effects of Climatic Legacy on Southern Appalachian Plant Communities in Coweeta Basin

Douglas Hart
Dr. Jeff Hepinstall-Cymerman, Warnell School of Forestry & Natural Resources

In recent decades, the eastern United States has experienced increased precipitation rates, along with a greater frequency of extreme wet and dry years. These trends, along with an absence of occasional fire disturbances, have been hypothesized to allow for "mesophication" to occur within eastern plant communities. Mesophication is a term recent studies have used to describe the recruitment of mesophytic (wet-adapted, drought-intolerant) plants within xeric (dry-adapted, drought-tolerant) plant communities typically dominated by oaks *(Quercus*). As moisture availability increases within these communities, mesophytic species such as maples (*Acer*), tulip poplar (*Liriodendron tulipifera*), and birch (*Betula*) begin to dominate the understory and, if disturbances permit an opening, the canopy. This study examines if mesophication is occurring across a 30-year precipitation gradient in the Coweeta Basin located in Macon County, North Carolina in the southern Appalachian Mountains. Vegetation surveys were conducted in the summer of 2015 across a precipitation gradient in the basin, with sampling locations representing a variety of slope aspects. Differences in the vegetation community are

being explored using multivariate community analysis tools, and are expected to show distinct differences in mesophytic and xeric species composition between communities. Understanding the phenomenon of mesophication is important when considering the future of plant communities under a changing climate. The widespread replacement of oaks and other xeric species with mesophytic species could result in forests with less valuable habitat and food availability for some species, along with less valuable timber for harvesting.

Need of the "Other": Paradox in Gordon Parks' *Airline Terminal* and *American Gothic*

Caroline Harvey
Dr. Janice Simon, Lamar Dodd School of Art

Through an analysis of two photographs produced by Gordon Parks in the mid-20th century, this paper seeks to highlight the paradoxical nature of race relations during the era of Jim Crow and segregation. Rather obviously, whites clung to the comforting idea of segregation as it raised them into the upper echelons of political and economic welfare while it simultaneously disenfranchised America's black population. Because the goal was to keep the races separated, it became less apparent that black and whites were mixing in a crucial setting—employment. Blacks were so economically cast down that they often needed employment from whites, a need that was met by the white's "need" of poor blacks to help with childcare, housekeeping and other menial, sometimes degrading, tasks. Parks noticed this problem, and saw in it the strange need of the "other" between the races. His documentation of this paradox is best seen in two works, *Airline Terminal* (1956) and *American Gothic* (1942), both of which were produced during his role as photojournalist for *Life* and the Farm Security Administration, respectively. Through complex visual analysis influenced by Roland Barthes' *Camera Lucida* (1980) and Connie Choi's contributions to *Witness: Art and Civil Rights in the Sixties* (2014), this paper examines Parks' photographic indictment of the American institution of segregation and Jim Crow law. Furthermore, this argument is additionally influenced by Parks' own memoirs, which bring further clarity to Parks' personal motivation behind his production of *Airline Terminal* and *American Gothic*.

Identifying the Monoclonal Antibody Epitope Peptide Expressed on Pancreatic Adenocarcinoma

Sarah Hatton, CURO Research Assistant
Dr. J. Michael Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Pancreatic ductal adenocarcinoma (PDAC) is one of the most deadly cancers with one-year and five-year survival rates of only 24% and 5%, respectively. Physicians currently lack useful biomarkers in the screening, diagnosis, and treatment of PDAC which unfortunately leads to the majority of patients being diagnosed in incurable, progressive stages. A mouse monoclonal IgG antibody, known as MAb109, has been developed, isolated, and shown to preferentially react with cancerous pancreatic tissues over non-diseased normal tissue in a disease progressive manner. This antibody binds an N-glycan containing epitope expressed on two specific glycoproteins, CEACAM 5 and CEACAM 6. Isolation of the MAb109-reactive glycopeptides followed by mass spectrometry analysis has identified a single glycopeptide that contains a N-linked glycan. My research focuses primarily on identifying this peptide sequence in model organisms such as the fruitfly (*Drosophila melanogaster*) and zebrafish (*Danio rerio*). A MAb-109 reactive band was detected in *Drosophila* pupae lysate after immunoblotting, and a peptide sequence was found within the fruit fly genome using bioinformatics that denotes a likely candidate

protein. By performing a similar experiment with zebrafish lysate, I hope to identify for the same or related peptide that reacts with the antibody. Future experiments will test the function of the protein containing this peptide during zebrafish organ development. An additional study will be to determine if quantifying the MAb109 epitope in human blood is useful for detecting and monitoring pancreatic cancer. The epitope expressed on cancer cell surfaces may also serve as a potential therapeutic target.

Ballot Initiatives and Voter Turnout
Rory Hibbler, CURO Research Assistant
Dr. Anthony Madonna, Political Science, School of Public & International Affairs

This research analyzes the potential effects of ballot initiatives on voter turnout in national presidential and congressional midterm elections. This research is significant in the political science field because while there has been significant research on ballot initiatives and voter turnout, nothing has been published on these topics since the 1990s to early 2000s. There is a desperate need for an update in this topic, especially since there's a historically low voter turnout rate in recent elections (36.4% in 2014 midterms). I plan on testing this by comparing the turnout of voters in states that utilized ballot initiatives and the turnout in states that did not utilize ballot initiatives throughout a series of presidential elections and midterm elections. No results are available yet.

Drift Between Two Specific Conductivity Probes
Sarah Hickey, CURO Research Assistant
Dr. John Dowd, Geology, Franklin College of Arts & Sciences

As a part of a larger study of the Lake Herrick Watershed, we will be measuring the time it takes for a specific conductance probe constantly taking measurements while submerged in a tributary stream of Lake Herrick to drift from a specific conductance probe calibrated before each measurement in the same stream. This work is significant because it will help us determine how long we can leave the probe in the water before collected data becomes inaccurate. I expect that the probe left in the stream will drift from the probe that will be calibrated before each measurement and will need to be re-calibrated once every four weeks. This study is important because there is limited research published on the amount of drift in the specific probes we are using. Results and conclusions from this research can help improve the data collected for the Lake Herrick Watershed Study and help identify the pollution sources for the lake.

The *speAk* Movement: Social Media for Global Issues
Taylor Hill, CURO Honors Scholar
Prof. Jennifer Smith, Grady College of Journalism & Mass Communication

The *speAk* campaign seeks to answer two questions: first, "What makes a social media campaign successful, reach audiences, or 'go viral'?" The second is "Can social media be used to successfully inform the public of global issues in a more approachable manner and lead to involvement?" In this case, the issue is ocean health and exploitation, which encompasses ecotourism, shark finning, and marine mammal captivity. The research will be broken up into three phases. The first phase involves shooting video shorts that convey these issues in a comical, rather than chastising, fashion. After the videos have been filmed, they will be shown to focus groups in order to gauge audience reaction in terms of their ability to convey these issues in a more informative, approachable, and engaging manner. Post-focus groups, the video shorts will be released through social media outlets such as Twitter, Facebook, and Instagram in order to see if these social media campaigns

are able to gain web traffic to an informative website that will serve as a platform for individuals to engage with organizations supporting these environmental issues. Studying social media and how it can be used as a platform for change is relevant in this digital age where the internet serves as a primary source of information and communication. It is valuable to study whether or not this new media can be used to connect larger audiences to reliable sources of information and involvement in global issues.

Dressing with a Disability
Shannon Hochschild
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

Cerebral palsy (CP) is a contracted disease impairing standard motor functions controlled by the cerebrum and cerebellum. Damage to one or both of these regions obstructs the body's physical mechanisms and intellectual development. Today, comprehending the complexity of CP relies exclusively on information produced by the field of medicine and science. Therefore, there is a need for extensive cultural and social research to solidify the CP population's position and wellbeing in mainstream society. Identification of those moderately and severely afflicted by CP is primarily dependent on dress. The physical abnormalities caused by CP require assistance through dress items such as braces and custom footwear, which indicate to society that a condition exists. Based on experiments regarding postural control and equilibrium in children with CP, continual backwards-walking training exhibited improvements in overall posture and coordination. These findings highlight an opportunity for potential modifications and innovations in dress that would aid the afflicted CP body. The neglect to study CP holistically hinders society's understanding of this medical condition and feasible improvements in the lives of people living with CP. Therefore, conducting future research of CP in the interrelated fields of dress, society, and culture will directly influence beneficial dress modifications and innovations for this population.

Digitally Delicate Primes
Jackson Hopper, CURO Summer Fellow, CURO Research Assistant
Dr. Paul Pollack, MATHEMATICS -- Arts & Sciences

Terence Tao has shown that in any fixed base, a positive proportion of prime numbers cannot have any digit changed and remain prime. In other words, infinitely many primes are "digitally delicate." Tao's work uses sieve methods, a departure from previous work by Cohen, Selfridge, and Sun on the topic using covering systems of the integers. We strengthen this result in a manner suggested by Tao: a positive proportion of primes become composite under any change of a single digit and any insertion a fixed number of arbitrary digits at the beginning or end.

Microplastic Sampling in the Atlantic Ocean
Adam Howington, CURO Research Assistant
Dr. Jenna Jambeck, College of Engineering

Based upon our work of annual mass flows of plastic into our ocean compared with what has been found in the ocean, there are millions of tonnes of plastic in unknown locations. In order to understand potential impacts, it is important to try to determine the location and form of this plastic. In our environment, plastic physically degrades into smaller fragments and pieces, called microplastic, that can both transport organisms (including invasive species) and host their own microbial communities. Plastics also absorb persistent organic pollutants. Plastic debris continues to be found all over the world, and the average size

of plastic particles in the ocean appears to be decreasing, but open ocean sampling published in the literature has consisted primarily of trawl collection of plastic samples 330 um and above. We analyzed open ocean water samples collected through filtration and fractionation on a path from the Canary Islands to Martinique, across the Atlantic. The samples were filtered in the lab and we counted suspected plastic particles in the size range of 20 um to 333 um. Plastic particles will be reported in number per liter of seawater collected.

Evaluation of Cas4 Function in CRISPR-Cas Adaptation

Jesse Hu
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Given that viruses are the most abundant biological entities on the planet, prokaryotes have evolved extensive protective systems to defend against genetic invaders. One component of this defense is CRISPR-Cas (clustered regularly interspaced short palindromic repeats–CRISPR-associated), an adaptive prokaryotic immune system found in nearly all archaea and half of prokaryotes. This system is composed of a CRISPR array and Cas proteins. The CRISPR array affords memory of past infections and contains identical repeats separated by sequences known as spacers, which are derived from foreign nucleic acids. CRISPR functions in three stages: adaptation, CRISPR RNA (crRNA) biogenesis, and crRNA guided interference. My research focuses on adaptation, in which Cas proteins capture spacers and incorporate them into the CRISPR array through a process called integration. In *E. coli*, Cas1 and Cas2 form a complex essential for spacer integration, with Cas1 contributing to integrase activity and Cas2 appearing to play a non-enzymatic role. However, the functions of other Cas proteins, such as Cas4, are poorly understood. I aim to elucidate the role that Cas4 proteins in *Pyrococcus furiosus (Pfu)* and *Thermococcus kodakarenesis (Tko)* play in CRISPR-Cas adaptation. Supported by previous *Pfu in vivo* data, I predict that Cas4 plays a critical role in the capture of foreign DNA into CRISPR loci. Therefore, I will evaluate the effect that different Cas4 proteins have on previously developed *in vitro* integration reactions. Further understanding of the roles of distinct Cas4 proteins in adaptation will clarify our understanding of a crucial step in prokaryotic adaptive immunity.

Legal Context to Violating Women

Michael Hutchison
Dr. K. Chad Clay, International Affairs, School of Public & International Affairs

This paper focuses on the role of legal systems on gender equality and human rights advocacy. Common law, Islamic law, Civil law, and Mixed law systems will be measured against physical human rights violations to determine which system performs best in context to religious influence on each legal system; in addition, this paper will discuss discriminatory law absent of religion, law influenced by religion, and the presence of religious extremist groups and how their interaction with a given state and population will affect human rights support and violations. Such a study has not yet been conducted, and results of this paper will illuminate the field of human rights pertaining specifically to women and the causes of violence against this sex in context to the law. This paper intends to discover the importance of religion's role in influencing the performance of legal systems pertaining to women's human rights support and violations.

Applying Computer Vision Analysis to Plant Phenotyping

Tate Hutwagner

Dr. Wayne Parrott, Crop & Soil Sciences, College of Agricultural & Environmental Sciences

Plant phenotyping lags behind in the plant breeding field because of advances in molecular biology making high-throughput genotyping easier. However, plant breeders need to asses plant phenotypes to interpret the genotypic data. Breeders still need to develop methodologies that affordably and efficiently categorize phenotypes. High throughput phenotyping would be useful to evaluate insect resistance in plants. For example, soybeans that resist damage from insects are desirable, as more than 20% defoliation leads to a significant yield and economic loss. Current methodology requires destructive sampling, as leaves must be detached from a plant before damage is measured. One current methodology under review for phenotyping is computer vision; computer vision visually assesses and scores images for characterizing crop traits. However, computer vision has been difficult to use to measure caterpillar damage. Thus, attempts are underway to adapt computer vision to measure insect-caused leaf damage. The first step has been to devise a way to get images of a whole plant—given the 3-dimensional aspects of a plant, imaging from several angles is needed. Next, Open CV, software written in Python and C++, was used to code a program to measure the amount of damage incurred by the plant. Photos of the plant are extracted from the background image utilizing the program. After, the program evaluates holes in the leaves caused by a caterpillar and calculates the percent defoliation. The ability to conduct these measurements in intact plants overcomes the traditional phenotyping bottleneck by utilizing high-throughput methods facilitated by computer vision.

The Influence of Psychosocial Functioning on Tic Severity in Children with Tourette Syndrome

Emily Ivey, Olivia Carlson, Colleen Keeler
Dr. Ronald Blount, Psychology, Franklin College of Arts & Sciences

Objective: Prior research has demonstrated relationships between comorbid psychological disorders, social problems, and increased tic severity in children with Tourette Syndrome (TS). There is also evidence that social problems positively correlate with tic severity. Less research has examined if and how psychological and social problems jointly predict tic severity. This study investigated how social impairment and symptoms of psychological comorbidities in children with TS relate to tic severity. *Methods:* The sample included 46 caregivers of children with TS (M age= 12.80, SD = 2.32). Caregivers reported on children's psychological functioning, social impairment, and tic severity. *Results:* Separation anxiety symptoms, OCD symptoms, and social impairment were significantly correlated with tic severity (rs = .31 to .40, $p < .05$). OCD symptoms were the only significant predictor of tic severity (β = .32, p = .04; R2 = .18, p = .01). Social impairment accounted for significant additional variance when added at Step 2 (ΔR2 = .08, p = .04) and was a significant predictor of tic severity (β = .30, p = .04). OCD symptoms remained a significant predictor of tic severity at Step 2. The overall model accounted for 26.4% of the variance (p = .005). *Conclusion:* More prevalent symptoms of OCD predict greater levels of tic severity. Social impairment also relates to greater tic severity, beyond the contribution of OCD symptoms. Treating comorbid psychological disorders and social skills impairments may reduce tic symptom severity. *Significance:* These findings may guide the development of novel evidence-based treatments for children with TS.

Abstracts

Financial Literacy, Risk Tolerance, and Goals-Based Savings Behavior

Benjamin Jacobs, CURO Research Assistant
Robin Haas
Dr. Swarn Chatterjee, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

This study uses a national dataset to examine the association among risk tolerance, financial literacy, and goals-based savings behavior of households. The results indicate that three out of five households do not have any emergency funds set aside, and about two out of three households have not calculated how much money they will need for retirement. However, financial literacy is positively associated with risk tolerance; separately, both financial literacy and risk tolerance are associated with goals-based savings behavior, such as saving for emergencies, saving for children's education, and planning for retirement, among households. We also find that the likelihood of goals-based savings behavior of moderately risk seeking households is positively associated with financial literacy. Although risk tolerance appears to be an important factor in the savings and investment decisions of households, the findings of this study provide further evidence regarding the role of financial literacy in improving household financial capability. Implications for policy makers, scholars, and researchers in the area of behavioral economics and household finance are included.

When Coca-Cola Grows Citrus on the Nile, Who Wins? Revisiting the Arab Boycott in Egypt

Andrew Jarnagin, CURO Summer Fellow
Dr. Shane Hamilton, History, Franklin College of Arts & Sciences

The Coca-Cola Company was barred from the Egyptian market in 1966 under the Arab boycott of Israel and firms conducting business with Israel. The company responded by mobilizing its influence in the American government to assist in negotiations. It succeeded in inking a deal in 1977, two years before Egypt officially ended its participation in the boycott altogether, whereby Coca-Cola agreed to invest $10 million ($39 million in today's dollars) in agriculture and factory infrastructure, insured by the U.S. government. However, in secret talks in 1975 with the U.S., Egypt had already agreed to end the boycott (thus allowing Coca-Cola to return) as a part of the peace deal with Israel. When Egypt allowed Coca-Cola to re-enter the country, it was facing a foreign exchange crisis as a part of larger economic woes. In the first decision to ban Coca-Cola and the second allowing it to return, economic circumstances rather than anti-imperialist ideology dictated Egypt's negotiating position, and it extracted a desperately needed inflow of foreign investment from Coca-Cola in exchange for a right to sell that it had already secretly negotiated away as part of an American-backed peace deal with Israel. These findings are based on analysis of internal Coca-Cola documents and U.S. State Department cables.

Understanding the Rise of the Sadrist Movement in Iraq

Andrew Jarnagin, CURO Summer Fellow
Dr. Kevin Jones, History, Franklin College of Arts & Sciences

When the Ba'th Party came to power in Iraq in 1968, Saddam Hussein spelled out the party's opposition to "sectarian, racism, and tribalism." By the mid-1990s, however, the Ba'th regime was itself a proponent of those three –isms, whether openly or indirectly. This study demonstrates that government policies promoting sectarianism, racism, and tribalism contributed to the rise of a populist social movement led by Muhammad Sadiq al-Sadr which endured past his assassination by the regime in 1999. Sadr took advantage of

Iraqi Shias' growing feelings of alienation due to state oppression to create a public space for expressing Shia religious identity; used Saddam's long-held desire to see an Arab cleric rather than one with "Persian" links leading the Shia religious establishment to quickly grow in influence, initially with government consent; and appropriated the regime's revival of tribal identity to build a parallel network of tribal support across central and southern Iraq. Analysis of internal Ba'th Party documents shows that the despite the image of Ba'thist Iraq as an all-powerful totalitarian state, the government felt unable to control the growth of Sadr's influence. While the regime assassinated Sadr after he began to publicly challenge government oppression, it was unable or unwilling to dismantle the movement's entire network, and Sadr's representatives remained active after his death. This study contributes to scholarship debating the totalitarian nature of Saddam's Iraq and also helps explain the rise of Muqtada al-Sadr, son of Muhammad Sadiq al-Sadr, as a major political and militia leader in Iraq today.

Education Level May Differentially Buffer Cognitive Decline in Older Adults Based on Race

Kharine Jean
Dr. Lloyd Stephen Miller, Psychology, Franklin College of Arts & Sciences

Although race and educational attainment have both been related to cognitive functioning in late life, the interaction of these two factors is surprisingly understudied. The aim of this study was to examine whether education level differentially buffers cognitive decline in Caucasian and African American older adults. Given that African Americans are at increased risk for cognitive decline due to a variety of socioeconomic and lifestyle factors, it was hypothesized that education level would confer greater advantage to African Americans relative to Caucasians during the cognitive aging process. A 2×3 analysis of variance was conducted on a sample of 580 older adults (mean age =69.9, 62.2% Caucasian) participating in the Family Relationships in Late Life Study with race (Caucasian and African American) and education (< high school, high school, and higher education and above) as the between-subjects factors. Cognition, as measured by the Repeatable Battery for the Assessment of Neuropsychological Status global score, served as the dependent variable. Consistent with previous findings, significant main effects indicated that African Americans [$F(1, 574)=49.09$, $p=<.001$] and individuals with less education [$F(2, 574)=78.74$, $p=<.001$] evidenced lower cognitive functioning. As expected, the interaction term reached statistical significance [$F(2, 574)=5.724$, $p=.003$]. Upon further analyses, the effect size of education on RBANS score for African Americans was .33 and .14 for Caucasians. Our findings suggest that African Americans gain greater benefits from educational attainment; and that education may have greater clinical significance among African Americans in preventing dementia, given lower overall levels of cognitive functioning in late life.

Expression of Inflammatory and Coagulation Factors in Syncytiotrophoblast BeWo Cells Exposed to *Plasmodium falciparum* Derived Hemozoin

Tiffany Jenkinson, CURO Graduation Distinction, CURO Research Assistant
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Malaria is often considered a disease of the developing world, affecting more than 97 countries and an estimated 207 million people annually. Furthermore, children and pregnant women are a more susceptible population. High rates of maternal morbidity, as well as low birth weight and fetal loss, are attributed

to placental malaria (PM), a disease characterized by the accumulation of malaria infected erythrocytes in the intervillous space of the placenta, the invasion of inflammatory cells, and the release of pro-inflammatory mediators. While the specific immunologic mechanisms underlying the pathogenesis of PM are not fully understood, it is established that excessive fibrin deposition and an over-activation of inflammatory mediators are key components of the body's response to malarial infection. This study aims to investigate the progression of placental coagulopathy in a trophoblast choriocarcinoma cell line, known as BeWo. In order to mimic the pathological model of PM infection, BeWo cells were stimulated with stimulants such as lipopolysaccharide (LPS) and the *Plasmodium falciparum* by-product, hemozoin. Cellular mRNA levels were analyzed by quantitative PCR for possible upregulation of pro-coagulant factors, pro-inflammatory cytokines, anti-fibrinolytic factors, anti-coagulants, and pro-angiogenic factors. The underlying interrelation and corroboration of coagulation and inflammation is still not well understood. By gaining a deeper understanding of the role of coagulation and its relationship with inflammation in PM, we hope to provide insight into possible mechanisms of treatment or prevention.

Regulation of Base J Synthesis in Trypanosomes

Melissa Jennings, CURO Honors Scholar
Dr. Robert Sabatini, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Leishmania tarentolae (*L. tarentolae*) is a protozoan parasite that causes leishmaniasis, which affects people in parts of Africa, Asia, South America, and Central America. The Leishmania protozoa are part of a larger class called kinetoplastids which are responsible for deadly human diseases such African sleeping sickness in Africa and Chagas disease in South America. Research in the Sabatini lab is focused on a novel modified DNA base, called base J, that regulates RNA polymerase II transcription and gene expression in kinetoplastids. By understanding base J synthesis and function, researchers may one day be able to develop a specific treatment that will manipulate base J and kill these human pathogens. The initial step of J synthesis is catalyzed by two thymidine hydroxylases, JBP1 and JBP2, that somehow recognize specific regions of the parasite genome and modify a thymine base. Understanding the mechanisms involved in regulating the specificity of J synthesis in the kinetoplastid genome is essential to understanding epigenetic regulation of gene expression in the parasite lifecycle. Our hypothesis is that additional proteins are associated with JBP that direct the specificity of thymine modification genome-wide. My project has been to identify JBP associated proteins using tandem affinity purification of JBP1 and JBP2 in *L. tarentolae* followed by mass spectrometry. Utilizing this technique I have recently identified several potential JBP1 associated proteins. Characterization of these proteins is underway to determine their role in regulating JBP1 activity on chromatin in vivo and thus directing the modification of specific thymines in the genome.

Circulating Concentrations of Growth Differentiation Factor 11 Are Heritable and Correlate with Life Span

Zixuan Jiang
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

Growth differentiation factor 11 (GDF11) is member of the transforming growth factor β (TGF-β) superfamily of proteins. Circulating GDF11 concentrations appear to decline with age, and its depletion is associated with cardiac hypertrophy and other morbidities. Knowledge of GDF11 regulation is limited,

and the effects of natural genetic variation on GDF11 levels are currently undefined. We tested whether genetic background determines serum GDF11 concentrations using two classical inbred mouse strains: C57BL/6J (B6) and BALB/cByJ (BALB). B6 mice exhibited significantly higher GDF11 levels than BALB mice, and these strain differences were consistent throughout the life span. Overall, interactions between age and genetic background determined GDF11 concentrations, which were unaffected by sex. We then surveyed a panel of 22 genetically diverse inbred mouse strains and discovered a sixfold range in GDF11 levels at middle age. We estimated that 74.52% of phenotypic variation in GDF11 levels was attributable to genetic background. We used the Mouse Phenome Database to screen for phenotypes that correlate with GDF11. Interestingly, GDF11 levels predicted median strain life spans. This study revealed high heritability of GDF11 levels. Furthermore, our correlative data suggest that GDF11 may serve as a novel predictor of mammalian life span. (Zhou, Y., et al. J Gerontol A Biol Sci Med Sci. In Press. doi:10.1093/gerona/glv308)

Feeding Choice Characterization of *Euptoieta claudia* and Oviposition Choice Analyses of *Agraulis vanilla* in Relation to Cyanide Production of *Passiflora incarnata*

Zehneel Jiwani, CURO Research Assistant
Dr. Rodney Mauricio, Genetics, Franklin College of Arts & Sciences

Cyanogenesis is the release of hydrogen cyanide stored in forms such as cyanogenic glycosides and cyanogenic lipids within the tissue of certain plants. This release of HCN is used as a defense mechanism by certain plant species in order to deter or poison herbivores from consuming the plant. Some herbivores, however, have adapted in such a way as to not only withstand the effects of HCN release but rather seek out plants based on the production of cyanogenic glycoside for the purposes such as feeding and survival. Experiments were conducted in order to evaluate the strength of the defensive mechanism of cyanogenic glycoside production in the Purple Passionflower (*Passiflora incarnata*) against herbivory of a generalist herbivore, the Variegated Fritillary (*Euptoieta claudia*). Further analyses of the relationship between cyanogenic glycoside production by the Passionflower and herbivores was evaluated by an experiment examining the oviposition preference of a specialist herbivore, the Gulf Fritillary (*Agraulis vanilla*), on varying genotypes of Passionflower.

The Effect of the Colonial Past on Women's Representation in the Caribbean

Kimberlee John-Williams
Dr. Maryann Gallagher, International Affairs, School of Public & International Affairs

This paper focuses on the Caribbean region and the effect that the colonial past has on women's representation today. This paper analyzes the influence of colonial history on women's representation by comparing Ibero and Anglo Caribbean countries. The Anglo Caribbean had a relatively peaceful transition from colonialism to independence and it was expected that this would translate into higher women's representation in legislature than the Ibero Caribbean. However, the data demonstrated that Ibero Caribbean countries elect women at a slightly larger margin than Anglo Caribbean countries. This paper presents a novel explanation for why this occurs, based on women's participation in nationalist revolutionary movements.

The Role of Auditory Skill Development in the Advancement of Vocalization Development

Breana Johnson, Alexis Pope, Mackenzie McGraw, Sherry Sayavongsa, Meredith Towey, Hayley O'Hara, Courtney Todd, Anna

Fink, Sabrina Williams, Chase Kranzlein, Brianna Kelley
Dr. Sandie Bass-Ringdahl, Communication Sciences & Special Education, College of Education

Research supports the effectiveness of early intervention in lessening the impact of hearing impairment on speech and language development. Recent advances in hearing aid and cochlear implant technology make an audible speech signal possible. Audibility of the speech signal is critical for the development of speech and language and is a primary goal of assistive technology. The relationship between early speech development and auditory skill development needs to be defined in clinically useful ways if such information is going to meaningfully contribute to the treatment decision making process. The purpose of the current study is to investigate if there is a minimum amount of auditory skill development necessary for the emergence of canonical babbling. Canonical babble is a milestone in vocalization development and is an indication of emerging first word production. The current study is a retrospective analysis of data from 7 children with normal hearing with an average age of 14.25 months (range 5-25.67 months). Auditory milestone behaviors were collected using the IT-MAIS (adapted) parent questionnaire. The early vocalization data were collected using the LENA device. The LENA is a small digital language processor worn by the child throughout the day to record up to a 16 hour language sample in a naturalistic environment. The data will be segmented and analyzed to determine degree of canonical babble emergence. The results will be combined with the results from a previous investigation of children with hearing impairment to better understand the relationship of auditory and early vocalization milestones.

Knockdown of IFT Proteins Phenotypically Affects Primary Cilia

Grace Johnson, CURO Graduation Distinction
Mary Abkemeier, Catherine Waldron, Daniel Blumenthal, Vivian Vu
Dr. Jonathan Eggenschwiler, Genetics, Franklin College of Arts & Sciences

The purpose of this project is to investigate ciliogenesis of the primary cilia. On a broad scale, these cilia have large implications in the fields of human disease and developmental biology. There is a wide spectrum of diseases called ciliopathies that are caused by problems with ciliary processes. The ciliary proteins we are investigating include intraflagellar transport (IFT) proteins, motors, and regulatory proteins that play a role in regulating the primary cilia. To investigate these proteins, we employed the CRISPR/Cas genome editing system and a loxP flanked transcriptional stop cassette to induce reversible mutations in target genes. The specific genes that we investigated were Atat1, Kif7, CCRK, IFT122, and Bbs8. Atat1 is α-tubulin acetyltransferase and a knockout is expected to result in slower intraflagellar transport by assembly proteins and a lack of alpha-tubulin. IFT122 is transport protein whose knockdown results in an accumulation of transcriptional mediators at cilia tips. Kif7 is a protein that regulates cilia length and structure. A knock out of Kif7 results in phenotypically longer cilia. Our research attempted to couple a Kif7 null with a CCRK null, whose phenotypic effects are unknown. Bbs8 encodes for Barbet Biedle syndrome protein 8. A mutation should result in improper cilia movement. These phenotypes are observations that have been made and reported in the literature. Our goal is to explain these phenotypes at the mechanistic level by observing the effects on the overall structure of cilia, the rate of transport, and the ability to transport cargo within the cilia.

Abstracts

Parentification as a Predictor of Emotion Dysregulation in Young Adults

Sara Johnson
Amber Madden, Graduate Student
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

Parentification is a form of role-reversal within a parent-child dyad in which the parent looks to the child to act as his or her caregiver (Jurkovic, 1997); this disturbance of typical family-relationship boundaries is problematic when the demands placed on a child by the parent exceed developmental ability (Kerig, 2005; Sroufe & Fleeson, 1988). Parentification has been linked to poor social competence in childhood and worse college adjustment (Johnston, 1990; Hetherington, 1999). Peer attachment also predicts psychological well-being among adolescents; secure peer attachment is associated with increased well-being (Laible, Carlo, & Raffaelli, 2000). Based on this literature, we hypothesized that peer attachment would mediate the relations between childhood parentification and emotion dysregulation, given that disrupted parent-child relationships may impact the formation of healthy peer relationships, furthering the likelihood of dysregulated emotions in young adulthood. This study utilized data collected from a sample of 1654 undergraduate students (*M* age = 19.47; 71.4% female) through online surveys. Measures included a retrospective questionnaire of childhood parentification (PBS-III), current peer attachment, including subscales of trust, communication, and alienation (IPPA), and current emotion dysregulation problems (DERS). Consistent with hypotheses, peer trust and alienation were both significant mediators of the relations between childhood parentification and current emotion dysregulation (see Figure 1). These findings highlight the degree to which young adults are impacted by their relationships with the most important people in their lives: both parents and peers. Future research should explore the importance of peer attachment in associations between other childhood experiences and later psychosocial functioning.

Silencing in Chicana Literature: How Chicana Women Writers Navigate Marginalization in the Borderlands

Chandler Johnston
Dr. Dana Bultman, Romance Languages, Franklin College of Arts & Sciences

"*En boca cerrada no entran moscas*" is a well known Spanish saying, meaning "Flies don't enter a closed mouth." As Mexican Americans living in a hegemonic mainstream United States culture, Chicana women must navigate silencing in order to overcome marginalization and find agency and power. Silencing for Chicana women can occur through language, marginalization in the borderlands (living within the hybrid context of U.S., Mexican, and Mexican-American cultures and spaces), and the struggles of multiple "*mestiza*" consciousnesses. Ultimately, Chicana women often break through this silencing during coming-of-age narratives or use silence to their advantage as a form of agency. Using Gloria Anzaldúa's foundational Chicana text *Borderlands/La Frontera* as a theoretical framework, I investigate representations of silencing in more recent contemporary Chicana literature. Analyzing these narratives through a feminist lens, I argue that Chicana women use language, literary style, and strategic silence to find a voice amid the oppressive powers of both Mexican-American and U.S. cultures. Whether through more active or subdued feminist performance, Chicana women, facing issues of their intersectional identities that affect them through ethnicity, race, gender, class, and nationality, must struggle and survive through repressive settings. My paper studies these oppressions and reveals how current Chicana women writers represent how to

endure and thrive through outside silencing forces.

Quantitative PCR Detection of the SRY Gene of Male Dog Mesenchymal Stem Cells in Female Dog Brains with Experimentally Induced Ischemic Stroke
Susan Jones, Foundation Fellow
Dr. Elizabeth Howerth, Pathology, College of Veterinary Medicine

Intra-carotid-delivered mesenchymal stem cells (MSCs) may improve functional neurological outcomes after acute ischemic stroke (AIS). However, a large animal model is essential before beginning human clinical trials for patients with AIS. This study uses a dog stroke model in which female dogs with experimentally induced AIS receive male-derived MSCs via intra-carotid injection. It is hypothesized that the MSCs will successfully move to the site of infarction and participate in repair of damaged tissue. The objective of the present study is to target the Y chromosome in order to track the migration of the male-dog derived MSCs to various locations by using quantitative PCR. To detect the MSCs, a primer set was designed to amplify the SRY gene on the Y chromosome by qPCR. This technique was tested and optimized using male dog bone marrow. The qPCR technique was then tested using fresh brain samples from female dogs with experimentally induced AIS that were subsequently injected with male MSCs on the side of the stroke. This technique was effective at detecting the Y chromosome in the brain samples and is suitable for tracking male-derived MSCs in this dog model of stroke.

How do Middle School Students Define Sustainability? A Preliminary Analysis of Focus Groups
Usha Kaila
Dr. Jennifer Thompson, Crop & Soil Sciences, College of Agricultural & Environmental Sciences

This project aims to characterize how middle school students understand the concept of "sustainability." We highlight what domains of knowledge and experience students draw on to develop definitions of sustainability, and how they negotiate these definitions in a group setting. In order to impact students' attitudes and behavior around sustainability, it is essential to understand how they think about this issue. As part of a larger research project studying the impact of integrated sustainability programming at a local middle school, we have conducted focus groups with 6th graders (2 groups, with 4-6 students each). We are in the process of analyzing this data and will be conducting a second round of focus groups this spring. Preliminary analysis indicates that students' definitions are influenced by their experiences at home and at school, and focus on students' collective responsibility to make resources last.

Evidence-Based Interventions to Increase Wait Time and Decrease Problem Behaviors in Children with Autism
Megha Kalia, CURO Honors Scholar, CURO Summer Fellow, CURO Research Assistant
Dr. Kevin Ayres, Communication Sciences & Special Education, College of Education

Participants in this study include two children with autism who display varying degrees of aggression, non-compliance, or self-injurious behavior (SIB) when waiting to request for items. The purpose of this research is to decrease the quantity of their problem behaviors and to increase the children's waiting time when waiting to request for items. A picture exchange system will be used within a changing criterion design to systematically increase wait time before the item is available. The function of a picture exchange system is to provide children with

communication deficits with another mode of communication using photographs.

The Effects of Two Different High-Fat Diets on Appetite

Fatima Kamal
Dr. Jamie Cooper, Foods & Nutrition, College of Family & Consumer Sciences

Studies show that eating a single meal rich in poly-unsaturated fats (PUFAs) results in greater fullness compared to a meal rich in mono-unsaturated fats (MUFAs). Purpose: Determine the effect of a high-fat diet rich in either MUFAs or PUFAs on feelings of hunger and fullness. The study used a randomized, cross-over design consisting of 2 trials that were each 10 days. Seven adult males (age 18-45) were recruited. Each 10d trial consisted of a 3d lead-in diet, two 9h testing visits, and a 5d intervention diet. During the 5d diet, subjects received meals enriched with either cottonseed oil (high in PUFA) or olive oil (high in MUFA). The diets were 50% fat, 35% carbohydrates, and 15% protein. During each 9h testing visit, subjects received a breakfast and lunch meal, high in the fat designated for that trial. Subjects completed Visual Analogue Scale (VAS) questionnaires to rate feelings of hunger and fullness before and every 30-min following the two meals. There was no difference in fasting hunger or fullness VAS scores from pre to post PUFA or MUFA diets. Postprandial area under the curve was not different from pre- to post-diet for hunger in MUFA (pre:314.1±41.7, post:308.4±35.3, p=0.9) or PUFA (pre:351.4±61.1, post:326. 9±43.1, p= 0.7). Fullness was also not different pre- to post-diet in MUFA (pre:414.7±62.6, post:399.1±64.8, p=0.8) or PUFA (pre: 412.8± 64.2, post:391. 9±67. 9, p= 0.8). High fat diets rich in either MUFA or PUFA did not have an effect on feelings of hunger or fullness in adult men.

Finding Optimal Designs Using Genetic Algorithms

Andrew Kane
Dr. Abhyuday Mandal, Statistics, Franklin College of Arts & Sciences

In order to extract meaningful information from experimental data, the experiment needs to be designed carefully. Practitioners often use statistically optimal designs for conducting such experiments. With the advent of modern technology, sometimes the experiments have different constraints and it may be difficult or impossible to obtain such designs theoretically. We propose using numerical algorithms for obtaining such designs. Genetic algorithms, which find optima using search algorithms based on natural gene transmission, mutation, and fitness, have been applied successfully to various fields requiring numerical solutions. We examine their effectiveness in finding optimal experimental designs under different situations and demonstrate that they find good designs successfully based on various optimality criteria.

Age Related Metabolism of Pyrethroids in Rat Brain Microsomes

Marshall Kastens
Dr. Catherine White, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Pyrthroids are commonly used insecticides and insect repellants that are known to exert neurotoxicity. The objective of this project is to determine if the toxicity is age-dependent since children (1-3 yrs) have higher exposure risks than adults. Preliminary studies have shown that 15- and 21-day-old rats have higher brain levels than adults; however, while adult brain concentrations remain high, the levels in younger rats decrease at a faster rate. To understand these dispositional differences in brain the role of brain metabolism must be examined. Pyrethroids are metabolized by carboxylesterases and cytochrome P450 which

are both found in brain tissue. However, very little information is available regarding age-related maturation of these enzyme systems in the brain. Brain homogenates and microsomes will be used to explore the possible age-dependent metabolism of pyrethroids. Brains will be harvested from day 10, 15, 21, 30, 40 and 90 day-old rats and pooled. Tissues will be homogenized and microsomes made using standard methods. Deltamethrin, cis-permetrhin, trans-permethrin and cis/trans permethrin will be incubated at 37C with brain homogenates (carbocylesterase + Cytochrome P-450) and microsomes (cytochrome P-450) and loss of parent compound will be monitored by HPLC or GC/MS. Data will be analyzed with WinNonlin/Prism. The results of these studies will determine if there is an age-related difference in the metabolic capacity and/or binding affinity with pyrethroids and cytochrome P-450/carboxyesterase enzymes.

O-Linked Glycosylation Patterns of Cervical Mucins in HIV Infection

Hammad Khalid, Foundation Fellow
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Mucosal surfaces, well known for their role in sensing their environment (nose, mouth), nutrient absorption (gut), gas exchange (lungs), and reproduction (vagina and uterus), also function as a complex immunological barrier at these common sites of entry for pathogens and viruses. However, surprisingly little is known about the complex post-translational modifications of the mucin proteins expressed at these surfaces and about how these modifications provide protection. This project focuses on an in-depth characterization and comparison of the glycans found on cervical mucins from HIV and non-HIV patients aimed at identifying unique modifications that may play a role in mucosal immunity. Samples were collected and prepared to analyze by direct injection nanospray ionization mass spectrometry (NSI-MS). Glycan structures were probed using collision induced disassociation (CID) and assigned using software developed in-house for high-throughput analysis. Experimental data obtained suggests a decrease in sialylated and fucosylated structures and a decrease in sulfated O-linked glycan structures in HIV patients indicating a possible defect in terminal glycan processing. Additionally, data from lectin blots indicate a decrease in the abundance of anti-inflammatory mucins in non-HIV patients. By understanding the fine structural features of the mucosal interface, new approaches for eliciting mucus-tethering antibodies can be considered. Additionally, this research has the potential to develop a more efficient, standardized platform for evaluating the mucus barrier, which could enhance future research on natural and vaccine-induced defenses against other sexually transmitted infections.

Investigating the Post Translational Modification of CaaX Proteins

Haeun Kim
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Many neurodegenerative diseases are associated with aggregation of proteins into amyloid plaques due to defects in protein modification. Examples of such diseases include Alzheimer's and progeria. Hsp70 and DnaJ/Hsp40 are co-chaperones that serve to facilitate protein translation, modification, translocation, and destruction. More specifically, within the family of DnaJ/Hsp40 proteins lies a group of CaaX proteins that are characterized by their highly conserved four-amino acid sequence at the carboxyl-terminus. A recent observation by the Schmidt lab directly contradicts what was previously understood in

literature regarding Caax proteins. It was previously understood that all proteins with the CaaX motif follow a strict 3 step model of post-translational modification. It is now known, through the experimental investigation using genetic and microbiological approaches involving the yeast system, that the Ydj1p CaaX protein does not follow this traditional scheme. Ydj1 is a DnaJ family protein that is hypothesized to only go through the first step of the modification pathway rather than all three. This study further investigates the possible cause for the difference in post-translational modification associated with Ydj1p by using S. cerevisiae. Approaches to study this phenomenon involve mutations of the CaaX motif and genetic assessment of a Ydj1p-dependent thermotolerance phenotype.

A Computer Program for Planar Truss Analysis

Sokngim Kim, CURO Research Assistant
Dr. Siddharth Savadatti, College of Engineering

Trusses are some of the most efficient load carrying structures that are extensively used in the design and construction of physical infrastructure like bridges, housing, and power transmission towers. This project discusses the development of a computer program for analyzing planar trusses. The inputs for this program are loads, sizes of members, material properties, and truss geometry. The outputs are support reactions, member forces, deflections, and the deformed shape of the truss. This program can be used to analyze trusses of varied geometry quickly and allows the user to choose the most optimal truss design manually. Further development of this program will support the automatic determination of optimality.

Diet-Induced Obesity Differentially Regulates Glutathione Homeostasis in C57BL/6J, BALB/cByJ, and AKR/J Mice

Stephanie King, CURO Graduation Distinction
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

Cellular metabolism generates free radicals and other reactive oxygen species (ROS), and accumulation of these molecules disrupts homeostasis and drives oxidative damage. The endogenous antioxidant defense system detoxifies ROS and confers cellular protection against stress, and the ubiquitous tripeptide glutathione (GSH) coordinates many diverse mechanisms within this system. Higher GSH concentrations and redox status (GSH/GSSG) are therefore associated with augmented cellular defenses and stress resistance, while lower levels reflect oxidative stress and disease. Tissue GSH concentrations and GSH/GSSG are highly heritable in humans and mice, and interactions between genetics and diet appear to regulate these traits in model organisms. Currently, the dietary components that intersect with genetic background to regulate GSH homeostasis are not completely defined. In this project, we tested the hypothesis that dietary fat regulates tissue GSH homeostasis in a manner dependent on genetic background. To characterize these effects, GSH levels and GSH/GSSG were quantified in tissues from C57BL/6J (B6), DBA/2J (D2), and AKR/J (AKR) mice fed a control or high-fat diet for 12 weeks. Diet-induced obesity caused an increase in renal GSH/GSSG in B6 mice only. D2 mice fed a high-fat diet exhibited an increase in hepatic GSSG concentrations and a decrease in GSH/GSSG, while the livers from other strains were unaffected. Diet-induced obesity did not alter the GSH system of AKR mice in either tissue. In all, these data indicate that high dietary fat and subsequent diet-induced obesity regulate GSH homeostasis in a strain-dependent manner. Future studies will clarify the mechanisms by which genotype and diet-

induced obesity interact to control the cellular antioxidant system.

Effects of Cognitive Reserve and MPOD Levels on Personality in Older Adults

Evan Knox, Ramsey Scholar
Dr. Lloyd Stephen Miller, Psychology, Franklin College of Arts & Sciences

Previous research has established both cognitive reserve and the five-factor traits of personality as impacting cognitive impairment in older adults. The early determinations of cognitive reserve and theories as to cognitive reserve's physical meaningfulness both support a potential relationship between cognitive reserve and the five-factor personality traits. This relationship may be altered by levels of lutein in the brain over a long period of time. The results of any such analysis could provide insight into the physical manifestations of cognitive reserve, and also establish how cognitive reserve's effects on aging and cognitive impairment are mediated by personality. The authors performed a regression analysis between 2 proxy measures of cognitive reserve and the gender-accounted NEO-FFI scores for a sample of older adults (n=58, ages 64-92). Several multiple regression and moderation analyses were performed using cognitive reserve proxies and several macular pigment optical density (MPOD) readings (460 nm, 490 nm, and average) in a smaller sample (n=40, ages 64-92). Both proxy measures were found to be significantly positively related to openness (p=.002, p<.001) alone. For the average MPOD levels, both proxies demonstrated significant positive moderation effects with conscientiousness (p=.017, p=.005). While the lack of a cognitive reserve – neuroticism relationship is unexpected, the cognitive reserve – openness relationship confirms our expectations. The relationship between MPOD, cognitive reserve, and conscientiousness presents new information that must be further examined for replicability, but could provide new insights into the physical meaning of cognitive reserve.

Response of *Helianthus annuus* Biomass to Nutrient Stress

Ellen Krall, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

The cultivated sunflower (*Helianthus annuus)* is an important oil and food seed crop throughout the world. Both intensive cultivation of sunflowers in developed countries and low-input methods of cultivation in developing countries would benefit from nutrient stress resistant cultivars of sunflower that perform optimally under low nutrients. The ultimate goal of this experiment is to identify which of twelve previously identified genotypically diverse strains of *Helianthus annuus* L. perform similarly under low nutrient stress as they do in an optimized nutrient setting, and determine what characteristics could have contributed to their improved response. Three replicates of each strain (total n = 153 plants) were grown in four levels of nutrients and harvested at the seedling stage while three additional replicates (total n = 308) were grown in eight levels of nutrients and harvested at the budding stage. Evaluation of data from seedling harvest suggests that lines PPN027 and PPN240's pronounced allocation of biomass to roots at low nutrients may contribute to their more uniform growth across nutrient levels. Data are currently being collected and analyzed for sunflowers harvested at the budding stage, but it is reasonable to assume the same patterns, perhaps more defined, in terms of biomass allocation will be observed and data may also unveil other strains that perform well over a longer period of time.

Identifying Genetic Suppressors of ZYG-11

James Kraus, CURO Graduation Distinction, CURO Research Assistant
Dr. Edward Kipreos, Cellular Biology, Franklin College of Arts & Sciences

The ubiquitin-proteasome pathway is a process for targeted protein degradation. The protein substrates include cell cycle-related proteins that need to be degraded in a timely manner to allow proper cell cycle progression. In this pathway, the protein targets are marked for degradation by addition of a poly-ubiquitin chain, which acts as a signal for the proteasome. Cullin-RING ligases (CRLs) are a class of protein complexes that target proteins for poly-ubiquitination. The different substrate recognition subunits (SRSs) provide the specificity for the protein substrates of the CRLs. CRL2/ZYG-11 is a CRL complex that uses ZYG-11 as the SRS. Our lab has showed that CRL2/ZYG-11 is required for the meiotic metaphase II to anaphase II transition in *C. elegans*. There are many *zyg-11* mutant phenotypes including defects in chromosome condensation, polarity and cytoplasmic organization. The goal of my research is to further understand the role of CRL2/ZYG-11 in these cellular processes by identifying its substrates. Currently we are identifying *zyg-11*(ts) suppressor mutations by positional cloning of mutants, whole genome sequencing, and RNA interference of candidate suppressor genes.

Analysis of Pancreatic Cancer Biomarkers

Anjali Kumar, CURO Honors Scholar
Dr. Lance Wells, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Of all cancers, pancreatic cancer has the lowest survival rate. The high mortality rate, due to lack of diagnostic tests, has created an important role for pancreatic cancer researchers to change these statistics through discovering more efficient methods for detecting pancreatic cancer. We study pancreatic ductile fluid and patient serum samples which contain proteins and sugars that aid in finding early diagnostic biomarkers. Pancreatic ductile fluid contains pancreatic cancer biomarkers that can be detected by glycoproteomic approaches. Due to the invasiveness of drawing pancreatic ductile fluid from patients, we are studying patient serum as a means to identify proteins. Immunoblotting analysis is used on serum samples from pancreatic cancer and pancreatitis patients to compare the conditions of serum, using pancreatitis as a control condition. Prior to conducting immunoblotting techniques, serum samples are normalized through a cleanup of albumin and IgG. Western blotting techniques are used to identify the level of protein changes present between the two conditions as well as to observe potential shifts in bands due to glycosylation. Target proteins for western blot analysis include pancreatic amylase, pancreatic lipase related protein 2, phospholipase A2, REG family proteins, Elastase 3B, and GP2-1. We are currently undergoing procedures in analysis of the proteins of interest; evaluation of the results will provide insight into the strength and correlation of biomarkers with either condition. The findings may be used to develop an early detection, non-invasive assay to identify biomarkers for pancreatic cancer more efficiently and increase the survival rate of pancreatic cancer patients.

The Impact of Blood Circulation on Cancer Metastasis Patterns

Jason Kwak, CURO Research Assistant
Dr. Ying Xu, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Cancer metastasis is a process of cancer cells spreading throughout the body, and building new colonies in organs that are distant from the original location of the primary tumor. The tumor microenvironment is defined by the interaction between molecules around a tumor and the normal cells, and its study is significant in understanding the process of

tumor progression, and the mechanism behind metastasis. Noting that cancer metastasis occurs in the venous system, in our research, we are interested in how the blood circulation system has an impact on the metastatic patterns of primary cancer. Therefore, we studied the correlation between blood circulation rate and metastatic distribution of different primary cancers by using Spearman's rank correlation. 4012 autopsies of 40 primary cancers and 30 metastatic sites from five medical centers were used, and the blood circulation data for 14 normal organs were obtained from literatures. Our study has shown that the lungs had the highest Spearman's correlation value of 0.6073 between the rate of metastasis to each distant organs and the organs' blood circulation amount, and the p-value of 0.01 was highly significant to state that lung cancer evidently preferred to metastasize to sites with abundant blood circulation. On the contrary, some cancer type such as retro-peritoneum showed a significant negative correlation. These suggest different primary cancer type expresses different preference towards sites with abundant blood circulation, and further studies are needed to improve our understanding of the role that blood circulation rate poses in cancer metastasis.

Xenophobic Ants: Social Form Discrimination in the Tropical Fire Ant

Kip Lacy, CURO Summer Fellow
Dr. Ken Ross, Entomology, College of Agricultural & Environmental Sciences

Elucidating the genetic components of animal social behavior continues to be a biological holy grail. Fire ants have become a model system in which to explore the intricacies of social behavior. They exhibit the highest level of animal sociality—eusociality—and are often socially polymorphic within species. This is the case with the Tropical Fire Ant, *Solenopsis geminata*, in which there are two social forms: monogyne (single queen colonies) and polygyne (multiple queen colonies). The factors that maintain these two social forms sympatrically are unknown, however. In this study I investigated the interaction between workers and queens across different social forms and sites of origin by conducting behavioral choice assays for queen acceptance or rejection. I found that polygyne workers rejected all queens not from their site of origin, regardless of social form. Since ants presumably recognize each other on the basis of genetically determined pheromones, this inability to recognize such closely related conspecifics as kin may indicate unusual reproductive modes in the polygyne social form.

Effect of Strategic Marketing on Healthier Vending Machine Sales

Annie Ladisic
Dr. Leann Birch, Foods & Nutrition, College of Family & Consumer Sciences

Rationale: Regardless of the overwhelming evidence that consuming excess calories can contribute to obesity and chronic diseases, low-calorie snack options are not prevalent in most college campus vending machines. Even when offered, these items are frequently out-purchased by consumers in favor of higher calorie snack options. The use of strategic marketing to effect change in purchasing, encouraging consumption of lower calorie snacks, could help reduce the overall caloric intake of vending machine consumers. *Objective:* This study examines the effects of implementing a message spotlighting the "healthy" vs. "unhealthy" rows of products in a Dawson Hall vending machine. *Methods:* Rows 1 and 2 were stocked with "unhealthy" products that contained between ~250-500 kcal/package. The third row was stocked with "healthy" products, all ≤ 200 kcal. Sale data was collected over 12 weeks. A nutrition intervention sticker was installed on the machine during weeks 5–9, emphasizing high calorie (Rows 1 and 2) vs. low calorie (Row 3)

options. Three weeks of post-intervention data was collected to reveal whether the presence of the sticker had enduring effects on sales. *Results:* Using baseline data gathered in the initial 5 weeks of the study, I will compare the purchase choices of consumers prior to the intervention stage to those during, as well as after the intervention. I anticipate that during the intervention weeks, the product sales for Rows 1 and 2 will decrease, while sales of Row 3 items will increase. Following the intervention phase, I expect for sales to return to slightly below pre-intervention counts.

Super-Resolution Microscopy vs. Epifluorescent Microscopy of Aurora Kinase C and SYCP3 Localization in Mouse Oocytes and Spermatocytes

Ashley Lall
Dr. Rabindranath De La Fuente, Physiology & Pharmacology, College of Veterinary Medicine

Being able to more closely examine cells on the molecular level is becoming increasingly important to researchers in order to understand the complex pathways and interactions that occur during meiosis. Unveiling information about these interactions is extremely critical in order to understand problems that occur during pregnancy and reproduction which will hopefully remedy long-lasting issues that often result in pregnancy loss and genetic mutations in surviving embryos. The purpose of this experiment is to analyze two chromatin remodeling proteins that are essential for proper chromosomal division to occur during meiosis. Aurora Kinase C is primarily localized at the centromeres of mouse oocytes, and Synaptonemal Complex Protein 3 (SYCP3) is localized along the cohesions between homologous chromosomes in the lateral position of each chromosome. This experiment will specifically be studying lymphoid specific helicase wild type mouse oocytes and Trichostatin A-treated mouse spermatocytes. Epifluorescent microscopy, a common method of imaging chromosomes, is used in this report. However, advances in technology have allowed super-resolution microscopy to yield higher-resolution imaging of chromosomes. Super-resolution microscopy will allow the observation of Aurora Kinase C and SYCP3 on a molecular level in the mouse germ cells with hopes of uncovering more information about the roles of both Aurora Kinase C and SYCP3 during meiosis. The primary goal of this report is to compare and contrast the two microscopy methods, epifluorescent microscopy and super-resolution microscopy, and discuss the relative strengths and weaknesses of using each microscopy method.

Efficient Cloning by Temperature Upshift

Paige Lane
Dr. Cory Momany, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Traditional cloning methods use restriction endonucleases, which are enzymes able to recognize and cleave specific DNA sequences within a plasmid. Ligases are then used to glue the cleaved products together in a second step. In routine cloning, purification of the insert and plasmid and then a selection or screening process (*e.g.* blue-white screening) is necessary for identifying appropriate clones. This complicated process is due to inefficiencies in the overall cloning reactions that result in vectors that lack inserts and low transformation numbers. A streamlined cloning method (Galloway *et al.*, 2013) utilizes only one restriction enzyme, an enzyme that cuts outside its recognition site, and concurrent ligation at room temperature. Introduction of a temperature upshift (from room temperature to 50°C) appears to be very effective in reducing the background of incorrect products. The ligase is inactivated at 50°C, while the restriction endonuclease cuts empty vector. Most restriction endonucleases

are used at 37 °C, a temperature in which the ligase is still active. The goal of this project is to identify restriction enzymes that are compatible with temperature upshift (e.g., are stable at 50°C in the time frame of the upshift). Endonucleases will be evaluated for their cutting efficiency at 50°C. The use of a blunt-end cutter with ligase and a temperature upshift results in very efficient cloning that does not require significant screening of clones. The results of this project have wide application to the standard genetic engineering methods used in research laboratories.

Examining the Antioxidant Properties of Hops

Caroline Langley
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Hops, used most commonly in brewing beer, contain the powerful flavonoid Xanthohumol. The only way to access this compound is through the consumption of beers. Though this compound has been proven as a potential longevity-increasing compound, there is little known about it. Xanthohumol inhibits the metabolic activation of harmful carcinogens, and can help eliminate free radicals in the human body that have been shown to cause cancer. The purpose of this study is to determine if hops teas can compete against commonly consumed teas in terms of antioxidant content. The hypothesis of this study is that a hops strain with a high alpha acid content will have an equal or greater phenolic content than most herbal teas. To do this, 20 strains of Hops with different alpha acid contents will be analyzed for antioxidant content via Total Phenolic Content and Ferric Reducing Ability of Plasma (FRAP) tests. Different times will be applied to each strain, consistent with beer brewing times. The FRAPS and phenolics values obtained in the lab will be compared to those of other commonly consumed teas, such as chamomile and green. With these values, we will be able to compare how Hops tea may affect oxidation as compared to other herbal remedies.

A Retrospective Study Analyzing the Relationship between Blood Coagulation and Liver Shunts

Caroline Langley
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

In veterinary medicine, when canine patients are diagnosed with liver shunts, they are often given blood coagulation tests. The correlation between the two may not be as strong as believed. The purpose of this study is to determine if running blood coagulation tests on patients with post systemic shunts is a worthwhile endeavor both financially and medically. The hypothesis is that in most cases it is not beneficial to run blood coagulation tests. The results were obtained by cross analyzing medical cases and comparing recovery rate. Abnormalities in the coagulation tests were gathered in patients with liver shunts, with fewer the abnormalities corresponding to a decreasing need to run the tests. This study used cases from the past five years.

Experimental Evolution and Sperm Precedence in *D. recens* and *D. subquinaria*

Thomas Layman, CURO Graduation Distinction, CURO Research Assistant
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

This study investigates the dynamics of speciation between two closely related fruit fly species. *Drosophila recens* and *Drosophila subquinaria* are found across northeastern N. America and northwestern N. America respectively. Their ranges overlap in the Canadian Rockies. Female *D. subquinaria* from populations that overlap with *D. recens*

discriminate against mating with *D. recens* males, whereas *D. recens* females from this region do not discriminate strongly against mating with *D. subquinaria* males. This presentation will discuss the results from two experiments. First, we will discuss an experimental evolution study that aimed to test whether a population of *D. recens* females subject to very strong selection against hybridization will acquire the ability to discriminate against mating with *D. subquinaria*. Second, we will discuss an experiment that tests for post-mating selection against *D. subquinaria* sperm in the female *D. recens* reproductive tract.

Effects of Mitochondrial-Targeted (MitoQ) Antioxidants on the Lipidome of a Transgenic Mouse Model of Alzheimer's Disease

Thao Le
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Alzheimer's disease (AD) is a neurodegenerative disorder that causes deterioration in memory and thinking skills. It is the sixth leading cause of death in America, and experts estimate that there are over 5 million Americans with AD. Given the considerable evidence implicating the role of oxidative stress and mitochondrial dysfunction in AD, antioxidant compounds have been targeted as therapeutics. MitoQ (mitoquinone mesylate), is a drug candidate that easily crosses the blood-brain barrier to reach the site of formation of most reactive species, the mitochondria. In this study, we used lipidomics to assess the effect of MitoQ on the blood and brain lipid profiles of AD-transgenic mice. Phospholipids were extracted using the Bligh-Dyer method from whole blood and hippocampi of 13-month old and 18-month old 3xTg female mice treated with 100mM MitoQ via drinking water for 5 months prior to blood collection. Lipid phosphorus content was quantified using the Bartlett inorganic phosphorus assay. The samples were analyzed using electrospray ionization-mass spectrometry (ESI-MS), and principal component analysis (PCA) was performed. PCA analysis demonstrated distinct differences in lipid profiles across 13- and 18-month old mice based on age as well as MitoQ treatment. The lipidome of both age groups demonstrated alterations in glycerolipids, and the majority of changes were detected in 18-month old mice treated with MitoQ. Diacylglycerol and triacylglycerol lipid species decreased along with several phospholipid classes such as phosphatidylcholine and phosphatidylserine. These data indicate a potential effect of age as well as MitoQ on the lipidome within an AD mouse model.

Fractionation and Analysis of Wild Type and Galacturonosyltransferase 14 (GAUT14) Knockdown Switchgrass Cell Walls to Determine the Structure Synthesized by GAUT14

John Lee
Dr. Debra Mohnen, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Researchers have made progress in understanding plant cell wall structure and function. However, much remains to be learned about wall biosynthesis and fine-scale wall structure. Pectin is a major cell wall polysaccharide that provides structural support to the plant, is important in cell signaling, and binds adjacent cell walls together. Galacturonosyltransferases (GAUTs) are enzymes that synthesize the cell wall glycan pectin. In the model plant *Arabidopsis thaliana*, there are 15 GAUT genes which have either proven or putative pectin biosynthetic activity. Switchgrass is a biofeedstock crop being studied as a source of biomass for biofuel production. Modification of the expression of GAUT14 in switchgrass can potentially increase the quality of this

feedstock for biofuel production. The goal of this study was to determine the structural differences between cell walls from six GAUT14-knockdown (KD) lines compared to WT switchgrass. Cell walls from wild-type and the KD lines were extracted using solvents of increasing severity. The yield differences between the extracts from wild type and the knockdown lines were measured and will be discussed in regards to GAUT14 function. Such data also provide base-line data regarding possible ultrastructural changes in the cell walls of GAUT14-KD plants compared to the wild type. The cell wall fractions from the KD and WT lines are also being analyzed by glycome profiling, monosaccharide composition analysis, and linkage analysis. The goal is to identify which wall polymer(s) GAUT14 synthesizes and to determine which ones are modified in the GAUT14-KD switchgrass lines.

The Effect of Supplemental Vitamin E Form on Blood Oxidative Stress Parameters Measured in Exercising Horses

Kendall Lee
Dr. Kylee Duberstein, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Vitamin E is a component of the antioxidant system of the horse and is commonly included in commercial horse feeds in the form of synthetic alpha-tocopherol acetate. The purpose of the research was to test the effect of supplemental vitamin E form on blood oxidative parameters in exercising horses. The project utilized 16 horses previously housed on pasture. Horses were kept in stall confinement for the duration of the study with 2–4 hours of dry-lot turnout per day. The horses underwent a two week "wash-out" period in which horses were fed a low vitamin E diet with no supplemental vitamin E. Following the wash out period, horses began a two week feeding trial where they were fed the same diet plus 4,000 IU/day of supplemental vitamin E. Horses were randomly assigned to one of the following supplementation groups: synthetic acetate powder, natural acetate powder, micellized d-alpha-tocopherol (liquid), and micellized d-alpha-tocopherol (powder). At the completion of the feeding trial, horses began a two day standard exercise regime. Whole blood and serum were collected four hours post supplementation prior to exercise on the first day and four hours following completion of the standardized exercise test (SET) on the last day. SET protocol was conducted by free lunging in an enclosed round pen at controlled and incrementally increasing speeds. Pre and post exercise serum was analyzed for alpha-tocopherol. Whole blood was analyzed for reduced, total, and oxidized glutathione to assess exercise induced oxidative stress.

Investigations of Chromium Photocatalyzed Cycloadditions

Sang Min Lee, CURO Research Assistant
Prof. Eric Ferreira, Chemistry, Franklin College of Arts & Sciences

Photocatalysis is an emerging area in modern organic synthesis which allows previously inaccessible transformations to be achieved using readily available visible light as an energy source. As of now, Cr photocatalysts have been employed in the radical cation Diels-Alder reaction of electron-rich dienophiles. In this transformation, the electron-rich alkene is rendered electron-poor after single electron oxidation by the catalyst, allowing it to cyclize with the diene. Electron-poor dienophiles have also been employed in this net [4+2] reaction, but because the Cr complexes are not strong enough to oxidize the electron-poor alkene, current research in the lab promotes the idea that it reacts with the diene through a different pathway. Experimental evidence suggests a light-mediated [2+2]-cycloaddition, followed by a

Cr-catalyzed vinylcyclobutane rearrangement. Importantly, this rearrangement yields the net [4+2] product with reversed Diels-Alder regioselectivity. Although a powerful transformation, a limitation of this reaction was that the electron-poor alkene had to be substituted with an electron-rich arene in order for the vinylcyclobutane rearrangement to occur. The possibility of a substrate where the dienophile was tethered by an additional alkene would also undergo the cycloadditions was considered as the proposed products would allow for further structural modification. Two variations of the tethered alkene dienophile substrates with electron-withdrawing substitutes were studied. Neither variation yielded the expected net [4+2] addition product, showing further limited restriction of the Cr catalyst transformation. The research suggests that the cycloaddition with the inclusion of this additional alkene section is not possible with solely the Cr catalyst.

Foreign Aid: Helping or Hurting Democracy?

Benjamin Leigh, CURO Graduation Distinction, CURO Research Assistant
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

Does foreign aid foster democratization—either globally or specifically within Africa? There are conflicting arguments and evidence over the answer to this question. Some scholars maintain that foreign aid hinders development by encouraging corruption and propping up ineffective leaders. They note that although aid can promote democratization in democracies, it often does the opposite in autocracies. In contrast, others find evidence that aid can support and encourage viable opposition parties, improve the strength of an independent media and civil society, and elevate quality of life for citizens. Finally, some scholars strike a middle ground, stating that the attachment of conditions—such as permitting opposition parties or funding specific development projects—to foreign aid can help encourage the development of democracy. What many researchers overlook, however, is the role of intervening factors that may influence the foreign aid- democracy relationship by altering state and leader preferences. This paper therefore re-examines the relationship between foreign aid and democracy, with particular attention to the factors that may impact the effectiveness of foreign aid in encouraging democratization. In the end, I find that there is no cut and dry verdict on aid's efficacy. Instead, a combination of factors, including natural resource wealth, opposition party strength, and respect for human rights unite to impact if and how foreign aid engenders democratization.

Analysis of Surfactant Patterns Induced by Carbon Nanotube Arrays

Christopher Lenear, CURO Research Assistant
Dr. Xianqiao Wang, College of Engineering

As the interest in nanofluidic and nanostructural devices grows, there is an increasing need for nanoscale fabrication techniques that are both accurate and reliable. One novel strategy includes the patterning of block copolymers that can be degraded under ultraviolet radiation, resulting in channels or cracks on surfaces. In this project, we aim to study how carbon nanotubes can be strategically located on surfaces to generate a desired self-assembled pattern of surfactants using coarse-grained molecular dynamic simulations. This may provide a robust design strategy for many devices used for biosensing, electronics, purification techniques, and chemical separations for technology such as lab-on-a-chip and nanocapillary array membranes. By designing a variety of carbon nanotube patterns and studying the effects they have on the organizations of surfactant solutions, we can propose an algorithm to

produce many desired nanostructures. This study will offer an affordable method for creating unique self-assembled surface patterns from surfactant and thereby aid in the progression of many biological and electrical applications.

Far Red LEDs Effect on the Morphology and Flowering of Marigolds
Mary Lewis, CURO Research Assistant
Dr. Marc van Iersel, Horticulture, College of Agricultural & Environmental Sciences

Better control over the growth and development of greenhouse crops can help growers increase profits. Control over when plants flower is especially important. Far-red light is known to be important in triggering flowering responses of many plants. Our objective was to determine whether far-red light from LEDs can make marigolds flower faster. Marigolds (*Tagetes erecta*) typically flower fastest when exposed to long nights. We also wanted to determine whether far-red light affects plant morphology, including height and leaf size. Each day, marigolds were exposed to 16 hours of light and 8 hours of dark, simulating summer time. At the start of the dark period, plants received 0, 15, 30, or 60 minutes of far red light. All other growing conditions were kept as similar as possible. Plants that did not receive far-red light flowered later (~104 days) than those in any of the other treatments (~76 days). Plants that did not receive far-red light were 30 cm tall compared to a height of 87 cm for those exposed to far-red light. Plants grown without far-red also had smaller leaves than those in far-red treatments. Our results show that growers can speed up flowering of marigolds with far-red LEDs, while also producing larger plants. The amount of far-red light required is very low, which makes practical applications easy and cheap.

Conjugated Polymers
Xueying Li, CURO Research Assistant
Dr. Jason Locklin, Chemistry, Franklin College of Arts & Sciences

Organic photovoltaic devices have been made, but the thickness is hard to control. In our lab, we are synthesizing different conjugated polymers and grafting them onto various substrate surfaces to form polymer brushes using SI-KCTP (surface initiated Kumada catalyst-transfer polycondensation). This way, the thickness of the polymer layer of organic photovoltaic devices can be controlled. Ni(0) catalyst is used to make reactive initiator monolayers followed by ligand exchange and then growing polymer brushes from these reactive initiator monolayers. Organic photovoltaic devices have the advantages of covering large areas and flexible surfaces of solar panels over inorganic photovoltaic devices. The controlled thickness polymer coating provides more control on the energy harvest process.

Lung Cancer Cell Enrichment with Buffer Stream via Biocompatible Ferrofluid and Microfluidic Device
So Hyun Lim, CURO Research Assistant
Dr. Leidong Mao, College of Engineering

Metastasis due to circulating tumor cells (CTCs) is the major cause of cancer related deaths. The difficulty in metastasis prevention is due to rarity of CTCs in the bloodstream which is estimated to be one CTC per billions of blood cells. Existing methods to separate cancer cells from whole blood pose three problems: expensive cost, long duration for procedure and physical and chemical damage on CTCs which reduces cell viability, hindering further analysis with separated cells. In this study, lung cancer cell enrichment from buffer stream via microfluidic device with biocompatible ferrofluid, in laminar flow with whole blood sample, provides low cost, short duration lung cancer cell separation with minimized damage on the cell. Lung cancer cell is separated from whole blood based on

the difference in cell sizes. Biocompatible ferrofluid is used to allow transitioning of lung cancer cell from the whole blood to a buffer stream, which minimizes the contact time between lung cancer cell and ferrofluid, allowing least amount of physical and chemical damage done to the cell by biocompatible ferrofluid, as well as increased cell viability. Furthermore, buffer stream was collected to enrich lung cancer cells, allowing not only medical analysis such as diagnosis, prognostic monitoring and treatment plans, but also laboratory analysis including but not limited to therapeutic efficiency, physical and chemical studies of cells as well as genetic studies.

A Romance: A Creative Writing Project
Christian Lisa, CURO Graduation Distinction, CURO Research Assistant
Prof. LeAnne Howe, English, Franklin College of Arts & Sciences

A Romance is an episodic novella about student-athletes. The work follows the parallel storylines of Sarah Jenson, a cross country runner at The University of Vermont, and Darius Williams, a highly-recruited linebacker at Notre Dame. The work is a coming-of-age story that covers themes of social isolation, ambition, drug use, and depression—all through the lens of collegiate athletics. While working on the project, I was interested in an avant-garde, maximalist style. The work employs humor, colloquial language, pop-culture references, footnotes, and social media posts as found objects to convey a substantial amount of detail and achieve intimacy with the reader. The work is written from the shifting perspectives of several different characters—jumping between scenes and people, the story presents reality in a fractured non-diachronic way. Complicated but never confusing, *A Romance* follows characters that are united by their relentless ambition and escapist tendencies. It is an examination of physical achievement and the American dream, and the larger cultural implications of a society-wide obsession with sports.

The Effect of Gender Identification and Division of Labor on the Work and Family Experiences of Same Sex Couples
Lauren Locklear, CURO Research Assistant
Dr. Malissa Clark, Psychology, Franklin College of Arts & Sciences

Although work-family conflict has been thoroughly researched for heterosexual couples (e.g., Byron, 2005; Michel, Kotrba, Mitchelson, Clark, & Baltes, 2011), minimal research exists about the work and family experiences of same-sex couples. With the recent ban on same-sex marriage lifted, it is more critical than ever to understand the work and family experiences of same-sex couples. In heterosexual couples, traditional gender role expectations suggest that men tend to contribute more financially while women place greater focus on home and family responsibilities (Blair-Loy, 2001). The small amount of research on gender identification and division of labor for same-sex couples is inconclusive. Therefore, this study explores gender-identification and division of labor in both gay and lesbian couples, and how this affects levels of work-family conflict. Participants will be recruited through advertisements posted on Facebook. To be eligible for the study, couples must be currently in a long-term same-sex relationship, cohabitating with their partner, and employed full-time. During the first phase of the study, each partner completes a questionnaire that assesses their gender role identification (Bem, 1974), division of labor in the household (custom measure), partner support (Shakespeare-Finch & Obst, 2011), and job demands (van Veldhoven & Meijman, 1994). Two weeks following completion of phase one of the study, each partner completes a questionnaire that assesses work-family conflict (Carlson, Kacmar, & Williams, 2000). Multiple regression analysis will test the

relationship between division of labor and work-family conflict, as well as the moderating role of gender role identity, job demands, and partner support.

Third Party Reactions to Mistreatment: A Meta-Analysis

Lauren Locklear, CURO Research Assistant
Ian Armstrong
Dr. Marie Mitchell, Management, Terry College of Business

Mistreatment in the workplace is commonplace, and may involve supervisors, peers, and even organizational outsiders such as customers. This mistreatment manifests in many forms such as abusive supervision (Tepper, 2000), social undermining (Duffy, Ganster, & Pagon, 2002), incivility (Andersson & Pearson, 1999), bullying (Einarsen & Skogstad, 1996), exclusion or ostracism (Ferris, Brown, Berry, & Lian, 2008; Hitlan & Noel, 2009), deviance or counterproductive behavior (Robinson & Bennett, 1995), and sexual harassment (Lim & Cortina, 2005). Previous research focused on the employer-employee relationship, particularly the reaction of the employee (the victim) to mistreatment by his or her employer (Skarliki & Kulik, 2005). However, recent research has moved beyond the victims of mistreatment to examine the reactions of third parties who witness abuse events. A third party witness is as an individual who forms impressions of organizational justice based upon direct, indirect, or vicarious experience of an organization. At present, this research stream has reached a critical mass, making it necessary to analyze the empirical findings to reveal the direction third party abuse research should take moving forward. Using the meta-analytic techniques outlined by Schmidt & Hunter, (2014) we will examine the effects of mistreatment episodes on third parties. We propose that witnesses will have cognitions (i.e., thoughts of revenge) and emotions (i.e., feelings of anger) following the abuse event which will lead to changes in behavior, well-being, and job attitudes. This meta-analysis aims to determine which of the previously explored relationships in the existing empirical research have the strongest support. Findings will provide a model for researchers to use moving forward in third party research.

Investigating the Role of Cyanogenic Glycosides in *Passiflora incarnata* (Maypop)

Atul Lodh, CURO Research Assistant
Dr. Rodney Mauricio, Genetics, Franklin College of Arts & Sciences

Plants produce the largest variety of metabolites of any organism on the planet. However, the evolutionary forces that generate this diversity are still unresolved. A leading hypothesis is that these metabolites serve as defenses against insect herbivores that utilize plants for food. Defensive metabolites produced can alter a plant's fitness and the fitness of the herbivore that feeds on it, resulting in a co-evolutionary relationship between the two. One putatively defensive metabolite is cyanogenic glycoside. Hydrolysis of this compound leads to the production of hydrogen cyanide, a toxic compound that interferes with cellular respiration. A plant species that produces cyanogenic glycoside is *Passiflora incarnata*, a plant species native to Athens, Georgia. To test the hypothesis that cyanogenic glycoside is a defensive metabolite and therefore is under natural selection by insect herbivores, a common garden experiment was conducted over the summer of 2015 using the plant species *P. incarnata*. A split-plot design was used where clonal replicates of genotypes were exposed to herbivores or protected from them using a pesticide. If herbivores are selecting for cyanogenic glycoside production, then plants that produce the most cyanogenic glycosides should have the highest fitness (measured by looking at fruit production)

when exposed to herbivores. Furthermore, when plants are protected from herbivores, there should be relaxed selection on cyanogenic glycoside production. This work provides further insight into the importance of metabolites in mediating plant-herbivore co-evolutionary interactions.

Regulation of Intracellular Membrane Fusion by V-ATPase Subunits

Michael Lopez, CURO Research Assistant
Dr. Vincent Starai, Microbiology, Franklin College of Arts & Sciences

Eukaryotic organisms must properly package, sort, and deliver proteins and membranes to a number of essential intracellular organelles during normal cell growth, which usually demands the fusion of transport vesicles with their target membranes. For these membrane fusion events to occur, a conserved "core" protein machinery consisting of SNARE proteins, Rab-family small GTPases, and multisubunit tethering factors must be present on both membranes. While much of the fundamental mechanistic information regarding the activity of this core machinery during fusion is known, additional factors which precisely regulate the SNAREs/Rabs/tethering factors during fusion remain to be characterized. It is now thought that a number of accessory proteins and lipids help catalyze specific fusion events by directly regulating the activities of these "core" proteins. Previous research has potentially identified one such accessory protein, the membrane-bound multisubunit subdomain of the eukaryotic V-ATPase (Vo). In the budding yeast, *Saccharomyces cerevisiae*, vacuolar (lysosomal) membranes lacking the Vo subdomain fail to homotypically fuse *in vitro*, and it has therefore been proposed that Vo serves a structural role in regulating endolysosmal SNARE-dependent fusion events. To test the hypothesis that the Vo domain plays some role in vacuolar fusion, modified yeast strains lacking both subunit "a" isoforms (Vph1p and Stv1p) of the V-ATPase Vo domain will be modified to express TgVha1, the Vph1p/Stv1p ortholog originating from the apicomplexan parasite, *Toxoplasma gondii*. Yeast strains expressing TgVha1 in place of Vph1p/Stv1p displayed a fragmented vacuolar morphology similar to yeast strains unable to properly fuse their vacuoles *in vivo*. Furthermore, these strains were able to grow in the presence of zinc and caffeine, suggesting that the V-ATPase formed with TgVha1 was functional for vacuolar acidification. These results suggest that this biochemically active V-ATPase was unable to properly regulate yeast endolysosomal fusion events, thus providing evidence that subunit "a" may play a physical role in regulating membrane fusion. Further characterization of this activity will require the isolation of intact vacuoles from yeast strains expressing TgVha1 and measuring V-ATPase activity *in vitro*, and the direct measurement of homotypic fusion of TgVha1-containing vacuoles. These results will help elucidate the role of the V-ATPase "a" subunit in endolysosomal fusion events.

An Analysis of Trends in Difficulties Faced by Beginning Music Educators, with Discussion and Implementation of Effective Classroom Solutions

Duncan Lord
Dr. Joshua Bynum, Hugh Hodgson School of Music

This project will provide a meaningful look at the challenges of beginning a career in education, with the goal of addressing a common problem among early educators: a perceived lack of sufficient experience to handle situations faced early on. This research will conduct a cross-sectional survey of primary and secondary music educators, with the intent to locate trending difficulties observed by the sample group within the first five years of teaching. An analysis of these trends will be presented, looking at why

certain experiences and difficulties were specific to a specialization, while others were shared across the entire field. Discussion of effective solutions suggested by the subjects will be presented along with recommendations for application in the classroom. By providing application and implementation strategies, this project will be a resource for pre-service and beginning music educators.

Motherhood, War and Ownership in Bertolt Brecht's "Mother Courage and Her Children" and "The Caucasian Chalk Circle"

Kelsey Lowrey, Foundation Fellow
Dr. Martin Kagel, Germanic & Slavic Studies, Franklin College of Arts & Sciences

I studied the presentation and implications of motherhood in two famous epic theatre plays by the German author Bertolt Brecht: Mother Courage and Her Children / Mutter Courage und ihre Kinder and The Caucasian Chalk Circle / Der kaukasische Kreidekreis. The concept of motherhood was examined first through the lens of war and peace, the main characters of these plays are women displaced by various historical wars; the fruitfulness of their motherhood was found to be closely related to the justness of different violent conflicts. As the women all lived in exile, their motherhood was also examined through its relation to the home and homemaking, as well as the historical context of real-world mothers in exile and in the home, and Nazi propaganda of the era dealing with racial and land-based ideals of motherhood. An in-depth look was taken at the character Kattrin from Mother Courage and her status as a role accessible to female and otherwise oppressed audience members, as well as her complicated relation to performative gender, female sexuality, and sexual violence. Ultimately, the findings deal with motherhood and female disenfranchisement on one end, and motherhood as an allegory for the Marxist concept of "ownership" on the other, and its aptness as such.

Modeling and Analysis of Virus-Bacteria Interactions in the Marine Environment

Angela Lucero
Dr. Adrian Burd, Lamar Dodd School of Art

Viral infections in the ocean are a major source of mortality in marine bacteria, thereby influencing the composition of bacterial communities. The purpose of this study is to investigate the interactions between viruses and bacteria in the marine environment to determine the extent to which these interactions influence dissolved organic carbon (DOC) concentrations and the bacterial community composition. Consider a lysed bacterial cell. It will produce a small cloud rich in both dissolved nutrients and viruses. The high nutrient concentrations will likely attract motile bacteria, while the high viral concentrations will increase their chances of infection. This study will use mathematical descriptions of virus-bacteria interactions and bacterial chemotaxis that will be investigated analytically and numerically. The study is expected to produce a model indicating how bacterial communities and DOC concentrations change as functions of viral concentration and infection rates. This is important because changes in bacterial community composition, especially in the deep ocean, affect the amount of carbon that can be sequestered by the oceans, which in turn has implications for the amount of carbon dioxide in the atmosphere.

Fluorescent Protein Incorporation in *E. coli* for Determination of Gene Expression Levels

Andrew Lyon, CURO Research Assistant
Dr. Yajun Yan, College of Engineering

The following research project focuses on a metabolic engineering approach for the creation of a biosensor. The overall goal is to

clone a fluorescent gene in a microorganism to determine expression levels of a protein of interest. Green Fluorescent Protein is derived from the crystal jellyfish *Aequorea Victoria*. By cloning the fluorescent gene under the promoter of interest, gene expression can be monitored. In essence, the protein can be used as a transcription reporter. Following the construction of the plasmid containing the fluorescent gene, we introduced the plasmid in *E. coli*. It is known that acrylic acid has an effect on gene expression levels by interacting with the specific promoter. Shake flask fermentations were subsequently carried out to determine the sensitivity of the fluorescence activity with the addition of varying acrylic acid concentrations. Due to issues with the machine that measures fluorescence intensity, we are still waiting on results. We expect to see an increase in fluorescence activity with increases in acrylic acid. This approach is very useful when studying transcription of genes under various promoters. This is very important for the optimization of microbial processes for the production of chemicals, renewable fuels, biopharmaceuticals, etc.

Exploring Alternative Mechanisms of RidA-Independent 2AA Stress Relief

Samuel Macfie, CURO Research Assistant
Dr. Diana Downs, Microbiology, Franklin College of Arts & Sciences

Many proteins that belong to the widely conserved RidA/YER057c/UK114 protein family hydrolyze reactive enamine/imine intermediates generated by some pyridoxal 5'-pyrophosphate (PLP)-depedent enzymes. The RidA protein in *Salmonella enterica* catalyzes the hydrolysis of the reactive enamine, 2-aminoacrylate (2AA), produced by PLP-dependent serine/threonine dehydratases, preventing 2AA from diffusing through the cell and damaging cellular targets. In *S. enterica*, cystathionine β-lyase (MetC) participates in methionine biosynthesis by cleaving the β-carbon-sulfur bond of cystathionine to yield homocysteine. Suppressor analysis showed overexpression of the *metC* gene in trans could overcome the growth defects of a *ridA* mutant strain. The molecular mechanism that mediates this suppression is currently unknown. Preliminary experiments indicated MetC does not possess RidA activity, suggesting an indirect mechanism of overcoming 2AA stress. β-cystathionase (MalY) and tryptophanase (TnaA) from *Escherichia coli* are PLP-dependent enzymes that perform β-elimination reactions similar to MetC and share a conserved protein fold-type. Our investigation seeks to determine if these enzymatic similarities to MetC allow MalY and/or TnaA to alleviate 2AA stress in the absence of RidA. Work presented here describes the molecular cloning and heterologous expression of *malY* and *tnaA* from *E. coli* in *S. enterica* lacking RidA. Insights from this work will aid us in elucidating the mechanism of MetC suppression of *ridA* strain growth defects.

Eradicating Food Insecurity in Metro Atlanta

Mallika Madhusudan, Foundation Fellow
Dr. Jerry Shannon, Geography, Franklin College of Arts & Sciences

The USDA defines households as food insecure if they are located more than one mile away from a source of fresh produce or are generally unable to purchase fresh food. Because of the high price of fresh produce and the lack of transportation, many Atlanta citizens are considered food insecure. This means they are forced to turn to fast food restaurants or convenience stores for their dietary needs, both of which rarely sell healthy alternatives. A continuous diet lacking in fresh produce contributes to high rates of obesity, heart disease, and hypertension. These diseases not only have serious health implications, but also account for major economic losses. This leaves us with the

question: What action must be taken to address the issue of food insecurity? This paper begins with a background of the issue of food insecurity in the context of Atlanta, describes the issue's various causes, symptoms, and implications and then develops four policy alternatives, including the status quo. The other policy alternatives are a Healthy Corner Store Initiative, Food-to-Institution programs, and public-private partnership loan funds. The paper will then utilize a policy matrix to compare and contrast these various policy alternatives based on health outcomes, change in fresh produce consumption, political feasibility, and a basic cost-benefit analysis. Through this method of policy analysis, this paper concludes that the Healthy Corner Store Initiative best addresses food insecurity within Atlanta. Following this recommendation, the paper will review implementation of the chosen policy and identify potential challenges.

Correspondence between Family Needs and Family Goals: Implications for Early Childhood Interventions for Low-Income Families

Emily Maloney, Foundation Fellow
Dr. Stacey Neuharth-Pritchett, Educational Psychology, College of Education

Children living in poverty often encounter adverse childhood experiences (ACEs), placing them at-risk for prolonged negative cognitive, emotional, physical, and mental health issues. Research from neuroscience suggests children living in toxic stress conditions demonstrate decreased executive functioning skills--the higher cognitive functions responsible for memory, inhibitory control, and mental flexibility. The Head Start program serves as a stabilizing preschool environment for children with ACEs to attenuate the effects of living in poverty. When applying for Head Start, families supply background information on ACEs and family needs. Head Start, then theoretically, uses the family needs assessment to help the family set attainable goals realized by program exit. What is missing from this process is often congruence between stated goals and identified risk factors. Further, interventions that support the needs of families are often misaligned with the true needs of families resulting in less than efficacious outcomes. The research question for this casual-comparative study was: What is the relationship between number of ACEs, family needs and goals, and child developmental outcomes for families with children in home-based and center-based early care and education programs? Results indicated the number of ACEs experienced by families was related to needs expressed by parents including employment, finances, mental health resources, parent/child bonding, and education. About a quarter of children with more ACEs had parents who specified goals inconsistent with needs. Children in families experiencing more ACEs had poorer cognitive development scores. Implications for the highest-need families where goals were misaligned with interventions will be discussed.

Reducing Teacher Turnover in Georgia Public Schools

Emily Maloney, Foundation Fellow
Dr. Linda Renzulli, Sociology, Franklin College of Arts & Sciences

This policy research investigated the teacher turnover rate in public schools in Georgia, particularly in schools with high percentages of low socioeconomic status and minority students. This research considered the symptoms and causes of turnover in these environments, and why previous policies enacted by the Georgia Department of Education have failed. Through the literature review and interview process, some common themes were identified as to why teachers consistently leave schools. These qualities of school environment typically included

practices that de-professionalized teachers, culminating in teachers losing a sense of autonomy within the school, discovering a lack of support from other teachers and administration, and being unsatisfied with their salary in relation to how many hours they put into their jobs both in and out of schools. To address these causes, three policy alternatives were developed: a research and development program, an intensive district-wide mentorship program based off of a highly successful model in Maryland, and treating departments within schools as designers by removing some of the bureaucratic accountability measures which cut into teachers' time both at and away from school. After using a policy matrix to analyze the effectiveness, cost-benefit, and feasibility of each alternative against the status quo, this policy paper asserts that the best option is the research and development model.

A Policy Proposal for the Reduction of Violence in Georgia's State Prisons

Taylor Martin
Rachael Andrews
Dr. Andrew Whitford, Public Administration & Policy, School of Public & International Affairs

Georgia has the 6th highest incarceration rate in the United States and operates the 5th largest prison system in the nation, costing approximately one billion dollars annually. As a result of the high incarceration rates, overcrowding has led to violence and astronomical costs on behalf of the Georgia taxpayers due to housing inmates. In 2014, the Southern Center for Human Rights released a report detailing Georgia's violent prison crisis. Georgia has seen a rise in the number of homicides and assaults throughout the prison system. In 2012, the number of homicides in Georgia surpassed those of many states in the past ten years, from 2001–2011. Despite the State of Georgia's attempted criminal justice reform, prison populations remain high, continuing the cycle of violence and high prison costs. This paper proposes policy options to the Georgia Board of Corrections in an attempt to reduce current prison populations or implement new strategies and policies to decrease the likelihood of violence in the future. The policy options evaluated include: the reworking of current legislation pertaining to drug possession, including but not limited to the de-criminalization of marijuana and the increase in the minimum amount of drugs considered to be possession with intent to distribute; the rehabilitation and improvement of vocational training programs; and the increased provision of resources available to prison officials to facilitate effectiveness and supervision. Ideally these policy approaches would be included in a comprehensive three-pronged approach; however, it is recommended that the State of Georgia adopt policy number two.

Cooling Fabric: The Future of Keeping Cool

Molly Mastin, CURO Research Assistant
Dr. Suraj Sharma, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

Smart textiles are the future of the textile industry. As technology becomes more readily available, it is integrating into many facets including the textile industry. It allows for more sustainable practices and allows people to be safer, and more comfortable. One such textile is a fabric called Brrr!. This fabric is a cooling, and wicking fabric that uses powered air to keep the wearer cool. Being powered by air means that the air flow through the fabric is used to regenerate your cool, verses a finishing that would wash off over time. It also provides UV protection. There are many instances in which cooling fabric could greatly improve the wearers' experience, and save firms a lot of money. One such case is in the use of health care workers in very hot areas

such as in the case of EBOLA workers in West Africa. Another use could be in military personnel in desert settings. I tested Brrr! Fabric in order to find out more about the fabric's structural characteristics, in order to determine alternative uses outside of the fashion industry. I used several different test methods including determining yarn strength, and wicking capability of the fabric. The result is that this fabric could be suitable for more than just fashion uses. Cooling fabrics could be used in uniforms and other ways in order to help keep wearers safe from overheating, and keeping them cooler in general. This also lead me to ask the question of the appropriateness of using this and other smart fabrics in alternative ways in order to keep users safe, and comfortable.

Male Participation in Chronic Disease Self-Management Education (CDSME) Programs

Jamarcus Mathis, CURO Honors Scholar
Dr. Matthew Smith, Health Promotion & Behavior, College of Public Health

Females outnumber males in the older adult population and are more likely to participate in evidence-based health promotion programs. Despite the widespread availability of Stanford's Chronic Disease Self-Management Education (CDSME) programs, and their known health-related benefits, male participation remains low. This study: (1) compares personal characteristics between males and females who attended CDSME program workshops; and (2) identifies factors associated with successful intervention completion (attending 4+ of the 6 workshop sessions) among male participants. Data were initially analyzed from 62,757 adults collected during a national dissemination of CDSME programs spanning 47 states and two territories. Logistic regression was performed with males only (n=13,088) to examine factors associated with workshop attendance. Of the 62,757 adults who enrolled in CDSME programs, only 20.9% were male. Compared to female participants, male participants were younger ($x^2=316.86$, $P<0.001$) and reported fewer chronic conditions ($x^2=414.94$, $P<0.001$). Among male participants alone, those age 65+ (OR=133, $P<0.001$) and those residing in non-metro areas (OR=1.14, $P=0.019$) were more likely to successfully complete the intervention. Compared to attending workshops in senior centers, males who attended workshops in healthcare organizations (OR=0.79, $P=0.001$) and residential facilities (OR=0.73, $P<0.001$) were less likely to successfully complete the intervention. Men who participated in workshops with a larger proportion of male participants were more likely to successfully complete the intervention (OR=2.21, $P<0.001$). Once engaged in CDSME programs, male participants obtain a similar intervention dose as their female counterparts. Findings highlight opportunities to tailor CDSME program recruitment and retention strategies for men.

An Investigation into the Complex Viral Interactions between *Microplitis demolitor* Bracovirus and TnAV-2a, an Ascovirus

Johnathan Mayfield, CURO Research Assistant
Dr. Gaelen Burke, Entomology, College of Agricultural & Environmental Sciences

Parasitoid wasps are a diverse and abundant group of organisms that spend part of their development either within or on their host. One group of parasitoid wasps, the superfamily Ichneumonoidea, has evolved an obligate, beneficial symbiosis with the double-stranded DNA Polydnaviruses. *Microplitis demolitor* bracovirus, or MdBV, is a polydnavirus found within the ovaries of the wasp host *M. demolitor* and has been shown to alter the immune system of the host to promote parasitism. Our project aimed to determine if MdBV interacts with other

viruses within the host, specifically the ascovirus TnAV-2a. TnAV-2a is a pathogenic, double-stranded DNA virus that infects early stages of Lepidopteran hosts and is only transmitted on the ovipositor of parasitoid wasps like *M. demolitor*. Based on quantitative PCR analysis, we have determined a species specific interaction between these two viruses. In parasitized hosts, TnAV-2a replication was lower at 24, 48, and 168 hours post infection within *Pseudoplusia includens*. In the hosts *Trichoplusia ni*, *Spodoptera frugiperda*, *Helicoverpa zea*, and *Heliothis virescens* we did not see any significant difference between parasitized hosts and unparasitized hosts in terms of TnAV-2a replication at 48 hours post infection. Within *P. includens*, we infected the host with both MdBV and TnAV-2a and determined that MdBV is the cause for lower TnAV-2a replication. Lastly, we unsuccessfully attempted to generalize the effect we saw in *P. includens* to a cell line derived from the same host suggesting that this interaction is more complex and involves many factors within the host.

Earning Disparity among White and Black Women in South Africa

Thomas McBrearty
Dr. Laura Zimmermann, Economics, Terry College of Business

This research will center around the decreasing race-based income inequality in post-Apartheid South Africa over the last 22 years. Before apartheid was abolished there was overt and legal discrimination against black individuals in the country that directly limited their educational and employment opportunities, and there exists thorough Census Data from both before apartheid's abolition and ten years after. This will enable using a difference-in-difference analysis using identical families and their earning potential and familial income over time, using the end of apartheid and extension of the lucrative South African-pension program to every working citizen (i.e., extension to non-white citizens) as the center point of the analysis. It is my contention that the extension of the pension program to the entire working populace drastically increased the educational opportunities for younger black South Africans, both male and female, and therefore drastically increased their lifelong earning potential. I will be using existing research on this topic and raw household Census data to measure if and by what degree the income inequality and earning potential gap has decreased.

An Exploration of Communicative Intent and Its Relation to Early Vocalization Production in Two Young Children with Autism Spectrum Disorder

MacKenzie McGraw, Breanna Johnson, Sherry Sayavongsa, Alexis Pope, Meredith Towey, Hayley O'Hara, Sabrina Williams, Courtney Todd, Brianna Kelley, Anna Fink, Chase Kranzlein
Dr. Sandie Bass-Ringdahl, Communication Sciences & Special Education, College of Education

Autism Spectrum Disorder (ASD) refers to the wide range of symptoms, skills, and levels of impairment or disability that children with ASD can have. The most common sign that prompts parental concern is the delay in onset of spoken words, including delayed or disrupted onset of babbling (beyond the typical 6–10 months of age) and gesture usage (Barenek; Mitchell et al.). Early identification and intervention are widely recognized as critical to language development and are significant variables in the development of communication (Yoshinaga-Itano, 1998). Children with ASD who have undergone early intervention demonstrate gains in verbal and nonverbal communication, intelligence test scores, and peer interaction (Wiggins et al.). The purpose of the current study is to determine if vocalization production is altered in the presence of a caregiver or an electronic

device. The current study is a retrospective analysis of data from two participants with ASD and their caregivers. The first child observed was a 3 year, 9 month old male diagnosed with ASD and developmental screen of 4 months. The second child observed was a 1 year, 7 month old male diagnosed with ASD and developmental screen of 8 months. A 12–16 hour vocalization recording was collected in the home using the LENA device. This recording was then segmented into 5 minute blocks using an automated algorithm for basic components. The results of this analysis may provide insight into intervention techniques that may increase vocal productions serving a communicative function. The results may also have implications for environmental modifications in the home.

Understanding the Public's Relationships with ISIS and Counter-Terrorism Digital Media

Katherine McKeogh
Dr. Juan Meng, Grady College of Journalism & Mass Communication

Purpose: The purpose of this research is to examine and analyze the digital communication strategies used by ISIS, as well as the strategies used by the US State Department against ISIS. The research aims to learn who is viewing ISIS's messages, as well as learn more about who is targeted by and most receptive to their messaging. It also aims to learn whether or not the anti-terrorism social media strategies of the US State Department are effective. *Design/methodology/approach*: The researcher used two research methods in this study to investigate the subject: (1) an online survey of UGA undergraduate students; (2) two focus groups—one with four participants and the other with two participants—with UGA students. *Findings*: Results suggest that students at the University of Georgia are generally unaware of ISIS's social media presence. Despite ISIS's 9,000 social media accounts, almost no students had seen an ISIS tweet. Of the students that had seen ISIS messaging, the majority had been exposed to videos and remembered those most clearly. Students felt negatively about the US State Department's counter-terrorism efforts when compared to ISIS's efforts on social media. *Practical implications*: Contrary to general opinion, most young adults are not exposed to or are aware of ISIS's social media presence. However, the US State Department needs to re-construct its counter-terrorism efforts via social media, especially in video creation as young adults are most frequently exposed in that way. The lack of sophistication in current US State Department videos as compared to ISIS videos, led students to feel more threatened by ISIS. *Originality/value*: This study provides insights into ways to improve the effectiveness of online counter-terrorism efforts. It is important to improve social media tactics now, as terrorist group's influence in the digital sphere will continue to evolve.

Implementation of picoSpin(TM) NMRs into Organic Chemistry Teaching Laboratories through Spectral Analysis of Fischer Esterification Products

Emma Meehan, Doyle Wallace
Dr. Richard Morrison, Chemistry, Franklin College of Arts & Sciences

1H NMR analysis is an important analytical technique discussed in the introductory organic chemistry lecture course as it is most useful in real-world applications for the identification of a product or product mixture. The Chemistry Department recently acquired three desktop 1H NMRs for the undergraduate organic laboratories. Until now, NMR analysis has been largely impossible for the vast majority of students in teaching laboratories. Using these new technologies, the picoSpin(TM) NMRs were integrated into the undergraduate instructional

laboratory to expose students to advanced analytical techniques in the exploration of experimental results. Students specifically used unknown starting alcohols to synthesize esters through Fischer esterification, identifying the unknown starting component via spectral analysis of the product. Over the course of three semesters, 483 students out of 636 (76%) students correctly identified the starting alcohol and 76% of students indicated via survey that 1H NMR was the most helpful identification tool in their analysis. This experience strengthened the concept of NMR spectral analysis and provided students with the opportunity to employ technology commonly used in academic research facilities.

Longitudinal Assessment of a Porcine Traumatic Brain Injury Model Utilizing Immunohistochemistry

Mary Mehegan, CURO Summer Fellow, CURO Research Assistant
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

In the United States alone, approximately 50,000 deaths result from traumatic brain injury (TBI) annually. At this time, there is no adequate TBI treatment. Neural stem cells may serve as a regenerative cell replacement therapy, as they are capable of differentiating into neurons, astrocytes, and oligodendrocytes and produce regenerative factors such as vascular endothelial growth factor. These cells have been shown to lead to structural and functional improvement in rodent models that have suffered similar neural injuries. However, treatments that have been developed in rodent models regularly fail in clinical trials, thus more predictive large animal models are needed. With a large gyrencephalic brain and gray-white matter composition similar to humans, the pig is an effective large animal model. The objective of this study is to longitudinally assess changes in brain cellular composition in a piglet model of TBI. Piglets underwent surgery to generate a concussive TBI. To assess the time course of TBI pathology, piglets were sacrificed and brain tissues were collected 1 day, 1 week, and 4 weeks post-TBI. At the site of neuronal injury we assessed TBI pathology using Olig2, NeuN, and GFAP markers. Although no significant changes in Olig2 were noted; we found that neuronal cell death results in a reduction in NeuN staining 1 week post TBI, and that the upregulation of astrogliosis results in increased GFAP concentrations at both 1 week and 4 weeks post TBI. Once typical TBI pathology is fully established, we can determine if cell therapy aids in recovery of the brain at the cellular level.

Determining the Effect of Gut Microbes on *Drosophila suzukii* Gene Expression

Elijah Mehlferber, CURO Research Assistant
Dr. Patricia Moore, Entomology, College of Agricultural & Environmental Sciences

Drosophila suzukii inhabit a unique ecological niche, rather than ovipositing on rotting fruits they target ripening fruits. The larvae of most drosophilid species obtain the protein in their diets by consuming yeast that grows on rotting fruit, a resource not readily available to *D. suzukii* larvae. This raises interesting questions as to how *D. suzukii* larvae have adapted to thrive in a low protein environment. Previous research has shown that *Drosophila melanogastor* are unable to develop without gut microbes in a low protein environment, due to the inability to modulate their insulin signaling pathways. However, *D. suzukii* are able to develop under the same conditions, leading to the assumption that some function of the gut microbes has been adapted into the organism. In order to test this hypothesis *D. suzukii* larvae will be reared on low/high protein diets and in the presence/absence of gut microbes, and the expression of genes related to the insulin signaling and nutrient management pathways

will be measured. We expect that the *D. suzukii* raised on the low protein diet without gut microbes will show altered expression of these genes due to their hypothesized ability to self-regulate these pathways. This will allow insight into the interaction of gut microbes and *D. suzukii* as a result of their adaptation to lower protein environments.

Proteome and Glycome Profiling of Medaka Exposed to Chronic, Low Level Ionization Radiation

Olivia Mendel
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Within the United States there are over 1000 locations that are contaminated with radiation. These places range from small laboratories to massive nuclear weapon facilities. Although this ionizing radiation (IR) is clearly recognized as problematic, there is minimal understanding of the mechanisms through which radiation influences organismal adaptation. Furthermore, most experimental studies focus on the effects of acute, high dose IR. Thus, little is known about the effects of chronic, low doses of IR on vertebrate. Using Medaka fish as the model aquatic organism, this study aims to 1) quantify comparative proteomic and glycomic responses of Medaka across varying levels of chronic, low doses of IR and 2) identify proteins and glycans involved in organismal adaptation. These goals will be accomplished through coupling mass spectrometry with current bioinformatics tools to analyze samples of Medaka exposed to chronic, low doses of IR. Progress in this study has been made and thus far over 875 proteins have been quantified and glycome analysis has revealed major differences in the glycan composition of the control carcasses as compared to the treated samples. In the long term, these findings will elucidate the physiological responses of organisms to chronic, low dose IR and may be used to generate testable hypotheses regarding the evolutionary pathways associated with IR.

A First Description of Nest Behavior in Red-and-Green Macaws

Courtney Meyer
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

The nest behavior of the Red-and-Green Macaw (*Ara chloropterus*; the largest species in the *Ara* genus) in the wild is largely unknown and undescribed in the literature. We provide the first description of wild macaw nest behavior in which behaviors are directly observed and quantified. To understand the nest behavior of *A. chloropterus*, we have the following three objectives: to document the behavioral repertoire of nestlings; to examine behavior of the parents in the nest; and to determine nestling behavior in the presence vs absence of an adult. Video footage, recorded from approximately 6AM to 6PM within one nest over 6 days between August and October 2013, recorded the behavior of 4 individuals, including 2 adults and 2 nestlings. Videos are currently being coded using the Observer XT software. We report findings from the first two days, when the chicks were approximately 25 and 40 days old. Stationary behavior (e.g., perching) constituted the majority of the nestlings' time budget (91%). Adults were present with the nestlings 41% of the time, and when there, spent 24% of their time feeding the chicks, 36% stationary, and the remainder of their time in other activity. Nestlings vocalized six times more frequently than adults and only when adults were present. We plan to perform additional analyses of adult and nestling behavior as coding continues. Preliminary results show that Red-and-Green Macaws provide bi-parental care to young chicks, and in particular spend much time feeding them while in the nest.

Computational Modeling of Laboratory X-Ray Emission Due to Low-Energy Collisions of H-like and He-like Ions with H2

Ansley Miller
Dr. Phillip Stancil, Physics & Astronomy, Franklin College of Arts & Sciences

Charge exchange between highly-charged ions and neutral molecules, which occurs when the solar wind, or other astrophysical plasmas, collide with cool gas, emits observable X-rays with specific line intensities. Recent experiments of this process at Lawrence Livermore National Laboratory measured the X-ray hardness ratios of low-energy collisions between hydrogen- and helium-like ions with H2. Using our recently developed X-ray modeling package, Kronos_v2, which utilizes multi-channel Landau-Zener charge exchange cross sections, we have computed theoretical hydrogen-like hardness ratios to aid in interpretation of the experimental data. While the computed hardness ratios are somewhat smaller than the experiment, it provides an improved representation over earlier classical trajectory predictions. We are also in the process of building Kronos_v3; further enhancing the comprehensive charge exchange database to include helium-like and multielectron ions to allow for comparison with experiments and for models of hot astrophysical environments such as supernova remnants, star-forming galaxies, and galaxy clusters.

Results of Gender and Personality Interactions on Mobility in a Sample of Older Adults

Katherine Miller
Dr. Lloyd Stephen Miller, Psychology, Franklin College of Arts & Sciences

Due to a growing elderly population, measures and factors that predict mobility outcomes for older adults could prove useful. The focus of this project is whether personality, as moderated by gender, has an effect on mobility outcomes in late adult life. Based off of the literature of the general adult population, and research of older adult samples, we expected a significant effect. The sample (N = 100) was gathered from baseline measures of several aging studies from the Neuropsychology and Memory Assessment Laboratory at the University of Georgia. The sample composed of 59 women and 41 men, ranging in age from 64.5 to 99 years of age (= 74.46, s = 6.92), with a majority (90%) self-identifying as Caucasian. Using the Five Factor Inventory as a measure of personality, the Short Physical Performance Battery as a measure of mobility, and self-reported gender, the authors performed five separate multiple regressions of the interaction between each factor of personality and gender on mobility. We failed to find any main effects between personality and mobility, and gender and mobility, and we failed to find any significant interaction between personality and gender on mobility (all p-values > 0.05). This result is surprising, since the literature typically shows effects of different personality factors on various aspects of physical health, but it might be due to a relatively healthy sample with overly similar personality profiles. The authors recommend that future studies use more diverse samples for their analyses.

Friends and Coworkers

Molly Minnen
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

Although gratitude has been connected to positive outcomes in close relationships, research has not yet examined how people experience and express gratitude in the workplace. In gratitude exchanges, a benefactor makes a sacrifice to provide a favor to a recipient. We expect the characteristics of the benefactor may influence the extent to which recipients perceive a sacrifice as difficult. Recipients may feel as

though it was more of a sacrifice for the low self-control benefactor to do the favor than it was for the high self-control benefactor. Consequently, recipients may experience and express less gratitude toward a high self-control benefactor. The goal of this study will be to assess how a recipient might feel different levels of gratitude towards a benefactor if that benefactor is perceived as having high or low levels of self-control. Participants will read personality profiles for a recipient and a benefactor followed by a scenario where the benefactor does a favor for the recipient. Participants will be randomly assigned to see a benefactor profile reflecting high (vs. low) self-control; the recipient profile will remain constant in all conditions. Participants will evaluate how they think the recipient will respond to the favor. We hypothesize that participants will predict the recipient will feel less gratitude towards benefactor in the high self-control condition than in the low self-control condition. Results from this study could provide novel insights into why people express gratitude differently towards others and how companies could foster positive workplace experiences for valuable employees with high self-control.

Investigating miRNA-195-Mediated Regulation of Cell Cycle Gene CHEK1 in Respiratory Syncytial Virus (RSV) Replication

Madison Miracle
Dr. Ralph Tripp, Infectious Diseases, College of Veterinary Medicine

Respiratory syncytial virus (RSV) is the most common cause of bronchiolitis in young children and the elderly, often resulting in complications such as asthma. A class of 21-23nt small RNAs called microRNAs (miRNAs) can regulate post-transcriptional expression of host genes and modify viral replication. Of the validated miRNAs known to influence RSV replication, we have focused on miR-195, which is predicted to regulate CHEK1—a host gene involved in cell cycle regulation and RSV replication. CHEK1 expression and its subsequent impact on viral replication will be monitored using qPCR and viral plaque assays following transfection of miR-195 inhibitors and mimics, such as silenced using short interfering RNAs (siRNAs). Additionally, we will assay for cell cycle regulation and DNA damage upon CHEK-1 and miR-195 modulation. These findings will increase our understanding of molecular mechanisms at the viral-host interface that contribute to virulence and aid future development of targeted RSV therapeutics using RNAi technology.

Differences in Brain Morphometry as a Predictor of Smoking Cessation Treatment Success in Nicotine-Dependent Smokers

Abigail Mistretta
Dr. Lawrence Sweet, Psychology, Franklin College of Arts & Sciences

Tobacco use is the leading preventable cause of death in the U.S, with most cessation attempts ending in failure. Although smokers have been shown to have reduced grey matter in certain brain regions compared to non-smokers, there is a lack of knowledge about how differences in neural structure affect smokers' ability to stop smoking cigarettes. In this study we aim to identify structural differences between the brains of participants who successfully quit smoking and those who failed to quit smoking. As part of a larger neuroimaging study, anatomical images were acquired for 51 healthy, nicotine-dependent participants**.** Following the MRI scan, participants completed an eight-week smoking cessation treatment program. Using the program FreeSurfer, we will analyze structural MRI data from these subjects to determine volumes of six a priori regions of interest (ROI) that have been previously implicated in nicotine dependence, habit learning, and drug reinforcement. These regions include the

thalamus, putamen, hippocampus, cuneus, dorsolateral prefrontal cortex, and anterior cingulate cortex. We will then test volume, thickness, and surface area of regions located in the cortex as predictors of treatment success using multiple regression analysis. Based on prior literature, we expect to find significant differences in the morphometric properties of the a priori ROI's between successful and non-successful quitters.

Assessing Trapezius Endurance Using Electrical Twitch Stimulation after Exercise

Kajal Mistry, CURO Research Assistant
Dr. Kevin McCully, Kinesiology, College of Education

Muscle fatigue from daily activities can cause problems in both healthy and diseased/injured populations. The purpose of the present study was to quantify fatigue in the trapezius muscle after carrying a weighted backpack. This project is important because we can compare a rested muscle to an exercised muscle and clinically use that information to make a positive impact on the affected population. Specifically, we are hoping to be able to translate the results to help people with mitochondrial diseases. We hypothesize that walking one mile with a backpack will alter the fatigue test results. Participants consisted of healthy, college aged students Muscle fatigue was measured using a tri-axial accelerometer to measure muscle contraction during five minutes of electrical twitch stimulation (6Hz) at a comfortable current level. The accelerometer was placed on the surface of the skin over the trapezius muscle, and fatigue was measured before and after carrying a loaded backpack one mile at a brisk pace. We initially identified a supermaximal current level for seven participants. Each of the seven participants were able to reach there maximal current (mean=59mA sd=7.35). Furthermore, each of the participants were able to go above there threshold (mean= 54% SD= 0.209). This allowed us to measure both the amount of fatigue and the response of a fatigued muscle to a fatigue test. Our study will demonstrate how muscle fatigue can be quantified as a result of daily activities. The results confirmed that the backpack does fatigue the muscle more than a rested muscle. To have a successful comparison, we first completely fatigued the muscle doing shoulder shrugs; therefore, we had the best possible comparison.

The Spatial Interaction between Cordgrass and Oysters across an Estuarine Gradient

Lucas Montouchet, CURO Summer Fellow
Dr. Jeb Byers, Odum School of Ecology

Spatial interaction patterns between the reef forming oyster *Crassostrea virginica* and marsh cordgrass *Spartina alterniflora* are not well understood. These species are the predominant ecosystem engineers in Georgia saltmarshes and provide extensive ecosystem services. However little is known about of what mechanisms drive their patch distribution and morphology, and how these patterns may vary over environmental gradients. This project describes these spatial relationships and how they change over an estuarine gradient. Through analysis, of high resolution unmanned aerial vehicle imagery, species patch morphology, distribution and relationship to one-another were obtained. Flow, salinity and wave energy predictor variables were assessed through multiple linear regression. The project analyzes the relationship in 4 different ways. Analysis (1a) characterizes the reef shape and how perimeter affects the area of oyster reefs. (1b) characterizes the reef length in relation to area. (2a) examines the distance between reefs and the closest *Spartina* patch. (2b) explores the area of *Spartina* patches in relation to oyster reefs. While this project enhances our knowledge of the spatial interplay between

two important ecosystem engineers, it also provides valuable data for resource managers. This project will directly inform sight specific Living Shoreline design and oyster restoration projects by describing oyster and *Spartina* distribution patterns.

Georgia SOL (Solar Optimization by Location)
Elena Morais
Dr. David Stooksbury, College of Engineering

We are using a minimum of 15 years of daily solar radiation date from Blairsville, Tifton, and Griffin, Georgia to improve the current recommendation for the installation of fixed solar photovoltaic panels. We are finding the optimal angle for fixed solar panels based on what most beneficial and when electricity demand is highest. The current recommendations are to maximize the total solar electrical production over a year. However, the recommendation assumes a cloud free sky. In the Southeast, it is common for summer mornings to begin clear and for clouds to form in the early afternoon. Thus a due south orientation, the recommendation, may not be the optimum for Georgia. There are many cases where optimization for certain seasons rather than for the entire year is better. Schools are in session during the fall, winter, and spring. It would make more economic and environmental sense to optimize for the part of the year that has a higher electricity demand. This research will give recommendations specifically for Georgia.

Trace Level Determination of Trichloroethylene in Plasma by Headspace Solid-Phase Microextraction Gas Chromatography/Negative Chemical Ionization Mass Spectrometry
Kyle Mott, CURO Research Assistant
Dr. Michael Bartlett, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Sensitive determination of trichloroethylene (TCE) is necessary for low-level doses given to rats during toxicokinetic experiments. An improved gas chromatography/negative chemical ionization mass spectrometry (GC-NCI-MS) method utilizing headspace solid-phase microextraction (SPME) was used for the determination of TCE in plasma. The method was optimized with respect to conditioning time of the SPME fiber, extraction time, desorption time, and inlet injection. The method displayed better sensitivity than previous bioanalytical methods, giving linearity over the range of 10 pg/mL – 10ng/mL, with a correlation coefficient (R2) of better than 0.99. The precision and accuracy of the method was determined to be better than 20% at the lower limit of quantitation and better than 15% over the remaining linear range, according to FDA guidelines. Validation determined that selected ion monitoring (SIM) of the 35Cl and 37Cl isotopes using NCI showed great sensitivity, down to ppt levels, due to the nature of NCI's affinity for halogens and the presence of three chlorine ions on the measured chemical of interest, TCE.

Characterization of murI, racD and racR of *Acinetobacter baylyi*
William Moxley
Dr. Ellen Neidle, Microbiology, Franklin College of Arts & Sciences

This project focuses on genes predicted to encode amino acid racemases. Such racemases are important for bacterial cell wall synthesis and biofilm formation. In higher organisms, D-amino acids are sometimes involved in cell signaling. Studies of amino acid racemization have broad significance and could lead to the development of beneficial drugs. As a first step toward such goals, we investigated *murI* (encoding D-glutamate racemase), *racD* (encoding D-aspartate racemase), and *rac*R (encoding a racD transcriptional regulator). Previous studies in *Vibrio fischeri* showed that

the lethal effect of deleting *murI* was counteracted by high-level *racD* expression, which appeared to be mediated by a RacR variant (M. Jones and E. Stabb, personal communication). These results suggest substrate ambiguity allowing RacD to produce D-glutamate. My goals were to improve understanding of *murI*, *racD*, and *rac*R by exploiting the ease of genetic manipulation in a bacterium, *Acinetobacter baylyi*. Mutants were created and characterized that contain deletions of the three genes of interest. As expected, the *murI* mutant required D-glutamate to grow. Site-directed and random mutagenesis methods were used to isolate strains that grow prototrophically despite the absence of *murI*. We predicted that these strains would have increased *racD* expression. Additionally, we tested the ability of *V. fischeri* genes to substitute for deletion of their *A. baylyi* homologs. Although these studies are not yet complete, our initial results indicate that this approach can improve our understanding of the function and regulation of *racD, rac*R, and *murI*. Alicia Schmidt, another lab member, contributed to this project.

Expression Analysis of Immune Genes in the Liver and Ceca of Blackhead Infected Turkeys

Adrea Mueller, CURO Honors Scholar
Dr. Robert Beckstead, Poultry Science, College of Agricultural & Environmental Sciences

Histomoniasis, commonly referred to as Blackhead disease, is a threat currently faced by the poultry industry. Blackhead is caused by infection of the parasitic protozoa *Histomonas meleagridis* in the ceca (and eventually liver). In turkeys this disease is highly fatal; symptoms include drooping head, pale neck, and yellow bile around the cloaca. There are no approved drugs on the market today that combat the disease and immunization attempts have only been partially successful. We hypothesize that feed additives such as fermentation products may be effective in prevention of colonization of *Histomonas meleagridis* and may also improve bird performance under a challenged situation. To test this, a yeast product was fed to turkeys and the immune response of control infected birds compared to birds fed a control diet. The weight of poults was taken prior to cloacal infection at day 18. Samples of liver and cecal tissue were collected from euthanized birds 5 and 10 days post infection. Initial data suggests that there is no statistical difference in treatment regarding infection percentage or in the liver and ceca lesion scores of infected birds on the control and treatment diets. Poult weight gain also remained statistically similar between control and yeast product diets. RNA from samples has been isolated and gene expression of CXCLi2, IFN-y, IL-10, IL-1B, IL-4, and IL-13 genes will be analyzed using rtPCR to examine immune response. Future research will be conducted to determine the yeast product's capability as a Histomoniasis prevention method and its effects on the immune response of turkeys.

Charge Exchange: Atomic Data of Astronomical Significance

Patrick Mullen
Dr. Phillip Stancil, Physics & Astronomy, Franklin College of Arts & Sciences

Charge exchange has emerged in X-ray emission modeling as a dominant process that must be considered in many astrophysical environments—such as comets, supernova remnants, the heliosphere, astrospheres of stars, galaxy clusters, and generally, highly ionized regions of the interstellar medium. With a motivation to bring resolution to the current lack of atomic and molecular data for such a vital process, we have applied the multi-channel Landau-Zener approach to quickly provide charge exchange data for any single electron capture system. By

implementing the resulting nlS-resolved cross sections into a cascade model for X-ray emission, we are able to generate theoretical emission lines and spectra for charge exchange. With this data, we pursue the application of such charge exchange data to modeling the X-ray emission of Comet C/2000 WM1 (linear). Further, sulfur charge exchange data is applied to develop a model that explains the anomalous ~3.5 keV emission line in nearby galaxy clusters that was previously attributed to dark matter. This work was performed in collaboration with R. S. Cumbee, D. Lyons, P. C. Stancil, B. J. Wargelin, L. Gu, and J. Kaastra. Work at UGA was partially funded by NASA grant NNX13AF31G.

Investigation and Structural Inhibition of Rce1 and Ste24 Activity in a Prokaryotic System

Rohit Munagala, CURO Research Assistant
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

There are two major CAAX proteases – Rce1 and Ste24. The protease Rce1 is involved in post-translational modification mechanisms in eukaryotes and has unknown functions prokaryotes. In eukaryotes, Rce1 is involved in the CAAX modification pathway where it cleaves the –AAX terminal sequence of GTPase enzymes such as RAS oncological proteins. Rce1 is considered an anticancer target because of its role in modifying RAS. Inhibition of Rce1 can potentially obstruct the function of RAS and prevent tumor formation. The functional roles of Ste24p in eukaryotes and prokaryotes is less well understood. Research in the Schmidt lab investigates the target site specificity of Rce1 and Ste24 in an effort to contrast the activities of the two proteases. The goals of this project are to develop activity assays for prokaryotic Rce1 and Ste24. These assays will be invaluable for contrasting the activities of the prokaryotic enzymes from their eukaryotic counterparts. Orthologs of Ste24 and Rce1, HtpX and MmRce1 respectively, were subcloned into an expression vector, transformed into *E. coli*, and over-expressed. Membrane fractions with these enzymes will be used in *in vitro* assays typically used to monitor the eukaryotic enzyme activities. Such assays will be useful for testing structure-function hypotheses related to novel Rce1 inhibitors and for evaluating novel functional properties recently assigned to Ste24. Long term medical applications of this project include anti-cancer drug developments.

White Matter Structure Differs between Schizophrenia and Healthy Comparison Groups as a Function of Cognitive Control and Age

Megan Murphy, Ramsey Scholar, CURO Summer Fellow
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Advances in neuroimaging have allowed researchers to study neural correlates of schizophrenia (SZ) *in vivo*. Despite contributions to the understanding of these correlates, neuroimaging studies have shown mixed findings regarding white matter (WM) abnormalities related to SZ. Some suggest discrepancies in findings may be due to heterogeneity of patient characteristics, such as variations in cognitive characteristics and age; a high level of cognitive control (CC) in healthy comparison groups may bias the results to differences in CC rather than the disease process of SZ, and WM follows a quadratic trend as age increases but differs between the healthy population and SZ. Poor CC is a hallmark behavioral trait of SZ and is likely related to WM abnormalities. Deficits in CC are not solely associated with SZ; a subset of the healthy population shows similar deficits. Given these potential confounds, this study aimed to explore the effects of CC and

age on WM comparisons between SZ and healthy subjects. Using diffusion tensor imaging, WM integrity was analyzed and compared between SZ and two healthy comparison groups with either high (HCC) or low (LCC) levels of CC, ages 20 to 50 years. The results showed differences in WM integrity depended on both CC capacity and age of the control group, with significant differences between HCC and SZ in the 41 to 50 age range. These results are important with respect to selecting appropriate control groups for psychiatric studies—future studies must control for both differing levels of CC and age.

The Role of Trehalose-6-Phosphate Synthase in the Development and Transmission of *Cryptosporidium parvum* Oocysts

Emily Myers
Dr. Boris Striepen, Cellular Biology, Franklin College of Arts & Sciences

Cryptosporidium is an apicomplexan parasite that infects the gastrointestinal tract of many animals. Cryptosporidiosis is the second leading cause of severe diarrhea in young children worldwide. No vaccine exists for cryptosporidiosis, and the only approved drug does not benefit those most in need of treatment—immunocompromised individuals and young children. Our lab developed tools to genetically modify *Cryptosporidium* using CRISPR/Cas9, and we developed a mouse model of infection. We can use these tools to better understand parasite biology and pathogenesis. We are interested in studying the oocyst, the transmissive life cycle stage of *Cryptosporidium*. The oocyst is a thick shell composed of proteins, lipids, and sugars that protect parasites from environmental stresses. One of the predicted components of the oocyst wall is trehalose, a dimer of glucose. Trehalose protects against desiccation in many organisms and is a virulence factor in *Mycobacterium* and *Cryptococcus*. We predict that this sugar plays similar roles in *Cryptosporidium*. In *Cryptosporidium*, trehalose-6-phosphate synthase (*t6ps*) catalyzes the final two steps of trehalose synthesis. Using our CRISPR/Cas9 and mouse infection model, we failed to generate a *t6ps* parasite knockout, suggesting that this gene is essential for parasite survival. We endogenously epitope tagged *t6ps* and observed cytosolic localization throughout the life cycle, with increased expression during oocyst development. To verify the biochemical function of *t6ps*, I am performing a genetic complementation test in *Saccharomyces cerevisiae* and *Escherichia coli* mutants lacking the orthologous gene. The results indicate a crucial role for trehalose in oocyst development and transmission, so this enzyme could make a novel drug target.

The Determination of Sunflower Growth in Different Genetic Lines and under Various Nutrient Conditions

Morgan Najdowski, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

Modern agriculture techniques commonly use excess amounts of fertilizers to grow crops, in both infertile and fertile soils, despite ineffectiveness past a certain threshold. In encouraging production of stress resistant crops, the amount of excess fertilizer used can be decreased and yield can be optimized under infertile conditions. This greenhouse study compared genetic lines of cultivated sunflower (*Helianthus annuus*) to determine which would have higher production across a variety of nutrient conditions, ranging from very nutrient poor to nutrient rich. One of the areas of emphasis in particular was discovering what traits are associated with plant performance and stress resistance in sunflowers. The traits of the most recent leaf (MRL) were analyzed using a variety of methods, including leaf area, thickness and strength. Data analysis is currently underway,

but we expect that the plants that are successful under higher levels of nutrient stress have physical traits that will optimize photosynthetic capability in their MRLs, leading to more efficient nutrient use and increased growth under such conditions. With this information, we can promote more sustainable crop production and enhance food security for people around the world, particularly in areas with infertile soils and limited economic resources.

Examining Intercellular Heme Transport via Freixenet Transgenic Zebrafish

Monisha Narayanan, CURO Research Assistant
Dr. Amy Medlock, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

It is currently thought that every cell in the human body produces its own supply of heme, an essential molecule required for many biological processes. However, recent data suggests that heme may actually be transported intercellularly and utilized by cells. To test this hypothesis, we are generating transgenic wild-type and heme-deficient (freixenet) zebrafish, which synthesize heme in specific tissues, to elucidate the role of putative heme transporters in growth and development. My role in this research is to genotype, via PCR, homozygous freixenet transgenic fish which are ferrochelatase null, thus lacking a crucial enzyme in the heme biosynthesis pathway. This will allow me to identify their inheritance patterns and assess their ability to survive. The goal is to rescue heme-deficient fish by instigating heme production in red blood cells and liver tissue, showing that heme can be transported and utilized by other body cells. As of yet, we have not found an adult fish rescued by the transgenes, but we are continuing to genotype fish of this line. Additionally, I began a crossing scheme to assess the heme rescue capability of these genes in freixenet zebrafish, comparing the offspring mortality rates with those associated with specific genotypes. I anticipate that these mortality rates will correlate with the proportion of freixenet fish without the heme rescue gene insert. The data obtained in these studies will be used to validate the rescue of heme-deficient zebrafish and heme trafficking for utilization, either confirming or refuting the existing scheme of thought on heme transport.

Examining the Relation between Stigma and Self-Esteem, Self-Efficacy, and Social Satisfaction in Young Adults with Autism Spectrum Disorder

Margaret Naughton
Dr. Ashley Harrison, Educational Psychology, College of Education

There is mounting evidence demonstrating the negative impact of stigma experienced by parents of children with autism spectrum disorder (ASD; Gray, 2002; Farrugia, 2009; Mak & Kwok, 2010), but much less research has investigated the consequences stigma has on the diagnosed individual. The current study examines the negative outcomes of stigma among five young adults (M = 21.54 years, range = 18.59-25.35 years) diagnosed with ASD by assessing the relationship between experienced stigma and social outcomes such as self-esteem, self-efficacy, and social satisfaction. Stigma was assessed using an adapted version of Stigma Scale (King et al., 2007). The participants also completed psychometrically supported measures of self-esteem, social satisfaction, and adaptive social skills. The relations between stigma and social outcome variables were examined by correlational analyses. Analyses revealed that young adults that have more experiences with stigma have lower self-esteem (r = .824, p = .043), and perceive more social hostility from others (r = -.826, p = .042). As rates of ASD continue to rise, more young adults with ASD will attend college or enter the workforce. They will likely

experience stigma and it is important to know how these experiences impact quality of life to determine how to best support young adults with ASD in these environments.

Cognitive-Behavioral Therapy for Adults with ADHD: A Meta-Analysis

Nicole Negri
Dr. Jason Nelson, Psychology, Franklin College of Arts & Sciences

Although empirical investigation of pharmacological treatment options for adult Attention-Deficit/Hyperactivity Disorder (ADHD) has indicated positive results, there is also evidence that medication alone is insufficient for many adults with ADHD. Approximately 20% to 50% of adults with ADHD are not responders to medication. Several nonpharmacological interventions have been developed and empirically investigated, but cognitive-behavioral therapy (CBT) has received the most empirical attention. The purpose of this current study was to conduct a meta-analysis to determine the efficacy of CBT in the treatment of adults with ADHD. To locate relevant studies, we searched a variety of psychology-related databases (e.g., PsycINFO). Inclusion criteria were that studies (a) used a group design (i.e., no case studies), (b) used adult participants formally diagnosed with ADHD, (c) implemented CBT as a treatment option, (d) had a control group, and (e) reported statistics necessary for calculating effect size. Of the 122 studies reviewed, 10 met these criteria. For these studies, we examined the effect of CBT on ADHD symptoms and emotional functioning. The overall effect size for ADHD symptom reduction was statistically significant ($z = 5.02$, $p < .001$) and medium in magnitude ($d = .76$); Improvement in emotional functioning was also statistically significant ($z = 3.87$, $p < .001$) and medium in magnitude ($d = .54$). The significance of this study lies in its findings that CBT is a promising treatment option for adults with ADHD. CBT participants demonstrated both improvement of ADHD symptoms and emotional functioning.

Alpha-Tocopheryl Succinate Encapsulated Nanoparticles for the Enhancement of Mitochondrial ATP Production

Noah Newman, CURO Research Assistant
Prof. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Mitochondria are the energy-producers of animal cells, converting chemical energy stored in the bonds of organic compounds into adenosine triphosphate (ATP), the main energy source for many of the human body's metabolic processes. While the body manages the rate of ATP production, it is of particular interest to find ways to stimulate ATP production in the mitochondria to increase the amount of available energy for the cell, without harming the cell in the process. A biodegradable polymer, PLGA-b-PEG-TPP derived from FDA approved polymers polylactide-co-glycotide (PLGA), polyethylene glycol (PEG), and a mitochondria targeting ligand triphenylphosphonium (TPP) cation which is used in FDA approved drug MitoQ has the ability to self-assemble into a nanoparticle (NP) with the ability to enter mitochondria due to their surface charge and size. This nanoparticle has demonstrated extraordinary abilities to encapsulate a variety of therapeutic agents and deliver to the mitochondria of cells in a controlled release fashion. A recent study from our lab has shown that *alpha*-tocopheryl succinate (*α*-TOS), a mitochondria-acting chemotherapeutic, increases ATP production in the mitochondria of cells. This research shows the nano-encapsulation of *α*-TOS in PLGA-PEG NPs with both targeting and non-targeting functional groups, the characterization and stability of the NPs, the cytotoxic effects of the NPs on various cell lines, and the energy-generating effects of the

NPs. Further studies will focus on the effects of these *a*-TOS-PLGA-PEG NPs on the energy production of other living systems.

"I Just Wanted a Roof over My Head": Possible Housing Solutions for Asylum-Seekers in Germany

Katherine Nichols
Dr. Katie Chapman, Germanic & Slavic Studies, Franklin College of Arts & Sciences

Since January 2015, over 1.1 million refugees have entered Germany seeking asylum after news spread of Angela Merkel's open door policy. Predominantly of Syrian origin, displaced people are making their way to Europe to escape war torn homes. In the wake of this massive refugee influx, Germany is seeking creative ideas to provide more housing. The most controversial housing strategy to date has been the attempt of a couple German cities to accommodate refugees in former outposts of concentration camps. I suggest living arrangements and reforms which would provide ethical shelter for refugees. Having created three policy proposals and examined their theoretical strengths and weaknesses as they related to effectiveness, cost, and decency, I will propose a final policy which includes both restrictions on living arrangements that could be viewed as unethical as well as guidelines for transforming alternate locations for refugee use. I will argue this policy to be superior due to its relatively low cost, high degree of effectiveness, and its ability to maintain respect for the human dignity of refugees.

The True Cost of Medical Credit Cards on Patient Credit Scores

Madison Nichols, CURO Research Assistant
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

The purpose of this research was to discover if using a medical credit card to pay off medical costs and procedures could positively or negatively affect a patient's credit score. A medical credit card mostly functions as a traditional credit card; the patient takes out a loan to cover the cost of medical care and then pays back the debt over time. However unlike traditional credit cards, medical credit cards use a deferred interest system, which results in the patient owing interest on the entire amount if the patient does not make the minimum monthly payments or pay off the debt during a zero percent promotional period. The first research phase included actively visiting medical providers in order to obtain the information presented to patients when inquiring about using medical credit cards as a form of payment. Additionally, online research of scholarly journals, reports from consumer organizations, and forms of primary literature were also consulted to gain knowledge about the effects of medical credit cards, and other medical debt, on credit scores. The second phase involved contacting the medical credit card companies identified in the first phase to learn if they report to credit bureaus and, if they did, we contacted credit scoring companies to learn if they considered medical credit card use in building credit scores. Based on gathered information we were able to determine how using a medical credit card to pay for a patient's incurred medical care bill could be beneficial or detrimental to their credit score.

Role of Human Intelectin-1 in the Innate Immune System

Brennan Ninesling
Dr. J. Michael Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Although its exact biological function and involvement in the human innate immune system are still unknown, HL-1, a homolog of XL35 and member of the X-lectin family, has been shown to have affinities for ribose as

well as galactofuranosyl residues. The affinity for galactofuranosyl residues is significant due to its presence on many bacterial cell walls. Some of the X-lectin family members have been shown to bind to other carbohydrate residues on bacterial pathogens, although the specific binding mechanisms and exact functions are unknown. HL-1 is expressed in human embryonic kidney (HEK) cells transfected with HL-1 cDNA in pTracer vector and secreted into the medium. To test whether HL-1 interacts with macrophage and bacteria, it was first isolated from the medium. Using affinity chromatography, HL-1 was purified and then used in binding assays to show whether it effectively bound to macrophage cells. The purity of the HL-1 samples isolated from the medium was confirmed by polyacrylamide gel electrophoresis followed by silver staining. Future research will help reveal the ligand-binding specificities used by HL-1 as a part of the innate immune system.

Re-evaluating Proposed Identities of *Brooksella alternata* of the Conasauga Shale of Georgia and Alabama

Morrison Nolan, Foundation Fellow
Dr. Sally Walker, Geology, Franklin College of Arts & Sciences

Brooksella alternata is putatively an important fossil of the middle Cambrian Conasauga Shale of Georgia and Alabama, USA, but its identity remains obscure. It has been variously identified as a jellyfish, multiple trace fossils, a concretion, and most recently a silica sponge (hexactinellid). Each of these identifications remains tentative. I examined and quantified the external and internal morphology, chemical composition, and in situ orientation of *Brooksella* in sediments to reevaluate these proposed identities. If a hexactinellid sponge, *Brooksella* would be expected to exhibit oscula, ostia, internal structures, and arranged spicules. After considering external morphology, computer assisted tomography of internal structure, and the geochemical and electron microprobe analysis of *Brooksella*, I found the evidence is not consistent with a sponge interpretation. Previous chemical examination of *Brooksella* has dealt largely with bulk composition; my analysis is more targeted, analyzing specific internal features of the specimens. Several weathering features, including the role of modern lichen and plant roots in modifying the surface of *Brooksella*, could have produced ostia-like features. Thin sections of the samples have not yielded unambiguous spicules, but they have shown many signs of root or hyphae weathering and possibly spores worked into the samples' interiors. My results indicate that *Brooksella* is incompatible with previously proposed identities and call into question the identity of other suggested Cambrian sponges of similar composition and structure.

How the Market Responds to Changes in Firm Health Policy

John-Jordan Nunnery
Dr. Sara Holland, Banking & Finance, Terry College of Business

With the costs of US healthcare growing faster than the economy, firms are taking novel approaches to manage healthcare coverage for their workforce. In this paper, I study the market's reaction to firms' announcements to invest or disinvest in employee healthcare. Using a set of 63 events classified as expansions, reductions, restructurings, and acknowledgement, I find that on average the market responds negatively to changes in healthcare policy. It responds less negatively when the firm market value and dividend yield are large, and it responds more negatively when the firm has a larger employee base and current ratio. Additionally, I find that restructuring events lead to significantly steeper declines in equity value. These findings have implications for the efficient market hypothesis and investor myopia.

Abstracts

Investigations of How *Lysinibacillus sphaericus* Bin Toxin Kills a Cell Line Derived from the Malarial Mosquito *Anopheles gambiae*

Onyinyechi Ochiobi, CURO Research Assistant
Prof. Michael Adang, Entomology, College of Agricultural & Environmental Sciences

Binary toxin (Bin) produced by the bacterium *Lysinibacillus sphaericus* is toxic to *Culex* and *Anopheles* mosquito larvae. It has been used world-wide for the control of mosquitoes that vector human diseases, including West Nile virus, lymphatic filiariasis and malaria. The Bin toxin interacts with a receptor in the gut of *Anopheles* mosquitoes. However, the exact mechanism of its mode of action is not clearly understood. The Adang laboratory developed an *Anopheles gambiae* Ag55 cultured cell line as a model for investigating the molecular action of Bin toxin. The Bin toxin, composed of BinA and BinB proteins, internalizes and kills the Ag55 cells via a process that is consistent with autophagy. The goal of this project was to determine whether BinA or BinB alone is sufficient to kill *A. gambiae* larvae and Ag55 cells or whether the BinA/B pair is required for toxicity. Our approach was to individually produce BinA and BinB in recombinant *Eschericia* coli and test the toxicity of each separately and together against *A. gambiae* larvae; followed by testing the cytoxicity of BinA and BinB against Ag55 cells. Preliminary results with purified BinA alone show toxicity to Ag55 cells and now we are beginning to analyze uptake of BinA by the cells. This information will contribute to the understanding of how Bin toxin kills mosquito larvae, and could provide insights into approaches to prevent mosquitoes from acquiring Bin resistance.

The Effect of Corporate Wellness Program Benefits Over Time on End-Of-Workday Strain

Selin Odman, CURO Summer Fellow
Lindsey Murry
Dr. Malissa Clark, Psychology, Franklin College of Arts & Sciences

In the current study, we examined changes in employee well-being by assessing employee perspectives of their organization's wellness program. We asked employees to rate their perceived change in medication use, weight, and eating habits since joining the wellness program. We then examined how these measures related to end-of-workday strain, which is based on how physically, mentally, and emotionally drained employees feel. To conduct a longitudinal study, surveys were administered in 2012-2013 and 2015 to employees undergoing a wellness program at a utility company in the Southeastern United States. We hypothesized that the composite of benefits from the wellness program is positively related to a decrease in end of workday strain from time 1 (2012-2013) to time 2 (2015). Our sample *(N*=78) consist of 65% males, with a mean age of 45.6. Of 78 the employees who complete both time 1 and time 2 surveys, 55% reported working inside while 45% reported working outside. On average, employees worked 42.3 hours per week. We ran a simple regression using R software to test whether the composite and individual benefits from the wellness program predicted change in strain by time 2. With the variables measured on a five-point likert scale, the mean of the composite program benefits was 3.5 *(sd = 0.53)* and the mean of healthy eating habits was 3.71 (*sd = 0.69)*. The average change in end of workday strain was 0.427 (*sd = 0.824)*. The results of the regression were not statistically significant: $F(1,76)(=0.02$, $p > .05$). We will perform additional analyses examining the facets of end of workday strain (physical tiredness, mental tiredness, and tenseness).

Structural Characterization of an LTTR in *Acinetobacter baumannii*

Kikachukwu Okolo, CURO Research Assistant
Dr. Cory Momany, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Bacterial transcriptional regulators such as the LysR-type transcriptional regulators (LTTR) are responsible for controlling many biological processes in different bacteria. Therefore understanding how these transcriptional factors function is important in the development of drugs that could target these proteins. This project is focused on elucidating the structural interactions between LTTRs and their various ligands, the DNA to which they bind, as well as the RNA polymerase that they interact with during transcription in the bacterium, *Acinetobacter baumannii*. *A. baumannii* is an opportunistic clinical pathogen that causes urinary tract infections and biofilm formation on plastics. Because of *A. baumannii's* ability to form a biofilm, *A. baumannii* is resistant to many classes of antibiotic drugs by intrinsic and acquired antibiotic resistance genes. One of the genes is *bfmL*, which encodes an LTTR that is responsible for controlling the expression of the chaperone-usher pilus assembly system needed for cell attachment and biofilm formation. The *bfmL* gene was PCR amplified and successfully cloned into an in-house engineered expression vector. A restriction digest confirmed that the cloning was successful, and the resulting plasmid was transformed into a protein production strain of *E. coli*. Preliminary results on the purification of the protein by metal-chelate chromatography indicate that the protein is poorly soluble. After improving the solubility of the protein, biochemical analysis and crystallization studies will be initiated. Successful crystallization of this protein and other LTTRs will pave the way for understanding their structures, which is a critical step in developing novel antibiotics targeted at *A. baumannii*.

Coalitional Stability: Apportioning the Legislature at the U.S. Constitutional Convention

Robert Oldham, CURO Research Assistant
Dr. Keith Dougherty, Political Science, School of Public & International Affairs

Principles of legislative apportionment determine the number of seats each state receives in Congress. Apportionment was one of the issues most fiercely debated at the U.S. Constitutional Convention of 1787. States small and large, free and slave, and poor and wealthy squabbled over the constitutional principle that would decide what interests would control Congress. Delegates eventually agreed to apportion the House by the number of free inhabitants plus three-fifths of the slave population and the Senate by equal state voting. However, there were nearly twenty other principles of apportionments that were proposed and debated. Assuming delegates wanted to maximize their state's vote share, we examine which principles of apportionment were coalitionally stable. We do this by comparing vote shares of all the principals proposed, both for a unicameral or a bicameral body. This allows us to ask whether the apportionment principle adopted was in equilibrium among those considered, to identify principles which dominate those enumerated in the Constitution, and to provide clear examples of vote cycling. Our research suggests that the coalitions that formed around different apportionment methods were unstable and that the adopted principle was not inevitable. Instead, it was a compromise between competing interests who, perhaps unknowingly, sowed the seeds of the American Civil War by over representing the south in the new republic.

Sensitive Liquid Chromatography/Mass Spectrometry Method for the Determination of the Lipophilic Anticancer Drug in Rat Plasma

Oluwasegun Olorunyolemi, CURO Research Assistant
Dr. Michael Bartlett, Pharmaceutical & Biomedical Sciences, College of Pharmacy

In this research study, a robust and sensitive liquid chromatography mass spectrometry (LC-MS) method was developed and validated to measure a preclinical candidate GH501 in rat plasma. This compound has been developed for the treatment of bone metastatic prostate cancer. GH501 was samples were prepared using liquid-liquid extraction and separated on a Waters AtlantisTM dC-18(30 mm x 2.1 mm i.d., 3 μm) column using a mobile phase of acetonitrile/20 mM ammonium formate (pH 4.25 adjusted with formic acid) with gradient elution. GH501 was detected in positive ion mode using MRM (multiple reaction monitoring). The MS response was linear over the concentration range from 0.4 – 200 ng/ml in plasma. The limit of detection (LOD) and quantitation (LOQ) were calculated from the peak-to-noise ratio as 0.2 and 0.4 ng/ml respectively. This method was validated based on FDA guidelines, and the measured signal was shown to be precise, accurate, and linear over the concentration range tested.

Tolstoy's Second Epilogue: On Page and Screen

Katherine Opacity, CURO Research Assistant
Dr. Charles Byrd, Germanic & Slavic Studies, Franklin College of Arts & Sciences

The breadth of Leo Tolstoy's *War and Peace* may indeed mean that the novel's plot and plentiful characters cannot be condensed to yield a faithful, abridged version. Tolstoy himself, however, captured the spirit of his work perhaps most completely in its final section: the second epilogue. Lacking any narrative structure, Tolstoy divulges his philosophy of history, including most notably a discussion of the struggle between free will and determinism, the nature of consciousness, and the essence of time. Such impenetrable subjects may leave readers and filmmakers alike wondering about the plausibility of including it in an adaptation. Sergei Bondarchuk, in his 1966 film version, successfully incorporates this portion of the novel. Bondarchuk's epic eight-hour film evokes the epilogue in both fundamental and nuanced ways. Film itself, I argue, is a most suitable medium for the epilogue. On a secondary level, camera techniques and stylistic choices of the director together reproduce one of Tolstoy's central philosophical struggles: reconciling immensity and fragments - of time, man, and existence.

Investigating a Potentially Novel Cache Valley Virus Variant in a Clinical Case in Missouri

Isabel Ott, CURO Honors Scholar
Dr. Daniel Mead, Population Health, College of Veterinary Medicine

The Southeastern Cooperative Wildlife Disease Study (SCWDS) investigates wildlife mortality events in the southeastern United States. In July of 2015, the Missouri Department of Conservation submitted samples from a white-tailed deer (*Odocoileus virginianus*) that was euthanized after showing signs of hemorrhagic disease. A virus isolated from submitted samples tested negative for hemorrhagic disease viruses and other major viruses of white-tailed deer using reverse transcriptase polymerase chain reaction (RT-PCR). Further tests detected an orthobunyavirus, a genus of arthropod-borne RNA viruses distributed worldwide. While exposure to several orthobunyaviruses has been detected in white-tailed deer, they are not known to cause disease in white-tailed deer, though they cause acute disease in other ruminants. Two orthobunyaviruses, Cache Valley and Potosi viruses, have been previously isolated from deer in Missouri; as RNA viruses, they lack proofreading mechanisms and frequently exchange genetic

material. The unusual clinical presentation of this case was seen as potentially resulting from infection with a mutant or hybrid orthobunyavirus capable of causing illness in deer. In order to explore this possibility, RT-PCR reactions were conducted to amplify partial segments of the virus's genome; these segments were then sequenced. Comparative analysis of the sequence data showed high similarity between this case and Cache Valley virus. Conclusive identification is still being pursued; orthobunyavirus species are often closely related and few reference sequences are available to compare experimental sequence results to. Further investigation will endeavor to sequence more of the viral genome and explore how the virus's structure and function are impacted by identified mutations.

To Close or Not to Close for Severe Winds: Two Cable-Stayed Bridges in the Georgia Coast Region

Maximillian Ovett
Dr. Mi Geum Chorzepa, College of Engineering

The ultimate goal of this research is to understand and model the behavior of the two cable-stay bridges, the Eugene Tallmadge Bridge located in Savannah, GA and the Sidney Lanier Bridge in Brunswick, GA and to propose to the Georgia Department of Transportation the criteria for closing the bridges to traffic. A cable-stayed bridge is readily open to the excitation forces of the wind. These aerodynamic forces result in vibrations emanating throughout the bridge-deck and cables. Once these vibrations reach a specific threshold, they can cause torsional divergence, flutter, galloping, and ultimately self-destruction. These two bridges are of similar structural nature were each has 2 main support towers and 2 planes of tension cables supporting the pre-stressed concrete bridge-deck. Due to the location of theses bridges being near the coast they are constantly under wind loading as well as in the direct path of hurricanes. The need to model and understand their performance and general cable-stayed bridge behavior in peak winds and large scale hurricanes is pertinent. These analysis and models will help further wind-resistant designs of cable-stayed bridges. This semester's research will focus in on understanding the underlying structural dynamics of cable-stayed bridges and their supporting structures. This will primarily be done through the review of published literature on the subject of bridge, wind, and vibration analyses. The study will be focused on conceptual understanding of modal vibrations, torsion, wind analysis, and flutter. If understanding and time allow, a simple model of one of the bridges may be built to validate conceptual understanding.

Exploring Uncertainty in Models of Mosquito Vector-Borne Disease

Jack Owen
Dr. Courtney Murdock, Infectious Diseases, College of Veterinary Medicine

Understanding the dynamics of the spread of mosquito-borne diseases such as malaria and dengue virus are important public health challenges as these diseases affect millions of people around the world. Mosquitos, like most ectotherms, are heavily influenced by the temperature of their environment. Recent work suggests that mosquito traits follow a unimodal response to temperature, with an "optimal range" in the middle that decreases as the temperature moves in either direction. Global climate change data indicate that different parts of the world may move into the mosquitos' optimal range in the coming years, changing the prevalence of mosquito-borne illnesses in those areas. Because mosquitos are prevalent in many hot, humid areas, little work has been done to investigate which factor is more responsible for mosquito transmission potential. This experiment will use a factorial design to monitor mosquito

mortality, bite rate, and fecundity across a range of humidity and temperature points. From the results, we will be able to further specify which variable is the more important driver of mosquito transmission potential.

Wild Bearded Capuchins (*Sapajus libidinosus*) Use Tools in Fazenda Boa Vista, Brazil: Positioning the Nut Predicts Success

Rachel Pack
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

What challenges capuchins learning to crack nuts? Prior studies showed that adults position (place) nuts precisely on anvils, often several times, before each strike, and that positioning the nut is the last feature of nut-cracking to appear in juveniles. We predicted that positioning the nut on the anvil would index juveniles' mastery of nut-cracking. We observed fourteen capuchin monkeys (eight juveniles - four that could crack nuts, four that could not - and six proficient adults) using continuous focal animal sampling during 2011-2013. After extracting episodes in which monkeys struck nuts, we examined correlations among the duration of cracking episodes, rate per episode of positioning a nut on an anvil, age and success at opening a nut. We found a positive correlation between juveniles' age and rate of positioning a nut ($r = +0.57$, $n = 8$, $p=.021$). Rate of positioning correlated positively with success for the juveniles that cracked, significantly for two of them. The rate of positioning a nut increased from juveniles who could not crack, to juveniles who could crack, to adults (mean=0.7, 2.3, 3.4 times/min). Coefficient of variation for rate of positioning the nut is highest in juveniles who cannot crack (CV=140, cannot crack; CV=11 and 24, can crack and adults). Consistently positioning the nut appears to be a key feature predicting efficient nut-cracking in young capuchins.

Psychiatric Drug Use and the Business Cycle

Meredith Paker, Foundation Fellow, CURO Research Assistant
Dr. W. David Bradford, Public Administration & Policy, School of Public & International Affairs

Previous literature suggests that many indicators of health improve during recessionary periods. This countercyclical health effect has been attributed to increases in leisure time due to lower employment, which can reduce job-related stress and permit higher investment in healthy lifestyle changes. However, earlier work by David Bradford and Bill Lastrapes finds that psychiatric drug utilization increases during recessions, suggesting that mental health is largely procyclical. Using the Medical Expenditure Panel Survey data from 1996-2012, we explore how changes in employment affect psychiatric drug utilization. We aim to understand the mechanism behind any increases in drug utilization due to the business cycle.

Effect of Different Concentrations of 25-Hydroxycholestrol on Osteogenic Differentiation of Mesenchymal Stem Cells (MSC) from Broiler Compact Bone

Daye Park, CURO Research Assistant
Dr. Woo Kyun Kim, Poultry Science, College of Agricultural & Environmental Sciences

MSC are multipotent progenitors that can differentiate into various tissue cells. The objectives of the study were to 1) isolate MSC from broiler compact bone and 2) study the effects of 25-hydroxycholestrol on osteogenic differentiation of MSC. This is important for the production and welfare facets of the poultry industry as chickens develop orthopedic problems such as lameness, tibial dyschondroplasia, and osteoporosis. MSC were isolated from the femurs and tibia of day-old chicks. The compact bones were

flushed with PBS, chopped to small pieces, and digested with a digestion buffer containing 0.25% collagenase and 20% Fetal Bovine Serum (FBS). Digested cells were filtered, centrifuged, and cultured in a growth medium DMEM containing 10% FBS. MSC were successfully isolated and left to confluent, with the media changed every 2-3 days. The cells were passaged until P4 and plated in 24 well plates at density of 20,000 cells/cm2. Upon confluency, cells were treated with the following treatment: control, osteogenic media (OM), and OM with 0.5, 1, and 2 uM 25-hydroxycholesterol. Cytochemistry was conducted on day 7 and 14 to detect osteogenesis. Cells treated with OM, and 25-hydroxycholestrol induced higher proportion of Alizarin Red and Von Kossa stain (mineralization), and Alkaline Phosphatase (early osteogenic marker) compared to control cells. However, 2uM 25-hydroxycholesterol was toxic to cells, causing cell death. Results indicated that 25-hydroxycholesterol has a stimulatory effect on MSC ostegenesis. Current results provide rationale for further study on regulatory mechanisms of 25-hydroxycholesterol on MSC which can help to address skeletal problems in poultry.

Genetic Analysis of *Exobasidium maculosum* Using Microsatellites

Sabrina Park, CURO Research Assistant
Dr. Marin Talbot Brewer, Plant Pathology, College of Agricultural & Environmental Sciences

Exobasidium maculosum is a recently described emerging fungal pathogen of blueberry in the southeastern USA. It causes leaf and fruit spots, with the latter resulting in unmarketable berries and economic losses. Previous studies showed an elevated level of genetic diversity based on the analysis of three loci: ITS, EF-1α, and CAL. This high level of genetic diversity, which is especially surprising for an emerging pathogen, is believed to have resulted from a combination of high mutation rates and recombination within populations. Our objective is to understand how this genetic diversity is hierarchically distributed within spots, leaves, bushes, fields, and regions. This information will provide information on the life cycle and dispersal of *E. maculosum*. To accomplish the objectives, we collected and genotyped 379 isolates from ten bushes in each of two different commercial blueberry fields in Georgia. Isolates were genotyped at ten loci using microsatellite markers. Spatial genetic diversity analyses and measures of population subdivision are currently underway. Results from this study will help us to understand the genetic basis disease emergence, as well as the life cycle and dispersal patterns of the fungus, potentially leading to improved disease management strategies.

Cytotoxicity of Gold Nanoparticles with Feline Injection Site Sarcoma, *In Vitro*

Arjun Patel, CURO Research Assistant
Dr. Robert Gogal, Anatomy & Radiology, College of Veterinary Medicine

Injection site sarcoma (ISS) is an aggressive cancer associated with vaccination in felines. ISS is locally invasive and can be difficult to control even with aggressive therapy. The focus of this study was to assess whether 15 nm gold nanoparticles could be employed as a cytotoxic agent. Nanoparticles have an increasing usage in numerous fields due to size and biological properties they possess. The study focused on culturing ISS cells with gold nanoparticles at 0.0, 0.25, 0.5, 1.0, 2.0, and 4.0 mM for 72 hr. Changes in cell proliferation, viability, and cytology were assessed. The data obtained suggested that gold nanoparticles concentration yielded an inverse correlation with ISS cell proliferation. Plating 5,000 ISS cells per well in a 96 well tissue culture plate, an IC 25 was determined to be 3 mM concentration. Results from this preliminary study suggest that 15 nm gold

nanoparticles at concentrations greater than 3 mM can induce cytotoxicity in ISS cells.

The Implications of International Intellectual Property Law on Global Access to Medicines

Ashka Patel, CURO Summer Fellow
Dr. John Dayton, Lifelong Education, Administration, and Policy, College of Education

The affordability of medicines remains an issue both in economically resilient countries such as the U.S. and in developing countries such as India. International intellectual property law and pharmaceutical patents complicate the matter. The balancing act between providing protection for innovation and honoring the universal right to health, including access to essential and life-saving medicines, creates controversy. One particular bilateral relationship, between the U.S. and India, has had a disproportionate effect on global access to medicines. The domestic intellectual property law of the U.S. and other developed countries was favored in the development of international law. Most notably, the TRIPS agreement demonstrates a global movement toward more rigorous intellectual property law. However, the pressure from major pharmaceutical companies in the U.S. to impose trade sanctions on India, as a result of the immense generic pharmaceutical industry built from the reverse engineering of drugs innovated in countries such as the U.S., France, the U.K., and Germany, directly contradicts the ostensible commitment to global health all of these countries have pledged. While respecting the concerns of domestically based pharmaceutical companies and maintaining protection of pharmaceutical patents, the U.S. must find a way to also defer to the interest of global health and access to medicines. India must find equilibrium between attracting foreign investment and continuing to create the generic medicines that are so vital for medically underserved communities globally.

Genetic and Metabolic Modeling the Methanogenic Archaeon *Methanococcus maripaludis*

Hirel Patel, Lucas Bougang, Rebecca Buchanan, John Buchanan
Dr. William Whitman, Microbiology, Franklin College of Arts & Sciences

Methanococcus maripaludis is a model organism for Archaea, which affords researchers the opportunity to take advantage of beneficial qualities such as (1) production of methane to be used as a biogas and (2) manufacturing high volumes of isoprenoids to be used as precursors for high-value biochemicals. However, there are few genetic tools for metabolic engineering available for Archaea. Our goal is to create, characterize, and model some useful tools for the utilization of this adept organism for synthetic biology. Building on our past *M. maripaludis* projects, which created and characterized a mCherry reporter system as well as a recombinant mutant making the high-value isoprenoid geraniol, our team is now working to (1) create, characterize, and model a ribosome-binding site (RBS) library using the mCherry reporter system and (2) model geraniol production of the recombinant *M. maripaludis* using flux balance analyses. Preliminary results have shown varying levels of expression in our developing RBS library, as well as the determination of growth substrates that can increase the yield of geraniol production. Additionally, our team has initiated an Archaeal InterLab Study to further characterize the reproducibility of our mCherry reporter system.

Maternal Obesity and Trabecular Bone Microarchitecture in C57BL Mice

Kayla Patel, CURO Research Assistant
Dr. Richard Lewis, Foods & Nutrition, College of Family & Consumer Sciences

Diet-induced obesity has a negative impact on bone microarchitecture by decreasing trabecular number and volume. However, the effects of obesity during gestation on trabecular bone architecture are unclear. Studying the effect of obesity on bone in the context of gestation is of particular importance given that nearly 40% of women of childbearing ages are currently considered obese. The aim of this study is to analyze the effects of maternal obesity on trabecular bone microarchitecture in C57BL mice. Female mice were either provided a low fat diet (n=12) or a high fat diet (n=12) over a 6-week period and were then mated with males. Trabecular bone at the tibia distal metaphysis was analyzed at the 6-week time point and prior to delivery using micro-computed tomography. For simplicity, we present data on bone volume to total volume (BV/TV), one outcome of particular interest. There were significant main effects for both obesity ($F(1,10)=10.07$, $p=0.010$), and pregnancy ($F(1,10)=144.8$, $p<0.001$). The interaction effect was also significant ($F(1,10)=8.768$, $p=0.014$), demonstrating that the effect of obesity on BV/TV is evident only prior to gestation. Our data indicate that the high-fat fed obese mice had lower BV/TV compared to the low-fat fed mice during pre-pregnancy. However, given the robust negative effect of pregnancy on BV/TV, this likely explains the lack of diet-related BV/TV differences during gestation. These findings underscore the negative effect of excess adiposity and pregnancy on trabecular bone microarchitecture. Fetal and offspring musculoskeletal outcomes warrant consideration in future studies.

Investigating the Antiparasitic Activity of Cry5B Protein against Fourth-Stage Nematode Parasites

Nirali Patel
Dr. Ray Kaplan, Infectious Diseases, College of Veterinary Medicine

Helminth infections in humans and animals are a prominent concern due to their ability to impair health, well-being, and productivity. In livestock animals, the problem has become further amplified due the development of drug resistance which is reaching critical levels. One possible and novel treatment is the natural antiparastic protein, Cry5B, produced by the bacterium *Bacillus thuringiensis (Bt). Bt* is a spore-forming soil bacterium that produces a variety of crystalline (Cry) proteins. Cry5B has shown high potency against several important parasites in lab animal models, and it is hoped it also can be used as a natural antiparasitic to treat livestock. Cry5B must be ingested by the parasite to be active, however, pre-parasitic third-stage larvae (L3), which are typically used for *in vitro* drug screening, are a non-feeding stage and thus are not a viable experimental model. In contrast, L4 have fully developed GI systems, making the L4 stage ideal for an *in vitro* model for determining the efficacy of Cry5B. *Cooperia* spp. are the most common and important nematodes infecting young cattle and are the focus of this study. Recently, our lab has developed a culturing system that permits the development and molting of L3 *Cooperia* nematodes to the L4 stage. Exsheathed L3 are added to a nutritive media consisting of LB, NCTC, and fetal bovine serum, and are incubated at 39oC under 20% CO2. As the research progresses, the efficacy of Cry5B will be tested using L4 stage *Cooperia* in a series of in vitro drug assays.

Evaluation of Electric Twitch Endurance Index of the Lower Back Muscles

Sahil Patel
Dr. Kevin McCully, Kinesiology, College of Education

Our lab has developed an Electrical Twitch Stimulation Fatigue test which measures fatigue as a decrease in contraction velocity. Back pain and fatigue is a common and

debilitating clinical problem. The purpose of my study was to use an electrically stimulated muscle twitch test to measure fatigue in the erectors muscles of the lower back. Healthy males and females between the ages of 20-30 were tested. The electrodes were placed alongside the T12 and L1 vertebrae separated by 5cm to allow space for placement of the accelerometer. Subjects are in a seated position for this protocol which makes this test clinically applicable to the elderly and wheelchair bound. The testing protocol was 5 minutes of stimulation at a frequency of 4Hz using a tolerable current level. The fatigue of the muscle will be represented as an endurance index value. The endurance index is the difference between the maximum acceleration value and the end value. A frequency of 4Hz will cause fatigue in the muscle which can be measured by an accelerometer. A sample of 5 participants all resulted in a fatigued lower back erector (Mean = 25.2 +/- 12.25). I hypothesize a lower endurance index in the lower back muscles could be possibly correlated to conditions such as lower back pain or poor spine stability. An evaluation of the endurance index of the lower back muscles has the potential to be clinically relevant in identifying causes of lower back pain.

The Role of Dual Oxidase 1 in Tracheal Immunological Functions

Urmi Patel
Dr. Balazs Rada, Infectious Diseases, College of Veterinary Medicine

Life-threatening viruses such as the Influenza A virus (IAV) have the ability to wipe out multiple bodily functions and can therefore be fatal to one's health. The innate mechanism by which our body shows viral inactivation is connected to Dual Oxidase 1 and 2; major oxidases in the NADPH oxidase family that play a role in the production of hydrogen peroxide (H_2O_2) in tracheal airways through the activity of lactoperoxidase (LPO), thiocyanite (SCN^-) and iodide (I^-). LPO catalyzes the reaction between SCN^- and H_2O_2 to form hypothiocyanite ($OSCN^-$). A similar mechanism is seen with I^-. These reactive oxygen species play a major role in the production of H_2O_2, which lead to the inactivation of IAV. In order to test this, rat tracheal cells are harvested, grown and infected with the H1N2 strain of the virus in a mixture with the presence or absence of LPO, SCN^-, and I^-. The supernatants collected are then used to perform plaque assays on Madin-Darby canine kidney epithelial cells (MDCK) to measure the extent of inactivation of the virus. The data arrays to several log differences between inactivation in the systems without the 3 components (LPO, I^- and SCN^-) versus the systems with. Another comparison is made between the SCN^- and I^- systems to visualize which one forms a stronger response. The difference seen in the 3-component system could potentially hint to future studies that not only develop the knowledge of the Duox1 mechanism but also enhance applied research on the treatment of IAV.

Integration of Multispectral Imaging into UAS

Aaron Patrick, CURO Research Assistant
Dr. Changying Li, College of Engineering

Remote sensing devices will soon become common place in the field of agriculture, as unmanned aerial systems (UAS) are an incredibly efficient means of gathering crop data with high spatial and temporal resolution. Information such as canopy coverage, plant height, and normalized difference vegetation index can be gathered and processed to determine which genotypes of a species exhibit the most robust phenotypic traits. There are many UAS on the market that have integrated cameras, but few that have integrated multi-spectral cameras. Our challenge is to integrate a multispectral camera into a hobbyist aircraft that is light, compact,

and relatively inexpensive. This is accomplished through the use of a microcontroller that records data from sensors including an accelerometer, gyroscope, magnetometer, and barometer. The UAS will also collect GPS coordinates and calculate orientation data that will be used in conjunction with the multispectral images to create 3D models of crops. All flight data and images are recorded onto SD cards. This project entails the design and fabrication of vibration dampening mounting hardware for a multispectral camera, the integration of electrical components, and the coding of a microcontroller and image processing. The resulting data acquisition system can be incorporated into variety of commercially available unmanned aerial vehicles.

Photodissociation of CS from Excited Rovibrational Levels in Interstellar Environments

Ryan Pattillo
Dr. Phillip Stancil, Physics & Astronomy, Franklin College of Arts & Sciences

This research is focused on determining the abundance of CS molecules in various ultraviolet (UV) photon-irradiated interstellar (IS) environments. Photodissociation due to UV photons is a dominant molecular destruction process in a variety of UV-irradiated IS environments, so having reliable photodissociation rates for CS is necessary to accurately determine its abundance in these environments. While most astrochemical models adopt photodissociation rates computed from cross sections out of the molecule's ground rotational and vibrational (rovibrational) level (v=0,J=0), they also assume a standard local IS radiation field and opacity due to standard IS dust. However, none of these conditions are satisfied in a host of environments including photodissociation regions, protoplanetary disks, and outflows from AGB stars. To allow for the calculation of more reliable photodissociation rates, we compute cross sections from all bound rovibrational levels of the ground electronic state of the CS molecule. The cross sections are computed for a large number of excited electronic states using a two-state fully quantum perturbation approach. New *ab initio* potential energies and transition dipole moment functions, used in the photodissociation calculations, were obtained at the MRCI+Q level of theory using the quantum chemistry package MOLPRO. Applications of the rovibrational-state-resolved cross sections will be presented as well as LTE photodissociation cross sections which assume a Boltzmann distribution of initial rovibrational levels.

Keyword Extraction Using Artificial Neural Networks and a TextRank Variant

Justin Payan, Foundation Fellow
Dr. Bill Hollingsworth, Computer Science, Franklin College of Arts & Sciences

Keyword extraction is an important task in natural language processing that aids in information retrieval, document clustering, summarization, and many other useful endeavors. The task involves automatically selecting the most representative words and phrases from natural language documents. Most approaches consider all nouns and noun phrases as candidates, and a classification model determines which of those candidate keywords should be included in the set of selected keywords. Some of these classifiers have used linguistic information, some have used statistical information, and others use machine learning. We combine the linguistically informed approach with the machine learning approach to select keywords from scientific abstracts in the journals *Computers and Control* and *Information Technology*. The candidate keyphrases are classified by an artificial neural network, a variant of Mihalcea and Tarau's TextRank algorithm, or a combination of the two algorithms. We measure the precision, recall, and F1-score of

our algorithm as compared to previous results on this dataset. Our approach gives promising results.

Functions of the Discourse Marker *"Bon"* in Spoken French

Joy Peltier, Foundation Fellow
Dr. Diana Ranson, Romance Languages, Franklin College of Arts & Sciences

This study seeks to determine the pragmatic functions of the discourse marker *bon* and their frequency in spoken French. Discourse markers, such as English *well*, are often misconstrued as nothing more than fillers used in moments of hesitation (Hansen 1998:238). However, research in pragmatics reveals them to be a means of communicating the structure of a conversation or the speaker's attitude to the listener. For example, Barnes (1995:813) considers *bon* to be a marker of transitions appearing at "junctures or points of discontinuity," whereas Hansen (1998:254) considers it to mark an "undesirable discourse phenomenon." An analysis of 223 examples of this marker in the Corpus Montpellier-Rognes, composed of conversations recorded in 2005 and 2006 with 37 native speakers (22 women and 15 men), has revealed a set of finely distinguished functions of *bon* ranging from indicating the insertion of a quote, to highlighting a contrast, to introducing an opposing point of view. These functions call into question whether *bon* always marks a transition (Barnes 1995) or an undesirable discourse phenomenon (Hansen 1998). This study advances our understanding of *bon* by uncovering new pragmatic functions, refining those previously mentioned in the literature, and responding to proposals regarding its central purpose in discourse. Furthermore, it presents for the first time a quantitative analysis of the frequency of the various functions of *bon*.

Words That Lead and Words That Follow: Lexical Indicators of Leadership

Jacob Pendergraft, Parker Nayman, Fatima Koko, Christiana Agbonghae, Nikita Meka
Dr. Dorothy Carter, Psychology, Franklin College of Arts & Sciences

Tackling large-scale societal challenges often requires multiple teams from different disciplines, organizations, and geographic locations to collaborate using virtual collaboration tools communication. Arguably, *leadership* can have profound effects on the success of these systems. However, in complex multiteam contexts, leadership is often an informal social process whereby leaders emerge and exert influence through their interactions with others. Novel analytic techniques are now providing the means to capture interactions in virtual teamwork contexts and link these interactions with critical social processes such as leadership. In this study, we analyze the digital traces of social interactions among participants in a multiteam system laboratory task in order to identify word choices that indicate *leader/follower emergence.* In this task, 12 participants are randomly assigned to a specific role on one of four 3-member teams and are required to apply their role-specific information during a multiteam decision-making activity. Throughout the activity, all inter-team communication is restricted to an embedded text-based chat system. We analyze this body of text-based chat using a semantic analysis program called LIWC that examines the frequency of certain key words that fall under a specific construct or language style (e.g., affect or pronoun use). Finally, we use a class of inferential models of network emergence called *exponential random graph models*, which identify statistically significant antecedents of relationship emergence. This allows us to identify the lexical indicators that predict leadership and followership relationships between teammates.

3D Distribution of High Galactic Latitude Interstellar Clouds

Chance Pittman
Dr. Loris Magnani, Physics & Astronomy, Franklin College of Arts & Sciences

The Milky Way Galaxy is composed of stars, gas, dust, and dark matter. The gas component can take very different forms. There is a cold; molecular phase; a cold atomic phase; a warm atomic phase; a warm; ionized plasma; and a hot, ionized plasma. The cold molecular component is especially important because it is the material that forms stars. Most of the cold molecular gas in the Galaxy is tied up in large structures called molecular clouds, most of which are distributed along the Galactic plane. About 10 percent of the clouds can be found away from the Galactic plane at high Galactic latitudes. Many of the objects appear to be a part of large structures, which might indicate a formation mechanism; however, it is difficult to determine whether these structures are real from two-dimensional maps. Recently, accurate distances to many of these high latitude molecular clouds have been determined (Schlafly et. al 2014). We present here a three-dimensional representation of the spatial distribution of these objects in an effort to discern global structure patterns.

Yield Improvement of *Pyrococcus furiosus* Soluble Hydrogenase I by Overexpression of Accessory Proteins

Cynthia Ponir
Dr. Mike Adams, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Due to the recent increase in demand for alternative sources of energy, hydrogen gas has begun to receive a great deal of attention. The focus of this study is Soluble Hydrogenase I (SHI) from *Pyrococcus furiosus*, an anaerobic hyperthermophile. SHI has been used in a highly efficient *in vitro* pathway for hydrogen production requiring a large amount of enzyme for up-scaling. Previous studies have shown that eight accessory proteins are involved in the biosynthesis of SHI. However, the expression levels of these accessory genes were unchanged when SHI was overproduced in *P. furiosus*. The purpose of this study is to determine if overexpressing the genes encoding the three key accessory proteins, FrxA and HypC/D, would lead to increased production of SHI. This objective will be carried out by creating two separate knock-in cassettes containing the FrxA and HypC/D genes, pyrF as the genetic marker and a stronger promoter, Pslp, to over express these genes. The parent strain MW450, with SHI over-expressed, lacks a pyrF marker and is therefore unable to synthesize uracil. After confirming overlapping PCR of these cassettes, transformations will be performed. Maintaining anaerobic conditions, subsequent strains will undergo plate purification, popping out the marker for reuse, and qPCR analyses to determine expression levels of the genes encoding the accessory proteins and SHI between the control and experimental strains. In vitro hydrogen production assay will also be performed to determine SHI activity. These procedures provide the basis for improving the yield of SHI and up-scaling the hydrogen production pathway.

Standardized Public Education Funding Formulas: A Best-Practice Evaluation

Laura Pontari
Dr. Jamie Carson, Political Science, School of Public & International Affairs

The use of standardized public school funding formulas by states across the US has become a widespread practice in modern education. Studies have shown that the cost of education varies per student based on identified factors such as socioeconomic status, disability, district size, and English language skills. Funding formulas are meant to allot state funds based on these factors, thus providing a comprehensive plan for equitable allocation. The factors considered in funding formulas vary state by state, as does the weight assigned

to each factor. The study examines the standardized public education funding formulas used by eight states, selected based on overall education quality and geographic distribution. The selected states are Mississippi, New Jersey, Colorado, Massachusetts, Indiana, Arizona, Michigan, and Texas. After an evaluation of the funding formulas used and education quality provided by each state, this study will provide a policy recommendation for a standardized funding formula best-practice.

Developmental Trends in Infant Temporal Processing Speed

Katelynn Porto, CURO Graduation Distinction
Dr. Janet Frick, Psychology, Franklin College of Arts & Sciences

Critical flicker fusion (CFF) is a measure of temporal processing speed, or the speed at which the visual system can detect changes over time. In adults, CFF has been determined to be a strong indicator of executive functioning, neural efficiency, and central nervous system health, and has been positively associated with dietary intake of the carotenoids lutein (L) and zeaxanthin (Z). Previous studies of infant CFF development have been limited and marked by methodological challenges (e.g., Regal 1981), leaving a gap in our understanding of how temporal processing speed develops early in life. The present longitudinal study sought to characterize the development of CFF thresholds in breastfed babies (from 3 to 6 months of age) using a repeated-measures design. Infant CFF thresholds were measured using a two-alternative forced choice preferential looking task displayed on a custom-built device. Growth curve modeling will be used to analyze all data. We anticipate that infants' CFF trajectories will depend upon their baseline (3 month) CFF threshold and their mother's self-reported intake of green leafy vegetables (rich sources of L and Z). In infants, deficits in basic cognitive functioning, such as temporal processing speed, can negatively impact more complex cognitive processes in a cascading manner with age. Therefore, identifying developmental trends in temporal processing speed, as well as potential moderating factors (e.g., L and Z intake), is the first step in being able to detect deficits in this domain early in life, before higher level developmental processes are negatively impacted.

Approaches to Reducing the Cost of Algal Biomass Production

Grace Power, CURO Summer Fellow
Dr. Manjinder Singh, College of Engineering

Alternative fuels must be developed to replace the dangers caused by burning fossil fuels and serve as fuel sources once fossil fuels are depleted. Algae biofuels offer a potential fuel for the future. The most prominent hurdle facing algae biofuels currently is cost. This project aimed to increase the yields of algae grown on a large scale to make algae production more cost efficient. 1-Napthaleneacetic Acid, a plant growth hormone, was used to enhance algal growth in 200L carboys. Two preliminary experiments were conducted to optimize growth medium and phytohormone concentration. The optimum media was determined to be 1-NAA concentration to be 5 ppm (parts per million) and the optimum medium to be F2 media. Algae was grown in a scale-up method to reach a total volume of 200 Liters. Two strains were grown, one inoculated with 1-NAA dissolved into a 1:1 ethanol/water solution and one inoculated with the same concentration of a 1:1 ethanol/water solution for control. Algae was grown in a 250mL flask until optimal density was reached, then was transferred to the next volume stage. This process was repeated until the algae was growing in a 200L carboy. Dry weight, chlorophyll, and optical density measurements were taken regularly between Day 0 and Day

16 in the 200L carboys. Control and treatment test groups showed similar growth rates. Nutritionally optimal harvest was obtained after 9 days of growth. 1-NAA-treated algae produced consistently higher biomass throughout the experiment.

Evaluation of Recovery of Skeletal Muscle after Fatiguing Contractions

Payton Prins
Dr. Kevin McCully, Kinesiology, College of Education

Skeletal muscle fatigue has been an extensively studied topic in order to understand the underlying physiological mechanisms of this occurrence. Our laboratory has developed an electrical twitch stimulation fatigue test for clinical populations. Past literature in the field has pointed to a significant difference in muscle function between populations with neuromuscular disease and deficiencies compared to healthy populations. The aim of my study is to determine the initial rate of recovery of muscle contractions after fatigue has occurred, and to evaluate whether the rate of recovery could be a useful measurement in patients with various neuromuscular diseases or injuries. Measurements were taken in the trapezius muscles of healthy human volunteers. Muscle contractions were induced with sub-maximal twitch stimulations at 6 Hz. Muscle force was estimated using an accelerometer to measure the speed of the twitch contractions. Five minutes of 6 Hz contractions resulted in fatigue of 70% (n=7). In the first three minutes of recovery, muscle force recovered to 30% of the initial force. The ½ time of this early phase of recovery was 15 seconds. Because the muscle is depotentiating as well as recovering during the early phase of recovery, we are in the process of characterizing the time course of depotentiation in order to separate out this effect from recovery. This study has the potential to characterize the rate of recovery after fatigue, a little studied but potentially useful muscle parameter.

The Role of Mitochondrial Maintenance in Skeletal Muscle Strength and Repair

Anita Qualls, CURO Research Assistant
Dr. Jarrod Call, Kinesiology, College of Education

Fukutin knockout mice serve as a mouse model of human muscular dystrophy, i.e., dystroglycanopathies, which are characterized by skeletal muscle weakness and impaired muscle regeneration after injury. Poor mitochondrial quality may underlie these phenotypes, as skeletal muscle mitochondria are responsible for producing the energy required to meet the demands of muscle contraction and muscle repair. Mitochondrial quality is maintained by the proper removal of dysfunctional mitochondria via a cellular process called autophagy. The primary objective of this study is to determine the extent to which enhancing or attenuating autophagy affects muscle strength and repair in the Fukutin knockout mice. We hypothesize that increasing autophagy will lead to greater muscle strength and greater recovery from myotoxic muscle injury. AICAR (an autophagy activator) or 3-MA (an autophagy inhibitor) will be administered to Fukutin knockouts and littermate controls daily for four weeks. To determine if autophagy activation improves dystrophic muscle function, muscle strength will be assessed after two weeks of treatment. To determine if autophagy activation enhances dystrophic muscle regeneration, muscle strength recovery will be assessed two weeks following a myotoxic injury. To determine if autophagy activation affects mitochondrial function in dystrophic muscle, mitochondrial respiration will be assessed from injured and uninjured permeabilized fibers using a Clark-type oxygen electrode. Immunoblots for autophagy-related proteins will be used to examine the autophagy signaling cascade

during muscle regeneration after injury. Overall, by utilizing a mouse model we can gain insight into the importance of mitochondrial maintenance in improving muscle function in muscular dystrophy patients.

Mental and Sexual Health Post-War: Trauma, Depression, and Interpersonal Violence— Attitudes among Liberian Women

Mehabuba Rahman, CURO Research Assistant
Dr. Tamora Callands, Health Promotion & Behavior, College of Public Health

From 1989 to 2003, Liberia experienced two of the most violent civil wars in African history. Fourteen years of war shattered the West African country's infrastructure and community resulting in one-third of population being displaced and 7% of the population being killed. Although millions of people were affected by the war-related violence, violence against women reached unprecedented levels. It is estimated that up to 70% of young women in Liberia experienced some form of sexual and gender-based violence (SBGV). SGBV has wide-spread implications for the mental health, sexual health, and the overall psychosocial well-being of young women. While significant strides have been made to reduce rates of SGBV, little empirical research has focused on consequences associated with violence exposure. Using cross-sectional data collected between November 2015 - February 2016 from 100 young women, ages 18-25, we aim to examine the relationships between violence exposure, war-related trauma, mental health and sexual risk behavior. We hypothesize that violence exposure will be associated with greater sexual and mental health outcomes. Preliminary analysis demonstrates that risky sexual behavior, such as multiple partners and lack of condom usage, is associated with violence exposure. These data underscore the impact that SGBV has on the mental and sexual health of young women. These findings suggest the need for continued efforts to change the policies and implement and infrastructure to protect young women in post-conflict settings.

Examining *Mycobacterium tuberculosis* Genes for Roles in B12 Synthesis

Ashitha Rajeurs
Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Mycobacterium tuberculosis (*M.tb*) is a leading cause of morbidity and mortality in humans. In 2013, *M.tb* caused 9 million new cases of tuberculosis (TB) and 1.5 million deaths. Understanding the physiology and biosynthetic capabilities of *M.tb* bacteria may aid in the development of new drugs and vaccines to fight this global health threat. Coenzyme B12 (Co-B12) functions as a cofactor in various metabolic enzymes in a wide range of organisms, but is only made by bacteria and archaea. Co-B12 is a complex molecule requiring over 20 enzymes for its synthesis. The *M.tb* genome encodes homologs of many Co-B12 synthesis genes; however, the coenzyme is not detected in strains grown under standard culture conditions. Either all of these strains have mutations in the Co-B12 synthesis pathway or production of this molecule only occurs under specific environmental conditions, such as those found inside a human host. *Mycobacterium smegmatis* is a non-pathogenic species of mycobacteria found in soil that produces Co-B12. The goal of this project is to determine if *M.tb Rv2228* and *cobS* function in Co-B12 synthesis. The approach is to first delete *MSMEG4305* and *cobS* from the *M. smegmatis* genome and demonstrate absence of Co-B12 production in the mutants. Next, a wild type copy of the deleted gene or the homologous *M.tb* gene (*Rv2228* and *cobS* respectively) will be introduced into the mutants and the resulting strains assayed for

production of Co-B12. If a *M.tb* gene enables a *M. smegmatis* mutant to produce Co-B12, then the genes likely encode functional homologs. The progress and results of this project will be presented.

Eliminating Cultural and Linguistic Boundaries in Healthcare: Creating Standards and Funding for Medical Interpreters

Vineet Raman, Ramsey Scholar
Dr. Richard Schuster, Health Policy & Management, College of Public Health

The U.S. has increasingly become more culturally and linguistically diverse with the influx of migrants from around the world. The number of Americans speaking a language besides English at home has increased by almost fifty percent, thereby also increasing the number of patients with limited English proficiency (LEP) by over fifty percent. However, weak federal regulation has allowed states to leave the use of appropriate language services at the discretion of individual hospitals, creating a gap in care between English-speakers and patients with limited English proficiency and a surge in the use of untrained *ad hoc* interpreters. The miscommunication that results from the underutilization of professional language services has inescapable consequences for health outcomes in LEP patients. New federal funding for interpreters is available via the Affordable Care Act, and states should be required to use these funds to implement a standard of interpreter of their choice in their hospitals.

A Review of the Use of Telemedicine in Nursing Homes

Sona Rao
Dr. Elena Karahanna, Management Information Systems, Terry College of Business

Telemedicine, the exchange of medical information through long-distance electronic communication, is a practice that nursing homes adopt to improve the effectiveness of their care and reduce health and financial risks. The purpose of this literature review is to evaluate research on the implementation of telemedicine systems in a nursing home setting. Review of this literature was conducted using CINAHL, EBSCO Electronic Journals, Academic Search Complete, ERIC, and PubMed databases and search terms included telemedicine, telehealth, nursing home and homes, elderly, and geriatric. This literature review is based on twenty-six studies related to telemedicine in nursing homes and the following themes were evaluated: benefits, challenges, and limitations in terms of cost and quality of care. Telemedicine is an innovative approach to making medical services more accessible to nursing home residents and nursing homes can experience significant benefits as a result of adopting telemedicine systems.

Behavioral Economic Analysis of Relative Reinforcing Value as a Predictor of Smoking Cessation Treatment Outcomes

Marie Rapoport, CURO Summer Fellow, CURO Research Assistant
Dr. Lawrence Sweet, Psychology, Franklin College of Arts & Sciences

Behavioral economic studies investigating demand for a substance represent an attempt to quantify the amount an individual values a substance relative to other reinforcers using a behavioral paradigm. This approach has been successfully used to characterize the progression of substance use and risk for future substance abuse. The cigarette purchase task (CPT) is designed to assess demand for nicotine in smokers by quantifying the value of cigarettes in monetary units. In the present study, we investigated the relationship between demand and smoking cessation treatment outcome in smokers after

nine weeks of nicotine replacement therapy and cognitive behavioral therapy. In this version of the CPT, participants were asked to report how many cigarettes they would hypothetically purchase across 23 price points, ranging from $0-$10 per cigarette. Principal components analysis was completed using responses on the cigarette purchase task to divide demand into two components based on previous research: amplitude (demand at low costs) and persistence (sensitivity to increasing price). The results showed that, controlling for income, amplitude was significantly predictive of days to relapse, days to lapse, and number of therapy sessions attended**.** The results suggest an individual's valuation of cigarettes independent of competing reinforcers is predictive of smoking cessation treatment outcome while sensitivity to increasing price does not appear to be predictive of treatment outcomes.

A Bright and Budding Future for Sunflowers: Understanding the Predictive Properties of *Helianthus annuus* Seedlings for Improving Adult-Stage Crop Yield

David Reagan, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

Sunflowers are a multibillion-dollar industry in the United States, are a crucial oil-seed crop, and offer extraordinary agricultural, environmental, and economic potential. Fertilizers are a major expense for farmers, as well as an environmental hazard if excessively applied to croplands. Finding Sunflower varieties that exhibit the relatively best growth under nutrient stress would increase yield, and subsequently reduce expenses for the agricultural and consumer sectors alike. Of even greater interest, better understanding the nutrient application versus yield relationship between the seedling and adult stages of Sunflowers allows for greater efforts on those seedling varieties that offer the greatest probability of success later in the growth cycle. Our greenhouse study examined 12 genetically dissimilar Sunflowers at the seedling and adult growth stages under variable nutrient applications, to better understand which Sunflower varieties demonstrated the best nutrient-stress resistance, and to determine if seedling performance is predictive of adult yield. Results from the seedling stage show that four genetic lines are excellent candidates for producing high yield under diverse fertilizer treatments, especially in low treatments. Results from the adult stage are ongoing, but we expect that many of the Sunflower lines that exhibited relatively high yield in the seedling stage will also exhibit relatively high yield in the adult stage. The results of this study will provide incredible information into correlations between yield and fertilizer application from the seedling to adult stage, benefiting farmers, consumers, and the environment alike.

Lutein and Zeaxanthin Are Unrelated to Performance on the Short Physical Performance Battery

Joshua Reynolds, CURO Research Assistant
Dr. Lloyd Stephen Miller, Psychology, Franklin College of Arts & Sciences

The carotenoids lutein (L) and zeaxanthin (Z) have been shown to benefit eye health and more recently cognitive function. The present study investigated whether L and Z may also benefit physical ability. In light of their strong antioxidant properties and prior research showing a positive relation between antioxidants and physical functioning, it was hypothesized that greater L and Z levels would be associated with better physical performance in late life. Pearson product-moment correlations were used to evaluate this relationship in a sample of 62 community-dwelling older adults (mean age=73.31, 57% female, 100% Caucasian). Physical performance was assessed using the

Short Physical Performance Battery (SPPB), while L and Z levels were measured using two standard, validated procedures: blood serum concentrations and macular pigment optical density (MPOD). Contrary to expectation, no significant relationship was found between SPPB total scores and L and Z, as measured in serum ($r=0.098$, $p>0.05$) or MPOD ($r=0.022$, $p>0.05$). Furthermore, no significant correlations were found between L and Z levels and SPPB subscale scores, which include measures of balance, gait, and lower extremity strength (ps all >.05). The observed findings suggest that the beneficial effects of L and Z may be limited to eye and cognitive health, perhaps due to their preferential accumulation in human retina and brain relative to other body tissues. However, it is possible that a more sensitive measure of physical functioning would reveal a relationship and replication is warranted in a sample characterized by greater variability in physical ability.

Subtracting the Effects of Carbonization of Hickory Nut to Predict Mean Annual Precipitation in Archaeological Sites

Sidney Reynolds
Dr. Laurie Reitsema, Anthropology, Franklin College of Arts & Sciences

Carbonized hickory nut from archaeological contexts could be indicative of mean annual precipitation in the past. By burning modern hickory nut samples from St. Catherine's Island, Georgia at different temperatures and using a mass spectrometer to produce δ13C values, we hope to subtract the effects of carbonization to estimate 13C values before the hickory nut was burned. Then, we will compare those δ13C values to the mean annual precipitation of the years for which we have modern nut samples to create a predictive graph that will be used to establish the relationship between archaeological carbonized nut samples and mean annual precipitation. Knowing the mean annual precipitation for archaeological contexts will greatly contribute to our understanding of paleoclimate and the conditions under which different populations, specifically the Guale Indian population on St. Catherine's Island, sustained themselves.

Synthesis and Surface Engineering of Fe5C2 Nanoparticles for Superior r2 Relaxivity in Liver-Specific MR Imaging

David Rink
Dr. Jin Xie, Chemistry, Franklin College of Arts & Sciences

Liver-specific magnetic resonance imaging (MRI) has been used extensively in detection of malignant liver masses, metastasis indication, as well as observing liver storage disorders. In order to enhance the imaging quality, T2 contrast agents, which induce hypo-intensities on MRI maps, are often administered before imaging. Magnetic nanoparticles, more importantly Fe3O4/Fe2O3-based nanoparticles, have emerged as one of the standards in T2 contrast agents due to their low toxicity, biodegradability, and facile synthetic conditions. However, the iron-based nanoparticles only have a moderate magnetic moment. In this research, iron carbide nanoparticles, here Fe5C2 based carbides, have been successfully synthesized by high temperature thermal decomposition. Fe5C2 nanoparticles possess a superior magnetic moment and do not have oxidation-induced magnetization drops. Samples of 5, 14, and 22 nm carbides were prepared for study. Their surfaces were modified via ligand addition with phospholipids, ligand exchange with zwitterion-dopamine-sulfonate (ZDS), and protein adsorption with casein. These engineered Fe5C2 nanoparticles all exhibit excellent aqueous stability, low toxicity, and high r2 relaxivity. In particular, the casein surface coating resulted in an r2 enhancement of more than two fold, measuring 973 mM-1s-1 for the 22 nm nanoparticles, which is

among the highest of all T2 contrast agents reported to date. Small animal studies further confirmed the improvement of the Fe5C2 nanoparticles over the iron oxides in inducing hypo-intensities on MRI maps and causing little toxicity to the host. This research expands upon our ability to modify contrast character of magnetic nanoparticles and helps to create a new class of MRI contrast agents.

Offensive Realism in a World of Hegemons

William Robinson, CURO Research Assistant
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

Offensive realism describes a world in which states try to maximize their relative power at the expense of every other state. Under this grand theory, the goal of each state is to become a (regional) hegemon (i.e., the most powerful state in the geographic area).The foundation for this aggressive behavior is the international system. Because no overarching entity sits above states to protect them from one another, every state develops offensive capabilities, remains suspicious of each other's intentions, and acts rationally to ensure its survival by working toward hegemony. If one accepts this theory and its premises, the behavior of many revisionist states becomes understandable; they want hegemony to ensure security. However, once a state reaches hegemony, as the United States has, the theory is lacking. I challenge the assumptions made by offensive realist theory about the rational behavior a hegemon should enact and consider the implications of a world with several regional hegemons.

Quantification of Contaminants of Emerging Concern in Fish and Shark Tissue from Sapelo Island, Georgia

Jackson Rodgers, CURO Research Assistant
Dr. Marsha Black, Environmental Health Science, College of Public Health

Contaminants of emerging concern (CECs) range from pharmaceuticals to industrial pollutants. There is little research on how CECs affect marine environments and the organisms living in marine habitats. Quantifying these pollutants in marine organisms may indicate inputs from sewage/septic systems from local populations. Research also indicates that CECs pose a potential risk to marine organisms through chronic exposures that could adversely affect their health and that dietary transfer of CECs to higher level organisms is possible. My CURO project investigated if CECs are present in fish tissue and shark plasma from estuaries at Sapelo Island, Georgia. Whole fish tissue samples from silver perch, striped mullet and sea trout were collected from 2013-2016 as part of a NOAA and Georgia Aquarium research project at Sapelo Island. Shark plasma was collected from Lemon and Atlantic Sharpnose sharks during the summer of 2015. These samples were analyzed for 30 pharmaceuticals and personal care products via LC-MS/MS analysis and over 200 pesticides via GC-MS analysis. Initial results indicate that CECs accumulate at low ng/g (parts-per-billion) concentrations in fish tissue and low ng/ml concentrations in shark plasma samples. My research supports evidence our lab has of CECs detected in oysters, water and sediment samples. The detection of diphenhydramine, DEET and sertraline in all media indicates accumulation in multiple levels of the food web. Chronic toxicity may be caused by a cocktail effect of CEC exposure on the organism with multiple modes of action in play, but how these chemicals interact is mostly unknown.

Who Is Better at Cracking Nuts: Humans or Monkeys?

Lindsey Roles
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Dating back at least 2.5-3.3 million years, tool-assisted percussion still remains a key technology for hominins. Tool-assisted percussion is not unique to hominins; wild populations of bearded capuchin monkeys, long-tailed macaques, and chimpanzees use anvil-and-hammer tools to crack open nuts and other encased food. To address fundamental questions about the evolution of tool-assisted percussion in hominins, we need to know about species-specific cognitive and motor skills. We quantified nut-cracking skill in wild bearded capuchin monkeys (*Sapajus libidinosus*) and novice and expert humans, as they used anvil-and-hammer tools to crack tucum (*Astrocaryum spp.*) nuts. The monkeys outperformed the novice humans, and the expert humans outperformed the monkeys. The monkeys cracked the nuts by undergoing multiple strikes with a moderate amount of force; the novice humans used the same amount of force the monkeys did, having to undergo multiple strikes in order to crack the nuts. The expert humans used a greater amount of force to crack the nuts and a fewer number of hits than the monkeys and novice humans. The monkeys also modulated the force of their strikes on the basis of the condition of the nut (i.e. presence of fracture in nut). These results indicate that the nut cracking skill involves motor actions that are learned over time with practice, and not just abstract knowledge of the affordances of the task, i.e., nut cracking is an embodied skill. We suggest that hypotheses linking tool-assisted percussion to traits unique to hominins need a reassessment.

Muscle Adiposity, Forearm Muscle Strength, and Radius Cortical Bone Geometry in Children

Emily Rollins, CURO Research Assistant
Dr. Richard Lewis, Foods & Nutrition, College of Family & Consumer Sciences

Background: Cortical bone strength is highly dependent upon skeletal muscle, specifically muscular contractile forces. Adipose tissue that infiltrates the muscle may influence muscle strength, and subsequently the muscle-cortical bone relationships. *Objective:* The aim of this study was to determine the effect of muscle adiposity on the relationships between forearm muscle strength and mid-radius cortical bone outcomes. *Methods:* This cross-sectional study utilized data from a cohort of 237 reportedly healthy black and white boys and girls who participated in a vitamin D supplementation trial. A hand dynamometer was used to measure forearm muscle strength. Mid-forearm muscle adiposity and radius cortical bone geometry were measured via peripheral quantitative computed tomography. Polar strength strain index (pSSI) provided an estimated measure of bone bending strength. A median cutoff determined groups of high and low muscle adiposity. Linear regression and hierarchical linear regression were performed adjusting for race, sex, and sexual maturation rating stage. *Results:* Handgrip strength was greater in the children with low versus high muscle adiposity ($P = .001$). Handgrip strength was a positive predictor of pSSI in both the low ($\beta = 0.252$, $P = .002$) and high ($\beta = 0.377$, $P < .001$) muscle adiposity groups. However, this relationship was significantly stronger in the high muscle adiposity group (Pinteraction = .014). *Conclusions:* Obese vs. normal weight children have a greater risk for fractures, though the etiology is unclear. Our data do not support the position that muscle adiposity hinders the muscle strength-cortical bone relationship despite corresponding deficits in forearm muscle strength.

Malaria in the Late Stages of Pregnancy and the Significance of Tissue Factor

Kerryn Roome
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Despite immunity in malaria-endemic regions, pregnant women have an increased

susceptibility to an infection. In these women, malaria infected red blood cells can accumulate in the maternal side of the placenta, causing drastic changes in the placental tissue, hampering fetal intrauterine growth, which leads to low birth weight, stillbirth, and abortion. Due to ethical and anatomical limitations in studying this in humans, murine models are a common alternative. We have previously shown that Tissue Factor (TF), the initiator of coagulation, is associated with abortion in C57BL/6 mice infected with *Plasmodium chabaudi*. While we know TF is upregulated in response to TNF, the relationship between TF and TNF signaling has not been investigated. TNF is a pro-inflammatory cytokine that has been associated with malaria pathogenesis in mice and in humans. TNF acts through its surface receptors, TNFR1 and TNFR2. We hypothesize that TNF signaling through its surface receptors is required for upregulation of TF and induction of the coagulation cascade followed by tissue damage and abortion. To verify this hypothesis, we will use mice lacking TNF, TNFR1, TNFR2, and wild-type C57BL/6 mice infected on day 0, 6, 8 or 10 of gestation and uninfected controls. The courses of infection and pregnancy will be monitored and mice will be sacrificed to have organs and plasmas collected for TF expression assessment on gestation days 10 and 18. We expect that wild-type C57BL/6 mice will have significantly higher expression of TF while mice lacking TNF and its receptors will have lower TF expression.

Predictable Variation in Temporal Transmission Potential: West Nile Virus as a Case Study

John Roquet, CURO Summer Fellow
Dr. Andrew Park, Odum School of Ecology

Generalist parasites such as West Nile virus (WNV) are characterized by their ability to infect, and transmit among, multiple host species. In the case of WNV, passerine song birds are particularly important in maintaining transmission, while other bird orders dilute the transmission potential because of relatively low viral replication in those hosts. Due to the predictable migrations of bird species, as well as the emergence and overwintering times of mosquitoes that vector the virus, we expect a given location to exhibit robust annual seasons when transmission is intense. As WNV spills over into human populations, we have the potential to develop risk profiles which vary in time according to the mosquito and bird population dynamics. To achieve this, we developed a set of equations describing the dynamics of WNV transmission in the mosquito-bird community system, and derived a metric of transmission potential. We parameterized the model using data on mosquito and bird dynamics in New York, confirming transmission intensity had pronounced, repeatable seasonal variation. We then tested the hypothesis that human cases of WNV in New York correspond to periods of high transmission intensity in the bird-mosquito cycle (with some delay expected in the human cases for various reasons). Using records of WNV in New York from 2000 to 2013, we found a significant correlation between our predicted timing of maximum transmission and peak cases in human populations, with a consistent 5-week delay. This novel approach to modeling disease outbreak potential may improve predictions of epidemics more generally.

Evaluation of Georgia Bridges and Development of Large-Scale Bridge Testing Procedure

Nicholas Rorabaugh, CURO Research Assistant
Dr. Mi Geum Chorzepa, College of Engineering

The primary goals of this research are to (1) evaluate existing bridge drawings to determine critical bridge parameters necessary for severe

storm evaluations and; (2) develop a test procedure for evaluating large-scale bridge components. How would these bridges hold up in severe weather, specifically hurricane weather, and how can traffic be simulated through single component force testing? The first part of this research includes a review of 50-60 bridge drawings and evaluation of critical bridge components for a Georgia Department of Transportation project. This includes gathering information from the drawings about the design, elevations, spans, slab, beams, girders etc. The other part of the research includes construction of a large-scale bridge beam specimen and development of test procedures for simulating ordinary highway traffic. The test procedure can be used for future research projects. For example, testing closure pours between precast elements utilizing Ultra-High Performance Concrete (UHPC) is of particular interest. The UHPC allows for tighter joints between precast elements and facilitates rapid construction. This semester's research will focus on identifying critical bridge parameters and testing a beam specimen for traffic or long-term fatigue loading. The beam testing will be done in UGA's STRENGTH lab by using a high tech camera and sensors to measure inflections not visible to the eye.

Analysis of Forces Acting on the Equine Navicular Bone in Normal and Dorsiflexed Positions

Kaitlyn Ruff, CURO Research Assistant
Dr. Elizabeth Uhl, Pathology, College of Veterinary Medicine

Navicular disease is one of the most common forms of lameness in horses and is generally thought to be a chronic condition that can be managed in some horses but not effectively treated. However, a pathomechanical paradigm may offer a better explanation of the disease and provide better treatment options. The navicular apparatus is a functional enthesis organ that is highly adapted to dissipate forces away from the osteotendinous junction between the deep digital flexor tendon and the third phalanx. Based upon functional analyses of horses with navicular disease, we have hypothesized that chronic overloading of the forelimbs, which induces the habitual and exaggerated dorsiflexion of the foot, changes the balance of forces acting on the navicular apparatus. We tested our hypothesis by comparing the forces acting on the navicular apparatus of an equine foot in a normal position to those acting on the navicular apparatus in a dorsiflexed foot, using the method of free-body analysis on 3D models, which were reconstructed from data of x-ray CT scans of a horse forelimb. Results indicate that the dorsiflexed position of the foot puts the deep digital flexor tendon under greater tension, thereby creating a larger compressive force on the navicular bone. This site of compression corresponds to the characteristic "bone bruise" of navicular disease. The dorsiflexed position of the foot also pulls taut the impar and suspensory ligaments, thereby increasing tension on their attachments sites on the navicular bone. This increased tension explains the presence of osteophytes along the entheses of these ligaments, which is a common lesion in navicular disease. Thus, decreasing the habitual and exaggerated dorsiflexion of the foot by taking the extra weight off of the forelimb is likely to be an effective treatment for many cases of navicular disease.

Investigating the Influence of Geospatial Attributes on Spider Species Richness and Diversity

Katherine Russell
Dr. Jason Schmidt, Entomology, College of Agricultural & Environmental Sciences

The maintenance of local biodiversity is an important aspect of the long-term sustainability of agricultural production.

Maintaining biodiversity, especially in regards to predator species, promotes natural pest control and many other ecosystem services. Spiders (*Araneae*) often prey upon common pest species, making them a beneficial component of agroecosystems. Spider species richness and diversity varies across landscapes and is often correlated with certain abiotic factors. This project investigates how four geospatial attributes – elevation, soil moisture, NDVI, and distance to edge habitat – influence spider species distributions across a farm-scape in South Georgia. Samples for the project were obtained from pitfall traps placed along a grid pattern within a farm-scape in the Tift county area. Spiders were later removed, preserved in alcohol, and manually counted and identified. Counts and species data were compiled into a spreadsheet and correlated with the four selected attributes using multivariate methods and geospatial statistics. Final results are pending. Preliminary analysis shows at least 12 different species of spiders present across the farm-scape, with wolf spiders (*Lycosidae*) numerically dominating the communities. Further identification of spiders and more in-depth analysis of the data will allow for greater exploration of the relationship between spider abundance, diversity, and the farm-scape's geospatial attributes. Ultimately, the results should help growers identify potential spider hotspots within their farm-scapes, which could then be maintained to promote healthy populations of this beneficial predator.

How the Recruitment of Female Fighters for Islam Has Changed Transnational Terrorist Organizations and What the Long-Term Implications of This Trend Will Be for Interstate Conflicts

Sarah Sammons
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

The purpose of this research is to answer the question of: what has made the messages of terrorist organizations so appealing to women, despite the fact that they come from an element of the Muslim spectrum that has sought to suppress and silence female participation in public life? The initial roots of the feminization of armed conflicts can be traced back to the revolutionary movements of the region of the Middle East during the mid to late 20th and early 21st centuries, with women serving as couriers, nurses, combatants, and intelligence officers. Since 9/11 there has been an empirical shift towards female involvement in terrorist activities, especially in participation in suicide bombings. My goal is to conceptualize these types of female violence in terms of a larger paradigm shift; I will accomplish this by examining quantitative data from feminist groups participating in civil societies across the Middle East and completing a literature review to produce new qualitative research. A new vision is needed in international relations to addressing issues such as female participation in terrorist organizations through a "gendered lens," where agency and the very identity of who a terrorist can be is adjusted at a theoretical level. On a very basic level, addressing terrorism means studying more than states and organizations. Terrorism is executed by people, increasing numbers of whom are women, and developing ways to see the societal framework that propels them toward destruction is crucial in approaching ways to combat the ever-evolving transnational terrorist organizations.

Evaluation of Novel Antiviral Drug NS95397 for Treatment of Swine Influenza Infections in Pig Cells

Preston Samowitz, CURO Graduation Distinction
Dr. Ralph Tripp, Infectious Diseases, College of Veterinary Medicine

The influenza virus causes morbidity and mortality in both humans and animals. Swine influenza effects pigs worldwide and can be

transmitted to humans. Additionally, the influenza virus possesses a major threat in the swine industry that may affect production output. Discovering countermeasures for the influenza virus has faced many obstacles because the virus constantly evolves, a feature often causing vaccines and antiviral drugs to be ineffective. In this study, swine influenza was assessed to discover if a novel antiviral drug could be used as a treatment option. A novel drug, NSC95397, targets host cell mechanisms captured by the influenza virus that are needed for replication. Importantly, NSC95397 has been shown to alleviate influenza symptoms in mice. A host cell factor, cell division cycle 25 B is the target for NSC95397 that indirectly inhibits a key viral protein NS1, involved in the replication of the virus. The goal was to characterize the escape mutant virus after serially passaging the virus in the presence of NSC95397. Drug sensitivity assays on various passages demonstrated that the strain does not appear to have resistance to this novel drug. This finding has implications on understanding how targeting host genes limits virus resistance and development of a novel influenza antiviral therapeutic.

Cognitive Control as Assessed by Multiple Eye Tracking Paradigms

Kodiak Sauer
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Ocular motor tasks are an effective way to assess cognitive control easily and accurately. One such task, the antisaccade task (AS), is used to measure inhibition in diverse populations, but requires more cognitive operations than inhibition alone to volitionally move the eyes to the mirror image location of a stimulus. Therefore, it is unknown if poor performance on the AS is due to difficulties in inhibition, working memory, or other factors. In order to differentiate components of cognitive control in ocular motor tasks, college-aged participants (n=51) completed an ocular motor battery. In addition to the AS task, participants completed an ocular motor delayed response task (ODR), which tests both working memory and inhibition, and a minimally delayed ocular motor response task (MDOR), which tests inhibition in isolation. Preliminary results (n=10) show a relationship between MDOR error rate and both ODR and AS error rate. This suggests that these tasks assess a similar construct, presumably inhibition. We also found similar reaction times in the ODR and AS tasks, which suggests that generating a volitional saccade to a blank location in both tasks requires similar processing time, despite differences in task demands. The findings from this study will clarify how various cognitive control processes interact in each of these ocular motor tasks and will inform the design of an efficient set of tasks to study people with cognitive control impairment.

The Relationship between Central Nervous System Xanthophyll Status and Brain Activation in Healthy Older Adults

Kodiak Sauer, Jacob Beckham
Dr. Lisa Renzi, Psychology, Franklin College of Arts & Sciences

Xanthophyll carotenoids lutein (L) and zeaxanthin (Z) are the only carotenoids found in the neural retina and are the dominant carotenoids in the rest of the central nervous system. An emerging body of literature suggests that high levels of these carotenoids in the neural retina are predictive of improved cognitive function in adults across the lifespan. Renzi and Hammond (2010) proposed a hypothesis for how lutein and zeaxanthin might influence cognition, known as the neural efficiency hypothesis. This hypothesis suggests that individuals with higher levels of the xanthophylls are capable of processing information rapidly and with less noise than individuals with low levels. In order to test this hypothesis, a total of 51

older adults (*M* = 73 +/- 8.2 years) were supplemented with either 12 mg L+Z or placebo. Retinal L+Z levels were measured psychophysically using heterochromatic flicker photometry. At baseline, participants in the highest and lowest quintiles for retinal L+Z levels were selected for analysis. High density electroencephalography was performed to measure brain activation at rest, as well as to measure steady-state visual evoked potentials at three driving frequencies. Participants with high retinal L+Z levels showed increased brain activation at each driving frequency, suggesting improved neural efficiency. These individuals also showed increased brain activation at rest.

Off-Campus Housing and the Gentrification of Downtown Athens, GA

Kari Saunders, CURO Research Assistant
Dr. Juan Meng, Grady College of Journalism & Mass Communication

Purpose: The purpose of this research is to study the effects of different types of student housing accommodations on the city of Athens, specifically in the downtown area. There has been an influx of large, luxury-style apartment complexes built within the last five years, and the impact of these complexes could prove meaningful to students, non-student Athens residents and city officials. *Design/methodology/approach*: The researcher used two research methods in this study to investigate the subject: (1) an online survey of UGA undergraduate students currently living in the Athens area; (2) two focus groups—one with five participants and the other with four participants—with UGA undergraduate students currently living in the Athens area. *Findings*: Results suggest that the downtown Athens area is certainly being affected by the large, luxury apartment complexes being built nearby and that students are drawn to these complexes most because of the location and proximity to campus. *Practical implications*: The influx of luxury apartment complexes has impacted the displacement of low-income Athens residents and aided in the wave of large chain retailers such as J. Crew and Urban Outfitters buying retail space in downtown Athens. The diversity in these complexes is low, and the individuality of the downtown Athens area is being reduced because of the shift in businesses located there. *Originality/value*: The study focuses on an issue that is inherently related to the University of Georgia. While the research did show some insights from Athens specifically, the specificity of this research is certainly unique. It is important that the change of the Athens area because of student impact is measured and explored.

The Effect of Maternal Diet on Gastrointestinal Health of Offspring

Ruth Schade, CURO Research Assistant
Dr. Claire de La Serre, Foods & Nutrition, College of Family & Consumer Sciences

The gut communicates to the brain the quality and quantity of nutrients in the gastrointestinal tract as a way of regulating food intake, and this regulation mechanism can be influenced by environmental factors like maternal diet. Bacteria are a source of inflammation in the gut, so hosts have anti-inflammation mechanisms to control for this. One of these mechanisms, Intestinal Alkaline Phosphatase (IAP), is a duodenal enzyme that detoxifies bacterial LPS products. Chronic high fat diets decrease the activity of IAP, and low IAP activity is associated with a propensity for obesity, so what is the effect of maternal diet on IAP levels in offspring? Female mice were put in three groups with each group consuming diets high in fat, low in fat, or high in fat with added glycan. These lasted from three weeks before mating, through the duration of pregnancy, and throughout a three week lactation period. After the offspring were weaned, they were either fed the same, high or low fat, diet as the mother, or the opposite diet, over the course

of ninety days. At the end of this period, tissue samples were collected and levels of IAP were analyzed. It was found that the offspring of mothers fed a high fat diet had decreased IAP activity, which may increase their risk for obesity.

The Effects of Lifetime Sports Participation and Sedentary Time on Muscle Capacity: Does More Activity Offset the Effects of Prolonged Sitting?

Nathan Schlies
Dr. Michael Schmidt, Kinesiology, College of Education

In concurrence with the infiltration of technology into our daily lives, emerging evidence suggests that sedentary behavior (SED) is rising, and that the population generally fails to adhere to physical activity guidelines. SED and inactivity have independent effects on a range of cardiometabolic outcomes but few studies have explored whether this is the case regarding muscle capacity. Muscle capacity is a predictor of cardiometabolic risk and all-cause mortality, and is positively associated with weight management and functional capacity through its close ties to lean mass and metabolic rate. Thus, greater muscle capacity is advantageous to health. Due to the pervasiveness of SED and inactivity, the aim of this study was to examine the extent to which lifetime sports participation might offset potentially negative effects of SED on muscular capacity. Participants were part of a longitudinally studied cohort [n=99 (n=33 male); 12-19 yo]. Lifetime sports participation was measured using the Bone-specific Physical Activity Questionnaire. SED was measured using the Adolescent Sedentary Activity Questionnaire. Muscle capacity was measured using the Nottingham Leg Extensor Power Rig (Power) and the Biodex isokinetic dynamometer (Strength), combining the greatest trial in each, with lean mass of the corresponding region from Dual Energy X-ray Absorptiometry to create normalized ratios. It is expected that frequent sports participation during youth will be positively associated with muscle capacity, and greater SED will be inversely associated with muscle capacity. We anticipate that the negative effects of high SED will be attenuated by greater lifetime sports participation.

The Effects of Migration and Infection on Resting and Flight Metabolism in Monarchs

Hayley Schroeder, CURO Research Assistant
Dr. Sonia Altizer, Odum School of Ecology

Long-distance migration requires physiological changes to prepare for and sustain energetically costly migratory movements. Some migrants, such as the monarch butterfly (*Danaus plexippus*), atrophy reproductive organs and enter reproductive diapause to minimize energetic costs. The ability to migrate, however, can be jeopardized by infection. This study explored the effects of reproductive diapause and infection by a protozoan parasite *Ophryocystis elektroscirrha* on flight metabolism of the monarch butterfly. We expected that migratory monarchs in reproductive diapause would have a lower flight metabolism than reproductively active non-migratory monarchs as a mechanism to conserve energy for the long journey. We also predicted that infected migratory monarchs would show higher flight metabolism than healthy migrants due to the accelerated dehydration and reduced flight performance that are known to result from infection. Wild migratory monarchs and lab-reared monarchs were used in the study. We used a tethered flight mill to induce 10 minutes of continuous flight, immediately after which we measured flight metabolism (quantified as an O2 consumption). Results indicate that migratory monarchs in reproductive diapause demonstrate a lower flight metabolism than reproductively active non-migrants. We also found no difference in

flight metabolism between infected and healthy individuals. Our findings enhance the understanding of the mechanisms underlying monarch migration and the implications of disease on this migratory species.

Comparing Immune Defenses and Pathogen Susceptibility in Closely Related Host Species

Hayley Schroeder, CURO Summer Fellow
Dr. Sonia Altizer, Odum School of Ecology

Closely related species often exhibit similar immune responses against parasites. However, exceptions occur in which closely related species can show different immune responses against shared parasites. Differences in host defenses can be influential for infectious disease dynamics in wildlife. Monarch (*Danaus plexippus*) and queen (*D. gilippus*) butterflies belong to the subfamily Danainae. Previous observations suggest that monarchs and queens could have different immune responses to shared parasites. As one example, both species are known to host a protozoan parasite that specializes on *Danaus* spp. Despite similar levels of exposure, queens are more resistant to the protozoan than monarchs in experiments and show a lower prevalence of infection in the wild. The goal of this study was to investigate if these closely related butterfly species differ in susceptibility and immune responses to a different, generalist pathogen commonly found in insects. We also tested if fitness measurements varied among species after infection. We inoculated both queens and monarchs with the generalist pathogen *Serratia marcescens*. The results indicated that queens were innately better defended, as demonstrated by higher hemocyte concentrations and greater phenoloxidase activity. There was also a trend of lower mortality in queens, but a larger sample size is required to determine if this trend is significant. Because wild monarchs must energetically invest heavily in migration in eastern North America, the possibility for a trade-off exists where monarchs might be less well defended, making them more susceptible than queens to infection by both generalist and specialist pathogens.

Nazi vs. "Soup Nazi": The Double-Talk of Holocaust Rhetoric

Rachel Schwartz, CURO Honors Scholar
Dr. David Williams, Religion, Franklin College of Arts & Sciences

Between 1933 and 1945, Jews in Europe were subjected to harsh dehumanization, which culminated in the systematic murder of more than six million Jews in what is now called the Holocaust. The persecution of European Jewry did not happen overnight. Rather, it was a slow and careful manipulation of the masses that turned humanity against itself. Seventy years later, this event still holds a central role in the world's psyche, influencing the way we use words related to it. The question posed by this project is, "How is Holocaust rhetoric used in the contemporary world?" Analysis of political speeches and popular media suggests that the Holocaust is used as a double-edged sword in the contemporary setting: with seriousness in the political arena, but with frivolity in popular culture. On one hand, the use of Holocaust rhetoric in the contemporary political arena confirms that Holocaust rhetoric remains powerful. Politicians routinely invoke the Holocaust to further their agendas, imbuing a malicious situation or individual ("He is another Hitler!") with such strong meaning that it triggers a collective memory and cannot be ignored. On the other hand, as time progresses we are becoming distanced and desensitized to the Holocaust. This has led, in turn, to flippant use of Holocaust terminology in popular culture. Thus, while once representing the epitome of evil, some terms specifically related to the Holocaust (e.g., Nazi) have become overused and

commonplace in popular culture (e.g., *Seinfeld's* "Soup Nazi").

"Brave Little Belgium": The British Home Front Response to Belgian Refugees, 1914-1918

Leah Scott, CURO Graduation Distinction
Prof. Steven Soper, History, Franklin College of Arts & Sciences

The outbreak of World War I brought with it an unprecedented rate of noncombatant displacement in Europe. Among the first populations displaced by German invasion were Belgian civilians, who fled to France and Great Britain. With a strong history of privately funded humanitarian aid, the influx of approximately 200,000 Belgian refugees was initially received with enthusiasm by British civilians isolated from the battlegrounds of the continent. But as the war stretched over years rather than months, British civilians became agitated by the continued presence of the Belgians. This paper examines the evolution of public perception of Belgian refugees in Great Britain from 1914-1918. Using the British Newspaper Archive and the text analysis program Voyant Tools, this paper tracks the words chosen in association with refugees over the course of the war in the most appropriate form of public discourse—the local newspaper. Personal diaries supplement the newspaper database to glean an accurate picture of the British home front experience with refugees. In the public eye, Belgians transformed from romanticized martyrs victimized by German brutality to burdens, troublemakers, and even criminals. This British disillusionment is due to a number of factors, including Victorian morals, employment concerns, and the failure of Belgians to live up to the highly idealized image promoted upon their arrival. The British response to the Belgian refugee influx reveals both an insight into the early 20th century British national identity and the patterns of emotion experienced by host countries the longer refugees remain.

Development of a Non-Radioactive High Throughput Assay to Detect Thyroid Hormone Uptake in Cryopreserved Hepatocytes in Suspension

Julian Selano
Dr. Jason Zastre, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Transporter proteins (transporters) play a large role in uptake and distribution of many natural and medicinal chemicals within the body. The liver specifically relies on transporters for the uptake and efflux of chemicals, as it is involved in the pharmacokinetic parameters of absorption, distribution, metabolism, and excretion (ADME). A multitude of radiolabeled transporter assays exist for the detection of chemical uptake and drug-drug interactions. However, few non-radioactive assays involving uptake transporters have been developed; and none, to our knowledge, have been developed specifically for the uptake of thyroid hormone. An assay for the detection of thyroid hormone uptake would be advantageous in identifying potential inhibitors. In this study, a high-throughput non-radiolabeled thyroid hormone uptake assay was developed using a procedure similar to the Oil Stop method commonly used with radioactive assays, however this technique employs the use of LC-MS/MS technology and cryopreserved hepatocytes. The 96 well assay exposes cells to thyroid hormone as a substrate and other chemical agents as possible inhibitors, and allows for the rapid assessment of potential inhibition. We hope to be able to employ this technique in future research to identify environmental chemicals as potential inhibitors of thyroid hormone uptake.

Use of Social Recognition Test and Open Field Test to Assess Piglet Cognition

Kathryn Sellman
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Due to similarities to children in brain formation and development, the piglet is an ideal model to assess cognitive function using behavioral tests. Two important cognitive tests utilized in this study are social recognition and open field tests, which quantitatively assess social memory and piglet behaviors including anxiety and willingness to explore. In the social recognition test, piglets are exposed to an unfamiliar pig and a novel object in a sociability test, followed by a 10 minute inter-phase interval, and then exposed to a familiar pig and a novel pig in a social recognition test. Piglets are expected to spend more time with the unfamiliar pig in the sociability trial than the novel object and are expected to spend more time with the novel pig in the social recognition trial than the familiar pig, indicating that the piglet had retained a social memory of the familiar piglet. In the open field test, piglets are placed in an open arena for 10 minutes to monitor different aspects of behavior such as ambulation, exploratory interest, and anxiety. Piglets are expected to explore fewer zones and become less ambulatory over time, demonstrating significantly decreased exploratory interest as time passes, and generally to become less anxious. This test overall should display that the piglets will become habituated to the arena. Taken together, these two tests will quantify normal piglet behavior, which can be used in the future as a basis of comparison to assess cognitive deficits associated with neural disease and injury models.

Susceptibility to Chronic Social Defeat Stress Increases Ethanol Consumption in Mice

Michelle Sequeira, CURO Research Assistant
Dr. Jesse Schank, Physiology & Pharmacology, College of Veterinary Medicine

Stressful life events are known to cause and worsen both depression and alcohol use disorders. In the human population, these stressful events are often social in nature. Because of the prevalence of these two disorders and their comorbidity, chronic social defeat stress has been used as a preclinical model in mice. The social defeat paradigm involves placing an intruder mouse into the home cage of a resident mouse and allowing the resident mouse to attack the intruder. Mice exposed to chronic social defeat stress display two phenotypes: resilient and susceptible. Susceptible mice display the depressive-like phenotype of decreased social interaction while resilient mice exhibit social interaction behavior that does not differ from controls. The goal of this experiment was to determine the effect of the social defeat paradigm on social avoidance and ethanol consumption. First, the phenotype of each mouse was determined using a social interaction task after defeat. Ethanol consumption was then measured using a two-bottle choice between water and 20% ethanol. The data indicated that susceptible mice display significantly increased avoidance behavior and ethanol consumption than both the control and resilient mice. The resilient mice display avoidance behavior and ethanol consumption that is not significantly different from controls.

Variation of Nanoparticle Surface Lipophilicity for Blood Brain Barrier Penetration

Nivita Sharma, CURO Honors Scholar, CURO Summer Fellow, CURO Research Assistant
Prof. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Several medical complications occur in the brain and cause significant damages. One such example is stroke: the third leading cause of death in the United States. Unfortunately, there is only one FDA approved drug for stroke treatment, tissue plasminogen activator. A plethora of drugs for stroke treatment is not available because the brain is protected by a layer of tightly packed endothelial cells, which forms the blood brain barrier (BBB). The BBB restricts movement of substances across the barrier and into the brain. This protects foreign and usually harmful substances from entering the brain and causing unwarranted damage. However, substances that can cross the BBB are small in size and highly lipophilic. A potential for stroke treatment that we are working towards is using aspirin to reduce inflammation in the brain after a stroke occurs. Reducing inflammation is the precursor to using stem cells to regenerate damaged neurons that can revive lost brain function. A highly lipophilic mitochondria targeted nanoparticle is ideal to deliver aspirin across the BBB. Therefore, this project focuses on optimizing the surface lipophilicity of nanoparticles by varying carbon chain lengths of the targeting ligands that are attached to the surface of the polymeric nanoparticles. The targeting ligands are comprised of a triphenylphosphonium cation attached to a carbon chain. Here, we study varying chain lengths from three to eight alkyl groups to evaluate which carbon chain length most effectively increases the surface lipophilicity of the nanoparticle; thus, optimizing the nanoparticle's ability to cross the BBB.

Parasite Infection and Host Behavioral Complexity

Caroline Shearer, Foundation Fellow, CURO Research Assistant
Dr. Vanessa Ezenwa, Odum School of Ecology

This study examines whether parasites affect the behavioral complexity of their hosts. We addressed this question by examining behavioral data collected from Grant's gazelles (*Nanger granti*) that were part of an experimental parasite removal study. Some of these gazelles were treated with an anthelmintic drug to clear gastrointestinal worms. The way that treated gazelles distributed their time among various behaviors was compared to the way that untreated control gazelles distributed their time. Behavioral complexity was measured as the time it took for an individual to switch from one behavior to another. We tested the hypothesis that treated gazelles have more complex behavior than untreated gazelles because they spend more time performing one behavior before switching to another. Preliminary analyses show that treated individuals had longer bouts of feeding before switching, when compared with their untreated counterparts. These findings reveal that parasite infection can influence subtle aspects of behavior in wildlife.

Using an Unconventional Tool: A Capuchin Monkey Becomes Skillful

Spencer Sheheane
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Skillful individuals adapt their movements in accordance with the changing constraints of the task, body, and environment. We explored how one tufted capuchin monkey developed skill in using a tool. We used a tool presenting unfamiliar properties to probe the monkey's dexterity. The task was to use a hoe to retrieve a token from a solid, smooth surface. The handle of the tool was rigid, or had one or two joints that permitted the head of the hoe to move at right angles (novel compositions). In Training, the monkey used the tool 100 times in each condition in fixed order (rigid, one joint, two joints). In a Test phase, the monkey was presented with 40 trials of each

condition (120 trials in total) in randomized order. The monkey's behavior with the tool in the first and last 20 trials of each condition in Training and the last 20 trials of each condition in the Test phase were coded using video playback. The number of all actions with the tool declined in each condition between start and end of Training, and again between the end of Training and the Test phase. Terminal performance with the jointed tools averaged 2.92 moves per trial, barely above the minimum possible (2 moves/trial). These results suggest that the monkey mastered using altered tools with a relatively small amount of practice.

The Influence of Nutrient Stress on Mass Performance Rankings among Cultivated Sunflowers

Kiara Shelby
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

As sunflower crops become of higher demand for their many uses as ornamentals, food and as a major oil-seed crop, there is also an increasing need for the development of nutrient efficient sunflower cultivars that can produced relatively high crop yields in varying nutrient conditions. Due to the nutrient availability around the world, the development of these cultivars can lead to a reduction in the economic and environmental impacts associated with fertilization. The purpose of this study is to serve as a pilot study for assessing a small subset of diverse cultivated sunflower lines in the greenhouse for resistance to nutrient stress using biomass as a measure of performance. Mass performance rankings are assigned to lines in each maturity stage, seedling and budding, across several nutrient treatments to determine whether or not line performance rankings change as plants at the seedling stage develop to the budding stage and across nutrient treatments. Rankings for both above ground shoot mass, a trait greatly associated with plant yield, and below ground root mass, a trait greatly associated with nutrient acquisition, were used to identify if line performance at the seedling stage is indicative of their performance at the adult stage for overall plant yield and nutrient stress tolerance. Analysis is currently under way, however, the traits noted in this study and in the later study to be conducted on a larger subset of the cultivated sunflower population can lead to further research towards breeding efforts in developing more nutrient efficient sunflower cultivars.

Personality Predictors of Team Work Relationships: Characteristics that Make Friends

Benjamin Shepard, Julia Willis, Alex Moore, Holly Wright, Nick Sciales
Dr. Dorothy Carter, Psychology, Franklin College of Arts & Sciences

Industrial and Organizational Psychologists have demonstrated repeatedly that individuals' stable personality traits, especially their levels of conscientiousness and emotional stability, predict *individual* job performance. However, in the 21st century, organizations are increasingly relying on flatter, team-based work structures, and individuals are required to *team-up* with other individuals to solve larger problems. Thus, there is a pressing need to better understand the degree to which the previously observed relationships between personality traits and individual job performance translate to team contexts. In our study, we investigate the degree to which the Big Five personality traits of Conscientiousness, Agreeableness, Neuroticism, Openness to Experience, and Extraversion predict the emergence of *teamwork relationships* between participants in a complex interdisciplinary multiteam task. In this task, 12 participants are randomly assigned to a role on one of four 3-member teams and are required to apply their role-specific information during a multiteam decision-making activity. Prior to participating

in the study, participants complete self-report measures of personality. Then, during the experiment, participants complete a series of self-report sociometric perceptual measures of teamwork relationships (e.g., information sharing, trust, collaboration, ease of interaction). This measurement approach identifies the networked patterns of teamwork relationships that have emerged during collaboration. In our analysis, we use a class of inferential models of network emergence and development called *exponential random graph models* that model the antecedents of relationship emergence. This analytic approach allows us to identify the personality traits that are the strongest predictors of effective teamwork interactions.

IO Variables in Gaming: When Work is Play

Benjamin Shepard
Dr. W. Keith Campbell, Psychology, Franklin College of Arts & Sciences

Over the past decade, virtual environments have become more and more prevalent in many people's day-to-day lives. Because of this increase, it has become important for us to better understand their impact on individuals and organizations. In this study, our research group will be examining variables from many different fields of psychology. Some of these variables include variables related to Industrial and Organizational (IO) psychology: personality, leadership, informal leadership, and judgement and decision making in virtual environments. The IO team in this study will be trying to develop an understanding of the individual differences in attitudes and behaviors in different types of virtual environments. We will also examine the impacts of the real world context on the virtual environment so that we may develop interventions to improve the experience and well-being of people in the work place. This section of the study will be specifically focused on finding player that are highly involved in guilds or clans in an online video game. Examining these variables in a virtual environment will help tell us what similarities and differences exist between these guilds and real world jobs. By identifying what similarities and differences are between these two environments, employers can better create their work environment to help have more committed and engaged employees.

Small Molecule Inhibition of CARM1 in Adipocytes to Control the Epigenome-Induced Risks of Obesity

Dhairya Shukla
Dr. Richard Meagher, Genetics, Franklin College of Arts & Sciences

Obesity is the condition of having excess body fat, and a Body Mass Index greater than 30. Obesity has reached epidemic proportions with 35% of adult Americans being obese. It is also the leading cause of preventable death in the USA, making it one of the top research priorities. Obesity results from the increased production and size of adipocytes in adipose tissue. This results from imbalance between food intake and energy expenditure, leading to an excessive accumulation of adipose tissue. The health risks of obesity and the difficulty individuals have losing weight is explained by epigenetic factors. One such epigenetic factor, Coactivator-Associated Arginine Methyltransferase 1 (CARM1) catalyzes modification of proteins at adipogenic genes and appears essential to the transformation of preadipocytes into mature adipocytes. The cellular memory of CARM1-catalyzes asymmetric arginine modifications in visceral and subcutaneous adipose tissue (VAT and SAT) adipocytes that may impact the ability to gain and lose weight. Dr. Meagher's laboratory recently developed innovative tools to enable adipocyte-specific epigenetic analysis of chromatin structures including fluorescence activated nuclear sorting of adipose tissue nuclei and a preadipocyte cell line that fluoresces when

cells become mature adipocytes (ADNp::RFP). In this project, I will begin by inhibiting adipocyte development of this cell line using the natural product CARM1 inhibitor Ellagic Acid and then move on to pharmaceuticals newly designed to inhibit CARM1. Our translational medicine goal is to reduce obesity and its harmful comorbidities including cardiovascular disease, some cancers, type II diabetes, inflammation, and dementia testing this next in mouse models.

Designing Chiral Metasurfaces and Understanding their Optical Properties

Joseph Skehan
Dr. Yiping Zhao, Physics & Astronomy, Franklin College of Arts & Sciences

When an array of micrometer or nanometer sized chiral patterns are arranged regularly in three dimensional space, they can show unique optical properties which do not occur naturally, and can be used to tune the polarization of light. When these chiral materials are made of noble metals, such as Ag, Au, or Pt, they are called chiral metamaterial and can exhibit enhanced chiral optical properties, which may result in a wide range of applications, such as negative refractive index material, stealth coating, improved detection devices, super resolution lenses, etc. However, production of these ordered, chiral structures usually requires expensive fabrication techniques, such as electron beam lithography. Here, we propose to combine close packed nanosphere monolayers, reactive plasma etching, and oblique angle deposition to fabricate large area chiral nanostructures. Based on a MATLAB program developed in our lab and modified by me, I have predicted the etching process and the resulting chiral patterns on the substrate. With a Labview program developed by me, I can deposit chiral patterns on the substrate by controlling the substrate rotation. The resulting chiral metamaterials are then characterized by scanning electron microscope, ellipsometry, and optical transmission measurements, and demonstrate large chiral optical activity. With the help of finite difference time domain simulations, their optical properties can be predicted. We will systematically vary both the etching and deposition conditions to generate different chiral metamaterials and to establish a good relationship between the optical properties and the chiral structures.

The Political Evolution of Malcolm X

Shaunteri Skinner, CURO Summer Fellow
Dr. Carolyn Medine, Religion, Franklin College of Arts & Sciences

The legacy of Malcolm X continues to undergo reinvention as researchers gain access to his personal life through the written work he left behind. The development in the theory in his religious and political thought is an important scholarly question, particularly in understanding the changes that he made after his split from the Nation of Islam (NOI). Elijah Muhammad, the leader of the NOI, discouraged political affiliations when Malcolm X was the national minster of his organization, leaving Malcolm restless to express his public voice. In my research, I examine the period after his break from the NOI and find that this movement gave him political independence. His religious commitments intersected with his politics as well. From African thinkers, he was inspired to adopt some of the methods they had used to attain independence from colonial powers in Europe. He developed strategies that he planned to implement during political campaigns as the founder of the Organization of Afro-American Unity (OAAU). In notes from collections of personal writings, housed at the Schomburg Center for Research in Black Culture, Malcolm X detailed these plans with the help of student researchers who accompanied him at political summits in Africa. The OAAU was modeled after the Organization of African Unity (OAU), which

called for the political and social unification of African nations. With the information that I collected as I completed research in Harlem, I ask: What new insights can be deduced about the political legacy of Malcolm X from his template for the OAAU?

Diazinon Promotes Adipogenesis in 3T3-L1 Preadipocytes

Adrianne Smith, CURO Research Assistant
Dr. Xiaozhong Yu, Environmental Health Science, College of Public Health

Diazinon, a common organophosphate, has been widely used in the agricultural setting, thus exposure in the general population is possible. Studies show diazinon has neurotoxic effects in humans and animals and possible adverse effects as an endocrine disruptor. However, its association with dysregulation of adipogenesis has been poorly investigated. Obesity is an increasing health issue. Research suggests that environmental factors play a role in the obesity epidemic in addition to diet and exercise. The current study investigated the mechanism of diazinon's effect on adipogenesis by examining adipocyte differentiation after exposure. 3T3-L1 mouse preadipocytes were used as an *in vitro* model and treated with increasing doses of diazinon (0, 1, 10 100 μM). Using Oil Red O staining for visualization, lipid droplet accumulation was found to increase in a dose-dependent manner. Multiple adipogenic specific proteins were measured via Western blotting at the three stages of adipogenesis (induction, differentiation, and maturation) in each treatment condition. Diazinon significantly induced expression of transcriptional factors CCAAT-enhancer-binding proteins α (C/EBPα) and peroxisome proliferator-activated receptor γ (PPARγ) and their downstream genes fatty acid synthase (FASN) and Acetyl-CoA Carboxylase (CoA) in a dose and time-dependent manner compared to the relative controls. The current study demonstrates that diazinon promotes lipid accumulation and activates the adipogenic signaling pathway in the *in vitro* model.

Ecosystem Decomposition Using Fluxes

Erin Smith, CURO Research Assistant
Dr. Caner Kazanci, Mathematics, Franklin College of Arts & Sciences

Ecosystems are often described as flows of biomass among species, which form ecological networks. These networks can be fairly large and complex. Decomposing an ecosystem model into smaller pieces for detailed analysis is often tempting. However, essential ecosystem behavior may be lost by breaking connections, or excluding species. Ecosystems are made up of organisms and flows of biomass, but neither can function by themselves. In this research, we propose a new building block for ecosystems, called fluxes. A flux is a smaller network within an ecosystem that can sustain itself. For example, a forest ecosystem may have hundreds of interconnected species and flows, but a flux would contain grass, rabbits, wolves, and the flow between these species. Any ecosystem can be broken apart into these fluxes and examined without losing any significant properties of the full ecosystem. Furthermore, flux decomposition can be used to identify essential organisms (keystone species) or flows, because an organism or a flow may appear in multiple fluxes. We have shown that it is possible to decompose any ecosystem model into its fluxes regardless of its size or complexity. We are currently developing the algorithms necessary to automate the process so that any ecosystem can be decomposed without requiring any manual work. Our research is ongoing.

Population Dynamics and the Ecology of the Common Bottlenose Dolphin of the Central Georgia Coast

Caroline Spohn, CURO Honors Scholar
Dr. John Schacke, Odum School of Ecology

The barrier islands and estuarine system of the central Georgia coast provide a unique environment for the study of dolphin population dynamics, ecology, and behavior as one of the few areas along the eastern coast that remains largely undeveloped. Bordered to the north by Savannah and to the south by Brunswick, this area is relatively untouched by human populations and commercial industry. The study of this population of dolphins over time will provide a baseline against which to compare the results of future coastal developments on terrestrial and aquatic environments. The results of my research will be valuable to environmental protection and conservation organizations, fishery departments, coastal development activities, and state and federal agencies in efforts to preserve and protect the region. The goal of this project is to identify and measure seasonal, annual, and other periodic fluctuations in the abundance and distribution of dolphin populations along the central Georgia coast. Data will be documented photographically to identify individual dolphins and catalog them. Through this process, we are able to observe the associations between the physical environment and dolphin population and ecology, which will provide us with insight into the positive and negative effects of coastal development on habitat health. In order to complete this analysis, boat-based surveys of the region are completed in order to collect photographic and demographic data. These surveys identify individual dolphins, their distribution over time, and behavior in specific geographic areas. Identification of individual dolphins is possible because scars on dorsal fins can be as unique as human fingerprints.

Acceleration of Human Transportation and Its Impacts on Energy Consumption
Lindsey Spreen, CURO Research Assistant
Dr. John Schramski, College of Engineering

Throughout history, the transportation sector, which is one of the fundamental areas of energy consumption, has been periodically revolutionized by technological development. The adoption of each successive technology—such as roads, carriages, cars, and planes—has been akin to shifting into a higher gear, where the new technology is leveraged to allow for faster, and therefore more expansive, travel. Increased travel requires increases in energy consumption. In this project, we mechanistically model the historical kinetic energy discharge of ever increasing and faster moving human populations. By comparing the resulting values to the published energy consumed by the transportation sector, we derive an energetic efficiency of the transportation sector over historical time. Understanding this trend with additional supporting data meaningfully quantifies and conveys the enormous impact of increasing human kinetic energy on the energetic balance of the planet. This information can be leveraged to engineer sustainable solutions grounded in a mass and energy balance perspective.

Recycled Tire Chips for Use in Concrete Barrier Walls and Other Applications
Katelyn Stallings
Dr. Stephan Durham, College of Engineering

In 2013, the Georgia Department of Transportation (GDOT) constructed more than 42,000 linear feet of concrete barrier utilizing a Class A concrete mixture design (3000 psi). There may be potential for the beneficial utilization of recycled tire chips in concrete barrier applications which may lead to improved safety for vehicle occupants as well as reduce disposed rubber from going to landfills or stockpiles, and potentially saving materials cost for GDOT. Additionally, there may be other applications requiring less compressive strength, Class B – 2200 psi, where rubberized concrete could be advantageous. However, GDOT has not

studied recycled rubber tires for concrete barriers or other concrete related applications despite the potential for safety, environmental, and economic benefits. Concrete safety barriers are one of the widely used impact attenuators that are intended to either decelerate vehicles to a safe stop or redirect them away from a fixed object. Concrete exhibits little plastic deformation when impacted by a vehicle and thus an undesirable trait for safety barriers. This study includes a thorough review of literature pertaining to the inclusion of rubber products in concrete mixtures for transportation related applications and the design, batching, and testing of rubberized concrete mixtures for potential use in barrier walls, curb and gutter, and other non-high strength concrete applications for GDOT. Specifically, coarse aggregate (i.e. rock) will be replaced with incremental proportions of tire chips. The primary goal will be to establish a benchmark concrete mixture for which tire chip inclusion is possible without significant detrimental effects on the structural performance of the concrete. Rubberized concrete mixtures will be tested for compressive strength at 1, 7, and 28 days of age to measure their mechanical performance as tire chip content increases. Ultimately, this research will better inform additional phases of a larger-scale study.

An Environmental Engineering Challenge: Improving the Energy Balance of Global Food Production

Garrett Steck, CURO Research Assistant
Dr. John Schramski, College of Engineering

Global energy consumption continues to exponentially rise as an increasing world population, currently at 7.4 billion, requires more resources to survive. However, despite rising global per capita energy consumption, significant food availability disparities exist between countries. Decisive amounts of energy are used for transportation, urbanization, and industrial development, while food energy (edible calories) for the global population, arguably the most important energy for civilization, is not being evenly distributed. Today, approximately 2 billion people lack one or more nutrients for survival. Organizing available data for 173 countries, we compare food energy surplus or deficit to per capita energy consumption between 1980 and 2005. The results show on average that energy consumption per capita and food energy production per capita are not correlated. This indicates that excess nonrenewable energy usage is not being implemented with intentions to feed a continuously growing population. To aid policy makers, areas of improvement in excess energy consumption above the metabolic needs of the population loads are identified.

Using Mutants to Understand Mechanisms of DNA Methylation in *Brachypodium distachyon*

Madeline Steffensen, CURO Research Assistant
Dr. Robert Schmitz, Genetics, Franklin College of Arts & Sciences

The mechanisms of DNA methylation in plants have been extensively studied in the non-grass species *Arabidopsis thaliana*. While differences in the patterns of methylation have been observed in grass species, the mechanisms for these differences remain poorly understood. *Brachypodium distachyon* is an emerging model for grass species. Genes known to regulate DNA methylation are studied using the WRRC *Brachypodium* T-DNA mutant collection. Tissues from plants with suspected mutant genes are harvested. PCR and gel electrophoresis are then used to genotype the plant and determine its zygosity. This process is used to identify plants that are homozygous for the mutation of interest. Homozygous mutants are then further studied to determine the effect mutations have on DNA methylation. It is expected that genotyping will identify plants that are both

homozygous and heterozygous for mutations. Heterozygous individuals will be carried to the second generation in order to obtain homozygous offspring. Further studies of these mutants are expected to show that the mutants have altered methylation levels compared to non-mutated wild-type plants. The research will provide important information about the mechanisms of DNA methylation in grass species. In this way, we can begin to understand differences that may be present between DNA methylation in grasses and non-grass species of plants.

In Search of Optimal Designs Using Differential Evolution Algorithm

Zack Stokes
Dr. Abhyuday Mandal, Statistics, Franklin College of Arts & Sciences

In statistical practice, no matter how excellent data analysis methods are, meaningful conclusions cannot be drawn from data that were not collected carefully. To prevent this issue, designed experiments can be used to target specific research questions and avoid frivolously using resources. Experiments like these can often be very expensive for the researcher due to either a high number of runs or a high per-run cost. This cost restriction is an example of one constraint that may be in place when attempting to generate a worthwhile design. To address this issue, there are different approaches for creating optimal designs. For simpler cases, optimal designs can be obtained theoretically, using formulae and theorems; however, as technology continues to advance, the processes that are being experimented on are growing more and more complex. In these situations it is not always possible to construct an optimal design analytically. This research deals with developing new, numerical techniques for approaching these problems. The Genetic Algorithm (GA) is a popular tool that already exists for identifying these designs; however, our preliminary study has shown that another technique, Differential Evolution (DE), can outperform this algorithm. DE is a search algorithm that has applications in an array of disciplines, but its usefulness in generating designs has never been explored. The goal of this study is to understand how DE compares with other algorithms like GA and then attempt to analyze designs for which optimal solutions have not yet been found.

Detritus Preferences in a Mangrove-Saltmarsh Ecotone

Jessica Story, CURO Summer Fellow
Dr. Jeb Byers, Odum School of Ecology

Climate change is driving range expansions of species worldwide, and warming temperatures are causing global shifts in species distributions to higher latitudes and elevations. In Florida, mangrove forests are advancing their northern limit in response to declines in the frequency of annual freezes. As the mangrove forests extend their northern boundary, they are moving into salt marsh habitats. As a consequence, the organisms in invaded marshes that utilize detritus as a resource may change or shift their food preferences to adapt to the new change in dominant vegetation. To test this, litterbags filled with mangrove and saltmarsh detritus were placed in 20 blocks (10 within mangrove habitat and 10 within saltmarsh habitat) along the mangrove-saltmarsh ecotone. Litterbags were analyzed individually to quantify species composition and abundance. After one month, the results showed more organisms overall in the mangrove plots over the saltmarsh plots. Within the mangrove plots, there were more organisms utilizing saltmarsh detritus than mangrove detritus. Thus, the mangrove detritus is a less than substitutable resource for salt-marsh resident species. However, this may change over time as marsh species adapt or as mangrove associated species also migrate northward.

Abstracts

Beneficial Use of Metakaolin for Georgia Concrete Pavements
Matthew Sullivan
Dr. Stephan Durham, College of Engineering

This study analyzes the use of metakaolin as a supplementary cementitious material (SCM) in concrete mixtures; particularly with the intent of adoption into current Georgia Department of Transportation (GDOT) Standard Specifications. Despite Georgia having significant kaolin deposits, GDOT does not currently allow its use for concrete pavements or other structures. During the last several decades the use of SCMs in Georgia concrete has increased and led to improved performance and lower cost. Fly ash and blast furnace slag have been the primary SCMs used for concrete pavements. Recently, the availability of these SCMs has become limited and resulted in the need to investigate alternative materials. Current research evaluating the use of metakaolin as a SCM is widespread with numerous state DOTs having already adopted specifications for its use. This research is timely in that it will be used to investigate the mechanical performance of concrete mixtures using metakaolin. Ultimately, the study results will allow for the modification of the GDOT Standard Specifications to allow its use. Metakaolin will be introduced as a partial replacement of cement for GDOT Class 1 and 2 concrete pavements. The performance will be examined using ASTM standardized tests for fresh and hardened concrete properties. The successful completion of this research will provide an economical and widely available alternative to the current SCMs being used in the state of Georgia.

Issue Framing and Beliefs about the Importance of Climate Change Policy
Meili Swanson, CURO Research Assistant
Dr. Shane Singh, International Affairs, School of Public & International Affairs

We use an experiment to examine whether the way in which climate change is framed affects individuals' beliefs about its importance as a policy issue. We employ frames that emphasize national security, human rights, and environmental importance about the consequences of climate change. Contrary to our expectations, we find no evidence that issue frames, on average, affect opinions about the importance of climate change policy. We do find some evidence that the effect of issue frames varies across ideological and partisan groups. We conclude by discussing our findings relative to extant literature and considering the implications of our findings for those who seek to address the issue of climate change.

The Effects of Iron Deficiency Anemia on Mitochondrial Capacity
Joanna Szymonik, CURO Research Assistant
Kelly-Ann Peters
Dr. Kevin McCully, Kinesiology, College of Education

Iron is an essential mineral needed by the body. In addition to carrying oxygen from the lungs to the rest of the body, iron is also an important component of enzymes that help to speed up biochemical reactions. Having an inadequate amount of iron in the body is a condition called iron deficiency. According to the World Health Organization, ~30% of the world's population is anemic. This makes it the most common nutritional deficiency in the world. With muscle weakness and fatigue being a major symptom of this condition, it can be hypothesized that a deficiency in iron may impact skeletal muscle performance. Specifically, it can be predicted that a deficiency can impair mitochondrial function in skeletal muscle. The purpose of this study was to compare the mitochondrial capacity of those with iron deficiency to controls. Participants were divided into two groups: an anemic group (n=4) and a control group (n=14). Blood samples were taken in order to

diagnosis anemia severity. Hemoglobin levels were (11.4 + 0.9 g/dL) and (14.3 + 1.3 g/dL), while the hematocrit levels were (36.0 + 4.7 %) and (40.6 + 3.3 %) for the anemic and control groups, respectively. However, there was no significant difference ($p = 0.940$) between the rate constant of the anemic (1.81/min) and control (1.82/min) groups. This study suggests that iron deficiency did not affect the capacity of mitochondria in skeletal muscle. These results suggest that symptoms of fatigue are unrelated to the impairment of iron usage in energy production.

Administration of Varying Carbon and Nitrogen Sources into a Defined Growth Media for Polysaccharide Secretion in *Bacillus cereus*

Syed Tahmid, CURO Research Assistant
Dr. Maor Bar-Peled, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The endospore forming *Bacillus cereus* species was recently shown to produce an exocellular polysaccharide (EPS) during later stages of sporulation. The biofilm is composed of an extracellular polysaccharide named X-polymer. While the structure of this X-polysaccharide was recently elucidated in our laboratory, less was known about the mechanism that regulates its formation. Here, we first showed that when *Bacillus* is growing in rich bacterial medium, a medium that support vegetative growth, both the EPS or the spores do not form. To further examine specific nutrient(s) that support glycan formation, we used a different medium. For these studies we used a defined medium containing different sources of carbon, nitrogen, or a combination of the two factors. Following bacterial growth, the polysaccharide was isolated and its composition was determined after hydrolysis by gas chromatography mass spectrometry (GC-MS). The relative amount of the polysaccharide as well as other glycans were recorded. In the presentation I will describe in details our findings.

Influences of Predators on Parasite Prevalence in *Crassostrea virginica*

Meghan Tait, CURO Research Assistant
Dr. Jeb Byers, Odum School of Ecology

Host-parasite relationships do not occur in isolation. It is increasingly recognized that other species, like predators, may both directly and indirectly influence the dynamics between hosts and parasites. If predators preferentially feed on infected or uninfected hosts, they may influence parasite prevalence in the remaining host population. Furthermore, when predators feed on infected hosts, they may release parasites from the prey facilitating their spread to new hosts. In this study we investigated if the blue crab, *Callinectes sapius*, preferentially selects prey (the eastern oysters, *Crassostrea virginica*), infected by one of its most prevalent parasites, *Perkinsus marinus*. Using a series of choice trials in laboratory mesocosms, we presented blue crabs with two oysters. Once the crab had committed to consuming one oyster, we removed both oysters from the mesocosm and assessed their *P. marinus* infection status. Using all trials that included a choice between one infected and one uninfected prey, we analyzed the preference of each predator. Blue crabs did not exhibit preferential feeding as a function of *P. marinus* infection status. Our data thus suggests that crab predators will not alter prevalence patterns of oyster populations through differential predation. This gives us a better understanding of the relationship between the biotic environment and host-parasite interactions.

Code Switching in Tunisian Arabic

Ayman Tartir
Dr. Timothy Gupton, Romance Languages, Franklin College of Arts & Sciences

Few modern languages can claim a sociolinguistic history as complex as that of Tunisian Arabic. Beginning with the ancient Berber languages of the Sahara, the Tunisian linguistic landscape was shaped over thousands of years by conquest and trade with nearly a dozen languages and peoples—most notably the Arabs and the French. Today, the language spoken in Tunisia is a precisely executed mélange with Arabic and French intermingling seamlessly in almost all levels of daily interaction. Code switching (CS), typically defined as the mixing by multilinguals of two or more languages in discourse on any level (Poplack 2001), has only recently become a topic of careful research. In the past, CS was thought to be a random and deviant linguistic phenomenon which lacked grammatical constraint. However, linguists have made great strides in quantifying and qualifying CS which in many cultures is fundamental to the way people communicate. From this research have emerged such theories as Poplack's 1978/81 Equivalence Constraint, which dictates that there are predictable "switching points" at which one is free to change languages. Using a corpus of linguistic data gathered from Tunisian television broadcasts, this study examines some of the most commonly switched elements, what social factors may affect them, and how they confirm the Equivalence Constraint.

UGA Campus Sustainability Initiatives: Awareness and Attitudes to Campus Recycling

Emily Taylor, CURO Research Assistant
Dr. Juan Meng, Grady College of Journalism & Mass Communication

Purpose: The purpose of this research is to identify student's awareness and attitudes to on-campus sustainability initiatives. The University of Georgia Office of Sustainability is involved in many different sustainability projects, but this paper chose to focus on one of the biggest: recycling. The research aims at discovering student's thoughts on the recycling programs on campus. *Design/methodology/approach*: The researcher used two research methods in this study to investigate the subject: (1) an online survey of UGA undergraduate and graduate students; (2) in-depth interviews with five UGA undergraduate students. *Findings*: Results suggest that students at the University of Georgia are very aware of recycling programs on campus, such as the recycling trash cans located in almost every classroom and building, and understand recycling on campus is important. Students felt less inclined to recycle at home where it is less convenient and also felt that recycling on game day is difficult. *Practical implications*: The Office of Sustainability needs to focus some of their efforts on making recycling more convenient on game days. They also should spread awareness about the importance of recycling at home and how easy it can be. *Originality/value*: The study provides insights into the awareness and attitudes of on campus sustainability programs, such as recycling. Making sustainable choices is important for the health of our planet and students need to know that they can make a difference with their efforts.

Effects of Campaign Finance on Legislator Polarization

Andrew Teal
Dr. Anthony Madonna, Political Science, School of Public & International Affairs

Gallup polls have indicated growing disapproval of Congress in recent years. Distrust with the legislative system stems from issues of gridlock and the public's perception of an ideologically polarized Congress. Polarization is problematic for both the legislative process and the American public, as it causes gridlock in policy making and rifts in societal interactions through increasing political disagreement. Therefore, it

is important to ask: what is causing Congress to polarize? Existing research shows that polarization is present and has been increasing since the 1970's. The two primary accepted causes of polarization are member replacement and member adaption. However, more specific explanations exist for increasing polarization. This research builds upon existing studies on the effects of campaign finance funding control. It is debated whether independent campaign donors or control of campaign funding by political party establishments might reduce Congressional polarization. Using state legislature data, different campaign finance laws can be simultaneously compared across state lines to analyze the effects of control over funding on polarization levels. Through data analysis, it should be evident that greater proportions of contributions by political parties correspond to less polarization in legislatures.

Biological Function of an AAK1-Like Protein Kinase in *Trypanosoma brucei*

Bryanna Thomas, CURO Graduation Distinction, CURO Research Assistant
Prof. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts & Sciences

Human African trypanosomiasis (HAT) is a potentially deadly disease endemic to parts of rural Sub-Saharan Africa. The causative agent, *Trypanosoma brucei,* is a protozoan parasite that proliferates in the blood, lymph, and eventually the central nervous system of humans and cattle. New potential HAT drugs may be repurposed from therapies for other illnesses, such as the compound AEE788, which was initially developed for the treatment of glioblastoma. AEE788 is a lead compound for trypanosomiasis drug discovery. An important step in mechanism of action studies is identification of pathways affected by a drug. In humans, AEE788 inhibits activity of the receptor tyrosine kinases EGFR and VEGFR. In trypanosomes, AEE788 is associated with several protein kinases, including casein kinase 1.2. On the basis of these facts, we checked for the effect of AEE788 on the phosphoproteome of *T. brucei*. AEE788 treatment altered the phosphorylation state of protein Tb427tmp.160.4770 (TbAAK1), among others. This protein shares some homology with the human protein kinase AAK1, which is involved in clathrin-mediated endocytosis through interactions with adaptor protein 2 (AP2). In this study, we present results of the effect of a TbAAK1 knockdown on endocytosis pathways in the trypanosome.

Reactive Microglia as a Biomarker in a Piglet Model of Traumatic Brain Injury

Meagan Thomason, CURO Research Assistant
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Traumatic brain injury (TBI) is a major cause of hospitalization and death in the United States, and patients with TBI often struggle with physical and cognitive impairments for months to years. The development of treatments for TBI have been performed on predominantly rodent models, but because the brain composition of mice is very different compared to humans, the research often fails to translate to human medicine. However, pig brains are more similar to human brains, which make them an appealing alternative for treatment development. The objective of this study is to assess changes in brain cellular composition in a piglet model of TBI. Piglets underwent surgery to receive a controlled cortical impact (CCI). Piglets were sacrificed one day, one week, and four weeks post-TBI and brain samples are collected for analysis. Microglia, which secrete inflammatory cytokines in response to injury, were quantified by immunohistochemistry utilizing Iba1 antibody. We expect that microglial activation will occur as early as one day post-TBI and will peak one week post-TBI. After

four weeks, we expect less activated microglia presence as they begin to return to a resting state. These research findings will be used to determine a normal pattern of TBI pathophysiology to serve as a platform for the development of effective treatments for TBI.

The Doctrinal Development of Sea-Launched Nuclear Capabilities

Bert Thompson, Foundation Fellow, CURO Research Assistant
Dr. Sara Kutchesfahani, International Affairs, School of Public & International Affairs

India, China, and Pakistan have transformed the face of South Asia over the last several decades. The rise of economic power in the region, coupled with the growth of conventional military might, has generated fierce strategic competitions between India and China, as well as between India and Pakistan. However, the development of nuclear arsenals in India, Pakistan, and China may be of the greatest concern to the international community. In this paper, the author examines the development of sea-launched nuclear capabilities, commonly in the form of ballistic missile submarines, among the Asian powers. He further observes the role of these developments on the nuclear doctrine of each individual state. He finds that India, Pakistan, and China have all faced similar problems in developing their sea-launched nuclear platforms, including challenges to their command-and-control practices and methods of storing and deploying nuclear-armed delivery vehicles. The policy implications of nuclear developments in and around South Asia – namely, the prospect of nuclear war – require attention from the international community.

Has *Laïcité* Transformed into a Law of Islamophobia?

Chelsea Thorpe, CURO Research Assistant
Prof. Lihi Ben Shitrit, International Affairs, School of Public & International Affairs

On November 13, 2015, terrorists unleashed a series of attacks on Paris, killing and injuring more than 125 civilians. As with the Charlie Hebdo attacks earlier that year, the shooters were of Muslim background. The aftermaths of these attacks again brought attention to France's 1905 *laïcité* law. As stipulated by *laïcité*, displays of any religious symbol, including, among other things, prayer, headscarves, and niqabs are severely restricted in the public sphere. Many French politicians use the 1905 law as a pretext for aggressive integrationist policies toward religious minorities. Yet, as a result, some argue, French society has further segregated and *laïcité* has become a form of religious suppression that inequitably targets certain religions and not others. This research highlights questions of religious freedom in relation to the integration of Muslim immigrant communities in France as they are being tested today in social and legal discourse. With a focus on Catholicism, a historical analysis of French majority and minority frameworks provides a thorough understanding of the legislation that led up to *laïcité*. Instead of integrating French society, recent "modifications" to *laïcité*, specifically the bans on the headscarf and the veil, have caused reverse integration by promoting strong Catholic morals as well as secular republican nationalism that excludes pious Muslim members of society. Varieties of Islam and French republican secularism clash as Muslim individuals struggle to form self-identities while simultaneously integrating into society. This study draws on qualitative analyses of local and national French newspaper articles in addition to recent academic literature.

Financial Knowledge amongst College Freshmen

Danei Ting
Dr. Brenda Cude, Financial Planning, Housing & Consumer Economics, College of Family & Consumer Sciences

Financial literacy is the capability to interpret how money works in society and how it is managed. For my research, I want to learn how financial courses are related to the financial knowledge and behavior of college freshmen. For my research, I was able to analyze college freshmen data collected through an online survey. I utilized Excel to filter out the data so I could segment my target group of freshmen students who attended high school in the state of Georgia. This group consisted of 288 students. My focus was questions related to financial literacy. The first question I examined was, "How would you describe how much you learned in course(s) about personal finance/money management in high school?" Ninety-nine of the 288 students responded that after taking the course they knew much more about money management, while 88 were neutral. Looking deeper into the survey I discovered the top two topics covered in high school personal finance courses were financial planning and investment strategies, each with over 100 students. Another question asked whether taking financial-related courses in high school helped the students improve their financial management behaviors. Only 4 students responded that taking a course did not help while the rest answered that taking these courses not only improved their knowledge, but their financial behavior as well. By analyzing these results, I discovered that the surveyed students believed that taking a financial course in high school definitely improved their knowledge and their financial behaviors.

Determining Gene Products Interacting with RtcB of the rsr-rtcBA RNA Repair Operon via a Synthetic Lethal Screen

Isabella Tondi Resta, CURO Research Assistant
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

Infections caused by *Salmonella* are among the most common food-borne diseases in the United States, causing thousands of hospitalizations yearly. Due to the increasing resistance to most effective antimicrobials, new targets in *Salmonella* for antimicrobial development must be identified. Our laboratory has identified a potential target as a novel RNA repair complex that is hypothesized to comprise three proteins, Rsr, RtcA, and RtcB, and two Y RNAs. The complex is encoded in a single operon whose expression is controlled by the transcriptional activator, RtcR. Expression of the RNA repair operon is induced by treatment with the antimicrobial mitomycin C (MMC) and cell viability increases in the presence of MMC. In order to further characterize the function of the RNA repair genes, a genetic screen for synthetic lethal mutants on MMC was developed to identify other genes whose products interact or cooperate with the RNA repair complex. In this work, a *Salmonella* strain that was deleted for the RtcB gene, an RNA ligase, and contained an unstable plasmid encoding *rtcB* was used for transposon mutagenesis to identify other gene products that specifically interact with RtcB. Synthetic lethal mutants could only survive in the presence of MMC if they maintained the unstable plasmid expressing *rtcB*. The transposon insertion site was determined for all apparent synthetic lethal mutants, thereby identifying genes whose disruption causes a synthetic lethal phenotype in the absence of *rtcB*. The potential function of these genes in the proposed RNA repair system of *Salmonella* will be addressed.

Investigating the Phenotypic and Genetic Mechanisms of Root Architecture Traits in Cultivated Sunflower Seedlings under Drought Stress

Nicole de Leon Torralba, CURO Research Assistant
Dr. John Burke, Plant Biology, Franklin College of Arts & Sciences

Approximately 70% of worldwide water is allocated for use in agriculture in the form of irrigation, thus loss of water is the greatest threat to crop productivity. With impending changes to the climate, droughts are predicted to increase in severity, intensity, and duration further limiting water availability for crop production. As such, the focus of this study centers on root architecture and a crop's ability to resist low water availability. First, we determined the natural phenotypic diversity in root architecture traits using cultivated sunflower *(Helianthus annuus L.)* as a model system. Cultivated sunflower seedlings from an association mapping population containing 272 lines were subjected to a well watered control and polyethylene glycol (PEG-6000) stress induced treatment. Root systems were dissected at 2 cm and analyzed using the imaging program, WinRHIZO v2, to determine various architecture traits in both the top and bottom portion. Results indicate significant root allocation differences between top and bottom, control and stressed, and the interaction indicative of a drought avoidance response. Second, we performed a genome wide association study (GWAS) to investigate the underlying genetic mechanisms of these root traits. GWAS analyses are still ongoing; however they should yield candidate genes and regions associated with these traits. This work will inform downstream molecular breeding approaches aimed at producing cultivated lines able to survive under low water availability.

Recycle or Landfill? Assessing the Efficacy of a Green-Themed Intervention

Lawrence Towe, CURO Research Assistant
Dr. James Coverdill, Sociology, Franklin College of Arts & Sciences

Problem Statement: Recycling programs have increasingly paired bins labeled "landfill" and "mixed recycling" to encourage and facilitate recycling. This study explored the accuracy of recycle-or-landfill placement behavior and a mechanism for behavior change.
Methods: Data came from a series of "waste audits" conducted in freshman dorms at the University of Georgia during the 2015 Fall Semester. A first audit was conducted the week before an energy- and water-conservation competition (the "Green Cup Challenge"). Three "intervention" dorms targeted by the Challenge were included along with a comparable "control" dorm that was not. Additional waste audits were conducted after the Challenge concluded and repeated a month later. In each dorm, waste-audit materials were collected from two floors and catalogued, producing 24 total audits and 2,362 individual items. *Findings*: Overall, 80% of items in landfill bins and 59% of items in recycling bins were correctly placed. The two most common misplaced items were plastic film and plastic food wrappers (56% of each were misplaced as recyclable); the two most common correctly placed items were cardboard and plastic bottles (88% of each were correctly placed in recycle bins). Dorms targeted by the Challenge showed no increase in placement accuracy, a pattern also found at the control dorm. *Significance*: Incorrect placement of items contaminates mixed recycling streams, creating an added cost to processing facilities, thereby decreasing the overall value of recyclables. The intervention studied here failed to increase placement accuracy. A follow-up study is underway in an effort to identify an effective behavioral intervention.

Impact of Video Captions in Mobile News

Kendall Trammell
Dr. Bartosz Wojdynski, Grady College of Journalism & Mass Communication

Mobile devices are one of the leading ways in which media audiences are consuming news. The present study sought to examine the impact of the presence of video and video captions in mobile news on attention to the news content, recall of news content, and

attitudes toward the news content. In a single-variable, 3-level between-subjects design (text and image story, video without caption, video with captions), participants (*N*= 83) viewed an online news story on a smartphone while having their eye movements and fixations recorded by an eyetracker and scene camera. Participants were randomly assigned to one version of the news story. The stories and video contained information about the importance of primary debates during presidential elections. After viewing the story, participants completed a questionnaire containing dependent measures, including knowledge, attitudes, fluency and perceived credibility. Preliminary results show differences between story conditions on story recall and attitudes toward the story. Participants who viewed the video versions of the story received higher knowledge scores than participants who viewed the text story; there are no differences when it comes to fluency (ease of use) or perceived credibility. Visual attention results are still being analyzed from the eye-tracking data. These findings are important because there is little research on mobile news consumption. This data is useful to the journalism industry because it enables digital producers at media organizations to make more informed, effective decisions when presenting news stories to the public on mobile platforms, and, thus increasing its audience engagement.

Blackout, the New Binge: A Case Study on Underage Drinking Patterns at the University of Georgia

Madison Turner, CURO Research Assistant
Dr. Susan Haire, Political Science, School of Public & International Affairs

From 2012-2015, the University of Georgia has made a consistent appearance on Princeton Review's annual list of Best Party Schools due to the collegiate underage drinking culture in Athens, Georgia. This paper explores the current underage drinking patterns at the University of Georgia by analyzing all publicly documented cases of underage drinking from the University of Georgia Police Department during the 2012-2015 timeframe. The research yields startling results. Data show that the eighteen-year-old and nineteen-year-old age categories require both UGAPD intervention and EMS treatment far more often than the 20-year-old age category. Across all age categories, the percentage of cases requiring EMS treatment has been increasing rapidly since Spring 2013. To test for a relationship, a linear regression was performed on the dataset with case number (time order) serving as the independent variable and blood alcohol concentration (BAC) levels as the dependent variable. The ANOVA table significance column value of .002 shows that BAC levels are, in fact, increasing over time. Underage students in 2015 are drinking to dangerously high levels of intoxication, surpassing the BAC levels known to originate from "binge" drinking, and instead, reaching levels that correlate with extreme intoxication, known by collegiates as "blackout" drunk. Therefore, there is evidence to show that when it comes to underage drinking patterns at the University of Georgia, "blackout" is the new "binge."

Testing for a Correlation between History of Shoulder Injury and Functional Movement Screen Score

James Tyson
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Studies have suggested that poor performance on a functional movement test contributes a 4.7 times greater increased risk of injury in athletes. However, it is unclear how a previous injury may affect functional movement test scores. Our objective was to determine if there is a significant relationship between history of shoulder injury and

Functional Movement Screen (FMS) score for shoulder mobility. Our participants were collegiate club rugby players **(**n=25; 13 female, 12 male; age=20.6±1.2years, height=172.2±9.0cm, weight=80.6±16.8kg). The athletes underwent a full FMS screening by a trained rater prior to a fall rugby season. Previous shoulder injury was defined as any self-reported or medically diagnosed injury or discomfort of the shoulder that affected sport participation. A point-biserial correlation test was used to determine the relationship between the presence of previous shoulder injury and FMS shoulder mobility score. No significant correlation between presence of previous shoulder injury and FMS score for both right (rpb=0.35, rpb2=0.12, p=0.08) and left (rpb= 0.03, rpb2= 0.001, p=0.90) shoulder mobility was found. There was no significant correlation between a previous shoulder injury and FMS shoulder mobility. Previous shoulder injury does not appear to be related to current FMS shoulder mobility score. Clinicians should be able to apply the shoulder mobility FMS test to athletes to interpret injury risk, regardless of previous injury.

The Use of Entertainment Education to Teach Nutrition Messages to Preschool Children: A Feasibility Study

Emily Tyus
Dr. Caree Cotwright, Foods & Nutrition, College of Family & Consumer Sciences

Twenty percent of US children are overweight or obese before they enter kindergarten. To address this problem, health intervention must begin in early childhood. An ideal location to deliver nutrition education is in childcare centers because of the amount of time spent in that environment. One way to promote healthy behavior to young children is to encourage higher intakes of fruit and vegetables. The purpose of this study was to examine the feasibility of using an entertainment education nutrition intervention (i.e. interactive performance lessons) to teach nutrition messages to young children. Researchers conducted a feasibility study at a childcare center in Athens, Georgia for children ages 3 to 5 (Teachers n=8 and Children n=37). The Freggie's Green Machine intervention included theater-based nutrition lessons and tastings for three fruits (blueberries, pears, and kiwi) and three vegetables (carrots, sweet potatoes, and broccoli). The program was conducted for 6 weeks with one new fruit or vegetable being introduced each week. Freggie (fruits + veggies), a fun character, promoted healthy choices with his Green Machine (fruit and veggie cart) by performing skits. Freggie's Friends, life-sized fruit and vegetable characters, accompanied Freggie to teach during performances. Changes in preschool children's willingness to try fruits and vegetables and preferences were measured. Results showed improvements in preschool children's willingness to try fruit and vegetables. Teachers and parents reported high program satisfaction and that children related to the Freggie characters. Findings indicate that entertainment education is a feasible and promising way to teach nutrition messages to preschool children.

Feeding the Urban Stream: How Nutrients and Microbes Impact Stream Carbon Reserves

Rachel Usher, CURO Summer Fellow
Dr. Amy Rosemond, Odum School of Ecology

Healthy streams and the ecosystem services they provide depend on energy to fuel the food web. Carbon (leaves and wood) from terrestrial landscapes is a vital source of energy for headwater streams where sunlight is limited. This carbon, along with colonizing microorganisms including bacteria and fungi, support stream life. Respiration (CO_2 loss) from microorganisms and associated mass loss rates of carbon deplete the amount of

carbon available for consumers. Streamwater nutrients and contaminants, which can both be elevated in urban streams, can stimulate or suppress microbial activity, respectively. We tested for these effects measuring respiration and breakdown rates on standardized carbon substrates in 9 streams in Athens-Clarke County, GA that differed in urban-derived inputs. Surface water nutrients, dissolved nitrogen (DIN), phosphorus (SRP), and conductivity (a surrogate for contaminant inputs) were measured and correlated to microbial respiration and breakdown rates. Streams with higher concentrations of phosphorus exhibited higher respiration and breakdown rates on carbon substrates, resulting in roughly doubling these rates across the 9 streams; no effects were due to either conductivity or DIN. These results suggest that phosphorus concentrations, which are typically elevated in urban streams, may impact the retention and transport of energy sources in streams.

The Role of Intraflagellar Transport in Ciliary Gliding

Rachel Vaizer
Dr. Mark Farmer, Biological Sciences, Franklin College of Arts & Sciences

The ability of cells to move through their environment is one of the most ancient attributes of living cells. One way in which cells can move is known as ciliary gliding, and it is thought to be both ancient and conserved, even among human cells. Developing an understanding of the mechanism of ciliary gliding in Euglenid flagellates may help us understand this mechanism in other cells. This study is designed to examine the role intraflagellar transport (IFT) plays in ciliary gliding, specifically the location of the IFT particles. The IFT protein complex plays an important role in transporting materials needed for the maintenance or assembly of flagella. As the IFT particle travels to the tip of the flagellum along the axoneme, it carries these materials. As the IFT particle travels back to the cell body, it brings materials that have already been used by the flagella and are being recycled back to the cell. To determine if the position of IFT, relative to the axoneme and the substrate affects ciliary gliding, transmission electron microscopy (TEM) was used to visualize the locations of IFT particles in the cilium. Visualization of the IFT complex can help to determine the role IFT may play in ciliary gliding.

Localization of Casein Kinase 1.2 in *Trypanosoma brucei*

Haley Vale
Prof. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts & Sciences

Trypanosoma brucei is a protozoan parasite responsible for human African trypanosomiasis (HAT). Drugs currently used to treat HAT are highly toxic and difficult to administer; new drugs must be developed. Casein kinase 1.2 (CK1.2) in *T. brucei* plays a vital role in cell division, particularly replication of the basal body (a microtubule-organizing center for flagella), and as such is an attractive candidate for lead drug discovery. In order to investigate possible mechanisms of regulation and gain a better understanding of how TbCK1.2 regulates basal body duplication, enzyme localization studies were performed using both genetic tagging methods and cell-penetrating peptides containing a fragment of TbCK1.2. Genetic tagging was performed endogenously through transfection of a construct containing the TbCK1.2 coding sequence as well as the coding sequence for an epitope tag. Cell-penetrating peptide TP10 was used as a delivery method for a C-terminal sequence of TbCK1.2 fused to a fluorophore. Gene tagging showed TbCK1.2 in cytoplasmic puncta, and partially at the basal body. Data will be presented on a test of the hypothesis that specific domains of TbCK1.2 are

responsible for targeting of the enzyme to the cytoplasm and/or basal bodies.

Green Power Solutions for Georgia
Ian Van Giesen, Haidi Al-Shabrawey
Prof. David Porinchu, Geography, Franklin College of Arts & Sciences

The purpose of this policy research is to delve into the fundamental legislation inhibiting Georgia's transformation from mainly fossil powered electric generation to mainly renewable energy generation. First we focus on why Georgia should adopt alternative energy from three different perspectives: environmental, health and economic. As well, we present an effective renewable energy policy alternative to Georgia's current legislation. As evidence, we examine various national and global initiatives designed to increase rate and scale of green energy adoption.

The Role of Cas1, Cas2, Csn2, and Cas9 in the Type II CRISPR-Cas Adaptation
Nikita Vantsev, CURO Honors Scholar
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

CRISPR-Cas, prokaryotic adaptive immune systems, provide a significant advantage for bacteria and archaea in their defense against invaders such as plasmids and phages. The three-phase systems work by first integrating fragments of invader DNA into the CRISPR loci of the host genomes followed by synthesizing crRNAs from the incorporated fragments, and lastly, preforming crRNA guided silencing of invaders by Cas proteins. Genetic studies showed that in Type II CRISPR-Cas systems, proteins Cas1, Cas2, Csn2 and Cas9 are involved in adaptation. My project focuses on using biochemical approaches to understand the molecular mechanism in the initial spacer acquisition in Type II CRISPR-Cas systems We demonstrated that Cas1 performs a non-specific transesterfication reaction on the branched dsDNA We also identified complex formations of Cas1, Cas2, and Csn2. We aim to discover individual functions of these proteins and protein complexes.

Proteomic Profiling of a Model Species (Medaka Fish) to Study the Physiological Response to Chronic, Low Level Ionizing Radiation in the Environment
Jerin Varghese, Jason Moraczewski, Brittany Tummings
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Ionizing radiation (IR) is recognized to cause proteomic changes in various organisms. Most prominent studies performed in the field of proteomics primarily focus on the effect of radiation at acute, high doses. However, very little is known about the biological responses of organisms when exposed to chronic, low levels of ionizing radiation. This study seeks to answer the research question: What are the physiological responses associated with exposure to chronic, low- dose IR in the model species Medaka (*Oryzias latipes*)*?* The proteome of Medaka is analyzed to quantify any changes that have occurred due to exposure to low levels of IR. The first part of the project is aimed to standardize the methodology for protein extraction and protein fractionation using a control group and a high dose group. Medaka were first irradiated at the Savannah River Ecology Laboratory (SREL). Following irradiation, in-gel trypsin digestion and liquid-chromatography and mass spectrometry (LC-MS) techniques were used to identify the unique proteins found in the control and high dose group. A total of 1013 unique proteins were discovered between the control and high dose samples and are currently being characterized using bioinformatics tools.

Prevalence of Current Season Injuries in Collegiate Club Rugby Players with a Previous Injury History

Alyssa Varsalona
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Injuries are prominent among rugby players due to the contact nature of the sport, but it is unknown if individuals with a history of injuries are more susceptible to sustain subsequent injuries. The purpose of this prospective study was to determine if previous injury history increased the occurrence of current season injuries among collegiate club rugby players during a fall semester. Participants were evaluated for self-report previous injury history and Functional Movement Screen (FMS) scores. The data were obtained from 25 participants (13 female, 12 male; age=20.58±1.21yrs, height=172.19±8.95cm, weight=80.64±16.84kg). A point-biserial correlation was used to determine the relationship between the presence of previous injury history and the frequency of current season injuries. Of the 25 participants, 20 (80%) reported having at least one previous injury, while 5 (20%) reported having zero previous injuries. A moderate positive correlation was observed between previous injury history and current season injuries ($r=0.39$), bordering on significance ($p=0.054$). Previous injury history explains 15% of the variation in current season injuries ($r^2=0.15$). Although the strength of this relationship appears to be moderate, it is likely influenced by a number of additional factors. Due to these confounding factors, we cannot conclude that a history of injury directly increases an athlete's chance of sustaining injuries in subsequent seasons. In the future, it would be beneficial to further examine what confounding factors exist and to what degree of influence.

DARC Expression in Triple-Negative Breast Cancer

Juhi Varshney
Dr. Melissa Davis, Genetics, Franklin College of Arts & Sciences

DARC (Duffy Antigen Receptor for Chemokines) is now primarily known for its role as a blood group antigen and is functionally recognized as an atypical chemokine receptor. DARC is associated with a host of inflammatory and angiogenic chemokines that are linked to cancer growth. The Duffy Null allele (Fy-) is one polymorphism that has long been associated with malarial resistance but was recently linked to altered regulation of DARC isoforms. The resulting Fy- phenotype exhibits the absence of DARC expression on red blood cells as well as distinct inflammatory responses. Over 98% of West Africans and 50-80% of African-Americans express this phenotype, compared to less than 1% of their European-American counterparts. Triple negative breast cancer is an exceptionally aggressive form of breast cancer that does not exhibit estrogen receptors, progesterone receptors, or HER2 receptors, making it a difficult cancer to target during treatment. It is well-documented that African and African-American women get triple-negative breast cancer at rates much higher than other women, and there is evidence that the DARC isoform variations may be linked to aggressive breast cancer. The objective of this research is to explore if and how the Fy- phenotype contributes to the rapid growth of triple negative breast cancer by examining the expression of differential DARC protein products in both triple-negative and healthy cell lines through Western blot. This study is ongoing, but it hopes to explain differences in triple-negative rates in women of different ancestry groups while providing insight into innovative treatment for the disease.

Abstracts

Computational Investigations of H2-HD Collisions in the Interstellar Medium

Clark Veazey
Dr. Phillip Stancil, Physics & Astronomy, Franklin College of Arts & Sciences

When we want to study the behavior of distant objects in the universe, we rely on measurements derived from astronomical observations. This is done by means of spectroscopy, as the only data available is in the form of radiation being transmitted to us from the source. Ideally, we can interpret this light, which is emitted by molecules throughout the interstellar medium, to understand the way that these molecules are behaving, which describes the temperature and therein the energy of the source. In order to interpret these observations, accurate dynamical information on interstellar molecules is needed. Most of the observable infrared radiation in the universe is emitted by excited molecules due to collisional processes in the interstellar gas, making accurate data on the rate of molecular collisions of salient interest to astronomical endeavors. Here, we evaluate the probability of H2 (Dihydrogen) and HD (Deuterium-Hydride) collisions as these species played important roles in star formation shortly after the Big Bang. We are interested in HD since it has a finite dipole moment and hence is a strong radiator, and H2 due its large abundance in the early Universe. Using a public-domain scattering package, cross-sections of H2-HD collisions are computed for a selection of rotational states over a range of relevant kinetic energies, then integrated to produce rate coefficient. We will also examine the critical density and cooling function associated with this process which will aid in studying non-equilibrium cooling/excitation and possible spectral signatures from the formation of the first stars.

Regulation of DARC Isoforms among Ancestry Groups and Associations with Aggressive Breast Cancer Subtypes

Kathryn Vollum, CURO Graduation Distinction
Dr. Melissa Davis, Genetics, Franklin College of Arts & Sciences

Despite the fact that White women are more often diagnosed with breast cancer, African-American women have more severe and deadly cases. Clues surrounding the tumor behavior in African-Americans point to physiological contexts and the immunological microenvironment of the cancer sites. We hypothesize that higher mortality rates coupled with lower incidence of breast cancer in this population suggests susceptibility is not necessarily a predisposition to cancer, but once a malignant cell forms, the individual's physiological make-up drives the aggression of tumors. We further hypothesize that chronic pro-inflammatory status and altered chemokine profiles in this population are key to tumor progression disparities. We are investigating the role of the ACKR1/DARC gene and its isoforms in influencing a woman's chance of developing aggressive breast cancer subtypes. We aim to demonstrate that altered expression of DARC isoforms plays a role in breast cancer severity by regulating the infiltration of specific immune cell types into the tumor environment by altering the levels of chemokines. We are investigating how the Duffy null allele, prevalent in all women of African descent, affects the ability of transcription factors to properly express ACKR1/DARC in epithelial and lymphoblast cells. Using bioinformatics and ChIP-PCR, we aim to define more precisely the transcription factors responsible for DARC isoform regulation. Currently, we are investigating the roles of GATA1 and GATA3. Once we know what transcription factors are involved with epithelial expression of DARC, we can develop tools to further investigate how

DARC plays a role in tumor progression in women of African descent.

Impact of Investment Bank Advisers on Merger Premiums and Merger Closing Times

Haris Vukotic
Dr. Jeff Netter, Banking & Finance, Terry College of Business

In an era of low growth, many companies turn to mergers and acquisitions as a way to scale up their operations by cutting synergistic costs and increasing revenues. This paper examines the impact of deals on the equity value of the acquired company and possible causes for this impact, also known as a merger premium. Data consists of company financial results, industry specifications, and investment bank advisors, among other deal-related metrics for mergers and acquisitions that have total values of over one billion dollars. I will test which variables drive a deal premium the most; for example, if companies within certain industries command higher premiums due to their growth prospects, or if a selected investment bank advisor results in higher or lower deal premiums, or quicker closing times, on average as compared to their competitor. The results of this study could be novel and interesting in that there is no available literature on which investment bank advisor delivers the best results for their clients in each sector; much of the business is driven by qualitative prestige factors. Preliminary data analysis indicates that certain banks are much more effective than others in demanding higher deal premiums in their sell side engagements and closing their deals in a shorter time frame within parallel industries.

Statistically Modelling the Determinants of Pathogen Transmissibility in Humans

Joseph Walker, CURO Research Assistant
Dr. John Drake, Odum School of Ecology

Every year, emerging infectious diseases enter the human population from external sources and cause outbreaks. After making the jump from its reservoir, a pathogen's impact is primarily a function of its ability to transmit between humans. The goal of my research is to investigate which pathogen traits are the most important determinants of transmissibility, quantify those relationships, and develop predictive models which can be applied to newly discovered pathogens. I have reviewed the literature and compiled a database of all known human viral and bacterial pathogens and associated biological and ecological variables. Machine learning is a field of computer science that concerns identifying complex patterns in data. I am now in the process of fitting boosted regression trees, one method for machine learning, to the data with the goal of developing models which can be used to predict and explain pathogen transmissibility. Preliminary results indicate that these models may be able to predict the transmissibility of viruses in humans with reasonably high accuracy. We've quantified the relationship between the biological and host variables of viruses and their transmission propensity in humans. While it is difficult to discern correlation and causation in these relationships, a framework for predicting the transmissibility of a virus would have immediate value for public health emergency preparedness. Our efforts to model the transmissibility of bacteria have been less successful. This wasn't wholly unexpected, as bacteria are orders of magnitude more complex than viruses and are generally less dependent on transmission for survival.

Large-Scale Plasmid DNA Purification for Gene Therapy of Hemophilia B in Dogs

Vincent Way, CURO Research Assistant
Dr. Dexi Liu, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The objective of this study is to learn basic techniques for plasmid DNA purification and validate the method of cesium chloride gradient centrifugation for large-scale DNA preparation. The preparation of a large batch of pLIVE-cFIX plasmids containing the canine clotting factor IX gene was performed and the purified plasmids were used for gene therapy treatment of hemophilia B dogs, a research project focused on developing the optimal procedure for hydrodynamic gene therapy. E. coli containing pLIVE-cFIX plasmids was cultured using LB medium with ampicillin and incubated at 37°C with shaking. The bacterial cells were pelleted down by centrifugation and lysed by lysozymes containing lysis buffer to release the cytoplasmic contents. Cesium chloride gradient centrifugation procedure was used to isolate the plasmid DNA from the lysate. The extracted DNA yield achieved was approximately 20 mg from 4 liters of bacterial culture. Agarose gel electrophoresis along with restriction enzyme digestion was used to determine the purity of the plasmid DNA. Furthermore, spectrophotometric measurements of purified plasmid DNA were taken and show a ratio of 1.87. These results demonstrate that using cesium chloride gradient centrifugation is a highly effective method for large-scale plasmid purification.

Regulation of Ovarian Cancer by RGS10 and BIN1

Andrew Webster
Dr. Shelley Hooks, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Ovarian cancer is the deadliest gynecological malignancy, and the poor prognosis of ovarian cancer patients is largely a result of the high incidence of chemoresistance in recurring tumors. Understanding and reversing the development of chemoresistance is critical to improving outcomes for ovarian cancer patients. Regulator of G-protein Signaling protein RGS10 has been shown to play a critical role in ovarian cancer cell survival and chemoresistance. Suppression of RGS10 enhances cell survival and promotes chemoresistance. Similarly, the nuclear protein BIN1 functions as a tumor suppressor in multiple cancers and has also been shown to play a key role in ovarian cancer chemoresistance. The pattern of BIN1 expression and function is strikingly similar to that of RGS10, but no functional link between the two proteins has been demonstrated. In the current study, we explore the possibility that BIN1 functionally interacts with RGS10 in an ovarian cancer cell model. Our data suggest that RGS10 and BIN1 may work together in a concerted mechanism to regulate ovarian cancer survival. We have demonstrated that siRNA mediated knock-down of BIN1 yields a near-complete reduction of RGS10, while overexpression of BIN1 yields increased RGS10 levels. Additionally, the ability of BIN1 overexpression to increase cancer cell sensitivity to chemotherapeutic drugs can be partially reversed by a subsequent knock-down of RGS10, indicating the effects of BIN1 and RGS10 on chemosensitivity are integrated. Better understanding role of RGS10 in mediating the effects of BIN1 can provide valuable insight into cancer progression and how to address the issue of chemoresistance.

Pathological Assessment of a Piglet Model of Traumatic Brain Injury Utilizing Non-Invasive Magnetic Resonance Imaging

Madelaine Wendzik
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Traumatic brain injury (TBI) is a major cause of death and disability in the United States. Stem cell therapies offer a promising treatment for TBI by producing regenerative and anti-inflammatory growth factors while

also functioning as a cell replacement therapy. Animal models not truly representative of the human condition have impeded development of a translatable TBI treatment, suggesting a more human-like animal model, such as a piglet, is necessary for developing a successful cell therapy. Magnetic resonance imaging (MRI) is pertinent in the analysis and treatment of TBI, and combining multiple MR parameters provides a comprehensive understanding of TBI pathophysiology. We hypothesize that controlled cortical impact (CCI) TBI in piglets will result in substantial deficits at the lesion site that can be measured and quantified non-invasively through MRI. TBI was induced in six male piglets. After 24 hours post-TBI, T2 FLAIR was implemented to visualize the lesion. Midline shift, lesion size, brain swelling and edema will be measured from the T2 weighted coronal images. Analyzing the multiple MR parameters will illustrate the differences in the injury 1-day post TBI and 12-weeks post-TBI. A reduced midline shift, lesion size, brain swelling and edema are expected 12-weeks post-TBI as damaged tissue is removed and the brain undergoes global regeneration and remodeling. Development and characterization of key cytoarchitectural changes in the CCI TBI piglet model utilizing MRI in this study will enable more robust and predictive assessment of novel therapeutics and treatments that will likely lead to more success in human clinical trials.

Forensically Influential Beetle Fauna in the Spring

Garrison West, Markus Cleveland, Alan Bosworth, Alexandria Lushaj
Dr. Marianne Shockley, Entomology, College of Agricultural & Environmental Sciences

What beetle fauna colonize carrion in the spring, and which stage of decay is the best time to find each beetle family? Forensic entomology plays a crucial role in urban and criminal court cases. Insects can unlock the hidden truths of a story that investigators may not uncover otherwise. Sadly, there has not been much research done in the field of forensic entomology and that is why we want to conduct this experiment. For our experiment, we are going to be examining beetle fauna that colonize carrion during the spring. The point of this experiment is to follow up on comparable research that was implemented in the fall. The trial conducted in the fall was extremely successful and will be the guideline for this research. As previously mentioned, there has not been much exploration of forensically important fauna. The science we will uncover can help forensic investigators in estimating a post mortem interval in potential homicide cases. The start of the experimental method will be to obtain a pig killed by a single gunshot wound to the head. Next, the pig will be placed in a cage to protect it from scavengers. After the simulated crime scene is in place, pitfall traps will be stationed around the pig, and the beetle fauna from the traps will be collected and examined. The results will be correlated with the fall data and will be arranged in an orderly manner to give an accurate comparison. Using this comparison we will create our presentation for the symposium and attempt to publish a written work of the results.

Social Perceptions of the Impacts and Benefits of Non-Native Species in the Garden: The Case of Chinese Privet in the Southeastern U.S.

Lindsey White, CURO Research Assistant
Prof. Eric MacDonald, College of Environment & Design

This study explores social perceptions of the impacts and benefits of non-native species in garden settings, focusing specifically on gardeners' attitudes toward Chinese privet in the southeastern U.S. Robert Fortune introduced Chinese privet (*Ligustrum sinense*) to the United States from China in 1852. Since

then, the species has escaped cultivation. In much of the U.S. it is widely regarded as an invasive species, and now covers a cumulative land area of roughly 3.2 million acres. Homeowners, gardeners, and institutions that perpetuate the use of *Ligustrum sinense* on their property help facilitate the further spread of the species. To better understand the reasons why homeowners may choose to plant, maintain, or remove non-native species like privet, fourteen semi-structured interviews were conducted with amateur gardeners in Athens-Clarke County, Georgia. The interview transcripts were subjected to qualitative thematic content analysis, which identified key themes and categories of responses. The preliminary interview data suggest that gardening practices are influenced by family connections, aesthetics, therapeutic benefits, and intellectual curiosity. Based on these results, the study concludes with several further questions about how gardeners' perceptions of non-native, invasive species might be changed in the future.

Implications of Inherited Microbial Profile in Long-Term Metabolic Health

Brittany Whitlock
Dr. Claire de La Serre, Foods & Nutrition, College of Family & Consumer Sciences

An obesity epidemic currently plagues the US and other western nations, threatening the health of millions across the globe. Research efforts over the last decade have pointed towards gastrointestinal microflora as a potential cause of obesity and other metabolic disorders. The following study focuses on the inheritance of obesity from mother to child, and asks whether the inheritance of unhealthy GI microbiota could be the vehicle that increases offspring propensity towards metabolic disease. Six week old female C57BL/6 mice were fed either high-fat or low-fat (control) diets, then mated. Dams were fed their respective diets throughout pregnancy. All subsequent pups were fed low-fat diets after weaning. Pups were examined for gastrointestinal microflora composition and GI tract viability. Previous stages of this study demonstrated that 21 day old pups of mother mice fed on a high fat diet (HFD) displayed significant alterations in gut microbiota composition associated with impaired GI epithelial permeability. This microbial profile has previously been associated with obesity and could increase their propensity toward metabolic disorder later in life. This project specifically explores differences between microbes of 21 day old pups and 90 day old pups, evaluating what implications the comparisons have for microbial profile persistence into adulthood.

How Does Mutagenesis of N-Linked Glycosylation Sites of C6f1 Fragment affect MAb109 Binding?

Christopher Whitlock, CURO Research Assistant
Dr. J. Michael Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

CEACAM6 is a glycoprotein found attached to the cell membrane of pancreatic adenocarcinoma cells that shows promise for use as biomarker in early pancreatic cancer screening. The five-year survival rate for pancreatic cancer is extremely low, making it important to find a reliable method of detecting pancreatic cancer at its earliest and most treatable stages. MAb109 is a monoclonal IgG antibody that binds specifically to CEACAM6, and recognition of the epitope is likely N-linked glycosylation dependent. N-linked glycans are carbohydrate chains added to proteins at consensus amino acid sequences of asparagine-x-serine/threonine as post-translational modifications. In this study, nine specific N-linked glycosylation sites on CEACAM6 were analyzed through site-directed mutagenesis of C6f1, a plasmid containing the fragment of the CEACAM6 gene expressing

its MAb109 epitope. C6f1 plasmids were mutated in order to alter specific amino acid residues of each particular N-linked glycosylation site, thus preventing N-lined glycan attachment. One test was performed with single mutations at sites N309 and T311 in order to determine if the final N-linked glycan of the C6f1 sequence affects MAb109 recognition, and a second test used nine different serially mutated plasmids, each with one more mutation than the last, for all N-linked glycosylation sites on the plasmid to examine how the loss of multiple N-linked glycans affected MAb109 binding. This study found that MAb109 would not recognize the C6f1 product without the N-linked glycan at N309 and that mutations past the first four N-linked glycosylation sites prevented the protein from being secreted by the cell.

Fracking Governance and Resistance in Western North Carolina

Elizabeth Wilkes, Foundation Fellow, CURO Research Assistant
Julia Connell
Dr. Jennifer Rice, Geography, Franklin College of Arts & Sciences

Hydraulic fracturing (fracking) is largely unregulated at the federal level and is exempt from nearly all federal environmental laws, leaving individual states and localities to regulate the industry. This fragmented landscape of regulatory responsibility has resulted in limited spaces to contest whether or not fracking should be permitted. Our research attempts to determine the spaces and practices of opposition that are possible under neoliberal forms of fracking governance. Using theoretical insights on the nature of democracy, we examine an anti-fracking movement in western North Carolina, one of the only such movements in the United States to coalesce before drilling had started. We argue that contemporary forms of democracy under neoliberalism limit resistance and activism to what we call "micro sites" of contestation. These include: letters to the editors in local newspapers; landowner rights workshops on fracking; local government resolutions against fracking; and the Mining and Energy Commission (MEC) hearing on the rules that permit hydraulic fracturing. This research contributes literature on state theory and environmental governance by showing the ways in which resistance is focused into narrow spaces of dissent under neoliberal governance.

Optogenetic Control of a Neuromuscular Junction Model on a Chip

Elizabeth Wilkins, CURO Honors Scholar
Catherine Callaway
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Currently, more than 300,000 people in the United States live with spinal cord injuries (SCIs). Such damage to the central nervous system frequently results in paralysis, impairing a patient's ability to function independently. In one downstream effect of SCI, motor neurons, which control voluntary and involuntary movement, die and fail to properly synapse on muscles at neuromuscular junctions (NMJs). No treatment effectively reverses the damage of an SCI. Pluripotent stem cells (PSCs) are an attractive candidate for post-injury cell replacement therapy because they can differentiate into the three germ layers responsible for forming all adult tissue. Optogenetics, or light control of cells, provides a groundbreaking means to stimulate neurons without electrical or pharmacological agents. Microfluidics devices serve as a high throughput investigative tool to demonstrate the therapeutic potential of PSCs. These apparti provide an optimal setting to mimic three-dimensional microenvironments within the body previously limited to animal model investigations. In this study, we utilized a microfluidic approach to demonstrate

functional optogenetic neuronal control of NMJs. We differentiated a line of PSCs constitutively expressing the optogenetic protein channel rhodopsin-2 (ChR2) into optically excitable motor neurons within a 3D aggregate. We co-cultured these aggregates with muscle strips in the microfluidics device to form NMJs. Our NMJ-on-a-chip will serve as model for cell replacement therapy. The selective activation of specific muscle sets with optogenetic control could be used to retrain an SCI patient to walk again.

Love, Lust, and Loyalty: Female Sexuality in the Auchinleck Romances

Camily Williams
Dr. Cynthia Turner Camp, English, Franklin College of Arts & Sciences

The Auchinleck manuscript, a medieval book produced between 1330 and 1340, is notable for its large collection of romances in Middle English. Many of these stories depict coming of age and the proper socialization of men and women and would have been used to instruct and entertain members of the middle-class household. While the male protagonists serve as models of gendered behavior, the female heroines do not, often seducing or coercing men to have sex. Conduct literature aimed at young women from the same period explicitly condemns these behaviors; however, rather than being punished, the sexually forward romance heroines are rewarded for their actions in the form of greater freedom and power. Because this text likely served instructional purposes, I argue that these misbehaving women offer a different picture of female sexuality that may have been accessible to young laywomen. "Le Fresne" presents a particularly important conversion of these messages since she acts in ways that are both exemplary and non-exemplary by the standards of conduct literature. Comparing these romances to each other in the context of "Le Fresne" reveals a pattern of young women using their sexuality in order to secure their futures. Considering this pattern in conjunction with more conservative conduct literature exposes conflicting messages about female sexuality. These differences are important because they provide insight into the alternate messages young women may have received about their sexuality and their power.

New Challenges: ADHD Goes to College

Sarah Williams, CURO Research Assistant
Dr. James Coverdill, Sociology, Franklin College of Arts & Sciences

Problem Statement: This research explores the experiences and challenges of those who are first diagnosed with ADHD in college. Many studies have explored childhood ADHD; few have considered college ADHD. *Methods:* Fifteen University of Georgia students aged 18-25 (10 women and 5 men) were recruited through social media and interviewed face-to-face. Semi-structured interviews presented a common core of questions followed by prompts for elaboration. Questions fell into three categories: circumstances surrounding the diagnosis; treatment approaches; and ADHD experiences. All interviews were recorded with permission and transcribed verbatim. Analysis involved multiple readings of the interviews to identify main themes. *Findings:* Four main themes emerged in the interviews. First, the circumstances prompting a diagnosis often included substantially lower grades in college relative to high school. Second, symptoms were often experienced and recognized prior to college, but were not acted upon because they did not substantially interfere with academic or social activities. Third, upon coming to college, students felt inadequate compared to peers in study habits, social capabilities, and academic outcomes. Fourth, participants felt that widespread informal use of ADHD medication and the belief that ADHD is a "childhood disease" were stigmatizing. All findings are presented via representative quotations from the

interviews. *Significance:* The results begin to fill a research void by suggesting that the experiences and challenges of those diagnosed with ADHD in college differ from those for children. By understanding the unique challenges that accompany a college-age diagnosis, physicians can better prepare and counsel patients.

Comparison of Oconee and Ocmulgee River Basins for Water Management Improvement

Joshua Willis, CURO Research Assistant
Dr. Ernest Tollner, College of Engineering

With increasing population in Georgia, water demand and wastewater generation are dramatically increasing. This requires refining water management strategies in order to meet future demands and support economic development of the region. The Oconee and Ocmulgee Rivers are adjacent basins and major tributaries that join to form the Altamaha River. Our study examines the ecological effects of alternative water management practices in both the Oconee and Ocmulgee river basins. These rivers harbor high aquatic biodiversity, and protecting these species is of high priority for the region. Thus, we simulate alternative environmental flow regimes and examine trade-offs in water management between ecological impacts and economic development. We simulate unaltered and altered flow regimes using historical streamflow discharge data, which are then examined relative to local hydraulic conditions and aquatic habitat needs. In order to model hydraulics of the river, we use the Hydrologic Engineering Center's River Analysis System (HEC-RAS) developed by the US Army Corps of Engineers. We also use the Hydrologic Engineering Center's Ecosystem Function Model (HEC-EFM) to link hydrologic management with ecological outcomes using fish Habitat Suitability Index (HSI) models. We analyze and evaluate various flow regimes and their environmental impact in order to provide insights into hydrologic similarities and differences when comparing the two river basins. This type of study informs development of environmental flow regulations in the Oconee and Ocmulgee river basins and contributes to the improvement of local water management and planning.

Learning beyond the Lines

Kalyn Wilson, CURO Research Assistant
Dr. Cheryl Hollifield, Grady College of Journalism & Mass Communication

In 2014, a series of police shootings of African American citizens led to widespread civil unrest across the U.S. Research shows that there is a large and continuing gap between the perceptions of Black and White Americans on racial issues in America, and the differences are largest on questions of racism among police and in the justice system (Gallup, 2014). After the racial upheaval of the late 1960s, the Kerner Commission (1968) found that a significant factor in those events was the lack of diversity in U.S. newsrooms, which caused the media to ignore issues important to African American citizens. This study asks what factors in journalism education help prepare 21st century journalism students to understand and cover sensitive issues, including racial issues in society, and what impact a university's environment has on journalism students' career outlooks. The study uses a comparative survey design. The population is journalism majors at the University of Georgia and at Albany State University, an HBCU. The study uses a census of journalism majors in both universities. The researcher hypothesizes that both African American and non-African American journalism students attending the HBCU will be more aware of issues of discrimination because of race, religion and other demographic factors than will journalism students in a non-HBCU,

regardless of the respondent's race. The findings from this project may provide information that will enhance our ability to more effectively prepare journalists to handle socially important, yet sensitive topics in the field.

Copy-Cats: Aphra Behn's *The History of the Nun* and Its Adaptations

Sydney Wilson
Dr. Elizabeth Kraft, English, Franklin College of Arts & Sciences

In this paper, I examine Aphra Behn's *The History of the* Nun and the key changes made in each of Thomas Southerne and David Garrick's dramatic adaptations and analyze possible reasons for the popularity of Isabella's tale in each adaptation's political and socioeconomic time periods. I argue that the reason for Isabella's descent into desperate murder stems from concerns about legitimacy, the conflict of two inheritances during the Succession Crisis, and William of Orange and King George III's reigns as monarch in each successive version of the tale. I also argue that these adaptations' use of children and murder significantly transform the costs and benefits of Isabella's choices, put a knife in her hands, and increase her risk of being caught. Furthermore, I hypothesize that Behn's original story may have itself been an adaptation, drawing inspiration from the French tale of Martin Guerre, a legal case involving a peasant masquerading as war widow's husband back from the dead. In using Isabella as the anti-heroine, Behn, Southerne, and Garrick transform a story of a female victim into one of empowerment, even if Isabella's tale never quite ends well for her. In conclusion, this project, by closely examining one of Behn's less popular works and its adaptations, sheds light on the era's obsession with women and its inability to decide what should be done with a woman who manipulates her own fate both legally, emotionally, and most shockingly of all, with a simple needle or knife.

Theoretical Investigation of the Combustion Chemistry of Acetaldehyde and Ethenol

Alexander Winkles, CURO Research Assistant
Prof. Henry Schaefer, Chemistry, Franklin College of Arts & Sciences

For butanol to be considered a viable fuel source, an understanding of its combustion chemistry is imperative. Incomplete combustion of butanol produces ethenol and acetaldehyde, a known pollutant, which were studied using ab initio techniques at a high level of theory. The focal-point analysis method was utilized to examine hydrogen abstractions of both ethenol and acetaldehyde. Ground electronic state geometries for each species and their radicals were optimized using the "NASA Ames" atomic natural orbital (ANO) basis sets and coupled-cluster theory up to perturbative triple excitations [CCSD(T)/ANO2]. Single-point energies were extrapolated to the complete basis set limit using Dunning's correlation-consistent basis sets and coupled-cluster theory up to full triples with perturbative quadruple excitations [CCSDT(Q)]. Additional corrections for relativistic effects, the Born-Oppenheimer approximation, frozen core approximation, and zero-point vibrational energies were determined. Anharmonic frequencies were obtained at the CCSD(T)/ANO1 level of theory. Our findings will be available to the chemical community to aid in the construction of a more complete combustion model of butanol as well as to identify spectroscopically the molecules in question.

Soldiers of Fortune: The Incidence of Mercenary Usage in Civil Conflict

Rebekah Worick
Dr. Sara Kutchesfahani, International Affairs, School of Public & International Affairs

Mercenaries, soldiers who fight for profit rather than patriotism, are as old as warfare itself. Contrary to international norms discouraging their use, however, mercenary forces still remain the most efficient and reliable source of combat personnel in many civil conflicts. Oftentimes, though, countries engaged in similar states of civil war may vary drastically in their levels of mercenary participation, with some countries dependent upon mercenaries and others avoiding their use entirely. Thus, this research will seek to explain the reasons for uneven incidence of mercenaries in civil conflict by examining two case studies, Algeria and Sierra Leone. Both of these countries experienced civil wars during the same ten year period (1992-2002), but while Algeria abstained from recruitment of mercenaries, Sierra Leone utilized mercenaries heavily. To explain this phenomenon of civil warfare, this research compared potential sources of economic divergence between the two case studies, eventually concluding that the presence of alluvial diamonds in Sierra Leone contributed to the asymmetrical recruitment of mercenaries. This argument was validated by comparing mercenary recruitment rates between countries with and without alluvial diamond deposits. Countries with alluvial diamond deposits were indeed more likely to recruit mercenaries during civil conflict, with a rate of 75% mercenary participation, as opposed to the global average of 36.8% in countries without alluvial diamonds. The conclusions of this research are therefore important in predicting which countries are more susceptible to mercenary involvement, and as such, these findings will help further understanding of mercenary incidence in wartime as a whole.

Divergent Selection in the Context of Source-Sink Dynamics

James Workman, CURO Graduation Distinction, CURO Research Assistant
Dr. Jill Anderson, Genetics, Franklin College of Arts & Sciences

Environmental conditions vary through time and across space, exposing natural populations to different abiotic and biotic regimes. In turn, divergent selection can favor specialization to contrasting environments, leading to the evolution of local adaptation. *Vaccinium elliotti,* a native species of blueberry, grows in two different habitats in the southeastern United States: drought-prone upland forests and flood-prone bottomland forests. Upland forests have dry nutrient-poor sandy soils, high light penetration into the understory, and increased susceptibility to drought. In contrast, bottomland forests that flood 1-2 times annually have nutrient-rich clay soils and dark understories. We hypothesized that natural selection in upland forests would favor traits that promote fitness under drought, including deep roots and high root: shoot ratios. In contrast, we expected selection to favor different trait values that promote flood tolerance in wetland populations. These particular populations of *Vaccinium elliotti* present an interesting case study because this species shows evidence of source-sink dynamics, with higher fitness in upland forests and asymmetric gene flow from upland into bottomland populations. In a source-sink demographic system, there is variation in habitat quality among patches. Gene flow from the source habitat allows the population in the sink to persist, despite less favorable conditions. This asymmetric gene flow could inhibit rates of divergence between the two populations, reducing the potential for bottomland (sink) populations to adapt to local conditions. To investigate patterns of selection in *Vaccinium elliotti* we conducted a greenhouse experiment simulating one of the primary ecological differences between the bottomland and upland habitats: long term flooding and drought. We found evidence for divergent selection favoring opposing trait values under different water stress treatments for several ecologically relevant traits. These findings suggest that local adaptation is possible even in populations experiencing

asymmetric gene flow from habitats with different selection pressures.

Wedding Apparel: A New Definition
Taylor Wright
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The legalization of same sex marriage directly impacts the wedding industry, specifically the cultural definition of what constitutes wedding apparel. Because the legal definition of marriage has recently changed, the traditional definition of wedding apparel is likely to change as well. Historically, wedding apparel has been reflecting traditional gender roles and accepted social norms. However, with the recent legislation, it has also become an important tool of self-identification within the LGBT community. While masculinity and femininity have become more fluid categories, this fact is not reflected in the sartorial options provided by the conventional wedding industry. To understand the issues at stake, I have conducted field research, analyzed blogs and scrutinized future trend reports. Based on the data I have collected, I hypothesize that there will be a significant change in the near future in terms of what is available for same-sex wedding apparel. My research has shown that while there is a considerable demand for alternative wedding apparel, the offering in the actual stores in the Atlanta area remains limited. Although the issue of gay marriage remains controversial, the discrepancy between supply and demand is still puzzling from a business perspective, considering that support for gay marriage among citizens has increased from 35% in 2001 to 55% in 2015. This major and rapid shift in social opinion will directly impact the apparel industry, which tries to stay ahead of popular social movements in order to make a profit. As a result of the legalization of gay marriage, the wedding market is growing and with it the definition of wedding apparel is also changing.

Severity of Cases Admitted into a Small Animal Hospital and the Phase of the Moon
Alyssa Wuellner, CURO Graduation Distinction, CURO Research Assistant
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

A correlation between the phase of the moon and human/animal behavior has a long tradition. Previous studies have suggested an increase in the number of cases seen or admitted into small animal hospitals during a full moon. In contrast, other studies have shown no significant effect of the full moon. All previous studies have looked only at numbers of cases, not severity of cases. The purpose of this study was to determine if the severity of the cases admitted into a small animal hospital is associated with the phase of the full moon. All data were obtained from the University of Georgia Veterinary Teaching Hospital. Cases were admitted to the hospital between 2009 and 2014. A full moon was defined as the date of the actual full moon plus and minus one day. Variables collected included cost of treatment and duration of stay in the hospital. A total of 82,455 cases were analyzed with approximately 9,935 being on full moon dates. The cost of treatment was 17.9% higher on dates of the full moon versus dates of non-full moons ($p=0.21$), and the duration of hospitalization was 19.7% ($p=0.48$) higher on dates of the full moon versus dates of non-full moons. 100 cases were randomly chosen and are being classified as mild, moderate, or severe illness to compare with duration and cost of hospitalization to establish the utility of those measures as proxies for disease severity.

Prevalence of Pain in Dogs with Cancer
Alyssa Wuellner, CURO Graduation Distinction, CURO Research Assistant

Kayla Hargrove
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Pain affects 52-77 % of people affected by cancer. The incidence of pain in dogs with cancer is unknown. The purpose of this study was to determine the prevalence of pain in dogs with cancer. We hypothesized that, like humans, dogs experience high rates of clinically significant pain associated with cancer. Dogs presented to the University of Georgia Veterinary Teaching Hospital's oncology service were considered for inclusion. Dogs with interfering medical conditions and those who posed potential risk to the safety of evaluators were excluded. Client consent was obtained for each participant, in addition to a survey assessing their dog's appetite, temperament, activity level, and level of pain they appeared to be experiencing. Each dog was evaluated by one of two undergraduate researchers under the supervision of oncology staff. A physical exam was performed by one of the two evaluators, and patients were given a pain score rating from 0 to 5. Out of 50 patients currently in the study, 61% had a pain score of none, 18% scored mild, and 21% scored moderately. Based on these results, dogs have a lower prevalence of pain compared to that reported in humans.

Heritability of Tissue Glutathione Levels and Redox Status in Aged Mice

Claire Yakaitis, CURO Research Assistant
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

The ubiquitous tripeptide glutathione (GSH) is a critical regulator of the cellular antioxidant defense system, and higher levels are associated with protection against disease-related deterioration. The ratio of GSH to its oxidized form, GSSG, also serves as an informative indicator of oxidative stress. We previously discovered that tissue GSH levels and GSH/GSSG are highly heritable in young mice, but it is unclear whether the genetic control of the GSH system changes over time. We predict that GSH heritability decreases later in life. To test this hypothesis, we employed high performance liquid chromatography (HPLC) to quantify GSH concentrations and GSH/GSSG in the kidneys, liver, pancreas, heart, striatum, and cerebral cortex obtained from a panel of genetically diverse inbred mouse strains. We calculated heritability of GSH levels and GSH/GSSG in the various disease-relevant tissues. The current study is the first to characterize the heritability of GSH in aged mammals. Our results will inform future studies of aging and its influence on redox dysfunction.

Blood Folate and Whole Blood Global DNA Methylation Response to Folic Acid Supplementation Dose during Pregnancy

Joann Yang, CURO Research Assistant
Dr. Hea-Jin Park, Foods & Nutrition, College of Family & Consumer Sciences

Folate is a water-soluble vitamin that is essential for DNA synthesis and epigenetic regulation. Pregnant women are recommended to take 400μg of folic acid (FA) daily for normal fetal development and most over-the counter prenatal vitamins contain 800μg of FA. In this double-blind randomized controlled study, we aimed to determine the effect of FA supplementation dose during gestation on folate status and global methylation in maternal and cord blood. Healthy young pregnant women were provided with 400μg FA/d (RFA; n=16) or 800μg FA/d (HFA; n=12) from their first prenatal visit (<12-weeks gestation) until delivery. Maternal blood at baseline and delivery and cord blood at delivery were collected to measure serum folate, RBC folate (microbiological assay) and global methylation (LC-MS/MS). At delivery, serum and RBC folate concentrations tended to be higher in

HFA compared to RFA in maternal (serum folate (nmol/L); 78.0±7.5 vs 67.9±6.1, RBC folate (nmol/L); 2424.0±304.6 vs. 2046.0±196.8 in HFA and RFA, respectively) and cord blood (serum folate (nmol/L); 98.5±5.1 vs 81.7±7.5, RBC folate (nmol/L); 2097.0±140.4 vs. 1691.0±155.1 in HFA and RFA, respectively), were not significantly different between groups ($p>0.05$). Interestingly, global methylation was higher in RFA than that in HFA in maternal and cord blood. Maternal serum ($p=0.036$, $r=0.285$) and RBC folate concentrations ($p=0.004$, $r=0.389$) correlated with global methylation, while folate status of cord blood was not correlated with global methylation. These data suggest that folate status may be associated with global DNA methylation status in pregnant women, but not in cord blood.

Cognition in the Crosshairs

Jacob Young, CURO Summer Fellow, CURO Graduation Distinction, CURO Research Assistant
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

Many studies have been conducted on how weapons affect cognition. However, these effects have been studied in pockets of research, most notably in research on the Weapons Effect, the Weapon Focus Effect and the Race-Weapon Effect. This meta-analysis seeks to integrate this literature to examine the overall effect of weapons priming on cognition. With 67 samples contributing effect sizes, the meta-analysis finds that, relative to mundane objects, weapons attract attention and draw attention away from weapon-holders (or object-holders) and surroundings. People also recall more incorrect information when a weapon present but do not demonstrate a corresponding drop in confidence.

Poverty and Shame: Implications for Social Work

Theresa Young, CURO Research Assistant
Dr. Mary Caplan, School of Social Work

Poverty and shame are interwoven in a complex relationship that is time and place-specific, and can be considered as a co-constructed and mutually-reinforcing social and psychological phenomenon (Walker 2014). The experience of shame among people experiencing poverty is nearly universal (Chase and Bantebya-Kyomuhendo 2015), but is largely unrecognized by the general population, as well as by the practitioners working within that population. It is critical for human service professionals to have a working knowledge about the relationship of poverty and shame in order to best aid those experiencing poverty with appropriate demonstrations of empathy and provision of resources. The foundation for understanding poverty and shame has been laid in the work of Adam Smith (1776) and Amartya Sen (1999). This presentation provides results from a research study on the psychosocial results of poverty and shame. The authors employ a method known as a "scoping review" to answer the following question, "What is known about the relationship between poverty and shame?" A scoping review is similar to a systematic review in that it is a transparent, rigorous review of the literature, and uses systematic searching and evaluation criteria within multiple databases to produce findings that are useful for practitioners and policy makers (Arksey and O'Malley 2005). Unlike a systematic review, a scoping review analyzes variety of types of research, including quantitative, qualitative, and conceptual work. The results of this review will enable participants to understand the relationship between poverty and shame more deeply. From our findings, awareness will be raised regarding the external and situational causes of shame and the practice implementations for human service professionals.

Center for Undergraduate Research Opportunities

April 3, 2017

Dear Students, Faculty, and Guests,

Welcome to the 17th annual CURO Symposium, UGA's celebration of undergraduate research across the disciplines. Many individuals—administrators, faculty members, staff, graduate students, and, of course, undergraduate students—have collaborated to make the CURO Symposium the premier undergraduate academic event at UGA.

Each year, the Symposium has grown larger, and the 2017 Symposium is the largest to date, with 550 undergraduate researchers communicating their substantial accomplishments to their peers, mentors, and the public at large.

From its inception, the CURO Symposium has showcased research and scholarship in all disciplines. The 2017 Symposium continues that commitment, featuring presenters pursuing 91 different majors from 13 schools and colleges who are conducting research with 311 faculty members from 72 departments. Thus, this two-day event displays UGA's broad and substantial support of research and the invaluable commitment of UGA's administration and faculty to mentoring and providing exceptional learning opportunities for our undergraduates.

Thank you for your continued support of undergraduate research and CURO.

Sincerely,

Dr. David S. Williams, '79, '82
Associate Provost and Director

Dr. Martin P. Rogers, '01, '11
Associate Director

Schedule

Monday, April 3, 2017

Oral Session I **11:15 a.m.-12:05 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session II **12:20-1:10 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session III **1:25-2:15 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session IV **2:30-3:20 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Awards and Keynote Session **3:30-4:30 p.m.**
Athena Room E

Poster Session and Reception **4:30-6:30 p.m.**
Grand Hall South (downstairs – use escalator in lobby)

Tuesday, April 4, 2017

Oral Session V **9:30-10:45 a.m.**
Athena Breakout Rooms A, B, C, D, G, H

Oral Session VI **11:00 a.m.-12:15 p.m.**
Athena Breakout Rooms A, B, C, D, G

Oral Session VII **12:30-1:45 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session VIII **2:00-3:15 p.m.**
Athena Breakout Rooms A, B, C, D, G

Oral Session IX **3:30-4:45 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

CURO Research Mentoring Awards

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the CURO Research Mentoring Awards, formerly the EURM awards, in 2001.

These awards recognize outstanding faculty who consistently engage undergraduate researchers through CURO Programming (courses, the symposium, summer fellows, JURO, theses, et al.) and enhance the learning experience of undergraduate researchers at the University of Georgia. Award recipients have provided superior research opportunities and mentoring and have collaborated with undergraduate researchers on publications and presentations at professional conferences.

Before 2014, awards were designated as "Early Career" and "Master Level" and were granted to corresponding faculty ranks.

2017

Dr. Kevin McCully, Professor of Kinesiology, Director of the Exercise Muscle Physiology Laboratory, College of Education

Dr. Brenda Cude, Professor, Financial Planning, Housing and Consumer Economics, College of Family and Consumer Sciences

2016

Dr. Mable Fok, Assistant Professor, Electrical and Electronics Engineering, College of Engineering

Dr. Richard Lewis, R.D., Foods and Nutrition, UGA Foundation Professor in Family and Consumer Sciences

2015

Dr. Jeb Byers, Professor, Odum School of Ecology

Dr. Erik Hofmeister, DVM, DACVAA, DECVAA, MA (Anesthesia), Associate Professor of Anesthesiology, Chief of Small Animal Surgery and Anesthesia, College of Veterinary Medicine

2014

Dr. Carl Bergmann, Associate Vice President for Research-Facilities; Associate Director, Complex Carbohydrate Research Center; Executive Director, Animal Health Research Center; Senior Research Scientist

Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

2013

Master Level Faculty Award
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Early Career Faculty Award
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

To view a complete list of recipients, visit: curo.uga.edu/faculty/research_mentoring_awards.html

CURO Symposium Best Paper Awards

Since 2001, CURO Symposium Best Paper Awards have recognized excellence in papers developed from work being presented at that year's Symposium.

Applicants may submit in one or more of the following categories: Arts, Humanities and Media; Business; Life Sciences; Physical and Environmental Sciences; Public and International Affairs; Social Sciences; and Technology, Engineering and Math.

Each recipient is recognized at the Symposium's Award and Keynote Session, and each award carries $100 in financial support. Winners for the 2017 CURO Symposium are listed below.

Arts, Humanities and Media:

Anna Jewell Davidson	Privileged Perception: An Examination of Supersensory Insight in Vladimir Nabokov's *The Gift*

Life Sciences:

Atul Lodh	Investigating the Role of Cyanogenic Glycosides as a Potential Defense for *Passiflora incarnata* against *Agraulis vanillae*

Public and International Affairs:

Hannah Catherine Turner	The Price We Pay: Analyzing the Over-Incarceration of Low-Level Juvenile Offenders in Georgia

Social Sciences:

Paul DuPont Oshinski	Women's Rights from 1985-2013: Using Gendered Theories to Explain Countries' Development

Technology, Engineering and Math:

Vineet Sundar Raman	Tablet-Based Data Collection for Leprosy Surveys

Program: Monday, April 3, 2017

Oral Session I: 11:15 a.m.-12:05 p.m.

Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**McKenna Barney**	Nutrition of Women and Adolescent Girls in Conflict Zones
	Jonathan Zot Sr.	Olympic Performance and Propensity for Interstate Conflict
	Ali Elizabeth Anderson	Chemical Weapons and the Legacy of War
Room B	**Maggie Naughton**	Examining Stigma and Social Functioning in Young Adults with Autism
	Evan Simone Johnson	How Do Parental Practices Influence Adolescent Food Choices?
	Sara Carroll Johnson, Amber Madden	Mothers' Childhood Emotional Neglect as a Predictor of Child Behavior Problems
Room C	**Chelsea Thorpe**	*Charlie Hebdo*: Moral Injury and the Display of Religion in Satirical Press
	Mohammed Khalifa Kredan	Understanding American and Cuban Perceptions of Migration to America
	Izzy Ceron	"Immigrants, We Get the Job Done!": Depictions of the U.S. Immigrant Experience on Broadway
Room D	**Emily Elizabeth Gale**	White Matter Integrity Decreases Similarly with Age between People with Schizophrenia and Healthy Individuals with Low Cognitive Control
	Evan Knox	Mild Traumatic Brain Injury (mTBI) Moderates Protection of Cognitive Flexibility by Cognitive Reserve
	Haley Cohen	Risk Factors for Social Isolation in Elder Care Recipients
Room G	**Jianna Justice**	Examining the Entropic: Locating Modernity in the Writings of Jane Austen
	Sarah Jane Dillon	*Tolak Reklamasi*: Rejecting Tourist Developments in Bali
	Nina Goodall	Concrete Art and Fascism in Argentina in the 1940s

Room H	**Chip Chambers**	The Role of Non-Cas Proteins in the Adaptation Stage of CRISPR-Cas in *Pyrococcus furiosus*
	Aaron Martinez	Decoding Higher-Order Relations in Biological Data by Learning Markov Networks
	Tae-In Lee	Off-Target Effects of the Inhibitor MRS2578 on the Formation of Neutrophil Extracellular Traps
Room I	**Katie Howard**	Genetic Determinants of Intracellular Survival and Growth of *Bordetella pertussis*
	Santosh Nimkar	Facilitating the Continuous Expression and Secretion of the Influenza Surface Glycoprotein, Hemagglutinin, within Human Cells
	Hannah Kemelmakher	Functional Evaluation of Porcine Kidney: A Thorough PSF Organ Storage Study
Room J	**Emily Maloney**	Effect of Polarization on Hierarchies of Committee-Representative Networks: Social Network Analysis
	Stephen Benjamin Jordan	Mapping Near Misses in Athens-Clarke County
	Taylor Withrow	The Ugly Duckling Narrative: Identity Development in Multiracial Individuals

Oral Session II: 12:20-1:10 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Bryson Culver**	Judicial Politics in the Obama Era
	Emil Dmello	An Empirical Analysis of Economic Influence on Election Outcomes
	Brad Louis Williamson	The Effectiveness of US Congressional Committees
Room B	**Sydney-Alyce Bourget**	A Comparison of Functional and Fitness Traits of *Alliaria petiolata* along a Forest Gradient
	Mallory Jessica Harris	Vector-Borne Disease Forecasting

	Raheela Charania	Compiling Studies on Pedagogical Content Knowledge within Topics of Evolution
Room C	**Amanda Molly Joffe**	Bent and Broken: Debating China Beyond the Great Firewall
	Cameron Ward Henderson	Fifty Years In: Just Warming Up : How the Nuclear Nonproliferation Treaty Can Effectively Combat Global Warming
	Chelsea Thorpe	How Does Resource Availability Affect Non-State Armed Group Recruitment?
Room D	**Bryanna Moppins**	Development of a Novel Three-Dimensional Model to Study Breast Cancer Metastasis
	Miranda Moore	Effect of Heliox through Airflow and Aerosol Deposition in Oral Airway
	Carter Fitzgerald	Techno-Economic Assessment of Anaerobic Digestion Technology to Produce bioCNG
Room G	**Julia Marie Petros, Chantal Van Landeghem**	Parental Support for Autonomy as a Predictor of Anxious and Depressed Behaviors in Elementary School Children
	Joshua Reynolds	Neuroanatomical Correlates of Functional Decline during Normal Aging
	Zoe Schneider	Investigation of Visual Event Related Potentials in Schizophrenia, Schizoaffective, Psychotic and Non-Psychotic Bipolar Disorders
Room H	**Kathryn Marie Youngblood**	Pedagogical Methods for Developing Empathy in Engineering Students
	Briel Power	An Investigation into the Dynamics of Faculty Learning Communities
	Carter Patrick Maguire III	The Effect of ePortfolio Use on Real-World Application of Classroom Skills
Room I	**Katie Maddox**	Effect of Invasive Macroalgae *Gracilaria vermiculophylla* on Feeding Behavior of *Callinectes sapidus*
	Eric Dykes	Characterization of a V-H+-ATPase in *Toxoplasma gondii*

	Alexandria Lushaj	Forensically Influential Beetle Fauna in the Fall of 2016
Room J	**Nanma Okeani**	Justice for All: Addressing Codified Discrimination in the Georgia Justice System
	Sam Tingle, Stephen Jordan	Mapping Diverse Bicycling Experiences in Athens, GA
	Zac Commanday, Brian Northern	Resiliency and Sustainable Organizations: Leveraging Weather Management Systems

Oral Session III: 1:25-2:15 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Ellen Grace Krall**	Characterizing Ty1 Gag - CCT Complex Interactions in Budding Yeast Through Co-Immunoprecipitation and Mass Spectrometry
	Erin Hollander	Protospacer Structure and Cas Protein Function in Adaptation of the *Streptococcus Thermophilus* Type II-A CRISPR-Cas System
	Nikita Vantsev	Adapting a CRISPR-Cas System into a Novel Gene Knockdown Platform
Room B	**Adam Salway**	An African American Oral History: Historic and Contemporary Experiences of Gentrification in the Hancock Corridor
	Chloe Schrader	Intersectional Failure: The Effect of Zero-Tolerance Policy on Girls of Color
	Genesis Castro	Latino Resilience Among Undocumented Families
Room C	**Stephanie Ann Jaipaul**	The Prevalence of Science Misconceptions among the Human Body Systems: Understanding, Targeting, and Applying Misconception Findings to Effectively Teach Students about Diabetes
	Eli Chlan	Autonomy and Health Literacy Relationships as a Link to Patient and Provider Satisfaction
	Catriona Geddes	Determining Fidelity of the Physical Activity and Learning (PAL) Program

Room D	**Jessica Ziling Ho**	Genotype-Phenotype Correlations for POMGNT1 and POMGNT2 in Dystroglycanopathies
	Catherine Waldron	Exploiting CRISPR/Cas Genome Editing System in Ciliogenesis
	Sunishka Thakur	Studying Gene Flow in *Boechera stricta* to Understand the Impacts of Climate Change
Room G	**Maria Granros**	Performance on a Measure of Multitasking is Related to Executive Function in Older Adults
	Jane Sutcliff	Cognitive Control Differences in Bipolar Disorder in the Presence or Absence of Psychosis
	Megan Murphy	The Effect of Aerobic Exercise on White Matter in Overweight Children: Studying the Effect of an 8-Month Exercise Program
Room H	**Rachel Collier**	Determining Water Usage of Lettuce under a Sodium Light Source for Indoor Agriculture
	Sokngim Kim	A Computer Program for Truss Design Optimization
	Adam King, Dustin Mizelle, Anurag Banerjee	Research and Development of Satellite Software and Electronics
Room I	**Jessica Lauren Reynolds**	Assessment of Spatial Distributions of Sea Turtle Nests In Relation to Artificial Lighting in St. Kitts, West Indies
	Jenna Kay Lea	Determining Reoccurring Tick and Tick-Borne Disease Associations with Mammal Hosts
	Lauren A Purvis	Effects of Form and Level of Vitamin E Supplementation on Kinematic and Physiological Measures of Muscle Damage Following Intense Exercise in Horses
Room J	**Anna Magdalena Goebel**	Goethe's Discovery of the Divine in Nature
	Lukas Woodyard	*Indecent*: The Show That Shut Down on Opening Night
	Abigail Elizabeth West	The Sapelo Island Coloring Book

Program: Monday, April 3, 2017

Oral Session IV: 2:30-3:20 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Nivedha Balaji**	Chondroitin Sulfate Glycosaminoglycan Matrices Promote Neuroprotection Sub-Acutely Post-Traumatic Brain Injury
	Kirsten Allen	Development of Polymer-Based Microspheres for Drug and Supplement Delivery
	Emily Nieves	Examining the Arrhythmogenicity of Dobutamine When Used in Conjunction with Isoflurane or Sevoflurane
Room B	**Jacob Beckham**	Two-Point Threshold as a Measure of Hyperacuity and Intraocular Scatter
	Sarah Caesar	The Relationship between Nutrition Status and IADLs in Community-Dwelling Older Adults
	Emily Stewart Moore	The Effect of Galanin on Stress Resilience in Rats and the Relationship between Stress and Inflammation
Room C	**Avni Ahuja**	Sex-Trafficking in Georgia: Equipping Our Hotel Workers with the Proper Resources
	Ashley Willard	Online Activism: The Movement to Combat Honor-Based Violence
	Eashaa Velamuri	Reducing and Preventing Sexual Assaults on Georgia College Campuses
Room D	**Shelbi Aldrich**	Textiles and Fibers Single Point of Contact (SPOC)
	Madeline Grace Harpham	Dior to Disco: Second Wave Feminism and Fashion
	Oloni Binns	Motown Styles and the 1960's American Dream
Room G	**Paul Lee**	The Effect of Lutein and Zeaxanthin Supplementation on Emotional Well-Being
	Shivani Singh	Fatigue, Executive Functioning, and Activities of Daily Living in Older Adults
	Emma Auger	The Effect of Age on Functional Connectivity of Cognitive Control Networks in People with Schizophrenia

Program: Monday, April 3, 2017

Room H	**Sonam Alka Brahmbhatt**	Exploring the Role of DNA Double-Strand Break Repair Proteins in CRISPR Adaptation
	Zack Flagel	Take Me Out to the Ballgame: A Legal Examination of Spectator Injury Risk at Major League Baseball Games
	Fatima Kamal	The Effects of Two Different High-Fat Diets on Appetite Hormone Levels
Room I	**Urmi Patel**	Substrate Specificity of the Lactoperoxidase/Thiocyanate/Hydrogen Peroxide Cell-Free System to Inactivate Influenza Virus
	Connor Matthew O'Neill	The Effect of Macrocyclic Lactones on the Canine Immune Response towards the Heartworm Parasite *Dirofilaria immitis*
	Jack Owen	Exploring Uncertainty in Models of Mosquito Vector-Borne Disease
Room J	**John Coffin**	Predicting Oyster Larval Recruitment and Growth Using Cheaply Obtained, Remotely Sensed Data
	Diamond Clarke	Cdal-1 Kinase of the Hippo Pathway in *Tetrahymena thermophila*
	Ian E. Van Giesen	Investigating the Grindability of Woodchips at Varying Torrefaction Temperatures

Awards and Keynote Session: 3:30-4:30 p.m.
Athena Room E

Welcome and Introductions	David S. Williams, Associate Provost and Director of Honors and CURO
Remarks	Jere W. Morehead, President
	Pamela Whitten, Senior Vice President for Academic Affairs and Provost
Introduction to Awards	Martin Rogers, Associate Director of CURO and Honors
CURO Research Mentoring Awards	David C. Lee, Vice President for Research
2017 Symposium Best Paper Awards	Rahul Shrivastav, Vice President for Instruction
UGA Libraries' Research Awards	Caroline Barratt, UGA Libraries

Program: Monday, April 3, 2017

Introduction of Keynote Speaker	Ms. Erin Hollander, Class of 2018, Department of Genetics
Keynote Address	Dr. Michael Terns, Distinguished Research Professor and Professor of Biochemistry & Molecular Biology, " CRISPR: From Basic Biology to Genome Editing Revolution "
Closing Comments	David S. Williams

Poster Session and Reception: 4:30-6:30 p.m.
Sponsored by the Office of the President
Grand Hall South

Poster # 1	**Camaria Moné Welch**	Needs Assessment to Assess the Use of a Mobile Food Pantry in the Child Care Setting
Poster # 2	**Madeleine Holden Snidow**	Designing Relevant In Vitro Models of Muscle Metabolism with Inclusion of Energy Expenditure
Poster # 3	**Megan Houston**	Effects of a PUFA-Rich Diet on Coagulation and Inflammation Markers in Healthy Adults
Poster # 4	**Fatima Kamal**	The Effects of Two Different High-Fat Diets on Appetite Hormone Levels
Poster # 5	**Leah Nicole Prine**	Metabolic Responses to Diets of Varying Fatty Acid Saturation
Poster # 6	**Olivia Shealy**	Infant Sleep Duration among White Breastfed and Black Formula Fed Infants at 16 Weeks
Poster # 7	**Savannah Carroll**	Child Disability and Maltreatment: Caregiver Support as a Protective Factor
Poster # 8	**Jordan Srochi**	Mentoring as a Protective Factor of the Association between Child Maltreatment and Substance Use in Adolescence
Poster # 9	**Abby Carden Jones**	Household Production of Health: Cambodian Refugees' Health Strategies in the United States
Poster # 10	**Anna Schramski**	Filipino Immigrant Social Networks and Their Influence on Settlement Experience

Poster # 11	**Amanda Peclat-Begin**	Cambodian Mental Health Therapists' Experience in Clinical Supervision: A Phenomenological Exploration
Poster # 12	**Emily Sands**	Utilizing Cultural Advisors in Marriage and Family Therapy Practice
Poster # 13	**Breana Johnson, MacKenzie McGraw, Anna Marie Fink, Brianna Kelley, Lauren Langan, Meredith Anne Towey, Alexis Pope, Jennifer Smith, Sherry Sayavongsa, Aleah Norton**	Newborn Hearing Screening and Follow-up in the Northeast Health District
Poster # 14	**MacKenzie McGraw, Anna Marie Fink, Brianna Kelley, Lauren Langan, Meredith Anne Towey, Alexis Pope, Jennifer Smith, Sherry Sayavongsa**	An Analysis of Early Vocalization Development from the Natural Environment of Two Young Children with Autism Spectrum Disorder
Poster # 15	**Allison N White**	Effects of Pre-Transition Warnings and Contingency Statements on Compliance to Pre-Transition Demands and Problem Behavior
Poster # 16	**Soundarya Kanthimathinathan**	Microaggression in the Eye of the Beholder: Perceiver Characteristics in the Detection of Microaggressions in the Workplace
Poster # 17	**Joshua Acosta, Erica Medrano, Allie Martin**	The Impacts of Narcissism on Individual Status in Interdependent Teams
Poster # 18	**Alex Moore, Gabrielle Moriah Richie, Carissa Urrea, Diana Enriquez, David Wyrembelski**	Likely Leaders: The Influence of Big Five Personality Traits on Leadership Dynamics

Poster # 19	**Neha Arun Madangarli**	A Correlational Study: The Relationship Between Critical Flicker Fusion Thresholds of Postpartum Women and Infants
Poster # 20	**Skyler Tuholski, Samrina Jamal, Katie Lee, Nidhi Thiruppathi, Abby Thomas**	Effects of Gender and Race on Speed and Accuracy of Facial Recognition
Poster # 21	**Samantha Delaney, Shruti Prathip**	Gender Differences in College Students with ADHD
Poster # 22	**Mary Elizabeth Moody**	Double-Deficit Hypothesis for Dyslexia: A Meta-Analysis
Poster # 23	**Selin Odman**	Attention-Deficit/Hyperactivity Disorder (ADHD) Subtypes: Cross-Informant Agreement and Stability from Childhood to Adulthood
Poster # 24	**Amanda Moeller**	The Language of Leadership: Investigating Speech as a Predictor of Leadership Capacity
Poster # 25	**Luvika Gupta**	Regional Brain Morphometry and Associated Cognitive Functions in Older Adults with Cardiovascular Disease
Poster # 26	**Aparna Kanjhlia**	Altered Neural Activity in the MCLS and NA linked to Alcohol Consumption
Poster # 27	**Sahl Hakim**	Effects of Lutein on Vision and Cognition in Children
Poster # 28	**Amita Joshua**	Attachment Orientation and Career Goal Pursuit: The Effects of Relationship Commitment and Workaholism
Poster # 29	**Dillon Patel**	Implicit Subjectivity Assessment and Guilt-Shame Proneness in Work-Family Conflict, Family-Work Conflict and Workaholism
Poster # 30	**Mitchell Lee**	All Things in Moderation: The Effect of Moderation Messages on Food Perceptions
Poster # 31	**Molly Eleanor Minnen**	Employer Expectations and Experiences of Gratitude

Poster # 32	**Divya Patel, Lindsay Burr, Grant Butschek**	Task Allocation between Established and Impromptu Dyads: A Test of the Transactive Goal Dynamics Theory
Poster # 33	**Arturia T Melson-Silimon**	Trait Activation Theory and Academic Performance: Does Academic Major Moderate the Relationship between Personality and Academic Performance
Poster # 34	**Lauren Ellis Arnold**	Family Functioning and Health-Related Quality of Life in Adolescent and Young Adult Transplant Recipients
Poster # 35	**Haley Bearden**	Psychosocial Functioning and Barriers to Medication Adherence in Adolescents Awaiting Solid Organ Transplants
Poster # 36	**Colleen Keeler**	Environmental Consequences, Psychological Comorbidities, and Tic Symptom Severity in Children with Tourette Syndrome
Poster # 37	**Amy Zhan**	Exploring Grief: Accompanying End of Life Support with Palliative and Bereavement Care
Poster # 38	**Sanjida Jahan Mowla**	Updates on Current Circumscribed Interest Object Categories of Children with ASD and Accuracy of Parent Reports
Poster # 39	**Brendan Harris**	Do Transparent Whiteboards Promote Learning from Online Lectures in STEM?
Poster # 40	**Elizabeth Cara Johnson**	Fostering Productive Beliefs about Failure and Intelligence to Improve Learning in STEM
Poster # 41	**Jamarcus Gregory Mathis**	Perceived Severity of Conditions Related to Obstructive Sleep Apnea among At-Risk College Students: Consequences That May Influence Academic Performance
Poster # 42	**Eliza Ali**	Archetypal Features of the Graphical User Interfaces of Electronic Medical Records and Their Cognitive Burden on Users
Poster # 43	**Prentiss Rachel Autry**	Punitive or Positive: How University Affirmative Consent Policies can be Framed for Maximum Effect
Poster # 44	**David Kobe**	Georgia Social Workers and DACA
Poster # 45	**Anna Bennett**	How Social Media Affects Higher Learning

Poster # 46	**Ellen Barrow**	The Financial Obligations of Owning a Pet
Poster # 47	**Marcus Chatman**	The Personal Touch of Discovering Money Solutions
Poster # 48	**Sarah Landa**	Retirement Planning Behavior and Retirement Plan Participation among Men and Women: An Examination of the Determining Factors
Poster # 49	**Victoria Ayse Yonter**	Educational Disparities between Rural and Urban Schools in the State of Georgia
Poster # 50	**Phillip Jones**	The Suburbanization of Poverty in Metro Atlanta
Poster # 51	**Simran Modi**	Redefining the Boundaries of Healthcare Technology Policy
Poster # 52	**Jonathan Waring**	Identification of Vaccine Misinformation Online
Poster # 53	**Christina Lee**	Interactive Animatronics in Consumer Environments
Poster # 54	**Zoe Li**	Competing Pressures: Tipping the Scales in the Prosecution of Rape and Sexual Violence
Poster # 55	**Samuel Driggers**	A Comparison of the 2014 Scottish Referendum and 2016 European Union Membership Referendum Campaigns
Poster # 56	**Rob Oldham**	Majority Party Factionalism and Gridlock in State Legislatures
Poster # 57	**Paul DuPont Oshinski**	The Rules Change the Game: Delegate Allocation Variations and Presidential Primary Season Length
Poster # 58	**Stephen Robert Pokowitz**	Promotion, Patronage and Merit in the Royal Navy during the Napoleonic Wars
Poster # 59	**Christian Michael Sullivan, Kathryn Kostel**	Evolving Racial Perspectives in Haiti, 1785-1820
Poster # 60	**Halle Brooke Hammond**	Southern Gothic Feminism: The Women of Flannery O'Connor's *Wise Blood* and the Women of the Bible
Poster # 61	**Adwoa Agyepong**	Cemetery Records and the Spanish Flu in Athens, GA

Poster # 62	**Prabhjot K Minhas**	Refugee Health and Migration
Poster # 63	**Kara Pemberton**	Using Syndemics Theory to Examine the Correlation Between Wealth, Disease Knowledge and Zoonotic Diseases in Panama
Poster # 64	**Hannah R Gilbert**	Fecal Composition and Its Relation to Diet
Poster # 65	**Rachel N Horton**	Diachronic Perspectives on Human Diet Variation in Greek, Roman, and Medieval Albania
Poster # 66	**Janae Marie Lunsford**	Investigating Diet and Stress in Medieval Polish Individuals Using the Bone Density Fractionation Method
Poster # 67	**Maria Munoz**	Non-Vocal Sounds in a Group of Western Lowland Gorillas
Poster # 68	**Samantha Keating**	The Evolution of Religion in Africa: A Test of the Big God Hypothesis
Poster # 69	**Rose Parham**	Identity, Cosmology, and Subsistence in Madagascar
Poster # 70	**Matt Pieper**	Animism and Foraging Economies
Poster # 71	**Taylor Alicia Hill**	The Necessity for Ethics in Developing Adaptive Management Strategies for Water Scarcity
Poster # 72	**Matthew Quinn**	Applications to Prolonging Data Collection Efficiency in Stream Channels
Poster # 73	**Tony Moraes**	Clay Mineral Concentration with Depth and Land Use History in the Critical Zone In Calhoun, South Carolina
Poster # 74	**David Forest Richards IV**	Rare Earth Elements Distributions in the Critical Zone: Possible Roles of Pine Versus Hardwood Vegetative Covers
Poster # 75	**Sam Svoboda**	Clay Abyss: Underclays of the Şile Region Critical Zone
Poster # 76	**Zaak Alvin Hinz**	Trilobite Coquina in Siliceous Concretions from the Middle Cambrian Conasauga Formation, Southeastern USA
Poster # 77	**Reid Jordan**	Evaluation of Middle-Miocene Barnacles as High-Resolution Paleoclimate Proxies

Poster # 78	**Evan Alden**	College Students' Beliefs and Perceptions Towards Nature and Campus Sustainability
Poster # 79	**Nirav Ilango**	The Accuracy of SfM-Generated Dense Point Clouds Given Varying Image Quality
Poster # 80	**Hollis Neel**	Implementation of Structure from Motion from a Cube Satellite in Low Earth Orbit
Poster # 81	**James Hugh Roach, Paul Hwang**	Laboratory Operations Support for Small Satellite Research Laboratory
Poster # 82	**Austin Thomas Bryan**	Assessing the Removal of Lead from Water Using Commercially Available Filters
Poster # 83	**Chris W Overbaugh**	From Ancient Artifacts to 3D Printers: Using Modern Engineering Tools to Enhance Our Understanding of Classical Athenian Elections
Poster # 84	**Paige Copenhaver**	Comparing Metallicity Measurements from Optical Spectra of Solar-Type Stars
Poster # 85	**Jessica E Doppel**	The Ratio of Gas to Dust at High Galactic Latitudes
Poster # 86	**Mackenzie Joy**	Turbulence at the Edges of Diffuse Molecular Clouds
Poster # 87	**Amanda Stricklan**	Carbon Monoxide Line Emission from Region of Molecular Cloud MBM 55
Poster # 88	**Josh S White**	Hydroxyl Tracing in Diffuse Molecular Clouds
Poster # 89	**Ryan McArdle**	Primordial Chemical Composition Through the Reionization Period
Poster # 90	**Ryan Pattillo**	Photodissociation of Carbon Monosulfide in Interstellar Environments
Poster # 91	**Jason Terry**	The Contribution of Double Electron Capture Processes to Charge Exchange with Multielectron Targets
Poster # 92	**Clark Goodman Veazey**	Computational Investigations of He-HD Collisions in the Interstellar Medium
Poster # 93	**Bjorn Leicher**	A Study of Interstellar Intermediate Velocity Gas Clouds

Poster # 94	**Elliott Williams**	Small Structures in the Magellanic Stream: Cloud-Cloud Interactions
Poster # 95	**Peter Hong, Michael Anthony Piseno**	Multi-Rotor Marsupial Drone System for Point Cloud Data Processing
Poster # 96	**Jenna Evelynn Al-saleh**	Studying Breast Cancer Metastasis to Bone Using Tissue Engineering
Poster # 97	**Kerri Andre**	Controlled Linoleic Acid Release in a Hydrogel-Based Mammary Adipose Tissue Model
Poster # 98	**Ridge Maxson**	Bioactive Scaffold Design for Bone Tissue Engineering
Poster # 99	**Jeremy Miller**	Self-Assembled Chitosan Nanoparticles for Breast Cancer Therapy
Poster # 100	**Chase Tenewitz**	Ferrohydrodynamic Separation of Prostate Circulating Tumor Cells
Poster # 101	**Cole Burgess**	Nuclear or Solar, Why Does It Have to Be a Choice?
Poster # 102	**Jawad Iqbal**	Optimization of MATLAB Code for Faster and More Consistent Image Analysis
Poster # 103	**Melanie Kemp**	Electroformation of Giant Unilamellar Vesicles
Poster # 104	**Katherine MacManus**	Mechanical Characterization of Lipid Membranes Using Micropipette Aspiration
Poster # 105	**Katie Homeyer**	Nitric Oxide-Releasing Urinary Catheters as a Method to Prevent Urinary Tract Infections
Poster # 106	**Jennifer McCarty**	Improved Nitric Oxide-Releasing Polymer with Surface Exposed and Crosslinked Zwitterionic Polymer for Antimicrobial Applications
Poster # 107	**Sai Nagula**	Biocompatible, Biodegradable and Antimicrobial Skin Substitute with Nitric Oxide Release for Instant Burn Wound Treatments
Poster # 108	**Dieu Thao Nguyen**	Instant Clotting Patch to Prevent Excessive Bleeding during Emergency Injuries

Poster # 109	**Christina Workman**	Hydrophilic Top Coat on Nitric Oxide Releasing Surfaces for Enhanced Antibacterial and Antifouling Properties
Poster # 110	**Wilfred Oluwafemi Benard**	Design and Development of Bioengineered 3D Scaffold Using Novel Biomaterials for Tissue Regeneration Cell Culture
Poster # 111	**Dylan Munn**	Meat Consumption as an Indicator of the Near Term Stability of Each Country's Food Supply in the Global Marketplace
Poster # 112	**Ben Burgh**	Effects of Tracking Scale on User Performance in Virtual Reality Games
Poster # 113	**Ryan Snowden, Erica Anstey**	Automatic Recognition of Periocular Facial Alterations
Poster # 114	**Phiet T Do, Luis Perea**	Jamming Avoidance Response: An *Eigenmannia* Phenomenon
Poster # 115	**Kimberly Mercedes Shumaker**	Formation of Natural Product Glucosides by *Escherichia coli* in Controlled Conditions

Abstracts

Life History Traits of *Boechera stricta*

Cherien Z Abou-Harb, CURO Research Assistant
Dr. Jill Anderson, Genetics, Franklin College of Arts and Sciences

Life history trait correlations are used to determine the evolution of life history strategies aimed at optimizing an organism's survival and reproductive fitness. Life history traits are typically: responsive to resource availability, heritable, and under strong selection. Therefore, life history trait correlations indicating enhanced adaptation (positive trait correlation) or genetic constraint (negative trait correlation) to life history trait evolution can be mediated by resource availability. Current predictions associated with climate change suggest altered precipitation patterns will shift water and nutrient availability along an elevational gradient in montane systems. Here, we investigate the role of altered resources on life history trait correlations at family and population levels in an ecologically relevant model organism, *Boechera stricta*. In a greenhouse setting, we will cross three water treatments (wet, semi-drought, and drought) with three nutrient treatments. We will record life history traits including growth, timing of reproduction, and number/size of offspring. We predict family level trait correlations may indicate trade-offs while the overall population level response may suggest enhanced adaptation due to variation in family resource acquisition. Most life history traits correlations are taken on a population level. However, this study will show that trait correlations at the genotypic level may vary, and test whether environmental stress will drastically alter life history trade-offs.

The Impacts of Narcissism on Individual Status in Interdependent Teams

Joshua Acosta
Erica Medrano, Allie Martin
Dr. Dorothy Carter, Psychology, Franklin College of Arts and Sciences

An individual's status in an organization can determine his or her access to important material and social resources; however, there are many individual-level characteristics that may determine whether or not an individual achieves the status necessary to succeed in their organization. Specifically, an individual's level of narcissism may greatly impact whether they are viewed as high status or low status members of their organization. Thus, the purpose of this study is to evaluate whether narcissism is a beneficial characteristic for achieving status. We assert that higher levels of narcissism will positively predict incoming status nominations in interdependent organizational contexts. We test our hypotheses in a sample of 240 undergraduate participants assembled into 20 unique 12-member teams tasked with combining disciplinary knowledge in a complex problem-solving task. Participants responded to self-report sociometric measures of status perceptions in relation to their teammates. We will analyze data from these surveys using a class of inferential models of network emergence called exponential random graph models, which identify key predictors of networked relationships. Our findings suggest important implications for organizations, because if narcissists are more likely to achieve status in organizations, they may overwhelmingly control important resources. In fact, although narcissism is related to leadership emergence, the trait has conflicting results predicting leadership effectiveness; thus, biasing status toward those with narcissistic tendencies may impede overall effectiveness of organizations.

Creation and Testing of Myogenic Promoter Reporter System in C2C12 Cells

Aaron Adams, CURO Research Assistant
Dr. Aaron Beedle, Pharmaceutical and Biomedical Sciences, College of Pharmacy

Transcription factors are proteins that bind the promoter region of a gene and alter the expression of that gene by activating or suppressing the affinity for RNA polymerase. Transcription factors allow for coordination in the expression of genes used in complex biological pathways. Muscle regeneration, for example, is controlled by a family of transcription factors, called myogenic transcription factors, which include: Myog, Myod, Myf5, and Myf6. Through the use of cloning and transformation in *E.coli* bacteria, a plasmid containing the promotor sequence of these myogenic transcription factors upstream of a destabilized fluorescent protein was created. By transfecting C2C12 muscle cells with this plasmid, we hope to create a real-time method for

visualizing the expression of the four myogenic transcription factors.

Density-Dependent Selection Model for the Sociality of *Ceratina (Neoceratina) australensis*

Alison Kay Adams, CURO Summer Fellow
Dr. David Hall, Genetics, Franklin College of Arts and Sciences

Ceratina (Neoceratina) australensis, the Australian small carpenter bee, is socially polymorphic with both solitary and social nests collected in the same populations. Solitary nests contain a single adult female and her developing brood and social nests contain two adult females and their brood. Research has shown that solitary nests tend to produce more offspring per female than social nests, but only when a parasitic wasp is absent. When the wasp is abundant, solitary nests suffer high levels of parasitism and loss of brood. Thus, solitary nests do worse in the presence of wasps and better in their absence. The parasitic wasp does better when solitary nests are common and worse when they are rare. These effects are hypothesized to allow maintenance of both nest types in bee populations: when solitary nests are dense, the wasp increases in numbers, which leads to an advantage for social nests, and vice versa. To address this hypothesis, several mathematical models were developed to capture the biology of this system. The models were analyzed to determine whether a stable equilibrium with both social and solitary nests was possible. Such equilibrium was found, indicating that the parasitic wasp may be what permits the existence of the social polymorphism in the bee in nature.

The Feasibility of Structure from Motion over Planetary Bodies with Small Satellite Systems

Caleb Ashmore Adams, CURO Summer Fellow, CURO Research Assistant
Dr. Marguerite Madden, Geography, Franklin College of Arts and Sciences

The majority of works using point clouds employ 3D representations from terrestrial/aerial LiDAR, but progresses in computer vision have made available a series of algorithms that allow for the generation of point clouds and surfaces that do not need a point-based collection characteristic of LiDAR systems. One such algorithm, Structure from Motion (SfM), can extract 3D features and reconstructions of objects/structures based on multiple photographs or video frames. The Mapping and Ocean Color Imager (MOCI) Satellite we are designing and constructing in the UGA Small Satellite Research Lab will use these techniques on a space-based platform and run a series of machine vision algorithms to produce a topographical mesh from MOCI-acquired images. A Scale-Invariant Feature Transform (SIFT) is first performed on the image set. A sparse point cloud, consisting of points identified as similar between a series of images, can be computed from a combination of SIFT and the parallax of satellite with its target area. This sparse point cloud can then be used to compute a dense point cloud. A surface mesh is computed with Poisson surface reconstruction. Initial tests have been performed to determine the feasibility of SfM mapping in Low Earth Orbit (LEO). Tests consisted of scaled graphics models in Blender software. Automatic scripts and programs were used to simulate image acquisition, then SfM was performed on the image set. Initial tests have shown SfM to be feasible at a landscape scale. Planetary SfM was performed with data from the International Space Station (ISS); it was demonstrated that cloud lines could be distinguished. Surface maps of Pluto were also generated using SfM with available data from the New Horizons Pluto fly-by.

Comparison of Anabolic Growth Factor Elution from Thrombin/Calcium Chloride Activated Platelet-Rich Fibrin Gels and Platelet-Rich Chondroitin-Sulfate Glycosaminoglycan Gels

Dru Adams, CURO Research Assistant
Dr. Sam Franklin, Small Animal Medicine and Surgery, College of Veterinary Medicine

Platelet-rich plasma (PRP) is commonly used to deliver anabolic growth factors to tissues in order to encourage tissue regeneration. However, previous studies have shown that growth factors are eluted very rapidly from PRP, potentially limiting the effectiveness of this therapy. Ionic bonding between positively charged anabolic growth factors and a negatively charged delivery vehicle could potentially result in sustained release

of these growth factors. The purpose of this study was to determine whether use of a negatively charged hydrogel would result in a more delayed elution of transforming growth factor-β1 (TGF-β1) from PRP. PRP was prepared from the blood of 9 dogs and split into two aliquots. One aliquot was activated with thrombin and calcium chloride and the other was combined with a negatively charged chondroitin-sulfate glycosaminoglycan (CS-GAG) hydrogel. The resulting gels were maintained in petri dishes for 13 days with eluent collected every 2 days. The concentration of TGF-β1 was quantified in each eluent sample using an ELISA, and differences between the two groups were assessed using a repeated measures ANOVA. The vast majority of TGF-β1 was eluted by day 5 from the thrombin gels whereas TGF-β1 elution from the CS-GAG hydrogels was more delayed. Significantly more TGF-β1 was eluted from the CS-GAG gels than standard PRP preparation for each sampling point between days 3 and 13 ($p<0.001$). The CS-GAG hydrogel resulted in a more sustained release of TGF-β1 than standard PRP preparation and further investigation of this delivery vehicle for clinical application is warranted.

Single Subunit Overexpression of NfnI in *Pyrococcus furiosus*

Leslie Adams, CURO Research Assistant
Dr. Mike Adams, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

The hyperthermophilic archaeon *Pyrococcus furiosus* contains two copies of genes that encode for the NADH-dependent Ferredoxin: NADP oxidoreductase I and II, referred to as NfnI and NfnII. NfnI is a two subunit enzyme recently characterized to be a bifurcating enzyme through its catalysis of the coupling of the oxidation of Fd and NADH to the reduction of NADP. However, NfnII, a highly similar enzyme to NfnI in regards to structure and spectroscopic properties, does not catalyze this same coupled reaction. To test whether NfnI and NfnII can form a chimeric protein, to obtain more in depth information on activity and redox properties of each subunit of NfnI, and to study the stabilities of the single subunits of NfnI, *P. Furiosus* strains were engineered to overexpress single subunits. Two of these strains, NfnI overexpression strains, are grown on a mass scale and are now being studied to determine their chimeric properties through gel filtration. Once the structure of the overexpression strains is determined, activity studies and assays will be performed to further study the overexpressed strains to give insight as to the specific kinetic and spectroscopic properties of each single subunit. The stability and interactions with Ferredoxin will be included in these ongoing studies as well to completely understand the properties of the NfnI enzyme and give insight as to why NfnII will not catalyze the same reactions despite having such a similar genetic makeup.

Attenuation of *Trypanosoma cruzi* by Fatty-Acid ß-Oxidation Monotetraallelic Knockouts

Nidhi Aggarwal, CURO Research Assistant
Dr. Rick Tarleton, Cellular Biology, Franklin College of Arts and Sciences

The hemoflagellate protozoan parasite *Trypanosoma cruzi* causes vector-borne Chagas disease, which is endemic to Central and South America as well as the southern United States, infecting >10 million individuals. Though it remains the greatest infection-based cause of heart disease, methods for diagnosing, treating and preventing *T. cruzi* infection remain ineffective. Our efforts to develop attenuated parasite lines for use in vaccination have been thwarted by technical and time-challenges of genetic manipulation of *T. cruzi*. However, recently developed CRISPR/Cas9-based methods now enable rapid gene knockouts (KO), insertional tagging, and whole genome library screens. The genes involved in fatty acid β-oxidation (FAO) in *T. cruzi* are essential; KO of both alleles of any of these genes in this diploid organism is lethal. However individual single allele KO of FAO genes attenuates parasite growth but is not lethal. To assure safety and to guard against reversion (i.e. future duplication of the remaining single allele), we propose to make multiple (up to 4) single-allele KOs in FAO genes in a single parasite line, using SaCas9 protein and specific gRNA complexes along with both serial and composite transfection strategies. Parasites with multigene KOs will be identified by monitoring gene tags inserted in the truncated gene. In addition to potential uses of these attenuated knockout lines for vaccine development, this research project is a functional application of

genome-editing tools in a high impact parasite that is both poverty driven and poverty promoting in the Americas.

Cemetery Records and the Spanish Flu in Athens, GA

Adwoa Agyepong
Dr. Susan Tanner, Anthropology, Franklin College of Arts and Sciences

Cemetery records hold unique insights to the past. They tell us more than who died; cemetery records can tell us the dates of birth, dates of death, as well as the gender of the dead. These records can give us demographic information for the cemetery and the local community, and can show us who is uniquely affected by certain diseases. This project will use cemetery records to better understand Georgia at the beginning of the 20th Century. I will focus on cemetery records from 1910 to 1920 in Athens-Clarke County, Georgia, and utilize public records, such as newspaper and public health records, for historical context. My primary goal is to compare demographic information from an Athens cemetery to records from similar cemeteries throughout the Southeastern US to assess if mortality patterns, including age at death are similar throughout the region. This project will also test for possible signatures of Influenza in the cemetery records. Newspaper accounts confirm the 1918 Influenza strain, otherwise known as the "Spanish Flu", was present in Georgia after October 1918. Previous research on the 1918 Influenza epidemic has documented that young adults were most vulnerable, with a peak of 28 years of age of death. I hypothesize that if the Spanish Flu had an effect, a rise in deaths will occur after October 1918, likely affecting young adults. This research will demonstrate how we can utilize cemetery records to better understand local history, including the health and lifeways of the community.

Microglia Activation in Rostral Nucleus Tractus Solitaries After Roux-en-Y Gastric Bypass Surgery

Mariam Ahmed, CURO Research Assistant
Dr. Krzysztof Czaja, Veterinary Biosciences and Diagnostic Imaging, College of Veterinary Medicine

One out of every 3 Americans suffers from obesity. According to the CDC, this number will only increase as the years progress, predicting that by the year 2030, 50% of Americans will be obese. An effective solution to attain long-term weight loss is Roux-en-Y gastric bypass (RYGB) surgery. During surgery, the vagus nerve is damaged, thus the brain communication with the gut is hindered. Previous research shows that innervation damage to the peripheral nervous system causes inflammation in the brain. The aim of this study was to understand these neuronal changes in the Nucleus tractus solitaries (NTS) 24-hours after RYGB surgery and 4 weeks after RYGB surgery. The experiment is conducted by collecting tissues from rats that have undergone RYGB surgery and those that had a sham surgery. The rats were perfused and their brains were dissected. The tissues were sectioned using a cryostat and stained using IBA1 antibody binding to activated microglia. Finally, microglia activation was analyzed in the stained tissues using the binary image analysis. The results of the study show that RYGB surgery is activating the microglia in the NTS both 24 hours and 4 weeks after surgery. In conclusion, RYGB surgery is altering gut-brain communication by inducing long-term inflammation in the NTS. This altered communication may be a key factor in the mechanism of reducing body weight post-surgery.

Sex-Trafficking in Georgia: Equipping Our Hotel Workers with the Proper Resources

Avni Ahuja, Foundation Fellow
Dr. Jody Clay-Warner, Sociology, Franklin College of Arts and Sciences

Human trafficking, referred to as "modern-day slavery," is a crime and a human rights violation. It is also the world's fastest growing criminal industry. The FBI ranks Atlanta as one of the top cities for child sex-trafficking, but this form of trafficking pervades almost every part of Georgia. Sex-trafficking, one of many forms of trafficking, is especially prevalent in hotels and motels. Traffickers and those purchasing sex capitalize on the privacy extended by lodging establishments and function with low risk of detection when staff and community members are unable to recognize signs of human trafficking. In this project, it is proposed that lodging establishments require their employees undergo training that teaches them to

recognize signs of sex-trafficking and report those signs to appropriate law enforcement agencies. Though the state of Georgia has taken many steps to counter sex-trafficking, many of these solutions are embedded within the justice system and seek to reform judicial process. While these solutions are important, more needs to be done on the forefront to identify victims and potential victims so that they can be removed from a dangerous situation and provided with restorative resources. Trafficking in lodging establishments presents a risk to the security of a hotel's business and its lawful hotel customers. Thus, the proposed policy benefits everyone in the state of Georgia. This project was completed by analyzing relevant research, legislation, and other government documents.

Studying Breast Cancer Metastasis to Bone Using Tissue Engineering

Jenna Evelynn Al-saleh, CURO Research Assistant
Dr. Cheryl Gomillion, Chemical, Materials, and Biomedical Engineering, College of Engineering

Breast cancer metastasis to bone can be detrimental for breast cancer patient outcomes. Currently, the mechanisms by which cancer is able to bypass bone tissue defenses, invade the tissue, and proliferate once settled in bone tissue sites are unknown. Many theories regarding chemical and signal cascades that allow for metastasis have surfaced; however, no clear cause has been identified. To develop more effective therapeutics, it is essential to understand this process. Tissue models of the microenvironments involved can help; several studies suggest that tissue stiffness has a direct correlation with breast cancer's ability to spread or metastasize. The objective of this work was to create an in vitro model of adipose tissue that mimics the breast tissue environment. Once a successful scaffold was created, we aimed to alter the stiffness of the scaffold to mimic native bone and study any resulting tumor cell changes. We prepared various percent solutions of low, medium and high molecular weight chitosan (1%-5% weight/volume), and hydrogel scaffolds were fabricated using chitosan cross-linked with sodium hydroxide. Scaffolds were characterized to evaluate the strength and storage modulus of the viscoelastic material to determine which solution best mimicked breast tissue's elastic modulus. Next, metastatic breast cancer cells were evaluated within the chitosan scaffolds to assess cell proliferation and signaling markers to determine if our model was feasible for further studies. Based on the research and results, we realized that further steps need to be taken to successfully study breast tissue stiffness and cancer metastasis.

College Students' Beliefs and Perceptions towards Nature and Campus Sustainability

Evan Alden
Dr. Jennifer Rice, Geography, Franklin College of Arts and Sciences

Our research on campus sustainability and the attitudes behind it aims to better understand the attitudes and beliefs behind the action or non-actions of students in the sustainability realm. We inquired, using a Qualtrics survey, into their personal actions, as well as their views and understandings of the actions for sustainability around them, whether this action is led by their peers or the university itself. We believe that the way students understand nature will affect the ideas they hold about their individual actions and therefore their ideas about sustainability and personal or large-scale involvement in sustainability efforts. After conducting our research, we connected the results back to this hypothesis and to social theory ideas such as social construction and neoliberalism. The results found that students who felt that their individual actions affected the environment were significantly more likely to attempt or adopt a lifestyle changes to benefit the environment, supporting our ideas about social (and therefore personal) construction of nature around us leading to the neoliberal trend towards individual action to benefit the environment. However, our results also supported that a significant portion of students tend to idealize nature, not bringing it into their personal realm and therefore not necessarily worrying about the effects of their actions.

Textiles and Fibers Single Point of Contact (SPOC)

Shelbi Aldrich, CURO Research Assistant
Dr. Suraj Sharma, Textiles and Merchandising, College of Family and Consumer Sciences

The goal of my research was to build an online textile database, or a Single Point of Contact, to be referenced by consumers and UGA Extension agents in the new Textiles division. The main research questions that I had to solve were, "What data should be included in the Single Point of Contact," and "What is the best way to organize the content online for both the consumer and the agent?" In order to address these questions, I did extensive research on textiles, garment quality and selection, and textile care through textile-related Extension files made available to me. Additionally, I worked with an IT professional to learn the best methods to use to turn my findings into an online database. The most logical place to develop the Single Point of Contact was on the pre-existing FACS Outreach web page, adding my research findings in a separate textiles section. The results are a fully-functioning web page for consumers to visit in order to find information on textiles, with a separate password protected portal providing information exclusively to UGA Extension Agents.

Comparing the AX3 and MetaSensor Accelerometers for Measuring Muscle Twitch

Rachel Aldridge, CURO Research Assistant
Nivita Sharma
Dr. Kevin McCully, Kinesiology, College of Education

Fatigability is an important characteristic of skeletal muscle, particularly in clinical populations. A clinically relevant endurance test has been developed that uses accelerometers to measure chances in muscle movement in response to electrically induced muscle twitches. We aimed to determine if transverse or parallel placement of the accelerometer on the muscle altered signal/noise ratios (s/n) and to compare the s/n of two triaxial accelerometers, each manufactured by a different company (MetaSensor and AX3). Twitch acceleration measurements were performed on the left vastus lateralis muscle of two able-bodied females. Electrical stimulation was performed using a medical grade electrical stimulator (Theratouch 4.7, Rich-Mar). The s/n was quantified by measuring the ratio between the vector amplitude of the first vibration of the muscle twitch and the peak to peak noise between muscle twitches. Transverse orientation of the AX3 and MetaSensor accelerometers yielded a 15% higher s/n ratio than the parallel orientation (transverse = 50.3, parallel = 36.6). Consequently, transverse orientation was used to compare s/n ratios between the accelerometers. The MetaSensor accelerometer (60.5) had a 50% larger signal to noise ratio than the AX3 accelerometer (29.9). Transverse orientation seemed to provide higher s/n ratios, even if the accelerometers are triaxial. The less expensive MetaSensor ($45 versus $200) may have better s/n ratios than the AX3. However, both accelerometers had adequate s/n ratio to perform measurements of muscle fatigability.

Archetypal Features of the Graphical User Interfaces of Electronic Medical Records and Their Cognitive Burden on Users

Eliza Ali, CURO Research Assistant
Dr. Dale E Green, Health Policy and Management, College of Public Health

This research examines common and arguably necessary attributes of electronic medical record (EMR) systems and the impact of their organization on end users. Specifically, this research will examine how to make the workflow of an ambulatory outpatient facility more efficient while optimizing quality. The specific groups of the workflow that will be analyzed are front desk staff, clinical support, and practitioners. The first part of the research involves designing a standard archetype of a graphical user interface of an EMR for each part of the chosen workflow in the form of a series of screens. EMRs are pervasively used in the United States today, and ill-designed EMR systems can cause issues with liability, privacy, and patient safety. Each health information system vendor designs their own user interfaces, often with staff from a technology background with little experience with or understanding of the health care system. Therefore, the second phase of research involves designing and administering an evaluation that will measure the cognitive burden the archetype has on volunteers that have used an EMR before. The evaluation will be in the form of a test in which each question will have a time limit. During the evaluation, an eye tracking tool will be used to monitor and later evaluate what the users' eyes are drawn to. Determining ways to alleviate

the cognitive burden of EMR systems on end users can provide insight to the creators of these systems and may lead to the development of more intuitive, safe and streamlined software.

Investigating Performance of *Agraulis vanillae* on *Passiflora incarnata*: A Geographic Mosaic Approach

Sehar Ali, CURO Research Assistant
Dr. Rodney Mauricio, Genetics, Franklin College of Arts and Sciences

Plant populations in different geographic locations are subject to interactions with multiple different herbivore species. These interactions can result in defense traits evolving in plant populations that are specific to the local herbivore community, which may ultimately result in differences in defense traits between plant populations across a large geographic distribution. This pattern is formally known as the geographic mosaic of coevolution hypothesis. One test of this hypothesis is to measure how interactions between plants from different populations affect herbivore performance with the assumption that herbivore species will perform differently on plants they are accustomed to (local populations) and ones they are naïve to (foreign populations). We tested this prediction by conducting two feeding experiments with *Agraulis vanillae* on *Passiflora incarnata* plants from different regions of the United States. We measured performance traits in *A. vanillae* including survival, development time, and pupation weight. We found that development time of *A. vanillae* did vary depending on which plant populations they fed on. This study provided another example of the incredibly intricate dynamics of the geographic mosaic of coevolution between plants and insect herbivores.

Development of Polymer-Based Microspheres for Drug and Supplement Delivery

Kirsten Allen, CURO Research Assistant
Dr. Karen J L Burg, Small Animal Medicine and Surgery, College of Veterinary Medicine

The development of polymer-based microspheres as a subset of novel drug delivery was investigated. These spherical beads have the potential to hold and release certain drugs such as various proteins and fatty acids. Within a specific environment in the body and at a set point in time, microspheres are degradable and will release their content. This allows for a controlled release of the drug at the target site of the body. To facilitate bead development, a sample drug, such as bovine serum albumin (BSA), or gelatin, can be encapsulated in microspheres composed of polylactide (PL) using poly-vinyl alcohol (PVA). Microspheres can be prepared using a single emulsion, solvent evaporation method. In this work, polymeric microspheres of varying BSA and gelatin concentrations were created to characterize their dimensions and thermal properties. The BSA and gelatin encapsulated microspheres were also quantified for their encapsulation efficiency using a BCA assay and a hydroxyproline assay respectively. Current work involves the encapsulation of fatty acids, like linoleic acid, within polylmeric microspheres to serve as a protective transport system in ruminant digestion. These lipid encapsulated microspheres will be characterized using microscopy, compression testing, differential scanning calorimetry, and biodegradability testing to measure encapsulation efficiency. The linoleic acid encapsulated micropsheres will be optimized to support ruminant nutrition and health.

Geography of Kurdistan

Bilind Amedi
Dr. Amy Ross, Geography, Franklin College of Arts and Sciences

In international affairs today, the region known as Kurdistan is vitally important. It is located in Syria, Turkey, Iran, and Iraq. The United States (US) is currently engaged in a battle with ISIS in the air while the Kurdish army has boots on the ground fighting. How important is the US relationship with the Kurdish people? Can the US ally with the Kurdish people, and if so, what might be the affects on the US relationships with Turkey, Syria, Iran and Iraq? The US has had a big impact on Kurdistan dating back to Saddam Hussein's regime and the Iraq wars. In addition, Kurdistan has its own issues, such as statelessness, corruption, and persistent persecution. In my research, I seek to learn from the history and geography of Kurdistan, in relation to the Middle East and the US. This preliminary study of the

geography and international relations of Kurdistan will help me develop my research objectives for a future field-based study in Kurdistan.

Chemical Weapons and the Legacy of War

Ali Elizabeth Anderson, CURO Honors Scholar, CURO Research Assistant
Dr. James W Porter, Ecology, Odum School of Ecology

Between 1940 and 1970, more than one million metric tons of chemical weapons were dumped into the world's oceans. As the official policy of disposal, this method has resulted in decades of environmental damage and put people at risk. Even three-quarters of a century after the end of WWII, coastal zone communities around the globe still encounter these toxic munitions. While scientists and policymakers have worked to quantify and address the hazards of chemical weapons in the Baltic Sea and several other European waterways, this study focuses on the location and quantity of chemical weapons dumped in the tropical Pacific, where these weapons were stockpiled as the United States advanced toward Japan in the closing years of the war. This study will assess the impact of chemical weapons on economic development on several islands, policies regarding chemical weapons, and examine the limitations of the Organization for the Prohibition of Chemical Weapons to address these problems. The study was conducted via the collection and analysis of primary and secondary documents from a variety of sources, including historical data, maps, government reports, and scientific articles. While the war is long over, the toxic legacy of these weapons lingers both in the ocean and on adjacent lands. The challenge to find, retrieve, and destroy them remains.

Controlled Linoleic Acid Release in a Hydrogel-Based Mammary Adipose Tissue Model

Kerri Andre, Foundation Fellow, CURO Research Assistant
Dr. Cheryl Gomillion, Chemical, Materials, and Biomedical Engineering, College of Engineering

The female breast is largely comprised of fat, or adipose tissue. There is evidence that adipose tissue-related factors, such as fatty acids, affect cancer cell growth and spreading to other tissues; however, these mechanisms are not clearly understood. We aim to develop a hydrogel-based in vitro model system, mimicking the mammary adipose tissue microenvironment, to study the effects of fatty acids, such as linoleic acid (LA), on breast tumor cell behavior. Chitosan is a favorable biopolymer choice for this model because of its many excellent properties, including being antimicrobial, biodegradable, and biocompatible, in addition to its crosslinking ability. Thus, chitosan microspheres (beads) were used to yield controlled, timed, and steady release of fatty acid to more closely mimic the in vivo environment found in breast tissue. A preliminary two-dimensional (2D) study of breast cancer cells treated with either high or low doses of LA showed that both doses resulted in a negative effect on cell metabolic activity over the course of seven days, suggesting that lower level, slower release would be more optimal for our model. In a follow-up study, the controlled release of LA from chitosan bead models was successfully documented over the course of ten days, suggesting that chitosan beads can be utilized to create a mammary adipose tissue model for studying breast cancer cell behavior. Interaction of breast cells with the fatty acid-loaded beads will be evaluated with future work to further demonstrate the feasibility of this model.

Family Functioning and Health-Related Quality of Life in Adolescent and Young Adult Transplant Recipients

Lauren Ellis Arnold
Dr. Ronald L Blount, Psychology, Franklin College of Arts and Sciences

This work aims to determine the impact of family functioning in relation to health related quality of life (HRQOL) for adolescent and young adult (AYA) solid organ transplant recipients. HRQOL in this population is significantly lower than that of the general population. The purpose of this project is to examine if family functioning within the AYA solid organ transplant recipient population impacts HRQOL. Participants include 64 liver, heart, or kidney recipients ages ranging from 12-21 years (Mage=16.91 years, SD=2.03) and their caregivers (N=64). Caregivers completed measures of family adaptability and cohesion, and AYA HRQOL. AYAs completed self-report

measures of HRQOL. AYA-self and caregiver-proxy-reports on HRQOL in relation to family function were related to one another ($r=.58, p<.01$). Caregiver-reported family cohesion and flexibility were positively associated with caregiver reported HRQOL (both $r=.35, p<.01$). Family flexibility was also correlated with AYA self-reported HRQOL ($r=.29, p<.023$). Family functioning is significantly related with AYA HRQOL. Better family functioning for these individuals is associated with HRQOL. Intervention efforts to improve family cohesion and flexibility may result in improved HRQOL for AYA solid organ transplant recipients.

The Effects of Phthalate Exposure in Female Germ Cells

Gazal Arora, CURO Research Assistant
Dr. Maria M Viveiros, Physiology and Pharmacology, College of Veterinary Medicine

Errors in meiotic division can lead to aneuploidy, which is a major cause of pregnancy loss and congenital disorders such as Down syndrome. Studies indicate that exposure to environmental toxins can disrupt reproductive function, including meiotic division in female germ cells (oocytes). An increasingly prevalent group of environmental toxicants includes phthalates, used to soften and increase the flexibility of plastics, which are considered endocrine disrupting chemicals. The objective of this study was to test the effects of di (2-ethylhexyl) phthalate (DEHP), a commonly used phthalate, on meiotic division in mouse oocytes. Cumulus-enclosed oocyte complexes (COCs) were collected from the ovaries of PMSG-treated female mice and cultured for 17 hours with increasing DEHP concentrations (0, 1, 10, 100 μg/ml). The oocytes were then fixed for immunofluorescence analysis. The spindle microtubules and the microtubule organizing centers (MTOCs) were labeled with anti-acetylated tubulin and pericentrin antibodies, respectively, and the chromosomes detected with DAPI. All oocytes were analyzed using an upright fluorescent microscope and imaging software. The rate of oocyte maturation to metaphase-II (MII) and incidence of chromosome misalignment did not differ significantly with increasing DEHP exposure. However, direct measurements revealed a disruption in meiotic spindle organization in response to DEHP, particularly in metaphase-II (MII) stage oocytes. The MII spindles were characterized by reduced spindle length and less focused (broader) spindle poles. These data indicate that DEHP can disrupt meiotic spindle organization, which is necessary for accurate chromosome segregation.

Insect Resistance Characterization of *IRP9* in Soybean

Praharshak Asireddy, CURO Research Assistant
Dr. Wayne Parrott, Crop and Soil Sciences, College of Agricultural and Environmental Sciences

Salicylic acid (SA) is an important signaling chemical in plants, most notably acting as a hormone for pathogen resistance. The *IRP9* gene is a SA synthase gene from the bacterium, *Yersinia enterocolitica*. When introduced into plants, *IRP9* increases SA production, leading to improved pathogen resistance. However, SA can have an antagonistic relationship with jasmonic acid (JA), which is vital to a plant's insect resistance. In particular, increasing SA levels in soybean, *Glycine max*, is of agronomic interest to obtain increased pathogen resistance, but due to the antagonistic nature of SA and JA synthesis, the plant's resistance to insects could possibly worsen as SA production increases. Therefore, four lines of soybean with the *IRP9* gene engineered into them will be tested for insect resistance. These lines show increased SA levels ranging from 2 to 14 times higher than normal, and will be tested for resistance to the soybean looper (*Chrysodeixis includens*), by determining if the plants can inhibit growth of caterpillars feeding on them for 14 days. The usefulness of this gene for agriculture will be determined by the extent to which it affects insect resistance.

Changes in Distribution of Black-Bellied Whistling Ducks (*Dendrocygna autumnalis*) in the Southern Atlantic Flyway

Samantha Askin, CURO Research Assistant
Dr. Michael Chamberlain, Forestry, Warnell School of Forestry and Natural Resources

Whistling ducks have been reported in Florida, South Carolina, and Georgia. To date, there have been no studies evaluating distribution of

whistling ducks throughout the southern Atlantic Flyway, or the potential for an expanded geographic range. My objectives were to describe and map changes in distribution of whistling ducks through the southern Atlantic Flyway, determine potential movement routes, and identify potential factors influencing expanded distribution. State agencies provided banding and recovery data sets from 2006 - 2016. Citizen scientist data from 2006 - 2016 from eBird.org and the Cornell Ornithological Laboratory was also used. I used ArcGIS v. 10.4 to create maps that represented location and potential movement routes, providing a unique way to visualize change in their distribution. I used these maps to identify potential movement routes and geographic distribution of whistling ducks. 109 counties had sightings of whistling ducks during 2006-2016; Florida had the most rapid expansion, followed by Georgia and South Carolina. The birds in the southern Atlantic flyway are migrating north to south, rather than east to west. Future work could expand this research to look at the genetics of birds in the southern Atlantic flyway to identify where they are originally from. My overall suggestion would be to use results collected from this research to propose new management strategies for Black-bellied whistling ducks in the southern Atlantic flyway.

Multimerization of Long DNA Inserts via Bombardment

Brooke Aspinwall, CURO Research Assistant
Dr. Kelly Dawe, Genetics, Franklin College of Arts and Sciences

To transform plants, transgenes are often introduced using *Agrobacterium* because of the stability of insertion. Gene inserts from *Agrobacterium* are limited to about 30kb in size. Transformation via particle bombardment, or biolistic transformation, can insert larger DNA constructs than *Agrobacterium*, but it is less stable and has lower gene expression than *Agrobacterium* transformation. DNA inserted with biolistic transformation is thought to have more rearrangement, but it has never been definitively proven. Bombardment is used to transform a wide variety of plants and can use DNA in a range of forms to insert genetic constructs. Still, there are many unanswered questions associated with biolistic transformation, such as how large of a construct can be inserted, if rearrangement occurs, and if DNA pieces could be inserted and assembled into a larger construct. To test these questions, rice and maize were biolistically transformed with lambda DNA, which has sticky ends that are capable of joining together. Whole-genome sequencing will be used to figure out where the DNA was inserted, if the DNA joined together, and if rearrangements occurred.

Mechanistic Relationships Between Mga and Myc During Zebrafish Development

Adam Greg Aston
Dr. Scott Dougan, Cellular Biology, Franklin College of Arts and Sciences

This study focuses on the normal interactions of MAX Gene Associated (MGA) transcription factor and Myc during zebrafish development as well as its possible role in tumorigenesis. The *mga* gene encodes a transcription factor with two DNA binding domains conserved in humans, mice, and zebrafish, and is involved in cell cycle regulation and differentiation. In vitro, Mga antagonizes Myc, an oncogene previously well-studied. There is no current evidence documenting the relationship between Mga and Myc in vivo. To study the transcriptional activity of Mga in zebrafish, the morpholino system is utilized to knock down Mga. A morpholino is an oligonucleotide that binds to specific mRNA sequences and blocks their translation or splicing resulting in reduction of expression of their protein products. Injection of *mga* morpholinos in embryos can yield phenotypes including a wide array of defects in neural crest development and organogenesis. Given that Mych, a c-Myc homolog in zebrafish, is reported to be involved in neural crest formation, we used a reporter construct to determine if the morphant phenotype is due to the antagonistic role of Mga. The reporter construct contains a luciferase gene under the control of a minimal promoter and four E-boxes. By analyzing the reporter gene expression, the results should allow for a better understanding of Mga and Myc interaction in vivo during embryonic development and in human cancer.

The Effect of Age on Functional Connectivity of Cognitive Control Networks in People with Schizophrenia

Emma Auger, CURO Research Assistant
Dr. Jennifer McDowell, Psychology, Franklin College of Arts and Sciences

The integrity of cognitive control (CC) is related to the functional connectivity of brain networks as assessed by resting-state functional magnetic resonance imaging (rsfMRI). Good CC is associated with strong within network connections, like those in the executive control network (ECN, composed of frontal-parietal regions and recruited during CC); and strong differentiation between networks, like between the ECN and the default mode network (DMN, composed of midline regions and suppressed during CC). Resting-state networks change over the lifespan in healthy individuals and reflect changes in CC. People with schizophrenia experience CC deficits and disrupted brain connectivity of both networks in early and mid-adulthood. While there is some evidence that schizophrenia may be a neurodegenerative disorder, it is uncertain if age-related connectivity changes are similar between schizophrenia and healthy comparisons, especially when healthy comparisons have similar cognitive deficits (low cognitive control, LCC). In this study, people with schizophrenia (n=28) and healthy comparisons with LCC (n=28) will complete a resting-state scan. Each group will be further subdivided by age: younger individuals (20-35 years) and older individuals (44-63 years). To quantify the effect of age on CC network connectivities and how they might be different across the two groups, we will perform a group by age ANOVA on functional connectivity of the DMN and ECN. We hypothesize that older individuals will have less network connectivity compared to younger individuals. Using the neurodegenerative theory of schizophrenia, we anticipate this difference to be larger in people with schizophrenia.

Punitive or Positive: How University Affirmative Consent Policies Can Be Framed for Maximum Effect

Prentiss Rachel Autry, CURO Research Assistant
Dr. Justine Tinkler, Sociology, Franklin College of Arts and Sciences

While many college campuses have recently changed their sexual misconduct policies, there has been little consistency in the framing of these statements. This study, conducted through the Laboratory for the Study of Social Interaction, seeks to determine how university policies can best be presented to affect the most social change. Participants in this study are undergraduate students, given one of four randomly assigned policy statements and then asked to answer questions assessing their memory and understanding. The study has been pilot tested and researchers are currently collecting data. The findings of this study could have direct impact on university policy framing and will shed light on how policies impact cultural beliefs and behavior.

Chondroitin Sulfate Glycosaminoglycan Matrices Promote Neuroprotection Sub-Acutely Post-Traumatic Brain Injury

Nivedha Balaji
Dr. Lohitash Karumbaiah, Animal and Dairy Science, College of Agricultural and Environmental Sciences

A traumatic brain injury (TBI) is defined as a penetrating wound to one's head that affects brain function. In the United States, an estimate of 2.4 million illnesses and deaths each year can be traced back to TBIs. There are two distinct periods in TBI: primary and secondary. The primary injury results from the initial force, causing tissue shearing and compression. The secondary injury results as a consequence of the primary injury and causes further tissue loss. Currently there are no effective treatments for the secondary loss of tissue post-TBI. We hypothesized that chondroitin sulfate glycosaminoglycan (CS-GAG) matrices or CS-GAG matrices along with rat PKH26GL labeled allogeneic neural stem cells (NSCs) help facilitate tissue repair. The treatments were delivered intracortically 4 weeks post-TBI. A histological analysis was conducted to demonstrate differences between treated and control groups. Nissl staining showed CS-GAG treated animals demonstrated enhanced neuroprotection ($p<0.05$) when compared to controls and NSC-only treated animals. Sox-1 and Ki67 staining indicated enhanced proliferation and maintenance of undifferentiated ($p<0.05$) NSCs in the CS-GAG-NSC treated rats. There was high retention of FGF-2 ($p<0.05$) in CS-GAG and CS-GAG-NSC treated animals. There was enhanced presence of

CD68+ macrophages ($p<0.05$) in animals treated with NSC only and CS-GAG-NSC. All treatment and SHAM control groups illustrated weakened presence of GFAP+ reactive astrocyte ($p<0.05$) in the lesion site when compared to TBI controls. These observations provide further evidence for the potential application of CS-GAGs as neuroprotective agents post-TBI.

Revising the Classics: Modern and Contemporary Female Authorial Treatment of Unactualized Characters from Greek Myth

Manisha Banga
Dr. Benjamin M Wolkow, Classics, Franklin College of Arts and Sciences

This work analyzes contemporary female authors' use of ancient Greek and Roman myth in their writing. The research is in two parts, where Part I analyzes authorial reinterpretation of marginalized characters from ancient myth and Part II analyzes authorial reinterpretation of heroes from ancient myth. Where female authors generally attempt to provide newfound voice and sympathy for ancient characters, a more complex process occurs in reinterpretations of heroes. In one method, contemporary female authors villainize ancient heroes as a mode of catalyzing sympathy for marginalized characters who are abused by heroes. In the second method, authors feminize ancient Greek heroes. By feminizing traditionally hypermasculine heroes, female authors reverse traditional norms and thereby engage in feminist revisionism. I analyze works from a diverse array of contemporary female authors, including Margaret Atwood, Anne Carson, Sarah Ruhl, Madeline Miller, and H.D.

Depletion of a Key Maternal Protein Impairs Early Embryonic Development

Wendi Bao
Dr. Maria M Viveiros, Physiology and Pharmacology, College of Veterinary Medicine

Aneuploidy in embryos is a major cause of congenital disorders as well as pregnancy loss, and is attributed to error-prone meiotic division in oocytes. The accuracy of chromosome segregation is dependent on stable spindle formation, which is regulated by unique acentriolar microtubule organizing centers (aMTOCs) in oocytes. To test aMTOC function we developed a unique transgenic (Tg) mouse model in which a key protein, Pericentrin (Pcnt), was knocked down exclusively in oocytes. We previously demonstrated that oocyte-specific loss of Pcnt in Tg mice disrupts spindle organization, leading to highly error-prone meiotic division and significant female subfertility. The current study assessed the basis of embryonic loss in Tg mice lacking maternal Pcnt. Ovulated metaphase-II oocytes were collected from control (WT) and Tg females and in vitro fertilized with control sperm. Presumptive zygotes were fixed for immunofluorescence analysis at 24 hour intervals post-fertilization to evaluate the development of pre-implantation stage embryos. While loss of maternal Pcnt delayed the first mitotic division, there was no significant difference between the WT and Tg groups in the overall 2-cell cleavage rates by 24 hours post-fertilization. Similar rates of embryos also developed to the morula and blastocyst stages. However, blastocysts derived from Pcnt-depleted oocytes showed an increased incidence of mitotic errors, and contained significantly fewer total cell numbers, attributed to a pronounced decrease in trophectoderm lineage cells specifically. These data demonstrate that ablation of maternal Pcnt disrupts early embryonic quality, which likely contributes to lower fertility in Tg females.

Organic Fertilizer Improves Revegetation of Roadside Soils

Evan Barnard, Ramsey Scholar
Dr. Nina Wurzburger, Ecology, Odum School of Ecology

Urbanization and road construction affect the global carbon cycle by releasing carbon from soil and reducing carbon inputs into soil from plant productivity. Revegetation of areas disturbed by construction can replenish soil organic matter, thereby increasing plant productivity and soil carbon storage. Plant restoration of disturbed roadsides can be facilitated by the application of fertilizers. However, fertilizers (i.e., organic or inorganic) vary in their effectiveness and carbon footprint. We conducted a plant growth experiment using *Elymus virginicus* and soils sampled along roads in Atlanta, GA to investigate how fertilizer treatments affect plant growth. We

performed a two-way factorial experiment, with two factors (inorganic or organic fertilizers), each with two levels (with or without), crossed to create four experimental treatments. We hypothesized that both inorganic and organic fertilizers would increase plant growth, but that plants grown with organic fertilizer would produce more biomass compared to those receiving inorganic fertilizer. Following twelve weeks of growth, we quantified plant growth, root:shoot ratios, soil microbial biomass, and soil nutrient and pH pools. We found that both inorganic and organic fertilizers increased plant biomass and decreased the root:shoot ratio, and addition of organic fertilizer increased plant biomass more than the addition of inorganic fertilizer. Our findings suggest the addition of organic fertilizer as an effective management tool for revegetating disturbed roadsides, promoting greater carbon sequestration in urbanized areas and counteracting the rise in atmospheric greenhouse gases.

Nutrition of Women and Adolescent Girls in Conflict Zones

McKenna Barney, Foundation Fellow
Dr. Maria Navarro, Agricultural Leadership, Education, and Communication, College of Agricultural and Environmental Sciences

This study focuses on the effects of malnutrition on women and children in conflict zones in developing countries and the efforts taken by governmental and non-governmental organizations to improve the health of these vulnerable community members. I used a meta-analysis of case studies completed on malnutrition in conflict zones including Chiapas, Afghanistan, Syria, and others to look for common causes and complications that could provide insight into how to better fight malnutrition in these areas. I also explore successful and unsuccessful attempts to assuage malnutrition in conflict zones and the reasons behind their relative impacts. By analyzing programs implemented by both governments and non-governmental organizations, this research can help to identify recurring problems with planning and implementation of nutrition promotion in regions plagued by conflict. Based on an extensive literature review, this research found that conflict exacerbates the issue of malnutrition due to disruptions in the food supply, economic instability, poor sanitation, safety concerns, and inadequate government services. On an individual level, exposure to trauma can interfere with breastfeeding among mothers and proper caloric intake among children. This study demonstrates that malnutrition in conflict zones is not simply caused by lack of food availability or improper utilization, and highlights key challenges development organizations experience when working to ensure food security.

The Financial Obligations of Owning a Pet

Ellen Barrow, CURO Research Assistant
Dr. Brenda Cude, Housing and Consumer Economics, College of Family and Consumer Sciences

This study was undertaken to discover the average financial obligations of owning a pet, especially for students in college. Specifically, we hoped to discover what pet related expenses are most common outside of regular expenses such as food and basic care. I wanted to explore the topic of pet insurance and whether students may find this service useful, as well as what plans are offered. To get a sense of what information would be relevant in analyzing these problems, informational interviews were conducted with students and other pet owners. The results were used to help formulate the questions we wanted to ask in our survey. Currently, the survey is planned to ask students and pet owners about their average expenses, un-planned expenses, and the costs and benefits of owning a pet. I have reached out to local veterinarians' offices to get their help to gain survey participants. After the survey results are available, I will analyze the benefits that having pet insurance provides compared to the average costs that pet insurance would cover. I will then use the data to make recommendations to students on whether pet insurance would be a beneficial endeavor. Finally, I hope to provide an average cost and time commitment in relation to pets to help better prepare future pet owners for their responsibilities.

Examination of Courtship Songs across *Drosophila subquinaria* Populations

Sophie Alexandra Barton
Dr. Kelly Dyer, Genetics, Franklin College of Arts and Sciences

The *Drosophila* genus is famous for its elaborate courtship behaviors that vary between species, populations, and individuals. Male fruit flies use a multitude of sensory signals to court a female, including pheromones, tapping, licking, and wing vibrations. Wing vibrations, which produce songs, are of particular interest, as they have been found to be acted upon by sexual selection and vary greatly between species. There are two major categories of song types produced by *Drosophila* flies—the sine song and the pulse song. The sine song is a continuous "humming" song that often comes before or after the more prominent pulse song. As its name suggests, a pulse song consists of a string of pulse sounds called a "burst." Many studies focus on the interpulse interval (IPI) between bursts because they are unique to each species and contribute to species recognition. *D. subquinaria*, a species whose songs have not been studied extensively, has been found to produce only pulse songs, which vary greatly between populations. In populations that are sympatric with the recently diverged *D. recens*, *D. subquinaria* females discriminate against conspecifics from other populations. This discrimination is likely in part due to fundamental song difference between populations. The present study sought to determine what differences in the characteristic songs of sympatric *D. subquinaia* and two other allopatric *D. Subquinaria* populations might be used as cues for discrimination. We recorded courtship songs of the three populations for analysis. It is expected that IPI will differ greatly across populations.

Unfamiliar Stone Hammer Use in Juvenile Bearded Capuchin Monkeys

Sophie Alexandra Barton
Sreinick Keo, Rushi Ketan Patel
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts and Sciences

Wild bearded capuchin monkeys in Fazenda Boa Vista, Piauí, Brazil regularly use stone tools to crack open nuts. They place nuts in shallow pits on anvil surfaces, which they strike with a hammer stone. Adults must accumulate years of experience to become efficient nut crackers—it takes more than six years for juveniles to become proficient. The monkeys use exploratory actions prior to striking the nut, such as flipping the stone and knocking the nut. Capuchin monkeys show individual variability in hand positions on the stone during the lifting and striking with the stone. The present study seeks to determine how the exploratory actions, stone grips, and strike success of juvenile capuchin monkeys differ from those of adults. Videos of individual monkeys cracking nuts using an unfamiliar stone at the field site in Brazil were coded for the first 20 strikes. We expect that juvenile monkeys use a more diverse set of exploratory actions, use more variable and inefficient stone grips, and have less striking success than adults, due to their smaller size and inexperience. Preliminary data suggests that juveniles are less consistent in stone hand positioning, use exploratory stone flipping actions more often, and frequently try to crack two nuts at once, which leads to lesser striking success. These and subsequent findings will provide insight into the development of stone tool use behavior of these monkeys and other species, including extinct hominins.

Obstructed Labor: Analyzing Realistic Implementations for Developing Countries to Decrease Maternal Morbidity

Hannah Bass, CURO Research Assistant
Dr. Trina Salm Ward, Health Promotion and Behavior, College of Public Health

Obstructed labor is one of the leading causes of preventable maternal death in underdeveloped countries. This mechanical problem occurs when the head of the fetus cannot fit through the mother's pelvis during child birth, even when healthy contractions are present. Cases of obstructed labor can be easily overlooked, especially since there are not definitive indicators for mothers at risk. Timely diagnosis is crucial for the heath of both the mother and child; however, there are several delays specific to developing countries that hinder a mother from obtaining the proper treatment in time. Once the obstructed labor is recognized, the mother can undergo cesarean section, have an assisted vaginal delivery, or undergo a symphysiotomy. The goal of my research is to understand risk factors and prevention of obstructed labor, as well as the best practices and treatment that could be realistically implemented in developing countries. I searched peer-reviewed articles between the years 2000 and 2017 that describe solutions for decreasing the chance of maternal morbidity due to obstructed

labor. I compiled article information and will synthesize literature results. This research will lead into a plan for deciding on the most effective practices and treatments, as well as areas for future work and improvements with regard to the available resources in underdeveloped countries.

Psychosocial Functioning and Barriers to Medication Adherence in Adolescents Awaiting Solid Organ Transplants

Haley Bearden, CURO Research Assistant
Dr. Ronald L Blount, Psychology, Franklin College of Arts and Sciences

Medication adherence is a significant concern for solid organ transplant candidates, parents and healthcare providers. Barriers to medication adherence have been related to treatment barriers (e.g., hospitalization, rejection episodes, and death) and internalizing symptoms in children and adolescents who have received solid organ transplants. Little research has been done to explore the association between medication adherence and psychosocial functioning (e.g., anxiety, depression, and attention problems) among adolescent patients before they receive their transplant. The purpose of this study is to examine medication adherence and psychosocial functioning among pediatric candidates awaiting solid organ transplants in order to prevent treatment barriers. The population includes 35 adolescents ranging from ages 12-20 (M= 15.99, SD= 2.35) awaiting solid organ transplants (54.3% kidney, 22.9% liver, and 22.9% heart). Participants were recruited at the Transplant Services Clinic at Children's Healthcare of Atlanta. Participants completed self-report measures on psychosocial functioning and barriers to adherence using paper-and-pencil measures while at their pre-transplantation evaluation appointment. Total barriers to medical adherence were positively correlated with attention problems ($r=.34$, $p=.05$) and depression ($r=.56$, $p<.001$). Correlations between barriers and anxiety and hyperactivity were not significant. Significant between-organ group differences in barriers to adherence were also found between kidney recipients (M=44.10, SD=36.75) and heart recipients (M=31.88, SD=39.63). Identifying the significant relationship between psychosocial functioning and barriers to medication can help prevent treatment barriers and improve the health of adolescents awaiting transplantation.

Two-Point Threshold as a Measure of Hyperacuity and Intraocular Scatter

Jacob Beckham, CURO Research Assistant
Dr. Lisa Renzi Hammond, Psychology, Franklin College of Arts and Sciences

Intraocular scatter from anterior optics and subsequent glare is one of the more prevalent forms of visual disturbance in adults and is a significant cause of automobile accidents in the US. This scatter forms a normally distributed intensity curve (the point-spread function), which can be measured. For example, two point sources of light produce two incident rays whose intensity curves may overlap, causing a subject to only perceive one light source (the Rayleigh criterion). The purpose of this experiment is to establish this two-point threshold as a measure of hyperacuity related to intraocular scatter, and to determine the contribution of both wavelength and intensity to that scatter. Emmetropic (20:20 uncorrected, Snellen notation) participants were recruited from the UGA student population. Two-point thresholds were determined using a broadband xenon light source, presented as two independent points whose distances from each other could be adjusted. Intensity of the source was varied during testing, and narrow-band interference filters were used to change the chromatic content of the stimulus. It is anticipated that two-point threshold distances and light intensity levels are inversely related due to increased levels of intraocular scatter at high luminance levels. These results will be used to inform the testing of novel contact lens technology, which may absorb the wavelengths of light most prone to scatter.

Optimized Enzyme-Linked Immunosorbent Assay to Assess Anti-Neuraminidase Response in Human Sera

Anne Kathryne Belocura
Dr. Ted M Ross, Infectious Diseases, College of Veterinary Medicine

Influenza virus is the causative agent of a febrile respiratory disease called influenza, or "flu," which can cause serious illnesses and death. The virus expresses two antigens on its surface,

haemagglutinin (HA) and neuraminidase (NA), which play essential roles in the budding and spreading of the agent. Current seasonal vaccines must be updated annually and protect poorly against antigenic drift variants, driving the search for improvements on the vaccine to ensure a broader protection. Flu vaccines have been developed to work against only HA, but NA has never been standardized for a vaccine. The goal of this experiment is to assess whether the current vaccine elicits antibodies against neuraminidase in an enzyme-linked immunosorbent assay (ELISA). We used virus-like particles (VLP) as an alternative influenza NA. For this experiment, sera from human cohorts vaccinated with A/California/7/2009 (H1N1)pdm-09-like virus and A/Hong Kong/4801/2014 (H3N2)-like virus were obtained day of vaccination (d0) and 21 days post-vaccination (d21). Sera were then incubated against VLP to test whether or not elicited antibodies recognized the expressed antigen and to assess antibody titer between d0 and d21. ELISAs have been tested on A/Switzerland/9715293/2013 NA VLP, A/Wisconsin/67/2005 NA VLP, and A/Panama/2007/1999 NA VLP.

Design and Development of Bioengineered 3D Scaffold Using Novel Biomaterials for Tissue Regeneration Cell Culture

Wilfred Oluwafemi Benard, CURO Research Assistant
Dr. Jaya Sundaram, Chemical, Materials, and Biomedical Engineering, College of Engineering

Extensive research has been conducted to determine a suitable material to promote new bone formation in clinical orthopedics. The biomaterials must be biodegradable, biocompatible, and bio-tolerable. This research focuses on the advantages of nanocellulose, such as mechanical reinforcement, surface chemical reactivity, biocompatibility, lack of toxicity, and high specific surface area. The structural advantages of nanocellulose are suitable for the production of a 3D cellular tissue scaffold material for bone tissue regeneration. Hydroxyapatite (HA) is an osteo-conductive material that stimulates muscle on bone fixation and enhances material rigidity, these two biomaterials (nanocellulose and hydroxyapatite) were combined to produce a suitable scaffold. In addition to nanocellulose and HA, alginate, a hydrogel biomaterial was used to give structural stability to the scaffold during development. We varied the concentration of each biomaterial to come up with the best possible scaffold support structure for tissue regeneration. Developed scaffolds were tested to analyze morphological characteristics, biochemical characteristics, and mechanical strength by measuring compressibility, swelling ratio, in vitro degradation analysis, and in vitro cell culture analysis. The nanocellulose is expected to have better cell matrix adhesion, cell differentiation and guided tissue regeneration.

How Social Media Affects Higher Learning

Anna Bennett, CURO Research Assistant
Dr. Lilia R Gomez-Lanier, Textiles and Merchandising, College of Family and Consumer Sciences

Today's higher education classroom setting is unlike it was a decade ago. The availability of smartphones, laptops, and tablets has increased considerably, and with them the ease of access to social media and various other applications. Most research regarding the impact of technology on learning has been focused on K-12 classrooms while only a small percentage has been conducted within the higher education community. Specific studies on Facebook use in college classrooms have been done, but beyond that, a minimal amount has been discovered on which social media and/or applications are currently being used to enhance the learning experience in today's college classrooms. The goal of this research is to determine which social media sites and/or applications are being used for educational purposes in higher education. Quantitative data will be collected through the use of an online survey host and will be taken from undergraduate and graduate students within the College of Family and Consumer Sciences at the University of Georgia. The findings will assist in discerning which applications and social media are being used most for learning, inside and outside of the classroom. They will also show student's personal preferences, based on gender and academic level, in utilizing these programs, as well as their overall preferences for these learning outlets. This information will assist educators in the decision of

incorporating social media into the learning environment, and if so, in what capacity, to enhance student learning.

Gold Nanoparticles, Cytotoxicity and Radiosensitization in a Feline Vaccine-Associated Sarcoma Cell Line, In Vitro

John Zachary Benton
Dr. Robert M Gogal, Veterinary Biosciences and Diagnostic Imaging, College of Veterinary Medicine

Vaccine Associated Sarcomas (VAS) are highly invasive feline malignant tumors that are frequently associated with routine vaccination. Current treatment modalities include chemotherapy, radiation, and radical surgery. VAS have been shown to be one of the more resistant of feline cancers to conventional therapy, with high rates of recurrence. Previous studies have shown that gold and other high atomic number nanoparticles have the ability to increase the dose of radiation deposited into tissue by generating secondary electrons. The current study evaluated the effects of 15 nm gold nanoparticles (AuNP) on VAS cells alone and when combined with electron beam radiation. Cells from an established VAS cell line were co-cultured with AuNp at 0, 0.25, 0.5, 1.0, 2.0 and 4.0 mM. Cytotoxicity of AuNP was evaluated by assessing changes in cellularity, cell proliferation, cell cycle and viability/cell death with the radiosensitizing potential of AuNP on VAS cells assessed by the clonogenic assay. AuNP, regardless of concentration, had a negligible effect on cellular proliferation, cell viability, cell cycle, and cell death. AuNP alone decreased colony formation in a dose dependent manor; colony formation was further suppressed when combined with radiation. Preliminary results indicate that 15 nm AuNp at less than 4.0 mM does not appear to be cytotoxic, but upon uptake within the VAS cell and irradiated does significantly impair colony formation. This would suggest that pretreatment of VAS cells with AuNP can enhance the efficacy of radiation therapy and thus have some level of therapeutic application.

Motown Styles and the 1960's American Dream

Oloni Binns, CURO Research Assistant
Dr. Monica Sklar, Textiles and Merchandising, College of Family and Consumer Sciences

The visual styles of iconic Detroit record label Motown held significance both during its prime in the 1960's and beyond. This research aims to evaluate two aspects of the costume history of Motown. Much of the design history is lost to the known record, and this project seeks to uncover the designers, labels, sourcing, and design development process as to how the performance clothing was selected, produced, and where it is archived. Through the examination of the garments and the development of the aesthetics, stories are revealed about the impact of Motown's dress choices on the wearer, the viewer, and in society in general regarding authenticity and identity. The label's aesthetic had relationships to the Vietnam War, the Civil Rights movement, and the overall culture of that era. This study conducts primary research by examining historic collections and exhibitions of the Motown museum, the Grammy Museum, and the National Museum of African American History and Culture, and speaking with historians, Motown artists, and their associates. Literature pertaining to the history of Motown also reveals information about the dress history embedded within greater narratives. This research deciphers interconnections and disconnections between the Motown artists' image, including on- and off-camera fashions, and the era of their greatest success.

The Effect of Sericea Lespedeza on Strongyle Fecal Egg Counts in Mature Horses

Marrissa Jean Blackwell
Dr. Kylee Duberstein, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Equine parasite control is primarily accomplished through deworming programs that utilize anthelmintics to target small strongyles, and due to their widespread use, resistance is now a major issue. Studies in small ruminants have shown that condensed tannins found in sericea lespedeza (SL) play a role in reducing parasite load. The objective of this study was to analyze the effects of sericea lespedeza hay as compared to Russell bermudagrass (RB) on parasite load in horses.

Sixteen horses were divided into two treatment groups, each receiving 1.5% of body weight daily over four weeks. Fecal egg counts (FEC) were conducted at days 0, 14, 28, and 42 (two weeks after removing from treatments). Horses were randomly divided and housed in two adjacent pastures, and were brought into stalls for 6 hours/day to consume treatment diets. Average initial (day 0) FEC for horses on both treatment groups was high and not statistically different (SL=447, RB=451, P=0.98). All horses showed significant increases in FEC by day 42 ($P<0.001$). At day 28 and day 42, there were numerical differences between treatment groups with SL having lower FEC compared to RB (SL=317, RB=505; SL=1008, RB=1220 at day 28 and day 42 respectively), but high individual variation rendered this data not statistically significant (P=0.24, P=0.18 at day 28 and day 42 respectively). It was noted that in horses with FEC<50 epg (N=5), there was a statistical difference (P=0.0082) in FEC response between treatment groups, with SL horses showing no FEC increase, while RB horses showed an increase of approximately 100 epg by day 42.

MRI Compatible Response Keypad for Communication with Nonverbal Subjects

Brian Lawrence Boland, CURO Research Assistant
Dr. Zion Tse, Electrical and Computer Engineering, College of Engineering

The study aims to evaluate a new MRI compatible human response keypad designed for nonverbal subjects which is inexpensive and easily manufactured. The device is 3D printed in PLA plastic. Once assembled, the system alerts the operator when it senses interruption to the path of light across fiber optic cables caused by button presses. A combination of nonverbal and verbal subjects is split randomly into two groups. Group 1 subjects spend 15 minutes without the device in an MRI simulator. Subjects rate their mood on a predetermined numerical scale. Group 2 uses the device for the 15 minute period, and they also rate their mood. Subsequently, all subjects will use the device to perform several set tasks so that the ease of use and reliability of the device may be evaluated. It is anticipated that using the device will help alleviate feelings of anxiety to some degree. We expect that nonverbal subjects will feel less isolated when able to communicate. Reducing stress inside the MRI can help prevent panic, especially for people with communication disorders, by providing a simple option for an otherwise isolated person to connect with another human being. Tools like this have the potential to make MRI procedures more agreeable to a community of people with similar disabilities. Having increased communication could easily reduce the occurrence of image-blurring disturbances and the need for repeating scans. These benefits are shared by everyone involved in the form of saved time and money.

A Comparison of Functional and Fitness Traits of *Alliaria petiolata* along a Forest Gradient

Sydney-Alyce Bourget, CURO Honors Scholar, CURO Research Assistant
Dr. James E Byers, Ecology, Odum School of Ecology

Alliaria petiolata, commonly known as garlic mustard, is an invasive herb that has been spreading throughout the United States for over 150 years. In recent decades, garlic mustard has begun to invade the intact forest understory communities of eastern North America. The expansion of garlic mustard's invasive range into these habitats is a great concern, as garlic mustard exudes a chemical compound that inhibits the growth of essential soil fungi. The objective of this study was to determine whether garlic mustard populations located along a forest gradient exhibited different functional and fitness traits. We also sought to determine average height and fruit body yield between these populations over time. To conduct this study, an observational field experiment was set up in which the traits of garlic mustard populations located within the edge of a forest, intermediate forest, and forest understory were measured. These traits include height, number of leaf nodes, and reproductive siliques. Based upon data analyses, garlic mustard populations found within the edge habitats exhibited, on average, greater heights, leaf nodes, and reproductive siliques than any of the other microhabitats observed. Garlic mustard populations in intermediate sites exhibited the next greatest heights, leaf nodes, and reproductive siliques, while the forest population produced the shortest plants with the fewest siliques on average.

This data, along with previous data collected, would suggest that a source-sink dynamic is occurring in which edge populations are sourcing propagules into the forest understory.

The Role of Technology and Statements in the July 2016 Turkish Coup Attempt

Tucker Boyce
Dr. Benjamin Ehlers, History, Franklin College of Arts and Sciences

The events that occurred the night and early morning of July 15th and 16th, 2016, shocked citizens of Turkey and the world. The attempt produced scenes of protest and violence in major urban centers and destabilized an already-precarious Turkish political environment. Unlike previous coups in Turkey and elsewhere, this short-lived attempt was broadcast live on social media around the world. What was the role of technology and government rhetoric in the Turkey's July 2016 coup attempt, and how does this attempt compare to previous coups in Turkey? This research analyzes and synthesizes a more accurate timeline of the attempt using numerous Turkish and English journalism reports, social media from that night, and an academic background on the role of coups and the military in Turkey. The timeline of events is used as a foundation for further analysis of key statements from government officials and pro-coup forces. The synthesis of these statements provides a more complete and nuanced picture of the role of rhetoric and technology during the coup. The attempt's ultimate failure was due to a variety of reasons, but pro-government mobilization via social media and government statements were particularly key in stopping a military takeover of the government. In addition, a historical overview of previous successful and unsuccessful coup attempts provides points of contrast to the July 2016 attempt.

Exploring the Role of DNA Double-Strand Break Repair Proteins in CRISPR Adaptation

Sonam Alka Brahmbhatt, CURO Research Assistant
Dr. Michael Terns, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

In many prokaryotic organisms, Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) and CRISPR-associated (Cas) proteins form a system (CRISPR-Cas) that provides adaptive immunity against foreign invaders such as viruses. The CRISPR-Cas system has three general stages: adaptation, crRNA biogenesis, and interference. While the mechanisms of the latter stages of the CRISPR-Cas system are well studied, many details concerning adaptation –the integration of foreign DNA into the CRISPR locus - remain obscure. Studies suggest that DNA double stranded break repair proteins, such as RecBCD in *E. coli*, may play a role in adaptation. The overall goal is to investigate the role of *S. thermophilus* DNA double-strand break repair proteins, RexA and RexB during the adaptation stage of the CRISPR process. RexA and RexB form a helicase–exonuclease complex and we hypothesize that the complex is important in generating short viral DNA fragments that are used by Cas proteins for integration into host cell CRISPR genomic locus. My project focuses on the expression and purification of these proteins for experiments to study and characterize their activity in an in vitro setting, with the expectation that the complex will generate short DNA fragments with properties similar to those observed to be integrated in CRISPR loci in vivo. This study is important to better understand the adaptation stage of CRISPR immunity. Developments in this field will reveal the exact mechanism of how foreign DNA is processed and incorporated into CRISPR loci.

Analysis of Genetic Diversity in *Asimina triloba* to Infer Historical Processes Responsible for Range Expansion

Jessica Mei Brown, CURO Research Assistant
Dr. Dorset Trapnell, Plant Biology, Franklin College of Arts and Sciences

The importance of natural versus pre-Colombian anthropogenic dispersal in post-glacial range expansion of the North American tree species *Asimina triloba* is being investigated. The large sweet fruit were highly prized by indigenous peoples and we hypothesize that humans were responsible for the dispersal of this species to the Northern US and parts of lower Canada, explaining 'Reid's Paradox' whereby plant species with limited dispersal ability migrated considerable

distances subsequent to glacial retreat. *Asimina triloba* samples collected throughout much of the species' range are being genotyped with nine nuclear microsatellite markers. Because neutral genetic diversity in contemporary populations contains the footprints of historical processes, we are able to discern natural versus anthropogenic origin of populations. Examination of four putative anthropogenic and four wild populations that are geographically paired revealed that wild populations had higher genetic diversity: a mean number of genotypes of 27.3 versus 1.3 per population, 89% versus 54% percent polymorphic loci, 4.5 versus 1.5 alleles per locus and expected heterozygosity of 0.562 versus 0.281. Ultimately, through the application of network analysis we will examine nodes of connectivity and infer patterns of movement and dispersal. This information can inform inference of the relative importance of natural versus anthropogenic dispersal, and provide a more complete understanding of how this species dispersed, colonized new habitats, and expanded its geographic range subsequent to glacial retreat.

Biochemical and Structural Characterization of vOTUs from Ganjam and Hazara Nairoviruses

Sarah Elizabeth Brown, CURO Research Assistant
Dr. Scott Pegan, Pharmaceutical and Biomedical Sciences, College of Pharmacy

Crimean-Congo hemorrhagic fever (CCHF), Ganjam, and Hazara are closely related nairoviruses. *Nairovirus* is a genus of RNA viruses including CCHFV. CCHF virus produces fever, prostration, and severe hemorrhages in humans. CCHF often has fatal effects in humans, while Ganjam and Hazara have only mild effects. However, Ganjam is often fatal in sheep. Hazara can be used as a model system for nairovirus infections. Within CCHFV is a viral homologue of the ovarian tumor protease (vOTU). Due to the close relationship between Hazara and CCHF, we can explore the differences between how the CCHF and Hazara vOTUs bind ubiquitin. Because Hazara is not our health concern, we can create and study structures of ubiquitin with Hazara and CCHF and ISG15 with Ganjam. As we study vOTUs, we can gauge between different viral proteases and their potential role in disrupting signaling pathways of the host cells that are dependent on ubiquitin or ISG15, such as the interferon type I response(IFN-I). These protein complexes must be purified and crystallized to create these structures which we will study. We anticipate creating Hazara with ubiquitin and Ganjam with sheep ISG15 structures to compare with existing structures of CCHF. Thus far we have preliminary data with some protein crystals that have some x-ray diffraction. These structures allow for a greater understanding of vOTUs as a class of proteases, so that we can address CCHFV in humans. By studying Hazara, we can create a model like CCHF to be able to discuss treatment and future therapeutic solutions.

Using Chlamydomonas as a Model for Oral-Facial-Digital Syndrome

Gehrig Broxton, CURO Research Assistant
Dr. Karl F Lechtreck, Cellular Biology, Franklin College of Arts and Sciences

Mutations in the *OFD1* gene are the cause of oral-facial-digital syndrome, a disease that results in severe malformations of the mouth, face, hands, and skeletal system. However, the cellular basis of this disease is not fully understood. The *OFD1* gene encodes for a protein localized to the base of the primary cilia, thin cell extensions with sensory and signaling functions also referred to as flagella. Here, we describe an *ofd1* mutant in *Chlamydomonas reinhardtii,* a widely used unicellular model for ciliary disease. Using polymerase chain reaction and gel electrophoresis, we confirmed an insertion of the paromomycin resistance cassette into the *OFD1* gene; we refer to this mutant strain as *ofd1-1*. The mutant strain was backcrossed to a wild-type strain to outcross potential second site mutations. We are now analyzing the phenotype of *ofd1-1*. Mutant cells possess flagella and are motile indicating that *OFD1* is not essential for the assembly of cilia in *Chlamydomonas*. I will now determine whether *ofd1-1* has a subtler phenotype such as changes in flagellar length or swimming behavior. *Chlamydomonas* facilitates the isolation of flagella allowing for a comparison of the biochemical composition of wild-type and *ofd1-1* flagella. Based on the severe phenotype of *Ofd1* mutations in mammals, we hypothesize that the mutation will have a noticeable effect on flagellar composition and function. Once the phenotype is characterized, the mutant strains will be rescued

by insertion of the wild-type gene, which should restore wild-type *OFD1* function.

Georgia Monetary Sanctions

Madison Lorene Brumbaugh, CURO Research Assistant
Jacob Scott Kepes
Dr. Sarah Shannon, Sociology, Franklin College of Arts and Sciences

This research project analyzes the application of fines, fees, and probation for misdemeanor criminal offenses throughout the state of Georgia. We collected three types of data to explore these processes. First, we collected quantitative data regarding fines and fees levied by each county from the years 2005 - 2015, including the total amount of money collected by each county per year, as well as the total amount of money collected for specific funds, per county, per year. Second, we systematically observed ~30 hours of court sessions in a large municipal court order to assess the application of these misdemeanor sanctions in a real courtroom. Third, we reviewed local governments' use of private probation companies to supervise people for misdemeanor offenses. We will present the current status of our research project and our exploratory findings to-date. Our analysis thus far shows that counties and municipalities in Georgia are collecting significant amounts of money, often at the expense of their own citizens, who are unable to pay.

Assessing the Removal of Lead from Water Using Commercially Available Filters

Austin Thomas Bryan
Dr. Kat Loftis, Vice President for Research Services, Research Units

Water sanitation, especially contamination with heavy metals, has attracted greater attention in recent years. The neurotoxic effects of chronic low-level lead exposure make its removal a concern for home water treatment systems. Commercially available faucet-mounted water filters are officially tested under controlled conditions that may not reflect in-home operation. In this study, commercially available faucet-mounted water filters were evaluated to determine whether lead-removal performance would be impacted by abnormally high concentrations of lead or varying degrees of water hardness. The goal of this study was to evaluate how varying conditions affect lead adsorptivity onto filter cartridges and the ability to remove lead from water samples. Two variables, lead concentration and water hardness, were evaluated for their impact on filter performance. Inductively Coupled Plasma Mass Spectrometry (ICP-MS) was used to determine lead concentration in the filtered test samples and unfiltered control samples. Filters were tested with 150 ppb and 300 ppb lead solutions. Preliminary data suggests that filters are capable of removing lead at concentrations two-fold greater than certification testing.

Nuclear or Solar, Why Does It Have to Be a Choice?

Cole Burgess, CURO Research Assistant
Dr. David Gattie, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

When it comes to carbon free energy, we have limited options for generation sources. In the US, nuclear, wind, and solar are the three predominant carbon-free energy generation sources. This research investigates the advantages of nuclear and solar energy in Georgia in an effort to recommend which if any energy source should be further developed to meet future demands. In Georgia, solar is an attractive source for energy generation because out of the fifty states, the state receives the 10th greatest concentration of incident solar energy. This concentration of energy combined with falling costs of solar panels has helped foster one of the top growing solar markets in the US. The growth of the solar industry is complimented with a growth in the nuclear energy sector of Georgia as well. Plant Vogtle is currently constructing the first new nuclear reactors in the US in over 30 years. This addition of 2,234 MW of electricity will help establish the base load power required to have a functioning electrical grid. Though both sources of energy are carbon-free, there are vast differences in their respective advantages and disadvantages. In an effort to transcend public perception for both energy sources, a comparative economic analysis referenced to identical generation (MWh) has been conducted for each. While both energy sources

have their limitations, Georgia should maintain its diverse energy portfolio and continue with future development of both carbon free energy resources.

Mechanical Ventilator Parameter Prediction

Nicolas Rousseau Burgess
Dr. Ramana Pidaparti, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Parameter estimations for mechanical ventilator settings are essential in giving optimal treatment for patients suffering from compromised lungs. Establishing a relationship between these parameters and the patient outcomes while using a decision-making model can support clinicians by improving accuracy and minimizing error during treatment. We developed an artificial neural network model in conjunction with inverse mapping for this parameter estimation. We applied a novel graded particle swarm optimization for inverse mapping, where the designed variant of particle swarm optimization involves gradation in the swarm and a hierarchical strategy. This model was tested on data collected from the ongoing study at the Small Animal Teaching Hospital (SATH) at the University of Georgia (UGA) for canines and felines and we were successful in achieving high percentages of accuracies in parameter prediction. Further, we plan to develop an application platform, allowing multiple users to connect to a server running this learning model. The final application aims to assist doctors in setting mechanical ventilator parameters; we will first deploy the application for the doctors at the SATH at UGA.

Effects of Tracking Scale on User Performance in Virtual Reality Games

Ben Burgh
Dr. Kyle Johnsen, Electrical and Computer Engineering, College of Engineering

We explore how scaling a user's tracking data may impact performance in an immersive virtual reality game, which may have implications for fairness and accessibility for many applications. In our study, which used an HTC Vive room-scale VR system, users play as a factory worker who must remove deformed bread from a production line. Users were scaled to a reference height, such that taller than average users were rendered shorter and had shorter reach and shorter than average users were rendered taller and had longer reach than normal. Users also performed with unscaled tracking data. Our analysis indicates that there was no systematic advantage of being taller or shorter than normal, and scaling users may have had a detrimental effect. Moreover, scale changes were noticed by many users who had conflicting preferences for various application-specific reasons, indicating that application strategy can be affected by scale. Results suggest that while virtual reality tracking data may be scaled to compensate for user differences in physical height or reach, care must be taken to ensure performance will benefit.

Characterizing the Role of Inhibitory Neurons in Regulating Seizure Activity in Embryonic Zebrafish

Branson Byers, CURO Research Assistant
Dr. James D Lauderdale, Cellular Biology, Franklin College of Arts and Sciences

More than 50 million people worldwide suffer from epilepsy. Unfortunately, cellular and network level mechanisms behind this condition remain poorly understood, and skull thickness and large brain size inhibit observing cellular and network activity simultaneously in mammals. As an adjunct model system for studying seizure generation and propagation, the small, transparent embryonic zebrafish allows for observation of entire neural networks with cellular resolution. Seizure-like activity can be induced in zebrafish through manipulating the signaling of the inhibitory neurotransmitter GABA. We have genetically engineered a line of zebrafish in which we can visualize both whole brain activity (GCaMP5G) and the location of GABAnergic, inhibitory neurons (gad1b:RFP). By using light sheet microscopy for high-resolution calcium imaging in vivo, we can image seizure activity in real time and eliminate noise from tissue in other planes of focus. Using RFP tagging of GABA expression, we compare the propagation of seizure activity to the location of inhibitory neurons. Reducing GABA levels in inhibitory neurons by inducing CRISPR-Cas9 mutations in gad1b, we can alter the efficacy of the subset of GABAnergic, gad1-

expressing neurons. By examining the effect of this mutation on the propagation of seizure activity, this study aims to characterize the role of inhibitory neurons in regulating seizure activity in the embryonic zebrafish.

The Relationship between Nutrition Status and IADLs in Community-Dwelling Older Adults

Sarah Caesar, CURO Research Assistant
Dr. Steve Miller, Psychology, Franklin College of Arts and Sciences

Dietary factors have been associated with neurocognitive health in late life, but the relation to functional independence remains largely unexplored. The present study sought to fill this gap in the literature. It was hypothesized that greater intake of fruits, vegetables, and fish would be positively associated with instrumental activities of daily living (IADLs) in a sample of older adults (N=134, 62% female, mean age = 74 years). IADLs were measured using the Direct Assessment of Functional Status-Revised (DAFS-R), a performance-based measure of cognitively-demanding tasks, such as handling finances and managing medications. MyPyramid guidelines were used to categorize participants into low versus high intake groups on each nutrition variable. Individual and combined effects of the nutrition variables on IADL scores were assessed. Education, gender, and age were considered as potential covariates. Results showed that older adults who consumed high amounts of fish were more functionally intact than their counterparts who consumed low amounts [$t(128) = 1.84$, p=.034, Cohen's $d = 0.359$]. However, this finding was reduced to non-significance when controlling for education ($p = .203$, $d = .237$). Fruit intake ($p = .757$, $d = -.238$), vegetable intake ($p = .910$, $d = -.124$), and overall nutrition status ($p = .382$, $d = -.155$) did not significantly relate to IADLs. These findings add to the limited literature evaluating the relation between nutrition status and functional ability in older adults. Results suggest fish intake may protect against age-related loss in functional independence, though education level attenuates this relationship.

The Affordable Care Act's Effect on Perceived Mental Health Outcomes and Substance Abuse Treatment

Trace Calloway, CURO Honors Scholar, CURO Research Assistant
Dr. R. Vincent Pohl, Economics, Terry College of Business

The Mental Health Parity and Addiction Equity Act of 2008 sought to improve insurance coverage for mental health issues and addiction treatment, two areas that many insurance plans did not adequately cover. The Affordable Care Act (ACA) continued down this path by altering the financing and delivery of mental health and addiction care even more profoundly in the attempt to cover more people and provide better care. Was it successful? Did the ACA improve substance abuse treatment in the United States through its mental health parity mandates? Improvement would be measured by an increase in patients receiving treatment, perceived mental health status, and reduced spending—both total and out-of-pocket. Using a difference in difference calculation on the mental health status and treatment use before and after the ACA rollout, I attempt to isolate and measure the effects of the ACA across state lines. My data concerns the perceived mental health status of surveyed individuals as recorded in the Behavioral Risk Factor Surveillance System and treatment data from the Substance Abuse and Mental Health Services Administration.

Women's Fate

Leighton Carlock
Dr. Joel Black, Comparative Literature, Franklin College of Arts and Sciences

Last year, I had the opportunity to study abroad in China, and through my studies, I came across a word I did not understand. Yes, this happened frequently, but this particular word had an odd translation. The word is shengnu, and the translation is "leftover woman." At first, I thought this was referring to an impoverished woman, but when I tried to use it in this context, people snickered. I had seen this word in the newspaper and in magazines, and when spoken I detected the odd reaction on my friend's faces. At last it was explained that a leftover woman is any woman over the age of twenty-six who is still single and has no prospects of marriage. My immediate reaction was confusion. Why are these women

leftover? Why are these women not allowed to be and do what they want to do? I knew there must be more to this, and I was right. Shengnu is a new term, originating in the last decade. However, my research project argues that the concept is influenced by Confucianism, the oldest reigning philosophy, ideology, and belief system in China. Confucian ideals are in many ways the underlying thread of many aspects of present-day Chinese culture: politics, art, literature, humor, and film. The rhetoric regarding leftover women structures a society that puts women at fault. Their happiness is put on the back burner in the name of ancient Confucian "harmony" and the "stability" of the People's Republic of China.

Role of Bacterial Polysaccharides in Bacteriophage Invasion

Alexandra Carlton, CURO Research Assistant
Dr. Maor Bar-Peled, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Bacteriophages are viruses that specifically infect bacteria, relying on the host bacterial cell to reproduce and propagate. In order to use the replication mechanisms within the bacteria, the phage must first enter the cell by means of recognition factors. Glycans, sugars that can be linked to a variety of different molecules, play a significant role in cell-to-cell communication and recognition of outside material. The components of this specific phage-bacteria recognition remain unknown. The aim of this study is to identify the role of bacterial polysaccharides in phage invasion or avoidance. Multiple glycolytically-mutated strains of *Bacillus cereus* will be tested for susceptibility to bacteriophage infection in vitro in order to monitor differences in biofilm formation, flagella glycosylation, and other key processes. We expect to find that some mutants will alter successful bacteriophage invasion. Previous studies of glycoproteins have aided our understanding of the mechanism of infection by particular phage strains. We hope that by identifying the polysaccharides affected by the mutant strains, we will further our understanding of specific bacteriophage recognition.

Child Disability and Maltreatment: Caregiver Support as a Protective Factor

Savannah Carroll, CURO Research Assistant
Dr. Assaf Oshri, Child and Family Development, College of Family and Consumer Sciences

Studies show that children with disabilities are at greater risk for maltreatment by their caregivers compared to children without disabilities. Therefore, it is essential to uncover risk and protective factors for maltreatment among children with disabilities in at-risk families. Evidence indicates that the level of social support caregivers receive can buffer against risk for child maltreatment. Despite the importance of caregiver social support, no research has empirically examined it as a buffer between child disability and maltreatment, measured by Child Protective Services (CPS) reports. Presently, we hypothesize that disability will be a predictor of four types of maltreatment (physical abuse, sexual abuse, emotional abuse, and neglect) and that social support will serve as a protective factor. To examine this hypothesis, we will conduct a secondary data analysis using a longitudinal sample from the LONGSCAN dataset (N = 1,354). A multiple regression will be used to examine how disability at age 4 influences the number of CPS reports between ages 4 to 8. Perceived social support will be examined as a protective factor. Preliminary results demonstrate that when there is low social support, child disability predicts higher rates of physical abuse, sexual abuse, and neglect compared to children without disabilities. Thus, higher levels of social support were found to buffer the link between disability and maltreatment. This research will inform policymakers, the medical community, and educators on the increased risk of children with disabilities to be victims of maltreatment and the importance of identification and prevention of child abuse and neglect.

The Insect Version of Oxytocin Influences Female Tolerance of Males in a Subsocial Beetle

Annika Carter, CURO Research Assistant
Dr. Allen J Moore, Genetics, Franklin College of Arts and Sciences

The ability to express the correct behavior is essential for the survival of most organisms. One such important behavior is sociality — the motivation to be around or tolerance of conspecifics. The insect ortholog of mammalian

oxytocin/vasopressin, inotocin, is known to be present in the subsocial beetle *Nicrophorus vespilloides*. During mating, female *N. vespilloides* beetles may be more or less accepting towards a male's mating attempts. Given the association between oxytocin/vasopressin and changes in sociality during mating in mammals, we hypothesized that the *inotocin* (*it*) and *inotocin receptor* (*itr*) genes would be differentially expressed across the female beetle's mating cycle and would be differentially expressed between females that are highly accepting or rejecting of a male during mating trials. To test this in *N. vespilloides*, we compared relative gene expression across stages of a breeding cycle: virgin females, mated females, mated females preparing a resource required for reproduction, directly and indirectly caring females and post-caring females. We also compared relative gene expression from virgin females who readily accepted males in mating trials to females who rejected males in mating trials from two different groups — one collected immediately after mating and one collected following 24 hours in an enclosed container. Expression varied for both *it* and *itr* across the five breeding stages. The expression of *it* and *itr* was significantly lower in post caring females and the expression of *itr* was significantly lower in resource preparation females. Expression of *it* and *itr* varied between the accepting and rejecting females and between the immediate and 24 hour time period. Both *it* and *itr* expression was significantly higher in accepting females. *it* expression was significantly reduced at the 24 hour time period. *itr* expression was significantly greater at the 24 hour time period. We suggest that *it* and *itr* are associated with the changing general sociality of *N. vespilloides* that occurs during mating, but not necessarily with parental care specifically.

Motivations and Barriers of Volunteering among College Freshmen

Alexandra Case, CURO Research Assistant
Dr. Jessica Holt, Agricultural Leadership, Education, and Communication, College of Agricultural and Environmental Sciences

The purpose of this study was to understand motivations and barriers behind volunteering practices of college freshmen at the University of Georgia (UGA). The demographics of gender, race, religion, income, and political ideology were included in this study to determine if those were related to students' volunteering behaviors. This study is timely due to a recent rise in college student volunteering and the implementation of the new experiential learning requirement for all UGA students. UGA freshmen were surveyed using an online survey (n = 348) disseminated through email. The survey was divided into three parts: motivations, barriers, and demographics. Preliminary analysis of the results has revealed that the top motivators for all demographics were related to personal beliefs and extra time, while the top barriers for all demographics pertained to a lack of time and a need to focus on oneself. It was also discovered that beliefs about volunteering were significantly more positive across all respondents and those who choose to volunteer felt supported and fulfilled. This study will give the Center for Leadership and Service a more comprehensive understanding of why or why not freshmen choose to engage in volunteering behaviors, as well as provide recommendations to engage those students not currently engaging in volunteering behaviors.

Latino Resilience among Undocumented Families

Genesis Castro, CURO Research Assistant
Dr. J. Maria Bermudez, Child and Family Development, College of Family and Consumer Sciences

The aim of this study is to examine effects of detention and deportation practices on mixed-status Latino families in the South. There is an urgent need and a significant lack of empirical data to help scholars and practitioners better understand the extent to which children and families are affected by current immigration policies and practices. We use a culturally responsive, community-based, participatory action mixed-method design. We assert that the untold disruption and immigration trauma among these individuals, families, and communities will help us formulate a framework for understanding Latino family risk and resilience and inform current immigration policies. Our goal is to be able to share what factors contribute to positive youth development among undocumented or Deferred Action for Childhood Arrivals students with the public, with the hope that schools, families, and

community members apply our findings to their interactions with students.

"Immigrants, We Get the Job Done!": Depictions of the U.S. Immigrant Experience on Broadway

Izzy Ceron, CURO Honors Scholar, CURO Research Assistant, Foundation Fellow
Dr. Edward A Delgado-Romero, Counseling and Human Development Services, College of Education

A recent crop of Broadway musicals, plays, and revivals delve heavily into the nuances of the immigrant experience in the United States. Given the current anti-immigrant and xenophobic political climate, what do popular Broadway productions tell us about the current perception of what it means to be an American? Broadway has played a crucial role in the American psyche since its inception, both reflecting and shaping perceptions of important social issues. From the revival of *West Side Story* to the runaway success of *Hamilton: An American Musical*, the immigrant experience has been at the forefront of theatrical content in the last decade. This study examines eight popular theatrical works performed on Broadway throughout the past decade and analyzes the depictions of various immigrant communities and experiences in the US. This study is still in the formative stage and summarizes preliminary conclusions from an extensive literature review. The study will be a qualitative analysis of each work's script, focusing on themes of immigration and the US immigrant experience. Ultimately, this study aims to gain insight about the broader implications of prototypes and stereotypes depicted on stage and the way these depictions may both reflect and shape public perception of immigrants in the US.

The Role of Non-Cas Proteins in the Adaptation Stage of CRISPR-Cas in *Pyrococcus furiosus*

Chip Chambers, CURO Honors Scholar, CURO Research Assistant, Foundation Fellow
Dr. Michael Terns, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

CRISPR is a powerful biological tool that has taken the scientific community by storm due to its powerful genetic engineering capabilities. Many of its basic biochemical mechanisms, however, have yet to be uncovered. CRISPR contains three stages: the adaptation stage, in which a prokaryote acquires DNA from an invader and integrates it into a CRISPR locus, the expression stage, where the CRISPR array is transcribed and processed to form crRNAs, and the interference stage, during which an effector complex uses the crRNA guides to target and silence invaders. My work investigates the potential roles of non CRISPR-associated (Cas) proteins in the initial adaptation stage of the CRISPR-Cas system. These include Argonaute (a DNA-guided nuclease), HerA (a helicase of Archaea), NurA (a nuclease of Archaea), and Hef (which repairs stalled replication forks). We are interested in the Argonaute protein because it serves as an innate defense system and plays a role in RNA/DNA-silencing. HerA, NurA, and Hef on the other hand, are all involved in DNA repair, but might also play a role in adaptation. We are specifically looking at the roles of these proteins in vivo within the host organism *Pyrococcus furiosus*, a hyperthermophilic archaeon used in various industrial processes. Utilizing knockout strains and polyhistidine tagged proteins, we performed assays to determine whether these proteins influence the frequency of adaptation and/or introduce a bias for the location or size of spacers. Ultimately, these findings may contribute to the body of general knowledge of this revolutionary technology.

Transcriptomic Investigation of Disease Tolerance in the Ochre Sea Star *Pisaster ochraceus*

Katelyn Chandler
Dr. John Wares, Genetics, Franklin College of Arts and Sciences

Sea Star Wasting Disease (SSWD) causes the tissues of echinoderms to decay rapidly and is responsible for a current mass mortality event among *Pisaster ochraceus*. Sick *P. ochraceus* were found to be approximately 20% less likely to be heterozygous for an insertion mutation at the elongation factor 1-alpha (EF1a) locus. This insertion at EF1a is known to be lethal when two copies are present; it appears to be maintained by heterozygote advantage in fitness. A statistically significant difference in gene expression between

the *P. ochraceus* genotypes might explain the possible advantage of heterozygotes in relation to SSWD. RNA was isolated from tissue samples collected from *P. ochraceus* individuals found in Friday Harbor, Washington. RNA-seq was then used to measure the differentiation in gene expression between individuals found to be the homozygous wild-type and heterozygous for the insertion at EF1a. Observations of differentiation in gene expression between the two genotypes found to be statistically significant were studied to interpret possible biological significance. Of particular interest were observations with high fold differences, expression present in one genotype but not the other, and doubled expression in the homozygotes versus the heterozygotes. The difference in propensity to be affected by SSWD based on genotype suggests that somewhere among these observations of interest a phenotypic difference is caused between the two genotypes, rendering SSWD inefficient or ineffective at infecting heterozygotes compared to homozygotes at EF1a. The mechanism of this phenotypic difference could be invaluable in understanding how SSWD works.

Compiling Studies on Pedagogical Content Knowledge within Topics of Evolution

Raheela Charania
Dr. Tessa Andrews, Genetics, Franklin College of Arts and Sciences

Understanding a topic in class is critical to learning the topic. The learning opportunities provided by the instructor are strongly associated with whether students learn (Smith et al. 2016). Pedagogical content knowledge (PCK) is one type of knowledge that helps instructors teach to facilitate student learning. PCK includes knowledge of misconceptions commonly held by students and addresses the misconceptions that can be critical to promote learning. In this project, we are identifying PCK currently available in the literature within the topic of evolution. To find relevant abstracts, we use a combination of search terms that allow us to locate articles that describe evolution PCK in various education levels and topic areas. This research will allow us to identify trends in the field of evolution education research and determine what has and has not been investigated previously. This will allow us to make recommendations for the progression of the field based on where there is a surplus and where there is a need. We will also be able to summarize PCK in evolution education for practical use in an undergraduate classroom.

The Personal Touch of Discovering Money Solutions

Marcus Chatman, CURO Research Assistant
Dr. Matt J Goren, Housing and Consumer Economics, College of Family and Consumer Sciences

The financial education curriculum, presented as PowerPoint presentations and hands on activities, of the Discovery Money Solution program is part of the Healthy Marriages and Relationship Education Program, and is purposed to aid families in bettering their economic stability. The 6-hour curriculum, which is separated into three 2-hour classes, is facilitated by two coaches. It addresses attitudes toward money and presents specific tools and solutions for participants. By collecting feedback from participants after each class, researchers will have a greater understanding of the subjective benefit of the various aspects of the class and curriculum. The assumption may be that the well-developed presentation and handout materials will be the most valuable aspect of the class for participants. Though the content will evolve based upon feedback over time, the presence of professionals may be of greater significance. If the interaction of coaches and participants supplies great value to the learning experience, as teachers do with students, then the opportunity to consult and collaborate with financial professionals creates the greatest impact upon the learning experience. The curriculum will always be predominantly consistent, but the presence of interactions between coaches and participants unique to each class will significantly influence the participant satisfaction with the overall course and resulting impact upon financial well-being. As displayed by the publicized dissatisfaction of automated customer service in telecommunications and web services, human interaction in cognitive learning and problem solving is critical.

Effect of Ground Granulated Blast-Furnace Slag (GGBFS) on Heat of Hydration Concrete

Jonathan Chelena, CURO Research Assistant
Dr. Mi Chorzepa, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Cement hydration produces a rise in internal temperature, and the outer concrete surface cools faster than the core of the section. By thermal expansion/contraction, the temperature differential induces thermal stresses at the surface. Once the maximum temperature in the interior exceeded the accepted threshold value, DEF (delayed ettringite formation) can occur in mass concrete elements. Therefore, DEF can be prevented by limiting the internal concrete temperature during its very early life. The maximum temperature suggested by prior research efforts to prevent DEF in concrete elements is 160°F. This reduced temperature can be achieved by direct specification of temperature allowable, by limiting the cement content, or by specifying the use of low heat supplementary cement materials. This study includes the design, batching, and testing of concrete mixtures with cement replacements of slag while keeping the total amount of cementitious material constant. Mechanical properties and heat of hydration are being measured for each mix design. An isothermal calorimeter is being used to measure the heat generated from the early hydration of cementitious materials. It is concluded that relatively low heat of hydration is observed in the slag mixture compared with the fly ash mixture.

Autonomy and Health Literacy Relationships as a Link to Patient and Provider Satisfaction

Eli Chlan, CURO Research Assistant
Dr. Lisa Renzi Hammond, Psychology, Franklin College of Arts and Sciences

Health literacy in the United States varies widely by gender, age, ethnicity, income level, and education status. It has been speculated that health literacy, in turn, limits patient autonomy. Despite this fact, patient autonomy has not been characterized in the majority of populations that frequently consume healthcare. The purpose of this proposal is to characterize autonomy, health literacy, and their relationship within two different populations. For the first part of this study, UGA undergraduates will be recruited to complete a survey assessing feelings of autonomy in recent health care visits. It is hypothesized that young, high literacy patients are also likely to be high in perceived autonomy. The second part of the study will involve undergraduates coming to the UGA Health Center (UHC) for medical visits and being randomly asked to fill out either a pre-visit survey on health literacy, or a pre-visit survey on autonomy. Following their visit, all participants will receive a follow up survey, and HCPs at the UHC will also receive a survey about their patient encounter but are masked to the intervention. It is hypothesized that patients primed with the autonomy survey will ask more questions about their diagnosis, will expect their HCP to be a partner in the decision making process, and will have higher adherence to prescribed treatments. The third part of the study will replicate this test scenario in a local free clinic that serves a largely impoverished population with low health literacy and low health access.

Development of Cellulose NanoFibrils (CNFs) Composites for Packaging Applications

Crystal Chu, CURO Research Assistant
Dr. Sudhagar Mani, Chemical, Materials, and Biomedical Engineering, College of Engineering

As consumers become increasingly eco-conscious, research into biomass derived polymers from replacing traditional petroleum plastics rises in importance and attention. These studies were conducted to determine water and chemical resistance of nanocellulose and alginate composite films for potential use in packaging. Five different film compositions were created with glycerol as the plasticizer for this research: a control of alginate, a control of nanocellulose, and three different ratios of alginate to nanocellulose composites. Three replicates per composition were used to support the accuracy of our results through a study of the standard deviations calculated. Water uptake testing was conducted by laying known weights of dried film samples in a desiccator with deionized water and measuring the water mass gained by the films over time. Water and chemical resistance studies were conducted by submerging known weights of dry film samples in either deionized water or a known solution, measuring the change in sample mass over time.

The percentage of water uptake by the films indicate that the nanocellulose control is highly hydrophilic while the composite films are more resistant to water penetration, both while submerged in water and while exposed to 100% humidity. Similar results as above, from water uptake and water resistance testing, are expected from the chemical resistance studies. The mechanical strength and biodegradability of developed films were also measured and compared to standards of current packaging products available as a benchmark for our development of cellulose nanofibrils composite films.

Examination of *Mycobacterium tuberculosis* Protein Expression in Infected Lung Tissue

Nicholas Ciappa, CURO Research Assistant
Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Tuberculosis (TB), caused by *Mycobacterium tuberculosis* (*Mtb*) is the leading cause of death by a single infectious agent in humans. In host tissues, *Mtb* can be identified through immunohistochemistry (IHC), a method that utilizes antibodies to detect specific proteins or other biomolecules. The focus of the current project is to determine where *Mtb* bacteria are located within the lungs of infected guinea pigs, a model system for human disease, and which *Mtb* proteins are expressed in this environment. Immunohistochemistry staining revealed Rv0097c-specific staining in the periphery of lung granulomas, but not within the necrotic granuloma centers. A granuloma consists of immune cells that surround an infectious center to contain the infection. The presence of Rv0097c in granulomas suggests that this protein is important for *Mtb* survival in this hostile environment. We are in the process of examining whether Rv0097c-specific staining is similar to immunohistochemical staining of *Mtb* secreted or bacterial surface-localized proteins. Such studies will aid in evaluating whether these proteins have potential as vaccine targets.

CdaI-1 Kinase of the Hippo Pathway in *Tetrahymena thermophila*

Diamond Clarke, CURO Research Assistant
Dr. Jacek Gaertig, Cellular Biology, Franklin College of Arts and Sciences

The ciliate, *Tetrahymena thermophila*, is a eukaryote that has a complex cortical pattern. These ciliates contain organelles such as an oral apparatus, contractile vacuole pores, and ciliary rows that are present at predictable positions on the surface of the cell. *Tetrahymena thermophila* undergoes equatorial cell division. CdaI is a Hippo/Mst kinase of the conserved Hippo pathway. In animals, this pathway controls organ size by regulating cell divisions and polarity. In the temperature-sensitive *cdaI-1* mutant of *Tetrahymena*, there is an improper anterior shift of the division plane that results in unequal cell division. This research focuses on the exact molecular role of CdaI in the equatorial cell division. A GFP-encoding sequence was added to the 3' end of the *CDAI* gene. We used immunofluorescence with anti-GFP antibodies to view the localization of CdaI. CdaI was not detected in interphase cells. Initially, CdaI-GFP localized to the anterior half of the dividing cell and later marked the newly-forming posterior end of the anterior daughter subcell. After analyzing the *cdaI-1* mutants, we also found that CdaI is not required for the formation of the new cortical organelles at the posterior end. CdaI's sole function appears to be the maintenance of the equatorial division plane. The Hippo pathway is highly conserved and present in all eukaryotic cells including mammals. Findings from this research could be applied to understanding of how other eukaryotic cells control their division plane.

Effect of Prescribed Burning of Riparian Zones on Stream Hyphomycete Fungi Productivity

Sarah E Clement, CURO Summer Fellow
Dr. Catherine Pringle, Ecology, Odum School of Ecology

Fires are an important structuring element of forest ecosystems – those naturally occurring and those used for forest management, and can vary in their severity and impact. Nutrient release in the form of nitrogen is one of the known short-term effects of forest fires in aquatic ecosystems, and this can potentially affect stream fungi. While nutrient enrichment has been shown to increase

aquatic fungal abundance, species richness and reproductive output (in the form of conidia production), there are very few studies on the effects of fire on stream fungi. This study aims to test if nutrient release from fires causes a similar effect on stream fungi as artificial nutrient enrichment using two different leaf types: one recalcitrant (Rhododendron) and one highly labile (Red Mable). This study is part of a USDA Forest Service Project that involved prescribed burning of Rhododendron-dominated riparian vegetation along a 300m stream reach in the Nantahala National Forest, North Carolina. To examine fungal response to the burn, leaves were incubated in the stream reach both pre- and post- burn. Fungal biomass was analyzed over time both pre- and post-burn by extracting ergosterol from incubated leaves. We predict that: increased nutrients post-burn will cause an increase in fungal biomass on both leaf types; leaf decomposition rates will increase as fungal biomass increases; and increases in fungal biomass will be greater for Red Maple than for Rhododendron.

Predicting Oyster Larval Recruitment and Growth Using Cheaply Obtained, Remotely Sensed Data

John Coffin, CURO Summer Fellow
Dr. James E Byers, Ecology, Odum School of Ecology

The Eastern Oyster, *Crassostrea virginica*, is an important ecosystem engineer in estuarine systems that physically alters and provides habitat for other species and stabilizes banks. 88% of reefs worldwide have been reduced by overharvesting and habitat degradation. Resource managers need better data to improve management practices. Larval recruitment and growth are key parameters governing the population dynamics of oysters, and are thought to be influenced by current velocity and wave energy. This study consisted of 60 sites surrounding St. Catherines Island, Georgia. Oyster reef sites were divided into three habitats—creeks, rivers, and sounds—based on different current and wave regimes, and sites were randomly selected from each habitat. Non-reef sites were also selected, as a control. Recruitment was estimated monthly by counting settled larvae on collection sticks, and average biomass and shell length over the four month study period provided growth information. Analysis by habitat revealed biomass did not vary between habitats, though average shell diameter was higher in sites containing a pre-existing reef than in bare sites, perhaps due to size-related selective pressures. Over the entire study, recruitment was lower in creeks than in rivers and sounds, suggesting water body width may impact recruitment, as larvae must travel greater distances to reach creeks, diminishing larval supply. Future work will utilize remote sensing to analyze how current velocity and wave energy drive larval recruitment and subsequent growth. A positive relationship is expected between current velocity and recruitment, while a negative relationship is expected between wave energy and growth.

Risk Factors for Social Isolation in Elder Care Recipients

Haley Cohen, CURO Research Assistant
Dr. Steve Miller, Psychology, Franklin College of Arts and Sciences

Physical and mental health and cognition are important variables for predicting older adults' social isolation. However, these relationships have not been addressed within the context of caregiver and care-recipient relationships. As relationships with caregivers may be important for older adults' well-being, this study examined how caregiver variables of physical health, mental health, and cognition relate to care-recipient social isolation in a sample of 450 caregiver/care-recipient dyads. We also examined the relation of care-recipient physical health, cognition, and functional independence (FI) to care-recipient social isolation. All care-recipients were cognitively or physically impaired older adults aged 60+ years. Physical health, mental health, and FI were assessed via scales adapted from Schultz et al., 1997, Katz et al., 1996, and Katz et al., 1963 and Lawton & Brody, 1969, respectively. Cognition was measured using the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). Hierarchical regression models were used to assess the unique variance contributed by each caregiver and care-recipient variable-of-interest on care-recipient social isolation, controlling for care-recipient dementia diagnosis and all other variables-of-interest. Contrary to expectations, none of the caregiver variables-of-interest significantly predicted social isolation above and beyond controlled variables. However,

as expected, care-recipient physical health (ΔR2 =.022, p=.033), FI (ΔR2 =.038, p=.001, and RBANS score (ΔR2 =.013, p=.045) each uniquely and significantly predicted social isolation, with declines in FI being the strongest predictor. Our findings have implications for patient care and highlight the importance of social interactions for elderly care-recipients, even in the context of declining physical and cognitive health.

Determining Water Usage of Lettuce under a Sodium Light Source for Indoor Agriculture

Rachel Collier, CURO Research Assistant
Dr. Bill Tollner, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

How can we make agriculture more sustainable? Water is a needed natural resource in agriculture and light is a needed input. Water is applied to crops using water use curves which have been developed based on the uptake rates and evapotranspiration rates of crops. The curves were developed for crops different than the current varieties grown today. Additionally, indoor agriculture is increasing as a way to grow crops while being sustainable and providing food in locations where there are food deserts. Therefore, this research investigates the growth of lettuce grown under sodium lights and two different water levels. The lighting used for this project was a 1000 watt high pressure sodium light. Lettuce was planted in 16 inch pots with Tifton Loamy Sand. The plants were watered at two different treatments. The treatments followed the application rate of water according to the current water use curve and let the soil get depleted by 20% and 50%. Water was measured and applied by hand in volumes equal to the required volume calculated from the evapotranspiration equations. Lettuce plants were measured for height to determine growth rate and will be harvested and weighted to determine yield per volume. This project will provide information on the water use rates of lettuce grown indoors under high sodium lights. The information gained from this project should provide information on the water use rate and evapotranspiration rates of crops grown indoors under artificial lights to determine if this is a sustainable method of growing crops.

Resiliency and Sustainable Organizations: Leveraging Weather Management Systems

Zac Commanday
Brian Northern
Dr. Richard Thomas Watson, Management Information Systems, Terry College of Business

In the face of the far-reaching and urgent consequences of climate change, organizations and governments around the world are seeking to mitigate their exposure to environmental risks within the broader context of a deteriorating planetary ecosystem. Fortunately, there are tools and technologies being developed to deal with the effects of climate change. This wave of emerging technology is helping guide a new frontier for information systems. Leading organizations and government are now leveraging these Information systems, such as Weather Resiliency Management Systems (WRMS), to mitigate their exposure to environmental risk. Specifically, we ask how climate change influences the creation, adoption, and use of WRMS. To help explain this phenomenon, we examine several cases where WRMS are likely candidates to inform resiliency-related decision making. Because cities have been at the forefront of resiliency (a stream of research referred to as "urban resiliency"), we selected this context for our inquiry. Our starting point is the list of "100 Resilient Cities," which was pioneered by the Rockefeller Foundation to help cities around the world become more resilient to physical, social and economic challenges. As part of our research, we will conduct interviews of Chief Resilience Officers (CRO) and other key stakeholders for the cities identified by the 100 Resilient Cities initiative. These interviews will provide information on plans for current or future implementations of WRMS and on system constraints and challenges associated with implementation in terms of both technical and organizational feasibility.

The First Amendment Protections Afforded to Student Newspapers at Public Universities

Aaron Conley, CURO Honors Scholar, CURO Research Assistant, CURO Summer Fellow
Dr. Barry Hollander, Journalism, Grady College of Journalism and Mass Communication

One of the most foundational ideas in the legal code of America comes in the form of the First Amendment of the United States Constitution. This amendment has served as the basis for many judicial decisions that have shaped the legal development of the US. In terms of the media, one of the most significant of those developments is the establishment of shield laws, which protect reporters from being forced to reveal the identity of confidential sources of information. Shield laws exist only at the level of state statutes, however, so a high degree of variance exists in how these protections are afforded to journalists. One area where this variance can be seen most plainly is in the protection that is afforded to those seen as professionals as opposed to amateurs. This is especially troubling for journalists at the collegiate level. This research examines this question surrounding this extension of protection, or lack thereof, by analyzing the variations in state shield statutes. This research also analyzes the recent events at the University of Kentucky, where the university has sued its own student newspaper in an attempt to force the paper to release documents that contain information that reporters are endeavoring to keep confidential.

Mushroom Biochar: The Properties and Potential Applications of Novel Biochars Derived from Mushroom Fruiting Bodies

Jared Conner, CURO Research Assistant
Dr. Valentine A Nzengung, Geology, Franklin College of Arts and Sciences

This research investigates the properties and applications of biochars derived from mushroom fruiting body feedstocks. We observed the unique hyphal structure of mushrooms, and hypothesized that these would produce a biochar with a unique structure that significantly enhances biochar applications that depend on surface area and morphology. The four species of mushrooms examined in this research were pyrolyzed at two temperatures. The biochar physical and chemical properties were analyzed, and then the biochar was evaluated for application potential in removal of multiple contaminants from agricultural and industrial wastewaters. This involved physical and chemical testing, as well as SEM imaging. Here, preliminary results are presented, along with pyrolysis data, pH data, and sorption test results for these biochars. Ongoing efforts to enhance the remediation capabilities of these biochars via iron impregnation are discussed. Sorption experiments for remediation of wastewaters showed that mushroom biochars can remove contaminants that conventional biochars cannot, and can remove ammonia more effectively than other biochars. pH testing showed that the three fast-growing, soft-tissue mushroom species had biochars with a high pH, while the slow growing, woody bracket species had a biochar with a lower pH. The results of this research indicate that mushroom biochars could be used as effective remediators of wastewaters, and therefore could decrease the impact of agricultural and industrial wastewaters on soil and water quality. SEM images revealed an open-celled morphology, which could indicate that these biochars have applications in industry that other biochars are ineffective at due to their porous, closed structures.

Effect of Mythic Primers on Psychological Well-Being

James Conners
Dr. Leonard L Martin, Psychology, Franklin College of Arts and Sciences

According to scholar Joseph Campbell, mythologies can provide for the "rapture of being alive," among other benefits (*The Hero with a Thousand Faces*, 1949). The present study examines whether certain mythic elements can serve to improve psychological well-being. We exposed n participants to "hero's journey" motifs found in popular films; specifically, in *Star Wars: A New Hope* (1977) and *Finding Nemo* (2003). A control group of n participants was exposed to an assortment of comparatively neutral tropes. For one week, both groups were instructed to observe their lives for occurrences of these respective motifs, and received daily reminders in the form of a mobile questionnaire (P.I.E.L. survey app, IOS) requesting that participants denote occurrences as they arose. At the end of the trial period, participants were self-assessed in regard to their perceived meaning in life, gratitude, awe, and capability for entering the state known as "flow" (Csikszentmihalyi 2008). We predict that exposure to "hero's journey" motifs will be associated with an increase in awe, gratitude, and flow.

Exposure to Synthetic Estrogens Disrupts Meiotic Division in Germ Cells

Madison Cook, CURO Research Assistant
Dr. Maria M Viveiros, Physiology and Pharmacology, College of Veterinary Medicine

Synthetic estrogens, such as Bisphenol-A (BPA) that are prevalent in plastics are recognized as endocrine disruptors that can adversely affect reproductive function, including meiotic division in germ cells. Errors in meiosis can lead to aneuploidy (an abnormal number of chromosomes), which is a leading cause of birth defects such as Down's syndrome. Previous studies showed that relevant concentrations of BPA promote meiotic errors. Bisphenol-F (BPF) is a commonly used substitute for BPA. While the effects of BPF on meiosis are less clear, it is structurally similar to BPA. This experiment tested the effects of varying levels of estrogens, both natural and synthetic, on meiotic division of female mouse germ cells (oocytes). Increasing concentrations of Estradiol-17β (0, 5, 15, 30μM) were compared to a high dose (50μM) of BPA and BPF during a 17 hour culture. The oocytes were fixed for immunofluorescence analysis to assess chromosome and meiotic spindle configurations. Spindle microtubules and MTOCs (Microtubule Organizing Centers) were labeled with anti-acetylated tubulin and pericentrin, respectively, and the chromosomes with DAPI. Oocytes were analyzed using an upright fluorescent microscope. Oocytes exposed to BPA and BPF showed lower maturation rates and increased chromosome disruptions compared to controls. Chromosomal errors were highest in the BPA group, and correlated with abnormal spindle organization. Oocytes exposed to high levels of Estradiol also showed chromosomal abnormalities. These data suggest that high estrogen levels including those from estrogen mimicking compounds, such as BPA and BPF, can disrupt oocyte quality.

Comparing Metallicity Measurements from Optical Spectra of Solar-Type Stars

Paige Copenhaver, CURO Research Assistant
Dr. Inseok Song, Physics and Astronomy, Franklin College of Arts and Sciences

Metallicity (where [Fe/H] is used as a proxy) is a stellar parameter that contributes to physical characteristics of a star, and it can reveal valuable information about the star. However, historically this quantity is difficult to measure, and there are several methods to derive it that show significant discrepancies in their results. We aim to quantify the discrepancies in the metallicity measurements between iSpec values, a Python-powered automated analysis tool, and known literature values. We want to determine the reliability of iSpec in obtaining metallicity of solar-type stars. To gather the sample of stars, we selected several G-type stars for which we have known [Fe/H], temperature, and surface gravity values. We used both the iSpec synthetic spectrum method and the equivalent width method in order to determine [Fe/H] from the absorption spectra. We then compared the results with the literature values. We show that iSpec parameters agree well with previously determined values. The known values of metallicity are generally well-accepted, but it is unclear at this time which method of obtaining the parameters is the most reliable. This study finds that the iSpec tool is a potentially reliable method for determining metallicity of solar-type stars. Having more reliable metallicity measurements can tell us more about the environment in which planets form. Only stars with high metallicities are good candidates for having planetary systems, since the cores of planets are formed from metals such as iron.

Hurricane Risk Assessment of Georgia Coastal Bridges

Paul Coughlin, CURO Research Assistant
Dr. Mi Chorzepa, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

The necessity of proper disaster preparedness has rarely been exemplified so well as in 2005, when Hurricane Katrina crippled the Gulf Coast and wrought over $100 billion in damage to property and infrastructure. Georgia's coastline is fortunate to have been spared the devastation of bearing the brunt of a major hurricane in recent history, but history suggests that we should be wary of developing a false sense of security. Our research intends to meticulously catalog and assess the vulnerabilities of Georgia's 560+ coastal bridges in accordance with AASHTO code, in order to more precisely inform the state where to allocate its resources in the event of a major hurricane. By

compiling both public and independently surveyed data for each bridge into a self-contained, comprehensive database, we look to determine the most critical parameters to a bridge's structural integrity in the event of a major hurricane. Once we have identified the bridges most susceptible to failure, we will run a more granular analysis to determine the most likely failure modes of each bridge and whether multiple at-risk bridges exhibit similar vulnerabilities. By diagnosing the sub- and super-structure bridge components most prone to be compromised under the forces exerted by a major hurricane, we can provide GDOT with the necessary information to mitigate risks in the short term and better prepare for disaster management in the long term.

Ethanol Production in *Pyrococcus furiosus* using High Temperature Alcohol Dehydrogenase AdhC

Alex Thomas Crowley, CURO Summer Fellow, CURO Research Assistant
Dr. Mike Adams, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Even with energy prices lower than in the previous decade, independence on fossil fuels for energy has raised concerns over continued costs, the environmental impact of carbon emissions, and a reliance on a resource that is nonrenewable. The creation of viable renewable resources as fuel has been a continually growing field of research, and to find a cheap, efficient production method for biofuels such as ethanol has been a major goal of this research for decades. The production of significant amounts of ethanol at 95°C has never before occurred. Through the overexpression of a native alcohol dehydrogenase in the hyperthermophilic archaeon, *Pyrococcus furiosus*, ethanol was produced in significant amounts at 95°C in comparison to the control strain, which did not contain the overexpressed gene. The pathway involved in the production of ethanol in *P. furiosus* saw a sharp jump in ethanol production during the last 3 hours of a 12-hour growth experiment after low and stagnant levels of ethanol production during the first 9 hours. This jump could be a coping mechanism meant to save the cell from extreme pH levels formed by the byproducts of its normal metabolic processes. The characterization of different ferredoxin oxidoreductases and their activity in conjunction with a native alcohol dehydrogenase show new relationships in this process that differ greatly at different temperatures, and the addition of a carbon monoxide dehydrogenase enzyme improves the yield of ethanol at 90°C in this system.

An Exploratory Investigation: Examining the Current and Future Prospects of Organizational Use of Business Process Management Tools and Technology

Fernando Arturo Cruz
Dr. Dave Chatterjee, Management Information Systems, Terry College of Business

This exploratory paper covers the current iteration and future prospects of Business Process Modeling Notation (BPMN) through analyzing a shift in its fundamentals and an aggregation of functions. First, Value-Driven BPM (VBPM) builds upon the previous BPMN practices by focusing on giving priority to processes that generate the greatest utility. VBPM includes three sets of tradeoffs: Efficiency or Quality, Agility or Compliance, and Integration or Networking. Although professionals continue to use BPMN for its routinization, the continued sacrifice of quality and agility reduces firm differentiation. Furthermore, businesses have been embedding Knowledge Management (KM) into BPMN fundamentals to maintain their competitive advantage. This theoretical combination creates a knowledge-intensive process that converts unstructured data to organizational wisdom. A diverse array of platforms using this methodology have expanded their functions from simple process modeling to complete implementation of automated systems. BPMN operates in two major domains, modeling and execution, while tools vary in interface and capabilities. A BPMN tool requires competency in four areas: BPMN compliance, syntax inspection, interoperability, and process executions. A brief qualitative investigation in this paper reveals a wide range of programs offering competency in all areas but with unique user focus and interface. In conclusion, BPMN supports interdisciplinary collaboration for business and technical professionals by offering a set of agile design principles coupled with a robust marketplace of modeling software.

Neutrophil Extracellular Trap Induction Dependence on Flagellar Motility

Christian Chandler Cullen
Dr. Balazs Rada, Infectious Diseases, College of Veterinary Medicine

Cystic fibrosis (CF) is a disease caused by a mutation in the cystic fibrosis transmembrane conductance regulator (CFTR) anion channel, resulting in severely impaired mucociliary clearance in the airways leading to chronic bacterial infections. *P. aeruginosa* exhibits a unique resistance to airway mucus and has become a common pathogen within airways. Despite the large-scale neutrophil recruitment in the airways, neutrophils fail to clear *P. aeruginosa* in CF. Instead, neutrophils release extracellular traps (NETs) composed of granule cargo and DNA into the airway lumen causing tissue damage. *P. aeruginosa*-induced NET formation occurs in CF airways and offers a likely mechanism for neutrophil-mediated lung damage. Previously, we have shown that bacterial flagellum is essential for planktonic *P. aeruginosa* to induce maximal NET release. Recently, we found that bacteria with motile flagellum trigger significantly more NET release than *P. aeruginosa* with immotile flagella. To gauge the role of flagellar structures, we tested 22 mutant strains of *P. aeruginosa* deficient in several of the motor genes moving the flagellum (motAB, motCD). Our results showed that deletion of both motility islands is needed to entirely eliminate flagellar motility-induced NET release in *P. aeruginosa*. However, partial deletion mutants revealed that the motAB island is more potent. From our work, we propose that bacterial motility is the primary virulence determinant responsible for triggering NET formation by enabling *P. aeruginosa* and neutrophil encounters. Our work adds to current literature by distinguishing bacterial motility machinery and proposes to target proteins driving flagellar motility as CF therapeutics.

Judicial Politics in the Obama Era

Bryson Culver, CURO Honors Scholar, CURO Research Assistant, CURO Summer Fellow
Dr. Susan Haire, Political Science, School of Public and International Affairs

The Federal Judiciary acts as an independent and apolitical body; however, in an era of growing partisanship, it is not immune from political influence. Looking at the Federal Appellate Courts, this project has determined that the voting behavior of judges aligns with the party of their nominating presidents. The researchers used thirty randomly selected cases from every Circuit from the years 2009-2012 and coded the judges' votes as either conservative or liberal. From this analysis, the researchers were able to determine that the presidential cohorts of judges voted more conservatively if the nominating president was a Republican and more liberally if the nominating president was a Democrat. Over time, the judges have become more moderate as cohorts of older presidents (Carter, GHW Bush, Clinton) are more polarized in comparison to the more recent presidents (GW Bush, Obama). The project also looks at change in circuit composition under Obama. In 2008, only one Circuit had a majority of democrat appointed judges. By 2016, eight of the twelve Circuits became majority democratic appointees. Additionally, every single Circuit gained a larger proportion of minority and female judges. The researchers found the composition to be important as judges' voting behavior was directly affected by the composition of the panel they sat on. The presence of a conservative judge on a panel increased the likelihood of liberal judges to vote conservatively. Additionally, in cases involving gender or racial issues, the presence of a minority or woman on the panel affected the outcome of the decision.

Design of a High Speed Water Tunnel and Associated Instrumentation

Haynes Curtis, CURO Research Assistant
Dr. Ben Davis, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

High-speed water tunnels are used to visualize the fluid flow around submerged bodies as well as study the corresponding hydrodynamic forces. Due to the extreme costs involved with purchasing a water tunnel from a commercial manufacturer, it was decided that a water tunnel would be designed and built in-house with the assistance of the UGA Instrument Shop. The goal of this study was to research the critical design aspects of water tunnels and their instrumentation

through literature review and site visits to existing tunnels. Additionally, one of the most fundamental pieces of tunnel instrumentation, a force balance, was designed for in-house fabrication alongside the water tunnel. The force balance will be used to measure lift and drag forces imposed on object tested in the water tunnel. It is expected that the high-speed water tunnel will be installed in the Dynamic Devices and Solutions Lab in the College of Engineering during the spring 2017 semester.

Histological Comparison of Various Coccidial Control Programs Used in Commercial Poultry

Ebun Dada
Dr. Susan M Williams, Population Health, College of Veterinary Medicine

Coccidiosis has been deemed the biggest parasitic threat to commercial poultry throughout the world and is caused by the protozoan *Eimeria*. To control the internal spread of the bacteria in chickens, traditional anticoccidial routes such as antibiotics and vaccinations have been implemented. Since chickens are a major contributor to modern consumer diets, it is necessary for the routine maintenance and clinical assessment of the gastrointestinal tract health of chickens. In the past decade, consumers have demanded more organic substitutes of coccidia control in the feed of chickens by removing in-feed antimicrobials. The shift from synthetic to organic means of control has not only been prompted by consumer demands but also biologically, as the extensive use of anticoccidial drugs has resulted in the emergence of drug-resistant coccidian strains. Examination of coccidia severity levels, and histological examinations were carried out within the gastrointestinal tract of birds during a 6-week treatment coccidiostat/antibiotic alternative trial. There was a systematic distribution of chickens where one bird per pen, from six pens per treatment, was examined weekly. These birds were either given a coccidiostat with some form of additives such as an antibiotic or the organic seed, weed, and feed option or a vaccination with the same type of additive. With our data, we observed the difference in coccidia severity levels in each treatment and, as expected, we saw greater severity levels in chickens given the antibiotic and growth promoter compared to that of the organic option. By the end of the study, it was concluded that the seed, weed and feed program did, in fact, result in lower severity levels of coccidia expression.

Effects of *Plasmodium falciparum* Derived Hemozoin on Expression of Inflammatory and Coagulation Factors in BeWo Cells

Trisha Dalapati, Foundation Fellow
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Plasmodium falciparum infection during pregnancy, which commonly progress into placental malaria (PM), is estimated to cause over 200,000 infant deaths annually. PM is characterized by sequestration of parasite-infected red blood cells (iRBCs) in the maternal space of the placenta. Pathogenesis is additionally marked by aberrant inflammation, adversely affecting nutrient and gas exchange in the syncytiotrophoblast, the outermost multinucleated cell layer of the placenta. Alongside inflammation, increased expression of tissue factor (TF) leads to activation of the extrinsic coagulation cascade and subsequent blood clotting. PM has been marked by excessive clotting, leading to low fetal birth weight and growth restriction. Protease activated receptors including PAR-1 and PAR-2 may be involved in positive feedback of inflammation and coagulation. Although inflammation and coagulation are often viewed separately, activation is concurrent. Because the pathology of PM remains ambiguous, quantifying gene expression of inflammatory and coagulation factors may provide essential mechanistic information. BeWo, a choriocarcinoma cell line, was used as an in vitro model to mimic in vivo host-parasite interactions. After reaching proper confluency, BeWo cells in duplicate samples were syncytialized and stimulated using lipopolysaccharide (LPS) or hemozoin. LPS, the positive control, is found on the outer membrane of gram-negative bacteria and elicits immune response. Hemozoin is the primary parasite by-product from the digestion of hemoglobin. After stimulation, cells were scraped at various time points for RNA isolation, cDNA generation, and real-time PCR. Three genes were chosen for study: TF, PAR-1 and PAR-2. Analysis

of gene expression of these targets will provide insight into inflammatory and coagulation responses during PM.

Structural Analysis of a Predicted Skp1 Glycosyltransferase PuGT8A

Nitin Daniel, CURO Research Assistant
Dr. Christopher M West, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Toxoplasma gondii (*Tg*) is an obligate apicomplexan parasite that can infect most warm-blooded animals. It uses a pathway that includes the glycosylation of the Skp1 Cullin-1 Fbox E3 ubiquitin ligase complex resulting in a pentasaccharide that is thought to aid the parasite in cell cycle regulation. The Skp1 complex in the model organism *Dictyostelium discoideum* is hydroxylated by PhyA and modified by glucosyltransferases GnT1, PgtA and AgtA. The Tg Skp1 hydroxyproline is modified by a similar mechanism and addition of the sugars is carried out by homologs of GnT1 and PgtA, but the last two sugars are added by GT32A and GT8A. This was unexpected because GT8A was previously predicted to encode a glycosyltransferase (glycogenin) critical for initiation of glycogen synthesis. To understand the relationship between GT8A and glycogenin, a structural study was initiated. After crystallization efforts of TgGT8A were unsuccessful due to poor diffraction, a homolog from the plant pathogen *Pythium ultimum* was chosen as an alternative candidate based on its sequence similarity to TgGT8A. Here we express the PuGT8A plasmid in *E. coli*, purify it using an IMAC column, and show its predicted activity as an alpha-galactosyltransferase through a radioactive assay. PuGT8A crystals were diffracted in an in-house X-ray generator and a diffraction pattern was obtained. Studies are ongoing to solve its 3-D structure. Structural studies on the glycosyltransferases that modify Skp1 are expected to help us understand the mechanism of their regulation, which in turn might lead to new opportunities for parasite control.

Analyzing TGF- ß Regulation of the Progenitor Motor Neuron/Motor Neuron Glial Fate Switch

Tarun Daniel, Foundation Fellow
Aditya Sood
Dr. Steven Stice, Animal and Dairy Science, College of Agricultural and Environmental Sciences

In the developing primitive spinal cord, termed the neural tube, motor neuron progenitor cells (pMN) undergo a temporal change in potency, first generating motor neurons (MN) and later, oligodendrocyte precursor cells (OPC). Oligodendrocyte transcription factor 2 (Olig2) is a critical fate determinant central to this fate switch. In vivo, Olig2 promotes self-renewal, and primes cells for neurogenesis, ultimately resulting in the generation of MN while maintaining a subset of undifferentiated pMN. pMN then co-express the transcription factor homeobox protein Nkx2.2 alongside Olig2, which together drive much of the genetic glial machinery, marking the initiation of oligodendrogenesis. The underlying mechanism(s) involved in this fate switch, namely the transcription and expression of Nkx2.2 in pMN, are poorly understood. Previous studies suggest that a soluble, secreted transforming growth factor beta (TGF-β) family protein can regulate similar neural progenitor fate switches. Sonic hedgehog (Shh), a morphogenic inducer of both Olig2 and Nkx2.2 transcriptions, is also an important component in driving this initiation event, though alone it is insufficient in triggering glial initiation. Using an in vitro, pluripotent stem cell (PSC)-based model of neural tube development, we hypothesize that TGF-β primes pMN for the glial fate switch by altering the post-transcriptional state of Olig2. Further, we expect Shh to drive Nkx2.2 transcription. Ultimately, our studies will aid in developmental and disease modeling, stem cell manufacturing, drug and toxicity testing and regenerative medicine.

Recycled Crumb Rubber for Use in Concrete Barrier Walls and Other Applications

Grace Hays Darling, CURO Research Assistant
Dr. Stephan A Durham, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

As the availability and storage area of landfills diminish, there is an increasing demand for finding new methods to incorporate recycled

materials into construction applications. The recycled material of interest for this study is rubber tires. Concrete safety barriers are one of the widely used impact reducers that are intended to either decelerate vehicles to a safe stop or redirect them away from a fixed object. Concrete barriers constructed by GDOT consist of a Class A concrete mixture design (3000 psi). A benefit for using recycled rubber in concrete barrier applications would be the possible reduction in materials cost. GDOT has not conducted any studies about the use of rubber tires in concrete barrier walls or any other application. This research project will involve extensive review of literature related to the use of recycled rubber tires, predominantly crumb rubber, in transportation applications. Crumb rubber is shredded recycled tire scraps consisting of only rubber that becomes granular in size. In this study, the fine aggregate component of concrete will be substituted with incremental proportions of crumb rubber. The intention of this study is to determine a concrete mixture with crumb rubber inclusion that is feasible without any significant disadvantageous effects on the concrete's structural performance. The compressive strength of the crumb rubber concrete mixtures will be tested at 1, 7, and 28 days of age to measure their mechanical performance as the crumb rubber substance increases. Ultimately, the data gathered from this study will be utilized in further phases of a larger-scale research analysis.

Privileged Perception: An Examination of Supersensory Insight in Vladimir Nabokov's *The Gift*

Anna Jewell Davidson
Dr. Charles Byrd, Germanic and Slavic Studies, Franklin College of Arts and Sciences

As one of the greatest achievements of Vladimir Nabokov's career, *The Gift* reveals the possibility of connecting with a world otherwise unseen and undetected. Such supersensory insight is the defining gift of the novel's hero, Fyodor Godunov-Cherdyntsev, in his attempts to achieve recognition as a writer despite continuous criticism by the outside world. As a result, Fyodor reveals his supersensory insight to no one except in covert statements that largely go unrecognized. This presentation examines Fyodor Godunov-Cherdyntsev's supersensory insight and the factors contributing to its presence in *The Gift*. We will first draw upon the ideas of the French philosopher and Nabokov's invented man of wisdom, Pierre Delalande, for greater understanding of supersensory insight followed by evidence of its existence in Fyodor. We will then explore evidence of supersensory insight in one of Fyodor's few literary supporters, Aleksander Yakovlevich Chernyshevski (the namesake of the renowned author and philosopher). We will later analyze the Kirghiz story told to Fyodor by his late father in which supersensory insight is a supreme influence. The final subject of analysis will be the novel's concluding paragraph and its relation to Aleksandr Pushkin's *Eugene Onegin*. Through Fyodor's experience, Nabokov teaches us to not only seek awareness of things beyond our own human comprehension but also to be slow to rebuke those who claim to understand things we do not. We are compelled to ask ourselves how often we value objects with mere temporary worth while rejecting those that are much more significant and invaluable.

An Investigation of Environmental Variable and Dispersal Patterns of North American *Photinus* Fireflies

Brandon Davis
Dr. Kathrin F Stanger-Hall, Plant Biology, Franklin College of Arts and Sciences

Among the genera of North American fireflies, the genus *Photinus* is the most diverse, with over 40 different species. The distribution of *Photinus* species across North America varies greatly, and little is currently known that can explain these observed distributions. This research study utilized state and county records for 36 North American *Photinus* species, which were collected over the last 50 years. All county coordinates (longitude and latitude) with observed *Photinus* species were entered into ArcGIS, a sophisticated geographic mapping program, and were used to test hypotheses on the influence of different environmental variables (average annual precipitation, soil composition, elevation, and average annual temperature) on species distribution. Insights from this study will be important in identifying key characteristics of *Photinus* habitats. Furthermore, this investigation may identify important habitats for conservation of *Photinus* fireflies across North America.

Abstracts

Gender Differences in College Students with ADHD

Samantha Delaney, CURO Research Assistant
Shruti Prathip
Dr. Jason Nelson, Psychology, Franklin College of Arts and Sciences

Limited empirical research investigating the subject of gender differences in attention-deficit/ hyperactivity disorder (ADHD) provides evidence for under-identification of ADHD in females. This poses a significant concern, as women with ADHD demonstrate significantly higher levels of other mental health comorbidities when compared to non-ADHD females. This study sought to contribute to the available research by examining potential gender differences in first-time ADHD diagnosis in college, ADHD subtypes, hyperactive-impulsive symptoms across the lifespan, and treatment-seeking behavior. Participants included 589 students pursuing postsecondary education who were diagnosed with ADHD using multi-method, multi-informant evaluations. The gender distribution was 51.4% male (n=303) and 48.6% female (n=286). Archival data from evaluations leading to the ADHD diagnoses were used for the analyses. Self-report and parent-report ratings were used to measure ADHD symptoms. Females were more likely than males to be initially diagnosed with ADHD in college. Females were not more likely to be diagnosed with inattentive type ADHD, though self-reported inattentive symptoms were significantly higher in females in adulthood. Females were more likely to present with comorbid anxiety and mood disorders. While females were also more likely to have attended therapy in the past, differences in stimulant usage between males and females were insignificant. Findings provide evidence that ADHD in females is more likely to be under-identified in childhood. Given empirical findings that males and females are both likely to experience significant impairment associated with ADHD, there may be reason to modify the approach in which practitioners identify the disorder.

Testing Immune Function in Naked Mole Rats During Periods of Wound Healing

Madison Demetry
Dr. Vanessa Ezenwa, Ecology, Odum School of Ecology

Typically, when an animal is wounded, the skin regenerated is characterized by abnormal collagen patterns and lack of hair follicles. Some species, such as *Acomys kempi*, can regenerate skin characterized by normal collagen patterns, both skin layers, and the presence of hair follicles. In animals where skin-regeneration is possible, it has been proposed that a biological trade off exists between immune system function and complete regeneration. I investigated by testing the innate bacterial killing capacity of non-regenerative animals and comparing it to data previously collected on the killing capacity of regenerative species living in the same habitat. By comparing the killing capacity of pre-wounded Naked Mole Rats (*Heterocephalus glaber*) to the killing capacity of four other species, I found that *H. glaber* had a killing capacity that fell between that of regenerative species (*A. kempi*, *A. percivali*) and non-regenerative species (*Myomyscus brockmani*, *Mus musculus*). Additionally, I found that the killing capacity of *H. glaber* significantly decreased 24 hours after wounding. Because *H. glaber* does not possess regenerative properties, it was expected that the killing capacity of this species would have been relatively close to that of other non-regenerative species. Interestingly, results instead indicated that the killing capacity of *H. glaber* (12%) was closest to one of the regenerative species, *A. percivali* (17%). This result could be contributed to many different factors, such as hyaluronic acid levels or fibroblast properties specific to Naked Mole Rats.

Investigating Genes Implicated in Ciliogenesis Using CRISPR/Cas

Kaley Ann Desher, CURO Research Assistant
Dr. Jonathan Eggenschwiler, Genetics, Franklin College of Arts and Sciences

Cilia, the hairlike organelles that project from the surface of eukaryotic cells, play several critical roles such as sensing the extracellular environment, cell signaling, and embryonic development. Disruption of these processes can lead to ciliopathies that compromise human health. Alpha-TAT1, Bbs8, Ick/MRK, Ift122, and Kif7 are all ciliary proteins implicated in

ciliogenesis that have undetermined functions. We generated reversible mutations in each of these genes using the CRISPR/Cas9 genome editing system and a Cre-LoxStopLox (LSL) transcriptional cassette containing the puromycin resistance gene. We also cloned a LSL/RFP/homology sequence cassette for each gene that will be utilized to generate double mutants. We plan to PCR screen our mutants, and then conduct phenotypic analysis to discover each gene's unique role in ciliogenesis.

The Effect of Litter Leachate from Fresh Riparian Rhododendron Leaves on Microbial Respiration in Headwater Streams in the Southern Appalachians

Desirae Ann Dickerson, CURO Research Assistant
Dr. Catherine Pringle, Ecology, Odum School of Ecology

This project aims to study the effect of fresh leaf litter leachate from Rhododendron on microbial respiration in headwater streams. When Rhododendron leaves decompose they release a mixture of labile and refractory organic compounds into the stream. This leaching process can take up to two months depending on the type of dissolved organic compounds (DOC) contained within the leaves. Microbes use mostly labile compounds for growth and energy whereas refractory compounds are harder to use and can inhibit microbial growth. As part of a USFS-LTER Rhododendron Removal Project, one treatment/management strategy involved cutting Rhododendron along a stream reach and leaving the cut branches and leaves within the stream for several months before burning. The leachate from these fresh Rhododendron leaves may negatively affect the microbial community in that stream, depending on the amount and quality of leachate compounds released. We hypothesize that: (1) the compounds found in Rhododendron over time will be more labile in the beginning and more refractory towards the end of the 5-week experiment; (2) microbial respiration will decrease over time in response to exposure to more refractory Rhododendron leachate; and (3) as leachate concentration increases, microbial respiration will decrease. This project is planned to be complete by April 2017 and we will combine our completed analyses of microbial respiration with chemical analyses of Rhododendron leachate to address our hypotheses.

Tolak Reklamasi: Rejecting Tourist Developments in Bali

Sarah Jane Dillon, CURO Research Assistant
Dr. J. Peter Brosius, Anthropology, Franklin College of Arts and Sciences

Bali is currently experiencing a massive growth in tourism and development that is affecting the culture, politics, and economics of the island. This influx of large-scale developments has caused unbalanced water access privileging tourists and created other environmental costs that are causing serious problems experienced throughout Bali. In response to this situation, a protest movement, called the *tolak reklamasi* or "reject reclamation" movement, has grown quite popular island-wide. Large developments created specifically for tourists are not new in Bali, but island-wide protest has only been occurring relatively recently. The factors that play into these current mass protests are varied; however, my thesis states that the main causes are the way land is viewed through Balinese cosmology; the history of the Indonesian genocide and its effect between generations; the historical and symbolic importance of the ritual, royal, and mass suicides that occurred in 1906 and 1908; the perception of cultural attacks Balinese feel are coming from Jakarta; and the confluence of environmental issues that such developments have already caused. I will assess each of these factors through a detailed scoping of the appropriate literature, and eventually on-site research in Bali. I anticipate that my findings will show that my hypothesis encompasses the root factors of why the *tolak reklamasi* movement is growing in popularity now. This research will also address an oversight in anthropological work, because, despite the importance of *tolak reklamasi* to the Balinese and to future developments in Bali, there is very little anthropological analysis on this subject.

An Empirical Analysis of Economic Influence on Election Outcomes

Emil Dmello, CURO Research Assistant
Dr. Nikhil Srinivasan, Management Information Systems, Terry College of Business

The United States has undergone a divisive election that has answered several questions, but has left more unanswered. One of these questions that political scientists and historians have continuously debated is the significance of economic variables on general election results. Historians postulate that economic conditions outweigh the quality of candidates, while political scientists stipulate the opposite. This debate can be distilled down to whether political fortunes are determined by great people or involve great circumstances. My research examines this dichotomy by assessing the significance of economic influences on the political fortunes of the two major parties in the US. I will collect economic data and perform Poisson regressions to assess whether economic variables influenced changes in representation within the House of Representatives and the Senate. As my response variables on Congressional representation are discretely valued, Poisson regressions are employed for continuous-discrete pairing analysis. Since Poisson regression assumes there is mean-variance equivalence within the response data, its assumptions must be validated prior to analysis. While traditional evaluations of this question may involve the least-squares model, I believe the Poisson regression can help us understand the driving forces in a discrete fashion. My research aims to determine if macro-level economic indicators such as unemployment and inflation, as well as subjective economic indicators including measures of economic anxiety, the Gini-coefficient, and measures of social mobility, influence election outcomes. Based on my research, I hope to highlight the role of personal charisma versus economic circumstance in defining the priorities of voters.

Jamming Avoidance Response: An *Eigenmannia* Phenomenon

Phiet T Do
Luis Perea
Dr. Mable Fok, Electrical and Computer Engineering, College of Engineering

The *Eigenmannia* is a species of South American fish that features the ability to perform a Jamming Avoidance Response - JAR. This electric fish uses electrical discharge pulses to sense its environment through electroreception. When the fish comes into contact with another gymnotiform electric fish producing an electrical discharge at a similar frequency, it results in destructive interference of the two discharges causing the electroreception to be distorted. Evolutionary modifications have occurred so that the two fishes employ a neural circuit behavior to avoid each other's specific frequency, restoring their respective electroreception. The objective of this research is to understand how the electrosensory lateral line lobe and the neural pathways interact to perform this neural behavior. There have been different, competing theories to explain the jamming avoidance response; for example, one theory emphasizes asymmetric amplitude, while another emphasizes on phase differences of the signals. In an attempt to simulate the *Eigenmannia* phenomenon, our biological model will consist of pass band filters, logic gates, a switch module, and a feedback control system. Applying this knowledge will help us begin prototyping a photonic and electrical circuit to replicate the jamming avoidance response, as we believe it has the potential to revolutionize radio communication.

Beyond-Design Basis Evaluation of Georgia Coastal Bridges

Adara Dodson, CURO Research Assistant
Dr. Mi Chorzepa, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

The evaluation of existing bridge drawings to determine critical bridge parameters necessary for hurricane vulnerability evaluation and the development of a load-capacity assessment procedure are the objectives leading the "Vulnerability Evaluation of Georgia Coastal Bridges" research project. To gather necessary criteria, two procedures must be completed. Initially, critical bridge components and bridge drawings are assessed as part of a Georgia Department of Transportation project. This assessment includes identifying significant bridge details and gathering them in a logical format for future uses. Subsequently, the research data gathered is used to develop a load-capacity assessment procedure for beyond-design basis hurricane categories (e.g., Category 4 or 5). During my semester of contribution, as well as the previous years' work on the project, the necessary bridge drawings were reviewed and the first phase

was considered complete. Currently, the vulnerability assessment of coastal bridges is underway in order to evaluate reliability of Georgia coastal bridges under, beyond-design basis, hurricane loads.

Relationships and Trade Offs between Food Insecurity and Healthcare

Jacy Donaldson, CURO Research Assistant
Dr. Abigail Borron, Agricultural Leadership, Education, and Communication, College of Agricultural and Environmental Sciences

Every day, there are people who struggle due to instability in their life. Survival often requires tough choices regarding food, health, shelter, education, and other daily needs. When focusing on one area, such as food insecurity, making ends meet through to the end of the month can be identified through varying resources for assistance. However, when food insecurity intersects with health-based concerns, an increasingly complex set of issues arise. This research project focuses on the tradeoffs and unique characteristics between food insecurity and health care. The majority of literature focuses on how food insecurity increases the need for health care due to health issues related to poor nutrition. While this is important, there is also an opportunity to consider how food insecure families perceive and deal with weighing the options between food and health care needs. The target population for this study is individuals utilizing food pantries in and around Atlanta, Georgia. Using qualitative research methods such as focus groups, in-depth interviews, and photovoice, we will gather information about people's choices regarding food insecurity and health from their own perspective. Couched in a larger multi-disciplinary project, this research will focus specifically on the intersection of food and health when analyzing the data. The findings will contribute to developing a more comprehensive understanding of this complex intersection, which is intended to inform the Atlanta Community Food Bank, as staff consider potential interventions for assistance at the agency level.

Development of Viscosity-Sensitive Fluorescent Molecular Rotors for Food Additives

Kevin Tuan Dong, CURO Research Assistant
Dr. Mark A Haidekker, Electrical and Computer Engineering, College of Engineering

Fluorescent molecular rotors are being utilized more for their probing properties; they are reporters of fluid viscosity with the major advantage of ultrafast measurement in extremely low fluid volumes compared to conventional mechanical rheology. Among many applications, some being the examination of microviscosity in the cell membrane of blood plasma and macromolecule suspensions, the rotors can be applied to food additives. In these applications, however, a substance's autofluorescence critically interferes with the fluorescent emission of the molecular rotor. Our investigation aimed at determining a method to separate this spectral emission interference, in our case, with wort solutions. Preliminary experiments with stained (with rotors) and unstained fluid samples showed that it was impossible to separate this autofluorescent interference. It was hypothesized that additional factors such as poor solubility of the rotor, viscosity sensitivity, or even temperature could also play a role. We proceeded by synthesizing a series of molecular rotor derivatives, containing a naphthalene core, as derived from the benzylidenemolonitrile motif. These rotors exhibited a strong bathochromic shift with an emission peak at 660nm (red). At this wavelength range, the contribution from the autofluorescent emission should be negligible. With this shift, however, viscosity sensitivity was reduced. Further experimentation and development is needed to improve the rotational freedom of the rotor to increase the dye's sensitivity.

The Ratio of Gas to Dust at High Galactic Latitudes

Jessica E Doppel, CURO Research Assistant
Dr. Loris Magnani, Physics and Astronomy, Franklin College of Arts and Sciences

The ratio of the column density of atomic Hydrogen (N(HI)) and the color excess (E(B-V)) varies over the different studies that have examined the ratio. Using the data from the Leiden/Argentine/Bonn (LAB) survey and the Schlafly et. al. color excess survey, the values of the column density and the color excess are

plotted against each other for specific points in the sky to determine the N(HI)/E(B-V) ratio. From these data sets, the value of the ratio has been determined to be $N(HI)/E(B-V) = 3.2 \times 10^{21}$ mag^{-1} cm^{-2}. It is anticipated that the N(HI)/E(B-V) ratio will be dependent on distance, region of the galaxy, and the technique through which the quantities are determined. This study sets out to both understand the differences in this value between this research and previous work and to tighten the understanding of the ratio of gas to dust in various regions of the galaxy, particularly at high latitudes ($|b|<20°$) using these newer, higher resolution data sets. The determination of a reliable relation between the gas and dust would allow for identifying and mapping molecular and atomic clouds in regions of the sky that have not yet been surveyed.

A Comprehensive Assessment of Cognitive and Motor Functional Outcomes After Traumatic Brain Injury in a Porcine Model

Neil Doshi
Dr. Franklin Delano West, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Traumatic brain injury (TBI) is a leading cause of death and permanent disability in the United States. Children between the ages of 0-4 years are at the highest risk of sustaining a TBI and are also the most likely to suffer cognitive and motor function deficits as a result of their premature neurological development. Currently, there is no effective treatment for TBI. Due to their similarities in neuroanatomy and physiology to humans, pigs may serve as a successful animal model for treatment development. The present study assesses changes in cognition and motor function in a piglet traumatic brain injury model. We hypothesize that TBI in a piglet model will elicit measurable deficits at the functional level, evident through changes in cognition and motor function. A spatial T-maze test was utilized to assess the spatial memory aspect of the piglets' cognition. Additionally, gait analysis was conducted to observe changes in the piglets' spatial-temporal gait biomechanics. The TBI piglets navigated the spatial T-maze slower than their sham counterparts ($p<0.05$) and made more ($p<0.05$) mistakes during the acquisition phase of testing. Interestingly, injured piglets saw a significant recovery in many gait parameters by the end of this longitudinal study. Key insights into TBI deficits garnered from this study will form the necessitous basis of all future treatment development studies for monitoring improvements in cognition and biomechanics.

A Comparison of the 2014 Scottish Referendum and 2016 European Union Membership Referendum Campaigns

Samuel Driggers, CURO Honors Scholar, CURO Research Assistant
Dr. Cas Mudde, International Affairs, School of Public and International Affairs

In the developed world, the United Kingdom has perhaps received the most attention for its nationalist, autonomist, and secessionist movements. Several UK political parties seek greater regional autonomy, and some advocate disunion from the European Union or UK based on: 1) frustration with political, cultural, and economic marginalization, 2) the strengthening of national identity, and 3) rights of self-determination. Composed of four distinct nations, and as member of an economically and politically powerful international organization, the UK is plagued by questions concerning its concentration and divisions of political sovereignty. In attempt to preserve political rights and to appease vocal segments of its populace, the UK Parliament continually allows constituents to vote in referendums which direct how the UK's sovereignty is divided and concentrated. The most recent referendums, the 2014 Scottish Referendum and 2016 EU Membership Referendum, had focal campaigns resulting in high voter turnouts and close percentage splits. By comparing the traditional nationalist movement in Scotland to the unconventional nationalist movement surrounding the EU Referendum, this project attempts to draw parallels between sovereignty-seeking movements within states and international organizations. Additionally, this comparison attempts to support the idea that movements need not seek traditional ideas of independence to be categorized as nationalist. Furthermore, comparison of each referendum's campaigns will further the understanding of nationalist movements, questions of political

sovereignty, and simultaneous trends of political integration and disunion. This project began with a review of literature on nationalist, autonomist, and secessionist movements before proceeding to comparison of campaign materials, speeches, and actions.

Reprogramming Mouse Embryonic Fibroblasts via Induced Expression of *Foxn1* and *Foxg1* Transcription Factors to Generate Induced Thymic Epithelial Cells (iTECs)

Lauren Dunavant
Dr. Brian Condie, Genetics, Franklin College of Arts and Sciences

The CRISPR/Cas9 system has revolutionized the field of genetics by allowing direct modification and regulation of genomic regions of interest. In this study, re-engineered versions of this system (subsequently referred to as CRISPR/dCas9), which are gRNA-directed but have nullified nuclease domains, were used to activate endogenous genes in mouse embryonic fibroblasts (MEFs). The goal was to generate induced thymic epithelial cells (iTECs) to mimic the function of TECs that naturally form a thymic microenvironment essential for T cell maturation. The *Foxn1* and *Foxg1* genes (of the Forkhead box protein family) are critical in early thymic development and were activated via transfection of MEFs with CRISPR/dCas9 systems and site-specific gRNA sequences. Multiple CRISPR/dCas9 systems were used, including a p300-dCas9 plasmid, a SP-dCas9-VPR plasmid, a TetO-FUW-VdC9BV plasmid, and a humanized VP64 dCas9-GFP plasmid. Various gRNAs were also tested to optimize activation, and resulting gene expression profiles were compared to those of iTECs generated from cre-activated transgenic mice. Current data shows that the p300-dCas9 plasmid-treated cells showed an approximate 10-fold increase in *Foxg1* expression (compared to an internal control), although further optimization may be required. Screening of the SP-dCas9-VPR, TetO-FUW-VdC9BV, and VP64 dCas9-GFP plasmids also gave strong evidence that the SP-dCas9-VPR plasmid may effectively activate both *Foxn1* and *Foxg1*. Research is ongoing, but if activation of these FOX proteins results in repeatable reprogramming of MEFs to iTECs, these results may have serious implications for the future of regenerative medicine, including treatment options for chemotherapy-related immune deficiency, autoimmune disorders, and age-related thymic involution.

The Effectiveness of Financial Education Mandates in Georgia Public High Schools

Ana Duron-Fleck, CURO Honors Scholar, CURO Research Assistant
Dr. Brenda Cude, Housing and Consumer Economics, College of Family and Consumer Sciences

In the state of Georgia, public high school students are required to take an economics course with a personal finance section in it in order to graduate from high school. Students are tested on their knowledge and take an exam worth 20% of their final grade. Last year's focus of this study was on the effects of this class on the students' financial behaviors. However, this year we are focusing on the class's overall effectiveness and its impact on students' financial literacy skills by asking students basic questions constructed to gauge their knowledge of personal finance. We distributed a 31 question survey via email to all freshmen in attendance at the University of Georgia. The questions ranged from the student's gender and major to questions about their savings accounts and knowledge of interest rates. Using the responses from students who graduated from Georgia public high schools, we limited our analysis to only those students that recall taking the course and identified the proportion that answered the financial literacy questions correctly. Through the use of different combinations of questions and answers we were able to determine if the style and medium of class affects what the student learned and if it changed how the student answered the financial literacy questions. We hope to find that students who took a standalone course covered more content than those who took a course only in part about personal finance/money management.

Atlanta, Race, and Housing: Racial Segregation in the Context of the Great Recession

Caskey Dyer

Dr. Steven Holloway, Geography, Franklin College of Arts and Sciences

The subprime mortgage crisis of 2007-2008 resulted in foreclosures, major losses of capital for financial institutions, and losses of equity for hundreds of thousands of homeowners. These effects were not evenly distributed. In the years leading up to the crisis, the subprime loans which so toxified lender's asset sheets were disproportionately given to lower-income, minority households. The causes for this are multifold - explicit mandates given by the federal government, implicit practices normalized by government-sponsored enterprises, and pre-existing practices of racial and class discrimination on the part of lenders combined to produce an environment in which discriminatory lending became institutionalized in the name of profit and growth. This paper will examine the degree to which these practices re-constituted historical socio-spatial racial and class divisions by focusing on the Atlanta metropolitan area, where historical racial segregation has been produced and re-produced across the decades, through similar governmental and financial lending practices. I will give a history of socio-spatial racial segregation in Atlanta and its suburban counties, focusing on how state and private actors managed to produce these conditions, before using data on housing and lending practices across the region to analyze if, and how, these divisions became re-created on a larger scale. I will end with a critical analysis of how the reality of these divisions contrasts with dominant narratives of growth in the context of a supposedly post-racial state and a globalized economy, before discussing the potential dangers of the post-Recession lending environment.

Characterization of a V-H+-ATPase in *Toxoplasma gondii*

Eric Dykes, CURO Research Assistant
Dr. Silvia N J Moreno, Cellular Biology, Franklin College of Arts and Sciences

Toxoplasma gondii is an apicomplexan parasite that causes chronic infection in humans through inadvertent consumption or contact with infected cat feces or undercooked meats. As many as 2 billion people are infected with this parasite worldwide, most of them unaware of their chronic infection. The available drugs used to treat the infection are only effective against the fast growing tachyzoite. We believe that it is critically important to understand better the physiology of *Toxoplasma* to discover better ways to block its lytic cycle, which is linked to pathogenesis. We are interested in proton transport and homeostasis and we are characterizing a vacuolar ATPase that localizes to both the plant-like vacuole (PLV) and plasma membrane of *T. gondii*. Vacuolar ATPases create proton gradients by coupling the hydrolysis of ATP with the pumping of protons across the membranes of vacuoles in cells. These pumps create a proton gradient, which can be used to exchange for ions or to maintain the membrane potential. We believe that *T. gondii* relies on proton gradients to help regulate such cellular functions as ion homeostasis, pH homeostasis, and membrane potential. Using conditional knockdowns, we are studying the physiological functions of this vacuolar ATPase; we will measure intracellular pH, proton extrusion, and the membrane potential of the vacuolar ATPase knockdowns. We believe our investigation into this important physiological pump will lead to increased understanding of parasite physiology and potentially identify an important gene(s) for a future drug target(s).

Predicting Horse Racing Outcomes Using Multinomial Logit and Probit Modeling Techniques

Jordan Eckert, CURO Research Assistant
Dr. Lynne Seymour, Statistics, Franklin College of Arts and Sciences

Can statistics beat random guessing in figuring out if a horse will win, place, or show for a race? The aim is to compare multinomial logit and probit models against random guessing, and themselves, to see if they are more accurate in predicting a horse's finish. The first step is to create the data set that will be tested by logistic regression. After research, the task begins of writing R-code to run the analysis. Ultimately, the goal is to create R-Code that could be used subsequently with other horse racing data from other years, a kind of plug and chug code. After both modeling codes have produced their outputs, a comparison of both against random guessing will be performed to see how accurate they are at producing the winning

horse. These methods will then be compared against themselves, and the most accurate model will be assessed. This accuracy will be gauged using each model's RSME. The anticipation here is that probit modeling will be better than logit regression modeling in predicting horse racing outcomes, but that both will be better than random guessing. Predicting horse racing has several other world applications. Horse racing markets follow a similar trend to time series markets such as the stock market, and are often theorized to move in similar manners. If these modeling methods prove efficient and effective in horse racing, then further research into other time series fields that fit a similar profile could be done using these modeling techniques.

Identification of Therapeutics that Target Zika Virus RNA Polymerase

Baker Edrees
Dr. Cory Momany, Pharmaceutical and Biomedical Sciences, College of Pharmacy

One aim of this experiment is to clone and purify the RNA Polymerase from the Zika virus. A second aim is to create an in situ method of making nucleoside triphosphates using human nucleotide metabolizing enzymes, like adenosine and uridine nucleoside kinases, for use in assays. The amino acid sequences of the proteins will be codon optimized to clone and purify the proteins in *E. coli*. The process of cloning involves using type IIS restriction enzymes simultaneously with ligation which allows for rapid cloning. The protein purification process entails using metal chelate chromatography. The goal of this project is to identify small molecules that inhibit the Zika virus RNA polymerase. This information will help with the fight against the Zika virus.

Disordered Drinking in College Populations: An Identity Issue?

Emily Edwards, CURO Research Assistant
Dr. Dawn T Robinson, Sociology, Franklin College of Arts and Sciences

It has been known for quite some time that Greek lettered membership is associated with greater alcohol usage in contrast to unaffiliated students. Traditional theoretical arguments emphasize peer affiliation and social learning to explain the differences in alcohol usage between affiliated and unaffiliated populations; however, comparable disordered drinking occurs beyond Greek populations. This project investigates whether the same processes explain problem drinking among fraternities and sorority members and non-members. We propose that a partier identity rather than fraternity or sorority involvement alone motivates disordered drinking. Affiliates and non-affiliates could share symbolic identity meanings associated with "partier"—one who participates in party culture. Both student populations, affiliated and unaffiliated, receive environmental signals to drink as encouraged from party symbols, such as drunken behaviors, friends drinking, underage drinking, etc., that cause an individual to enact the "partier" identity. This potentially dangerous identity manifestation is incorporated into the student's network; therefore, the individual prioritizes partying behaviors in order to maintain his social relationships or risk the loss of his network. We hypothesize that having more numerous and stronger social ties connected to the partier identity and consistent identification with meanings associated with the partier identity (e.g. self-descriptions of "fun", "social", "outgoing", and "irresponsible") will increase the level of disordered drinking, regardless of affiliation. To test this hypothesis, we surveyed a sample of 200, which consisted of affiliated and unaffiliated, male and female college students locally. After controlling for gender and race (male and white), students who participate in a fraternity have higher levels of disordered drinking as previous literature would predict.

Nitrogen Fixation of Biological Soil Crusts in Longleaf Pine Savannas Respond to Alterations in Precipitation Frequency

Sumaya El-Khalidi, CURO Research Assistant
Dr. Nina Wurzburger, Ecology, Odum School of Ecology

Biological soil crusts (BSCs) fix atmospheric nitrogen (N_2) into biologically available forms, and may be important to ecosystem recovery in longleaf pine savannas. BSCs must be exposed to moisture to be metabolically active, so the frequency of precipitation may affect their ability to fix N_2. Future climate scenarios for the southeastern United States predict a change in precipitation variability and little is known how

BSCs will respond to this shift. For this research, we investigated how variable moisture frequencies could impact N fixation in the BSC communities common in longleaf pine ecosystems. We performed a laboratory experiment in which we treated field-collected BSCs with low, moderate, and high precipitation frequency over an eight-week period. Nitrogenase activity was tested before treatment, at four weeks, and at the end of the experiment. A Repeated-Measures ANOVA was used to test whether N-fixation differed among treatments. We found that when exposed to high moisture frequencies, nitrogenase activity was undetectable, indicating that BSCs had difficulty in performing N-fixation. However, when exposed to the lowest moisture frequency, BSCs fixed a substantial amount of atmospheric N_2. BSCs observed response to variable treatment frequency simulates the likely response BSCs will reflect when exposed to climatic shifts. Since N is necessary for ecosystem recovery, determining BSCs' response may be important in understanding the resiliency of longleaf pine savannas to climate change, and how conservation efforts can be modeled to manage these rare environments.

Regulation of Sialic Acid Polymerization

Joseph Elengickal, CURO Research Assistant
Dr. Hawkeye Pierce, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Glycans are sugar molecules that are on the surface of cells. They are vital to cell functions such as cell signaling, immune responses, and protein folding. They have also been found to play a role in illnesses such as cancer, and biomarkers for cancer cells have originated from the study of these glycans. Nevertheless, unlike other vital biological molecules like DNA and protein, not much is known about how these glycans are produced or how they function. The purpose of this research project is to investigate a specific glycan, sialic acid. This sugar molecule is found in high concentrations in the brain and plays an important role in neural transmission. On cell surfaces, sialic acid monomers link together to form polymers, long chains of these sugar molecules. The process by which these chains are elongated is not well known and is the subject of this research. This project investigates how sialic acid's polymerization is regulated by glycosyltransferases by using high performance liquid chromatography. This process works by separating sialic acid and then detecting the sialic acid with a small molecule called DMB. The project also investigates how specific proteins influence the polymerization by setting up a tet inducible system, thus furthering the understanding of sialic acid regulation. This research could lead to a better understanding of glycan regulation during oncogenesis and may even lead to future treatments for cancer.

Has Gentrification Led to Increased Police Brutality in the United States?

Emmanuel Elsar Jr.
Dr. Jennifer Joelle White, International Affairs, School of Public and International Affairs

With the increased coverage of relations between the police and minorities in the United States, one key factor has been continuously ignored. With rent prices and cost of living in major metropolitan cities rising, citizens who before were able to afford living in their homes are now being forced to relocate to cheaper areas. This process of removing and renovating a neighborhood so that eventually more middle class individuals move there is known as gentrification; however, the social and political implications usually involve wealthier, whiter people moving into low-income, minority heavy areas. One notable aspect of the combination of rising rent and a changing demographic is the increase of calls to police departments. One may come to the conclusion that this is the result of new people in the neighborhood and their preconceived notions of longtime residents in the area; others may argue it is a result of different viewpoints on how to conduct oneself in your neighborhood. Nevertheless, there is a different dynamic of how the police interact with their respective communities and in some cases it has led to the deaths of primarily black and latino men. In order to fully answer my proposed question, I plan to collect data from calls sent to police departments in the 10 largest metropolitan areas in the United States listing disturbances in the area and cross reference them to instances of police altercations with individuals in those cities.

Genetic Mapping of the Chromosome Variant K10-L2 in Maize

Brianna Renee English, Foundation Fellow, CURO Research Assistant
Dr. Kelly Dawe, Genetics, Franklin College of Arts and Sciences

Meiosis is a process in which a diploid cell divides into four haploid daughter cells, capable of becoming the organism's next generation. During the stage of anaphase, sister chromatids are pulled apart towards opposite spindle poles through microtubule attachment to the centromeres of the chromosomes. In maize, there are two forms of chromosome ten: a common normal version and a rare abnormal version which contains repetitive sequences called knobs. Knobs are normally inactive regions of the genome, but in the presence of the abnormal chromosome K10L2 they can act as neocentromeres. When active, these neocentromeres move towards the spindle poles ahead of the centromere during anaphase. This study is focused on constructing a genetic map of K10L2 and developing a better understanding of how neocentromeres function. Using fluorescent in situ hybridization to observe knobs, PCR to amplify candidate genes, and the observation of phenotypes unique to chromosome ten, we analyzed the combinations of markers from each test to generate a genetic map. This study will ultimately provide more information about the origins of K10L2 and will help in finding the location of the candidate gene.

Effects of Asphalt Mix Characteristics on Dynamic Modulus and Fatigue Performance

Austin Etheridge, CURO Research Assistant
Dr. S. Sonny Kim, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Developed under NCHRP 1-37A, the Mechanistic-Empirical Pavement Design Guide (MEPDG) provides three hierarchical levels of design inputs (i.e., levels 1, 2, and 3). This allows the designer to select the level of details of design inputs according to the level of importance of the project. The dynamic modulus |E*| is considered one of the fundamental asphalt mix properties and is obtained from a series of complex modulus tests at different temperature and loading frequency conditions. Several State Highway Agencies (SHAs) have already created or are in the process of creating an |E*| database for the calibration and implementation of MEPDG. Georgia Department of Transportation (GDOT) has made a continued commitment to the performance enhancement of pavement and proactively calibrated and implemented the MEPDG methodology for the design of flexible pavement structures. However, the GDOT material input library includes |E*| based on only two sources of aggregate. Further, an |E*| library for Polymer Modified Asphalt (PMA) and Ground Tire Rubber (GTR) Asphalt mixtures has not been developed yet although the PMA mixtures are being used for high volume traffic roads in Georgia. The study will supplement the current |E*| database by extending the aggregate sources for different Superpave mixes and binder types. Secondly, three different laboratory fatigue tests will be performed on selected mixtures. Based on different fatigue test approaches, a local fatigue prediction model will be recommended for Georgia pavement. Finally, the effects on dynamic modulus and fatigue due to different asphalt mixtures will be determined.

In Vivo and In Vitro Activity Analysis of Acetylation on Fructose-1, 6-Bisphosphatase in *Salmonella enterica*

Akiel Gabriel Etienne, CURO Research Assistant
Dr. Jorge Escalante-Semerena, Microbiology, Franklin College of Arts and Sciences

Glucose is an important building block for cells of all domains of life. Not surprisingly, cells have evolved elaborate systems to acquire glucose from their environments. Because of the relevance of glucose to cell function, cells can also make glucose endogenously. The pathway dedicated to this purpose is known as gluconeogenesis (GNG). The enzyme fructose-1, 6-bisphosphatase (Fbp) plays a key role in GNG because Fbp generates glucose 1,6-biphosphate. Fbp function is regulated at many levels. Recently, we discovered that Fbp function may also be regulated by post-translational modifications. Reverse Lysine Acetylation (RLA) is a post-translational modification that is conserved across all domains of life, and is used to modulate protein function. Recently, we showed that STM1857 acetylates

Fbp. It is not known how many times STM1857 acetylates Fbp, or how Fbp function is affected by acetylation. We hypothesize that acetylation may lower the activity of the enzyme relative to the non-acetylated version of it. To test this possibility, Fbp activity will be assessed in vitro as a function of its acetylation state. To do this we will use a continuous assay that monitors the oxidation of NADH at 340 nm. We will also use high-resolution mass spectrometry to determine which lysyl residues of Fbp are acetylated by STM1857. Acetylation sites identified by mass spectrometry will be validated by site-directed mutagenesis. Finally, the effect of acetylation on Fbp activity will also be assessed in vivo under conditions that require the cell to use GNG to make glucose.

The Association between Body Image Dissatisfaction and Sports Participation in Mexican-American Youth

Rhiannon Euhus
Dr. Jennifer L Gay, Health Promotion and Behavior, College of Public Health

Youth sports participation has well-known physical health benefits. However, its mental health effects are less known, particularly for Mexican-American youth. The purpose of this research was to analyze sports participation and body image dissatisfaction (BID) among Mexican-American adolescents to: (1) determine sources of pressure that contribute to BID in sports participation (2) compare the prevalence of BID in students involved in non-aesthetic, aesthetic and no sports, (3) determine if general physical activity has the same effect on BID as organized sports involvement, and (4) determine the association between sports-related BID and unhealthy eating behaviors. The sample (n=826) is from a 2010-2011 survey of Mexican-American students in south Texas. Eighty percent of the students reported participating in organized sports. Twenty-one percent of the athletes felt pressure to "look a certain way", with 57% saying the pressure came from friends. Compared with those who did not play sports, non-aesthetic sport athletes were the only group that had a significant difference in BID, with those athletes thinking they were smaller than their ideal body image ($p=0.0117$). BMI percentile, sports participation, physical activity, and sex were significant predictors of BID ($p<0.05$ for all associations). Physical activity behavior was found to have similar effects on BID as organized sports involvement. BID was not associated with unhealthy eating behaviors. These findings provide a better understanding of BID among Mexican-American youth; the results may inform parents and coaches how to identify youth who are most at risk, and aid in the creation of programs that mitigate BID.

Development of Biodegradable and Biosourced Microcellular Polyurethane Foams for Foam-In-Bag Packaging

Caria Evans, CURO Research Assistant
Dr. Jason Locklin, Chemistry, Franklin College of Arts and Sciences

High volume packaging applications for high value products often use polyurethane foam-in-bag systems to save packaging time, labor costs, and packaging facility footprint space. Despite ubiquitous use, packaging compositions that are fully biodegradable or compostable have not been fully accepted by the packaging industry. The two components of foam-in-bag polyurethanes are typically a multifunctional isocyanate precursor formulation and a polyol precursor formulation which polymerize into closed- or open-cell foams upon mixing via step growth polymerization and CO_2 bubble formation. The project will focus on the development and characterization of the isocyanate and polyol precursors, surfactants, additives, and rheological modifiers from renewable sources that meet the appropriate reaction conditions to generate stable closed-cell and open-cell polyurethane foams. Developing recipes that have high biosourced material content, high impact resistance, proper viscoelastic properties, and fully compostable chemistries is principally important. Free standing monoliths of polyurethane foams will be prepared using a counter rotating mixer. The degree of functionality of the polyol and isocyanates, catalyst loading and type, viscosity modifiers, surfactants, and fillers of the formulations will be systematically varied to determine optimal cream and rise times and thermomechanical properties. Dynamic mechanical analysis and rheological measurements will be used to probe foam kinetics and tune material moduli (1 kPa – 1 MPa) over shipping temperature ranges, approximately -30

°C – 70 °C. Foam uniformity will be assessed by optical and electron microscopy.

Green Greenhouses: An Application of Energy Informatics

Nadine Fares, CURO Research Assistant
Dr. Richard Thomas Watson, Management Information Systems, Terry College of Business

In order to feed a growing and wealthier population within the next 30 years, food production must increase by an estimated 70 percent. Controlled-environment agriculture (CEA), such as indoor farms and greenhouses, is a key path to increasing food production; however, the industry's current practices can require considerable energy to power artificial lighting to maintain plant growth on overcast days to meet production schedules. This system is inefficient, resulting in energy waste and higher operational costs. Phytosynthetix has developed controllable LED lighting, in conjunction with the University of Georgia's Horticultural Physiology Laboratory, which uses a built-in light intensity sensor to set the level of artificial light to maintain plant growth when natural lighting falls below a plant's threshold needs. We are working with Phytosynthetix to build a discrete event simulator to understand how to create an effective information system to minimize the cost of electricity for a CEA while meeting plant production schedules. Sensitivity analysis of this simulation model will help us to identify horticultural studies to gain a greater understanding of the critical determinants of plant growth. We also intend to use the model to refine methods for descriptive analytics (plant database), predictive analytics (energy price and solar radiation forecasting), and prescriptive analytics (portfolio management). By running simulations using R, we have estimated over 90% decrease in electricity costs by using the smarter model instead of traditional lighting. If implemented, this project could contribute monumentally to food security and sustainability, which are necessary for our developing world.

Effects of Microbe Activators in an Organic Agricultural System

Brendan Fatzinger, CURO Research Assistant
Dr. Elizabeth Little, Plant Pathology, College of Agricultural and Environmental Sciences

In organic agriculture, maintaining plant health depends on soil microbial biodiversity. Soil microbes are important for nutrient cycling, pathogen suppression, and soil quality. The primary means of maintaining soil microbial populations is the periodic application of composted plant and animal wastes. In addition, commercial preparations are available which claim to enhance the activity of beneficial microbes. This study will assess the effectiveness of specific homeopathic preparations on soil microbiological activity and plant health. The project will be conducted at the UGArden on the UGA campus. The experiment consists of two different rotations, either cool season vegetables with a summer cover crop or warm season vegetables with a winter cover crop. All crops will be grown using organic methods either with or without the additional preparations. Basal soil respiration CO2 output from each experimental replication will be measured using alkali traps and titration. Populations of free-living and parasitic nematodes will be counted and specific microbial communities will be identified using gene amplification. Plant health will be quantified based on the severity of selected diseases and on growth parameters such as harvest weight and quality. Base line measures of soil microbial activity will be determined at the beginning of the experiment and repeated at the end of each cropping season. The long term goal is to identify practices that increase productivity and sustainability in organic agriculture.

Techno-Economic Assessment of Anaerobic Digestion Technology to Produce bioCNG

Carter Fitzgerald, CURO Research Assistant
Dr. Sudhagar Mani, Chemical, Materials, and Biomedical Engineering, College of Engineering

Animal manures, food waste and lignocellulosic biomass can be anaerobically digested into biogas, a mixture of carbon dioxide and methane. Anaerobic digestion is the series of biological processes where organic material is broken down by microorganisms, particularly methanogenic bacteria, in the absence of oxygen. The biogas can

be cleaned and compressed to produce compressed natural gas (CNG), or compressed even further to form liquid natural gas or burned to produce heat and power. The digested organic material can be used as compost or as fertilizer. The main objectives of this study were to develop a process simulation model to convert organic materials into bioCNG via anaerobic digestion technology and to evaluate the economic feasibility of producing bioCNG. An anaerobic digester plant capacity of 100 tons/day was simulated to produce biogas using a Superpro designer software platform. The biogas was cleaned and compressed to produce bioCNG. A detailed mass and energy balance was conducted and used for estimating the economic analysis. Finally, the capital expenditure, operating cost and the minimum selling price of bioCNG were calculated and compared with market price. A detailed sensitivity analysis was conducted to evaluate the impacts of process and plant parameters to minimize the energy cost of CNG. The developed model can be used for conducting the economic feasibility of small to medium scale biogas plants in the US.

Take Me Out to the Ballgame: A Legal Examination of Spectator Injury Risk at Major League Baseball Games

Zack Flagel, CURO Research Assistant
Prof. Nathaniel Grow, Insurance, Legal Studies, and Real Estate, Terry College of Business

Each year, over 1,750 fans attending Major League Baseball (MLB) games are severely injured by foul balls, a worrisome statistic that has increased each year. Despite this alarming trend, MLB does not currently have a standardized policy that requires ballparks to have nets protecting fans from foul balls flying into the stands. As such, fans sitting in the Danger Zone, areas of the ballpark that have increased in danger over time, often do not have such protection and are at risk to injury. Legally, however, MLB has no motivation to make any change due to a protection in the American legal system known as the "Baseball Rule," which essentially assigns full liability of any injury to the spectator (and zero responsibility of liability to MLB) due to the inherent risk of attending a game. The only exception to this rule is if the injury occurs in the "most dangerous part of the ballpark," historically considered only to be the area behind home plate, which already has protective netting in every MLB ballpark. Presenting original research on several quantitative factors that have increased the degree of spectator risk in the Danger Zone over time, this paper argues that the "most dangerous part of the ballpark" has expanded, and consequently should be reflected in decisions by American courts. However, until courts change their position on the "Baseball Rule," MLB is unlikely to change their policy on protective netting anytime soon, and the risk of injury by a foul ball will remain.

Volumetric Muscle Injury on Mitochondrial Function

Alexandra Bronwen Flemington, CURO Research Assistant
Dr. Jarrod A Call, Kinesiology, College of Education

Volumetric muscle injuries sustained during combat cost the Department of Defense a total of $42.4 billion a year. Currently, the specific pathophysiology of such an injury is unknown. This lack of knowledge leads to inadequate rehabilitation and recovery for patients. The primary objective of this study is to determine how the mitochondria of these injured cells are affected. We hypothesize that by determining the mitochondrial enzyme activity, specifically citrate synthase, in the muscle during the first couple of weeks post-injury, we will gain a better understanding of what occurs physiologically following such an injury. To determine mitochondrial enzyme function, we will perform a citrate synthase assay on the muscle samples. We first homogenize each sample in phosphate buffer and then freeze-thaw each one three times. We then dilute each sample and add an oxaloacetate solution in order to start the enzymatic reaction. We will then put the sample along with the oxaloacetate solution in a spectrophotometer while the reaction is occurring. The spectrophotometer will take readings at 412 nm every 15 seconds for 3 minutes. These readings are then used to determine the activity of the citrate synthase enzyme in the mitochondria of the injured muscle. Overall, we hope to clarify how the injury affects mitochondrial function, thus indirectly studying the effect on the rate of muscle recovery. We hope to apply this new knowledge to the creation of innovative and effective

rehabilitation programs for victims of volumetric muscle injuries.

Biophysical Properties of Pectins Isolated from Seed Mucilage of *Arabidopsis thaliana* Wild-type and gaut11-2 Mutant Plants

Haley Folmar, CURO Research Assistant
Dr. Debra Mohnen, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Pectin is a complex polysaccharide used extensively in the food and nutraceutical industries. Analysis of the biophysical properties of pectin from wild type and mutant plants will provide information on molecular targets in pectin structure that can be modified to enhance its properties for industrial materials applications such as food packaging. To test this, we are studying *Arabidopsis* seed mucilage, a source of pectin-rich fibers. Our earlier studies showed that mucilage from the *Arabidopsis* Galacturonosyltransferase (GAUT) 11 mutant (gaut11) is more easily released from seeds compared to mucilage from wild type (WT) seeds. We hypothesize that the lack of a functional GAUT11 pectin biosynthetic protein in the gaut11 mucilage leads to structural changes in pectin that result in changes in mucilage release compared to WT. To study the relationship between the physical properties and structure of pectin in wild type versus gaut11 mucilage, we isolated pectin from mucilage of both types of seeds. We fractionated the isolated mucilage over a diethylaminoethyl (DEAE) cellulose column with the goal of comparing the physical and structural properties of the different pectic components in the WT and mutant mucilage. Both types of fractionated mucilage will be analyzed for adhesion, thin film generation, and nanofiber formation properties in collaboration with Dr. Sergiy Minko's laboratory. We hypothesize that pectin from gaut11 may not exhibit the same adhesive properties as pectin from the WT. The significance of the results in regards to functional properties of pectin that may have applications in the materials area will be discussed.

Dialect Variation in the American South

Shawn Christian Foster, CURO Research Assistant
Dr. Peggy Renwick, Romance Languages, Franklin College of Arts and Sciences

There is not just one Southern accent. People from different states, social classes, and centuries may all sound Southern despite their speech having few features in common. Understanding the differences between the many accents of the South is a vital step towards understanding the peoples of the region. This project uses data from the Digital Atlas of Southern Speech to investigate how vowel pronunciation varies among populations of the American South. The vowel features to be examined will include the "Southern Shift," whose features are often perceived as the "Southern Drawl," and the pin-pen merger, a sound change in which the distinction between words like pin and pen, and tin and ten is lost. Phonetic analysis will be carried out on over 16,000 acoustic measurements. Then, tests will be run to compare measurements across demographic lines. Significant differences are expected to be found in participation in both of these sound shifts based on the race, gender, and age of the speaker. It may be possible to determine the chronological or social origins of these changes by examining differences in pronunciation across groups in the sample. Examination of how these sound changes spread throughout the region may reflect how the different speech communities of the South interact with and influence each other. The ultimate goal of this investigation is to determine which dialect features, if any, are common throughout the South, and which features serve to differentiate linguistic communities within the region.

A Novel Porcine Model of Vascular Cognitive Impairment Demonstrates Changes in Cerebral Blood Flow and White Matter Tracts

Lily Francis, CURO Research Assistant
Dr. Franklin Delano West, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Recent studies anticipate the prevalence of dementia will increase by three hundred percent in the next three decades. Almost all aging adults develop cerebral white matter damage that is

linked to poor blood supply, which progresses and leads to symptoms ranging from mild cognitive dysfunction to severe vascular dementia. Although there is no preventative treatment for dementia, preliminary results of remote ischemic conditioning (RIC) show promise of decreasing white matter damage by increasing cerebral blood flow. Most animal models of dementia use rodents, which are inadequate due to the extreme cerebral differences between humans and rodent species. For this reason, it is necessary a model more similar to the human brain is developed to test RIC treatment for vascular cognitive impairment (VCI). The aim of this study was to develop a chronic hypoperfusion porcine model to more adequately mimic dementia in humans. In order to decrease cerebral blood flow and induce corresponding white matter lesions, bilateral vascular constrictors were placed on the common carotid arteries (CCA). The efficacy of these constrictors and the resulting hypoperfusion model were studied using magnetic resonance imaging (MRI), diffusion tensor imaging (DTI), magnetic resonance angiogram (MRA), and arterial spin labeling (ASL) sequences pre-VCI induction and 4 weeks post-VCI induction. These sequences revealed thar gradual bilateral constriction of the CCAs resulted in a global decrease in cerebral blood flow and compromised white matter integrity. These findings suggest that bilateral vascular constriction of the CCAs produce a reproducible potential porcine model of VCI.

University of Georgia Amending and Roll Call Project

Ryan Freeman, CURO Summer Fellow
Dr. Michael S Lynch, Political Science, School of Public and International Affairs

As measured by roll call voting behavior, congressional polarization is up to the highest levels since the Civil War. As a result, congressional approval ratings are extremely low. While interest groups on both sides of the aisle have begun to research methods to fix the problem, there is comparably little scholarly research into Congressional institutions in recent decades. Moreover, the little work that exists focuses on existing data from roll call voting patterns of members. Oftentimes, these votes are taken out of context and no additional details regarding lawmaking are provided. My research proposal seeks to fill in some of these gaps. I have been working with the University of Georgia Amending and Roll Call project. This is the first systematic effort to model the roll call generating process. Professors Madonna and Lynch have headed the project to code data on all amendments to landmark enactments. It has shown a sharp increase in votes on "messaging" amendments. These are amendments offered solely for the purpose of putting partisan opponents on record, with little policy success. This may serve to artificially increase polarization. The information being looked at comes from *The Congressional Record*. We record data on the type of amendment, the party of the politician offering the amendment, the type of vote that was taken, the number of yeas and nays (if applicable), and whether or not the amendment passed or failed among other things.

White Matter Integrity Decreases Similarly with Age between People with Schizophrenia and Healthy Individuals with Low Cognitive Control

Emily Elizabeth Gale, CURO Research Assistant
Dr. Jennifer McDowell, Psychology, Franklin College of Arts and Sciences

Schizophrenia is a complex psychiatric disorder that may be indicated by positive symptoms, including delusions, disordered speech, and impaired cognitive control. Recent studies suggest that these cognitive deficits may be related to alterations of neural white matter. In the superior longitudinal fasciculus (SLF), a white matter tract that has been linked with cognitive control, white matter integrity (WMI) is decreased for people with schizophrenia relative to healthy people with high cognitive ability. Both WMI and cognitive control are known to decrease with age in healthy people, but little is known about how aging changes these in people with schizophrenia. This study sought to identify whether neural WMI is affected similarly by age in individuals with schizophrenia and healthy people with comparable cognitive function. Diffusion-weighted imaging was used to assess WMI in 26 participants with schizophrenia and 26 healthy participants with low cognitive control, who were further subdivided into younger (19 to 35) and older (44 to 63)

groups. Regions of interest were drawn on individual brain images to isolate left and right SLF. Measurements of fractional anisotropy (FA, an index of WMI) were then obtained and compared between groups. This analysis demonstrated no significant interaction between diagnosis and age. These results suggest that regardless of diagnosis, decreases occur in older individuals, and regardless of age, decreases occur in individuals with schizophrenia. Both diagnostic groups seem to age similarly, which suggests that decreases in schizophrenia are likely disease-specific rather than related to cognitive control ability.

Effects of Acid Rain on *Brassica rapa*

Luke Gamblin, CURO Research Assistant
Dr. Ford Ballantyne, Ecology, Odum School of Ecology

Acid rain is characterized as precipitation which has pH values that are lower than those of normal rain (<5.5). This increased hydrogen ion concentration is typically caused from the diffusion of industrial waste into the atmosphere. This research project is aimed at further understanding the effects of acid rain on plant life history through the manipulation of *Brassica rapa* (mustard plant) by using varying acidities of "rain" water. The experiment will consist of 4 experimental groups of *Brassica* which will each be watered solely with its corresponding "acid rain" solution. The solutions have pH values of 2.5, 3.5, 4.5, and 5.5, with the 5.5 solution being the control for naturally occurring rain. Every plant in the experiment will be watered with the same amount of corresponding solution (as needed), and each plant will be measured every other day for 45 days. Measurements will include stem height, leaf count and length (from stem), flowering time (# of days to first flower appearance), and number of seeds produced. Additionally, a general assessment of each plant's health will be made throughout the experiment. In general, it is expected that those plants which are watered with low pH "acid rain" will grow slower, be less healthy, and produce fewer seeds. These findings will be important because they will provide data for the probable detrimental effects of acid rain on plant life history, which could be broadly extrapolated to agricultural practices in those areas which are subject to acid rain.

Fighting a Pathogen with Its Own Medicine: Enzymatic Preparation of Carbohydrates for Effective Immune Response

Nikhil Reddy Gangasani, CURO Honors Scholar, CURO Research Assistantship
Dr. Fikri Avci, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Pneumococcal diseases like pneumonia are currently a major global health issue. Caused by *Streptococcus pneumoniae* bacteria, these diseases are responsible for up to 1.6 million annual deaths globally, according to a World Health Organization estimate. In particular, *S. pneumoniae* serotype III (*Pn3*) has increasingly victimized children under the age of five, who represent about half of global victims. The worldwide proliferation of microbial resistance to antibiotics accentuates the need for more effective pneumococcal vaccines. Glycoconjugate vaccines, composed of carbohydrates linked to carrier proteins, alleviate this issue. The *Pn3* bacterium expresses a carbohydrate coating on its microbial surface called a capsular polysaccharide (CPS). Breaking down this long, complex *Pn3* CPS into smaller fragments of suitable size and composition provides an appropriate carbohydrate source for studying how glycoconjugate vaccines activate a protective immune response against *Pn3* CPS. In 1931, a bacterium called *Bacillus circulans* was observed to generate an enzyme which degrades *Pn3* CPS into smaller fragments. Through experimentation, we purified the *B. circulans* enzyme and determined its size, studied the interactions between the enzyme and *Pn3* CPS, and determined the means of CPS degradation. Furthermore, we established ideal conditions for the enzymatic degradation of *Pn3* CPS, and confirmed the sizes of the main degradation products. Utilizing what is now known about *Pn3* CPS and the *B. circulans* enzyme that degrades it, future research efforts will work towards creating a means of effective protection from the harmful *Pn3* bacterial pathogen.

Fake News: The New Propaganda Machine

Jessica Garcia, CURO Research Assistant
Dr. Audrey Haynes, Political Science, School of Public and International Affairs

Throughout history, those fighting in the political trenches have found methods to manipulate the public to behave in ways to benefit the propagandist rather than the public. Often this manipulation has been through the use of campaign ads, jingles, and whisper campaigns. In 2016, the emergence of the widespread use of "fake news" created concern among those who study American politics. While "fake news" is not new, the significant increase and the political nature of this recent manifestation is concerning. There has been little systematic analysis of the "fake news" that has made its way into the political dialogue. While we know the dispersion of "fake news" surpassed mainstream, vetted news on social media platforms such as Facebook and Twitter, we have little understanding of what "fake news" usage really looked like. What were the sources, targets, and messages conveyed by this "fake news?" By exploring this data systematically, we can make better assessments and projections about the likely impact of this "fake news." We conduct this exploration by analyzing politically-related fake news stories generated during the 2016 campaigns and during the two months after the presidential inauguration. We have gathered information on "fake news" from this period through archived "fake news" on the Snopes.com website, and we have supplemented this data with additions gathered through our own searches. We use this data to explore patterns found throughout the "fake news" universe and discuss the implications of these patterns on the future of American political campaigns and policy-making.

Overexpression and Characterization of Two Pectate Lyases from *Paenibacillus amylolyticus*

Rebecca Marie Gardner, CURO Research Assistant
Dr. Joy Doran Peterson, Microbiology, Franklin College of Arts and Sciences

Cellulosic ethanol is an alternative fuel which has the potential to be cheaper than corn-based ethanol and cleaner than petroleum. However, further improvement in ethanol yields and reduction in cost is necessary for cellulosic ethanol to become a renewable fuel on a global scale. Many agricultural wastes used in cellulosic ethanol like citrus peels and sugar beet pulp are rich in pectin, a plant polysaccharide in the cell wall that provides structure. Pectinases such as pectate lyases degrade pectin and are conducive to higher ethanol yields for these pectin-rich biomasses. Besides cellulosic ethanol, pectinases are useful for other industries like textile manufacturing and food processing. Despite this, pectinases lack the research that other enzymes have received. *Tipula abdominalis* larvae can degrade cellulosic biomass due to bacteria in its hindgut. One bacterium which does this is *P. amylolyticus*. Two pectinases found in *P. amylolyticus*, PelA and PelB have previously been characterized and demonstrate activity on a broad range of pectin, singlehandedly doing the work of multiple pectinases. In fact, PelB has been used successfully to ferment cull peaches. An analysis of the genomic sequence of *P. amylolyticus* identified two additional pectate lyases. These two lyases, pamy_1763 and pamy_4669, will first be heterologously expressed in *Escherichia coli* KRX. Pectate lyase assays will then be used to identify optimum temperature, pH, etc. It is likely that the lyases will require calcium ions, prefer an alkaline pH, and have a broad substrate range similar to the two previously characterized pectate lyases in this system.

Determining Fidelity of the Physical Activity and Learning (PAL) Program

Catriona Geddes, CURO Honors Scholar, CURO Research Assistant
Dr. Jennifer L Gay, Health Promotion and Behavior, College of Public Health

Evidence suggests that being physically active can increase academic achievement, and that encourage giving children access to environments that allow them to play, run around, and interact socially with their peers. The Physical Activity & Learning (PAL) Program looks directly at the effect that physical activity can have on mathematic and reading skills in elementary school students. Each year, sixty 2nd-5th grade students from two elementary schools participate in PAL. Students are selected based on academic, behavioral, and social characteristics. One area that can impact PAL effectiveness is implementation, or how closely teachers follow the lesson plans, student engagement, attendance, and participant satisfaction with PAL. Preliminary analyses were conducted to examine fidelity in PAL. Choral reading is the most frequently used

teaching strategy, followed by partner reading. Addition was the most covered skill in math. Separate one-way ANOVA models tested differences in fidelity for teaching, student learning, and engagement by subject matter. Fidelity scores for teaching, student learning, and engagement were high relative to the maximum possible score. There were no significant differences in fidelity across PAG, reading, and math ($p>0.05$). This means that teachers follow the objectives of the program similarly across subjects. Future analysis will include the full implementation score, incorporating attendance and participant satisfaction. Associations between implementation and achievement in math and reading will be examined. Programs like PAL have the potential to improve academic achievement for children. Tracking program implementation is important to understand the relationship between PAL and academic learning.

Characterization of Causative Mutations in OGT for XLID

Stephan Nicholas George, CURO Honors Scholar, CURO Research Assistant
Dr. Lance Wells, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Approximately 1% of the global population is affected with intellectual deficiency, with males affected more than females. Approximately 5-10% of male non-syndromic cases have been attributed to abnormalities in the X chromosome. Recently, 7 missense mutations (L254F, A259T, R284P, A319T, E339G, T570A, Y835C) in the X-linked O-GlcNAc transferase (OGT) gene have been designated causative for the disorder. OGT catalyzes the reversible transfer of the glycan N-acetylglucosamine (GlcNAc) from UDP-GlcNAc to serine and threonine residues on its nuclearcytoplasmic and mitochondrial substrates, while the enzyme O-GlcNAcase (OGA) reverses this process. UDP-GlcNAc is a byproduct of the hexosamine biosynthesis pathway, of which approximately 5% of cellular glucose levels is directed. Thus, O-GlcNAc cycling by OGT and OGA affects cellular functions such as transcription, translation, cell cycle regulation, and proteostasis in a nutrient dependent manner. Consequently, abnormalities in O-GlcNAc cycling have been linked to diabetes, XLID, cancer, and Alzheimer's disease. The goal of this project is to determine how each OGT mutation impacts cellular function to arise in the disorder's phenotype. To accomplish this, the OGT variants will be biochemically examined with respect to stability/activity/kinetics by defining the altered interactome of the OGT mutants using common quantitative glycoproteomic approaches. Preliminary data suggests that altered cleavage of host cell factor C-1, a cell cycle regulator in neurons, is caused by OGT mutation. Additionally, a UDP-Glo assay found that other mutants displayed reduced glycosylation of CK2 peptide. Combined, the initial data suggest these mutations may cause XLID by impairing the catalytic and proteolytic activity of OGT.

Creation of Genetically Modified Pomgnt2-Knockout Neuro2A and C2C12 Mouse Cell Lines by CRISPR/Cas9 Gene Targeting to Further Understand Dystroglycanopathies

Umar Muhammad Ghilzai
Dr. Aaron Beedle, Pharmaceutical and Biomedical Sciences, College of Pharmacy

Pomgnt2 is a protein that plays a vital role in the glycosylation of α-DG, which is a protein found on the cellular membrane of many cells as a component of the dystrophin glycoprotein complex (DGC). α-DG has the important role (among others) of cell to matrix signaling through the binding of extracellular proteins. A specific type of secondary dystroglycanopathy can arise due to mutations within the Pomgnt2 gene that results in the hypoglycosylation and reduced binding capabilities of α-DG. To expand research into the study of secondary dystroglycanopathies, we developed Pomgnt2-knockout neuroblastoma and myoblast mouse cell lines that will allow us to extrapolate information about the inner workings of muscular dystrophy through laboratory testing. To minimize the possibility of off-target modification of the cell lines, we have used the "nickase" Cas9 strategy with specific gRNAs. We expanded many single clonal lines for both cell types and identified Pomngt2-knockouts by Western blot analysis of α-DG glycosylation. These new Pomgnt2-knockout cell lines can now be used to understand the role of Pomgnt2-deficiency in α-DG glycosylation and functional roles for α-DG in cellular biology.

Abstracts

Analysis of Discrimination Methods for Amplifying the Microbiome from Plants

Cecelia Giangacomo, CURO Research Assistant
Dr. Jason Wallace, Crop and Soil Sciences, College of Agricultural and Environmental Sciences

In order to analyze the DNA of the microbiome from plant samples, it first must be amplified through PCR. Conserved priming sequences and small starting percentages of microbial DNA create a situation in which it is difficult to exclude plastid DNA without a large degree of bias. Many methods have been used to discriminate against host DNA, but there has been no comparison of the accuracy and cost efficiency of the different methods when used on plant tissue. We compared the ability of anti-chloroplast primers, blocking primers and PNA clamps to discriminate against host DNA through amplification in PCR. Each discrimination method was tested on DNA samples from leaves, soil, and a known bacterial community under standardized conditions with appropriate positive and negative controls. The resulting libraries were sequenced, and the methods compared for their ability to accurately amplify target DNA while excluding host DNA.

Probing the Structural Basis of P-Glycoprotein Transport of μ-Opioid Receptor Agonists: Methadone and Loperamide

Morgan Gibbs, CURO Research Assistant
Dr. Arthur Roberts, Pharmaceutical and Biomedical Sciences, College of Pharmacy

P-glycoprotein (Pgp) protects the brain from toxins by acting as a gatekeeper at the blood-brain barrier. Pgp also limits penetration of therapeutics including μ-opioid receptor agonists into the brain for treatment of central nervous system (CNS) diseases. Although they are structurally similar, the μ-opioid receptor agonist loperamide is effluxed out of the CNS by Pgp at four times the rate of methadone. Because of these differences, methadone and loperamide were used to probe the mechanism of Pgp-mediated efflux. We hypothesize that higher Pgp-mediated efflux rates of loperamide are the result of multiple loperamide binding to Pgp. We found that loperamide was a more potent activator of Pgp-mediated ATP hydrolysis than methadone. Consistent with our hypothesis, loperamide-induced activation of ATP hydrolysis suggested at least two loperamide binding sites on Pgp, while methadone-induced activation suggested a single methadone binding site. NMR and fluorescence were used to develop a structural model for transport. Saturation transfer double difference NMR identified the functional groups involved in molecular recognition of Pgp and revealed that loperamide had more interactions with the transporter than methadone. Acrylamide quenching of Pgp fluorescence indicated that loperamide shifts Pgp into a conformation that promotes transport, while methadone shifts Pgp into an inhibitory conformation. This information combined with paramagnetic relaxation enhancement NMR experiments and computer modelling was used to pinpoint the binding locations of loperamide and methadone on Pgp. The drug-bound Pgp models suggest that multiple drug binding and conformational changes play a critical role in Pgp transport of this class of drugs.

Fecal Composition and Its Relation to Diet

Hannah R Gilbert, CURO Research Assistant
Dr. Laurie Reitsema, Anthropology, Franklin College of Arts and Sciences

Feces is an important substrate used in different analytical techniques with the purpose to see components of food that are digested, excreted, and how the body interacts and uses those different compounds for bodily processes; however, the actual micro-molecular composition of fecal samples and how exactly fecal composition is determined is still unknown to scientists. Through analysis of fecal samples from *Theropithecus gelada*, the gramnivorous gelada monkey, the very grass-rich and comparably low protein diet should result in a fecal sample that has little to no protein at all, but mostly carbohydrates like cellulose from the undigested stalks of grass. With a breast feeding infant, it is normal to find fatty acids in the feces from the mother's breast milk; but if there were proteins found in the fecal samples of weaned individuals, then the conclusion that feces are diet driven might have a different conclusion. Fluorescent protein assay and mass spectrometry carbohydrate analysis were used to analyse fifteen samples: six breastfeeding infants and their mothers, three behaviorally weaned individuals, four samples from one infant

across the longitudinally critical weaning period, and one sample that is from the youngest individual who has the highest carbon-nitrogen ratio of all. I hope to see how exactly how fecal composition correlates to the diet. The diet of the geladas is known and there is currently isotopic carbon-nitrogen ratio data from mass spectrometry to compare the data to.

Assessment of Oxidative Stress and Serum α-Tocopherol Levels in Exercising Horses in Response to Level and Form of Vitamin E Supplementation

Maddie Gloeggler
Dr. Kylee Duberstein, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Vitamin E is an essential antioxidant found primarily in fresh forages and commercial equine feed rations as synthetic all-rac-α-Tocopherol acetate. This study aimed to compare natural to synthetic forms of vitamin E, and determine if supplementing above NRC recommendations is beneficial to exercising horses. Following a 14 day washout period, 18 horses were divided into three treatment groups and fed the control diet plus (1) synthetic low (SYN-L), 1000 IU synthetic α-Tocopherol acetate/d, or (2) synthetic high (SYN-H), 4000 IU/d synthetic α-Tocopherol acetate, or (3) natural (NAT), 4000 IU/d micellized RRR-α-Tocopherol. After a 7 day acclimation period, horses began a 6 week exercise protocol, with standard exercise tests (SET) performed prior to and at the conclusion of the 6 week exercise protocol. Resting, pre-feeding blood samples were collected at days 14, 21, 42 and 63, as well as 2 hour pre- and post-SETs. Initially and at pre-SET1, no differences in serum α-Tocopherol were seen across treatment groups. At all other time points, NAT horses had higher serum α-Tocopherol compared to SYN-H and SYN-L ($P<0.05$). No differences were noted between SYN-H and SYN-L. Pre SET1, NAT had lower protein carbonylation compared to SYN-L ($P=0.048$). Only NAT horses showed a significant increase in protein carbonylation post exercise for both SET1 and SET2 ($P=0.0004$). SYN-L and SYN-H horses showed a tendency ($P=0.066$) to increased protein carbonylation post SET2 only. Results indicate that natural vitamin E is superior to synthetic in maintaining serum α-Tocopherol levels in response to exercise and resulted in increased protein oxidation post exercise.

Goethe's Discovery of the Divine in Nature

Anna Magdalena Goebel
Dr. Martin Kagel, Germanic and Slavic Studies, Franklin College of Arts and Sciences

Johann Wolfgang von Goethe (1749-1832), a German writer and a natural philosopher, spent much of his life studying nature and attempting to understand the emotions it evoked in him by focusing on the human perception of nature. Through his literary works he strived to understand and explain the divine that was hidden in the complexity and depth of the natural world around him. Examining Goethe's novel, *Elective Affinities*, autobiography, *From my Life: Poetry and Truth*, and poem, "On the Divine," my paper argues that Goethe found the divine in the orderliness that nature possesses. He is able to make sense of the world around him using a God manifested in nature's structure rather than the traditional Christian God image. In the poem "On the Divine," nature isn't able to distinguish between the good and the evil, treating everything as equal. This impartial characteristic makes it predictable, running its natural course, unable to be stopped by anyone. In Goethe's novel *Elective Affinities*, nature's order is continually established through the application of natural sciences, equating human relationships with simple chemical reactions. In his autobiography *From my Life: Poetry and Truth*, Goethe allows us to trace his discovery of the "Erhabenen" (the sublime); the connection he makes between the divine and nature's impact on him. By offering his readers insight into the orderliness of nature, Goethe shows us that God is embodied in nature and that the divine is actually all around us. This belief ultimately let him make sense of the complex idea of God.

Limb Elevation as a Model for Peripheral Arterial Disease

Shaun Goh, CURO Research Assistant
Dr. Kevin McCully, Kinesiology, College of Education

Prior studies have shown that limb elevation can decrease blood flow to the elevated muscle, similar to reductions seen in peripheral arterial disease (PAD) patients. The purpose of this study was to test if limb elevation can be used as a model for PAD and to look at the effects of oxygen saturation on the endurance test developed by the lab. Experiments consisted of an endurance test with oxygen saturation monitoring, followed by reperfusion and mitochondrial capacity tests. The endurance index (EI) was measured using accelerometry and electrical twitch stimulation. Blood flow and mitochondria capacity were measured using the rate of recovery of oxygen consumption through near infrared spectroscopy (NIRS). The mean EI after 6 Hz between 2 cm and 60 cm was 79.5 $\pm$ 8.6% and 74.4 $\pm$ 18.3% ($p=0.09$). The end of exercise oxygen saturation showed no significant differences with levels of 52.9 $\pm$ 12.4% and 49.7 $\pm$ 42.7% for 2 cm and 60 cm ($p=0.42$). Oxygen delivery was slower during the elevated condition ($p=0.04$) with time to half magnitudes of 11.3 $\pm$ 3.3 seconds versus 23.4 $\pm$ 16.2 seconds for 2 cm and 60 cm. Mitochondria capacity across both elevations were similar with rate constants of 2.8 $\pm$ .4 at 2 cm and 2.9 $\pm$ .4 at 60 cm ($p=0.38$). Conclusively, limb elevation is a limited model for PAD from a functional standpoint, but is reflective of previous blood flow and mitochondria capacity measurements. It may also provide validation for the accelerometer endurance test based on its relationship to oxygen levels.

The Convergence of Quantum Physics and Religious Mysticism

Kalvis Golde, Foundation Fellow
Dr. David Williams, Religion, Franklin College of Arts and Sciences

Science and religion engage in vigorous debate over truth about the universe. Today, however, there is evidence that religion and science are converging to a similar truth, while claiming to progress in opposite directions. Quantum physicists and religious mystics both agree that interconnectedness is a basic truth of our universe; each also believes that the other's methods should fail to produce valid understanding of any sort. This research investigated questions addressed by both quantum physics and religion, including Hinduism, Buddhism, Judaism, and Islam, especially forms of mysticism. It determined that the convergence of these intellectual traditions is real and significant, not a superficial phenomenon. The research then compared fundamental assumptions of both groups to discern why their divergent methods have arrived at a similar picture of reality, in particular the idea of an interconnected universe. Two possible conclusions were drawn. The convergence of physics and religious mysticism may foreshadow a new understanding of the universe based firmly on interconnectedness. Alternatively, the assumptions of both physicists and mystics are so rife with implication for their respective searches for truth that this agreement may push one branch into a crisis and spark a revolution in thinking among its members.

Concrete Art and Fascism in Argentina in the 1940s

Nina Goodall
Dr. Nell Andrew, Art, Lamar Dodd School of Art, Franklin College of Arts and Sciences

In the summer of 1944, a magazine called *Arturo: Revista de Artes Abstractas* ran for a single issue in Buenos Aires, Argentina. Although short-lived, this magazine signaled the formation of a group of artists intent on exploring invention and abstraction in art and denouncing the traditional picture frame. The group was interested in the European style of abstraction that offered a new language through the abandonment of representation. After an exhibition in 1945 at the Galería Comte in Buenos Aires, the Asociación Arte Concreto Invención (AACI) was created. Using their art to showcase their political aspirations in regard to the newly formed regime of Juan Perón, the group believed abstract art could unite and be understood by all people, and therefore, be used to better the world. They looked to the European tradition of abstraction, but this political purpose for abstraction was a uniquely Argentine invention. This paper will explore how and why the group used the artistic technique of geometric abstraction to display their Communist values. It will also examine not only how the AACI and the future of Argentine abstraction were affected by the government censorship of Perón but how the group was successful in their resistance to the fascist dictator.

Characterization of Antibody Response and Cell-Mediated Immune Response to Seasonal Influenza Vaccination

Connor Grady, CURO Research Assistant
Dr. Ted M Ross, Infectious Diseases, College of Veterinary Medicine

Influenza virus infection is a disease of global concern, causing significant morbidity and mortality in many individuals. Annual seasonal influenza vaccination is the most effective way to reduce the risk of acquiring infection and is recommended for all individuals 6 months and older. A robust cell-mediated immune response to influenza infection is necessary for viral clearance and recovery. The purpose of this study is to quantify the frequency of CD154/$CD4^+$ and $CD8^+$ T cells, CD27 memory B cells, CD138 plasma cells, CD107a Natural Killer cells, $CD11b^+$ myeloid-lineage cells, and immunoglobulin lymphocytes derived from human peripheral blood mononuclear cells before and after influenza vaccination of a split inactivated tri/quadrivalent intramuscular vaccine. By using flow cytometry, cell populations can be analyzed by comparing cell frequencies before vaccination and 21 days post-vaccination. These cell populations can then be compared to antibody titers, determined by hemagglutination inhibition assay, against the strains included in the vaccine along with historical influenza strains to determine if there is a correlation between humoral and cellular immune response. Based on prior studies, it is expected that the frequency of all cells assessed will increase in response to influenza vaccination and that HAI titers will positively correlate with immune cell populations.

Reducing Homelessness in Atlanta

Ammishaddai Sully Grand-Jean
Dr. Christopher Cornwell, Economics, Terry College of Business

There are over 6,000 homeless people who reside in the City of Atlanta. Each homeless person costs tax payers about $40,000 a year, which includes emergency visits, prison, and police activities. Since homeless people do not own homes, it is difficult for them to obtain jobs and, as a result, they are trapped in the cycle of poverty. Homelessness doesn't only negatively affect the homeless, but also businesses and the local economy. Atlanta already has transitional housing programs that put homeless people in shelters that give them skills to prepare them to go back in the workforce and become home owners. Still, there are not enough resources available to reach the total homeless population. There are three policies that can positively aid in the reduction and prevention of homeless people in Atlanta: tax breaks offered by the state & local government for businesses who hire homeless people for at least 6 months; increased taxes on citizens and businesses that make $1 million or more a year and use the revenue to increase the reach of the current initiatives to reduce homelessness; and housing homeless people in the 46,000 vacant homes in Atlanta. Housing homeless people will prove to be best in reaching the total homeless population and is the most cost-effective and efficient out of the three policies. Atlanta should move to use its vacant homes to house homeless people and thus reduce the many costs that homeless people bring on the city.

Performance on a Measure of Multitasking is Related to Executive Function in Older Adults

Maria Granros, CURO Research Assistant
Dr. Steve Miller, Psychology, Franklin College of Arts and Sciences

Current research suggests that cognitive training may retard decline in attention, memory, and executive functions in older adults. Age related decline is normal for both mildly cognitively impaired and healthy older adults. Executive functions are the skills necessary for organization, execution of goals, and inhibition of compulsory actions. Specifically, executive dysfunction demonstrates difficulty in multitasking activities of everyday life. To examine the relationship between executive functions and performance on a task representative of multitasking abilities, a sample of older adults (n=20) played *Neuroracer*, a video game customized to train, challenge and measure multitasking ability over 12 visits, completing 20 trials each visit. The game required participants to drive a vehicle on a road while periodically and simultaneously responding to interjected symbols on the driving screen field. The difficulty level of each trial run changed specific to each participant using an algorithm that considered performance

on previous runs. The executive performance status of the participants was assessed using validated measures including DKEFS subtests Verbal Fluency, Color Word, and Trails DKEFS as measures of executive function. Correlation revealed that average latency did not correlate with the DKEFS measures (n(18)=-.300, p= .106). However, DKEFS scores were significantly related to average driving accuracy (n(18)=.594, p=.004) and final difficulty level (n (18)= .507, p= .011). Findings suggest that successful multitasking may be dependent on executive functioning. Findings thus support the testing of multitasking interventions as tools for cognitive enhancement in older adults.

Design of Gallate-Based Persistent Phosphors in the Short-Wave Infrared Region

John Green II, CURO Research Assistant
Dr. Zhengwei Pan, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Persistent luminescence is the ability of a material to continuously emit light after the excitation is ceased. This capability has had many breakthroughs in recent years, specifically with the persistent luminescence in the near-infrared (NIR; ~700–900 nm) and short-wave infrared (SWIR; ~900–1700 nm) spectral regions. Both NIR light and SWIR light are not visible to naked eye. Although significant progress has been made in NIR persistent luminescence, the research in SWIR persistent luminescence is particularly lacking and is where my research takes place. SWIR persistent luminescence can be applied in the field of biomedical imaging, photovoltaics, and night-vision. Rare-earth metals are the main emitters used in SWIR persistent phosphors because of their unique energy-level structures suitable for emitting SWIR light. This research lab particularly deals with gallate-based phosphors (gallium oxide compounds) that have appropriate electron traps to store excitation energy and subsequently release the energy to emitter. The goal of this research is to develop optimal SWIR persistent phosphors with the ability to give long and strong SWIR persistent luminescence emission.

Influence of Corrective Exercise Compliance on Physical Activity Levels and Perceived Functional Abilities

Morgan Green, CURO Honors Scholar, CURO Research Assistant
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

One potential cause of physical inactivity, a leading risk behavior for many chronic diseases, is a history of athletic injury. Little research exists on how physical activity levels and perceived functional abilities change after injury. This study aims to determine if a corrective exercise program intervention, provided with minimal supervision, alters perception of function and sport participation after injury. By monitoring changes in physical activity level, compliance with a corrective exercise program and perception of function, we aim to gather information to further understand how injured athletes self-select to complete rehabilitation or not, and participate in activity or not, following injury. We hypothesize injured participants will report decreased levels of physical activity and an associated decline in perceived functional movement ability due to pain or injury. Following baseline movement screens, college-aged club sport athletes will complete weekly surveys detailing their participation in physical activity. Upon a lower extremity injury, participants will receive corrective exercises to complete as well as an additional weekly survey to assess compliance to the intervention and overall perception of lower extremity function. Chi-square or *t*-tests will be used to compare perception of function and level of activity between those injured participants who self-select to complete the corrective exercises and those who don't, controlling for injury severity. We anticipate the compliant injured individuals will see a quicker return to normal physical activity level. Therefore, the importance of aggressive treatment using corrective exercises should be heavily stressed as a primary prevention for long-term health issues.

Regional Brain Morphometry and Associated Cognitive Functions in Older Adults with Cardiovascular Disease

Luvika Gupta

Dr. Lawrence Sweet, Psychology, Franklin College of Arts and Sciences

Cardiovascular disease (CVD) describes a range of conditions that affect the ability of the heart and vascular system to supply sufficient blood flow throughout the body. Although research studies of older adults with CVD have consistently demonstrated increased risk of neurodegenerative disease, patterns of cognitive decline, associated structural brain changes, and the relationships between them remain under investigation. The aim of this study is to examine the relationship between cognitive decline and regional brain morphometry among older adults with CVD. As part of a larger study, 50 CVD patients and 46 age-matched controls underwent an MRI scan and neurocognitive testing using the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). Using the software program FreeSurfer, we will analyze individual MRI data to determine cortical thickness in eight bilateral a priori regions of interest (ROI) in the dorsolateral prefrontal cortex (DLPFC), inferior parietal cortex (IPC), and posterior parietal cortex (PPC) that have been previously implicated in morphometry studies of CVD. Group differences will be tested using an Analysis of Variance (ANOVA). Relative to controls, it is hypothesized that a) the CVD group will demonstrate lower performance on the RBANS attention and visuoconstruction composite index scores, b) the attention index will significantly correlate positively with DLPFC and IPC regional thickness, and c) the visuoconstruction index will significantly correlate positively with DLPFC and PPC regional thickness. The results are expected to increase understanding of cognitive and neural changes associated with CVD.

Effects of Lutein on Vision and Cognition in Children

Sahl Hakim
Dr. Lisa Renzi Hammond, Psychology, Franklin College of Arts and Sciences

Lutein (L) is a carotenoid found predominantly in green, leafy vegetables and brightly colored fruits. Although humans cannot synthesize their own L, consumption of L-rich foods causes L to be deposited in a variety of body tissues, such as the neural retina and the frontal and occipital cortices of the brain. In neural tissue such as retina and brain, L is thought to perform a few important functions, one of which is to directly influence neural signaling. Past research suggests that increasing dietary L levels, either by consumption of L-rich foods or via supplementation, can cause increases in neural L levels as measured in the neural retina (as macular pigment, MP). As MP optical density increases, cognitive performance also increases, across the adult lifespan. Whether or not L status relates to cognitive function in younger participants undergoing rapid neurological development is not yet known. The purpose of this study was to test this hypothesis. School aged children (7-12 years) were recruited from the Athens-Clarke and surrounding county areas. Food diaries were used to determine L-rich food intakes, and the Woodcock Johnson test battery (III) was used to measure cognitive function. Visual processing speed and reaction time were measured psychophysically, and MP optical density was also measured. Analyses are ongoing, and results will be presented at the symposium. It is hypothesized that children with higher dietary intakes of L and higher MP optical density will have improved cognitive function, reaction times and processing speeds compared with children with low dietary intakes.

Southern Gothic Feminism: The Women of Flannery O'Connor's *Wise Blood* and the Women of the Bible

Halle Brooke Hammond, CURO Research Assistant
Dr. Hugh Ruppersburg, English, Franklin College of Arts and Sciences

Flannery O'Connor's 1952 novel *Wise Blood* features three predominant female characters, Sabbath Lily Hawks, Leora Watts, and Mrs. Flood. It uses attributes of the Southern Gothic genre in addition to biblical parallels in order to outline the demise of Hazel Motes and his Church Without Christ. The objective of this research project is to analyze the three female characters of *Wise Blood* in their relationships with the men of the novel (Hazel Motes, Asa Hawks, and Enoch Emery), and in their own parallels and contrasts to various women of the Bible, but including the Old and New Testaments, Virgin Mary, and Mary Magdalene from the life of Jesus Christ. Using

several texts, including *Collected Works* edition of Flannery O'Connor's work, which includes *Wise Blood* and her letters and essays, and the Bible, this project seeks to analyze the novel's Southern Gothic attributes from a Gothic feminist perspective. The women of the Bible and specifically their sins directly parallel the women of *Wise Blood* and their contributions to the demise of Hazel Motes, including his blindness and eventual death. The use of femininity in the novel contributes to its status as a Southern Gothic work. The South and its complicated relationship with feminism relies heavily on its connection to Christian religion and culture. Flannery O'Connor's work as a Southern Gothic writer provides an opportunity to analyze the impact of this culture on the South and its women.

Religious Terrorism and Weapons of Mass Destruction

Elizabeth Alexandra Hardister, CURO Honors Scholar, CURO Research Assistant
Dr. Seema Gahlaut, Center for International Trade and Security, School of Public and International Affairs

Proponents of the theory of "new terrorism" conflate the lethality of contemporary religious terrorist organizations to a heightened motivation and capacity to create mass fatalities, and thus, greater motivation and capability to acquire weapons of mass destruction. This theory cites the cosmic worldview of religious ideology as a significant condition that legitimizes the mass casualties and destruction potentially caused by these weapons. However, literature on conventional terrorism does not uniformly support the key assumption that religiously-affiliated terrorist organizations that hold purely religious goals produce greater numbers of fatalities than those with limited, strategic goals. The functional traits of religion that increase terrorist organizations' capacity to carry out violence and could potentially facilitate the acquisition and use of WMD were identified. Additionally, in light of the view that nuclear devices present the greatest potential for the advancement of the capacity to commit violence, information on a number of attempted acquisitions of nuclear material and weapons by terrorist organizations were compiled for analysis.

Fund Balances in Georgia's Cities

Jennifer Ashtyn Hardister, CURO Honors Scholar, CURO Research Assistant
Tracy Arner, Carl Vinson Institute of Government, Public Service and Outreach

Fund balances are equity in governmental funds, and their accumulation over time is determined in part by the line governments walk between their revenues and expenditures. With the issuance of GASB Statement 54 in 2009, the classification and reporting of these balances was clarified. However, there still remains a "policy void" regarding uses and amounts of these balances. One common recommendation is for governments to maintain an unrestricted fund balance of at least two months of general fund operating revenues or general fund operating expenditures. In this study, the various policies regarding fund balances in cities in Georgia and their compliance with these policies will be examined.

Dior to Disco: Second Wave Feminism and Fashion

Madeline Grace Harpham, CURO Research Assistant
Dr. Monica Sklar, Textiles and Merchandising, College of Family and Consumer Sciences

This research aims to establish a connection between the literature of second wave feminism, and the changes mainstream women's silhouettes undertook from the 1950s-1970s. During this time period, clothing changed dramatically; shifting from the rigid shape of the 1950s that exaggerated the female form, to the A-line, shorter mini-dress of the 60s, to the free-flowing silhouette of the hippie movement, to the streamlined androgyny of the 1970s. This study utilizes pertinent feminist literature from impactful writers such as Gloria Steinem, Betty Friedan, and Simone de Beauvoir, as well as a critical analysis of those writings, and *Vogue* magazines from the era to develop a literature review of fashion and feminism. Articles of clothing from the University of Georgia's Historic Clothing and Textiles Collection and the University of Minnesota's Goldstein Museum of Design establish the links between the messages of the media with the fashions of the time. Material culture and content analysis methods

highlight the relationship between the changing silhouettes of women's fashion in the 1950s-1970s, and the feminist movement. The transition of the fashionable silhouette for women from the feminine 'New Look' of the 1950s to the sexually ambiguous styles of the 1970s has linkages to the second wave feminist movement through literature, the fashion cycle, and cultural changes.

Do Transparent Whiteboards Promote Learning from Online Lectures in STEM?

Brendan Harris
Dr. Logan Fiorella, Educational Psychology and Institutional Technology, College of Education

The current study tested the effectiveness of the Learning Glass technology, which allows instructors to write a lecture while maintaining face-to-face contact with students using a transparent whiteboard. How do instructional methods using transparent whiteboards affect student learning in STEM subjects? To help address this question, 80 college students were asked to view a 10-minute video lecture about the human respiratory system. Participants were randomly assigned to one of two groups. Students in the conventional whiteboard group viewed the instructor draw diagrams on a conventional whiteboard, which requires the instructor to frequently turn his/her back to the camera throughout the lesson. Students in the transparent whiteboard group viewed the instructor draw the diagrams on a transparent whiteboard, which allows him/her to face the camera throughout the lesson. Participants were assessed on their understanding of the lesson both immediately and after a one-week delay. We also assessed their feelings of motivation and social engagement with the instructor. We predicted that the transparent whiteboard group would outperform the conventional whiteboard group on immediate and delayed tests of understanding. We also expected the transparent whiteboard group to report higher levels of motivation and social engagement. There is growing research that supports the idea that a direct view of the instructor may offer benefits for learning in STEM by establishing a stronger sense of social partnership with the instructor and providing better access to the instructor's eye gaze. This project will increase our understanding of how students learn from social cues in multimedia lessons.

Vector-Borne Disease Forecasting

Mallory Jessica Harris, Foundation Fellow
Dr. John M Drake, Ecology, Odum School of Ecology

Especially in resource-depleted areas, costly control efforts are often abandoned when case abatement is mistaken for true elimination. Resurgent epidemics can reverse decades of progress in disease elimination. Resurgence may be defined as a shift between two stable states: elimination and epidemic. We propose a non-parametric disease forecasting software that would detect a threat prior to the first resurgent outbreak and mobilize preemptive responses. These methods draw from the theory of critical slowing down, which states that as a system approaches the tipping point of disease resurgence, its ability to recover from slight perturbations decreases. This behavior results in characteristic changes in statistical indicators, including lag-1 autocorrelation, variance, and the first difference of variance, which can be detected as early warning signals of an approach to criticality. We apply the proposed techniques to several vector-borne disease systems. First, we develop a theoretical framework using stochastic modeling to predict the trajectory of each indicator. We quantify each test's sensitivity as the area under the receiver operating characteristic curve. Then, we validate our predictions by testing a monthly malaria data set for early warning signals of a 1993 resurgence event in Kericho, Kenya. We find that variance and the first difference of variance are promising indicators of critical transitions in vector-borne disease systems. Finally, we generate a simulation of the campaign to eliminate malaria from Haiti by the year 2020 and demonstrate how spatial early warning signal testing could facilitate more targeted, efficient interventions.

Understanding the Determinants of Seeking Medical Attention for Injury

Emma Harrison
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Multiple determinants may influence athletes to seek medical attention. However, it is unknown if athletes seek medical attention based on previous injuries. Our objective was to determine if there is

a significant relationship between frequency and severity of previous injuries with seeking medical attention for in-season injuries. Our participants were collegiate club rugby and ultimate frisbee athletes (n=39; 20 male, 19 female; age=20.8 ±1.6years, height=172.48±8.6cm, weight=74.1±15.6kg). Athletes underwent injury history screening prior to competitive seasons. Throughout the season, athletes reported injuries and specifics (e.g., date, anatomical location, type, time lost, and medical attention sought). Previous injury was defined as any self-reported, medically diagnosed injury or discomfort affecting sport participation. A point biserial correlation was used to determine association between previous injury frequency and seeking medical attention for in-season injury. A chi-square test was used to determine association between previous injury severity (>3 weeks lost) and seeking medical attention for in-season injury. There was significant correlation between previous injury frequency and seeking medical attention for an in-season injury (rpb=0.37; p=.02), as well as significant association between previous injury severity and seeking medical attention for an in-season injury (phi=0.365; p=.02). Statistically significant weak-to-moderate correlation exists between previous injury frequency and severity and obtaining medical attention for an in-season injury. Athletes who seek medical attention for in-season injuries are likely to have a previous history of athletic injuries and/or to have lost at least 3 weeks of athletic participation due to an injury.

Investigation into Surface Glycan Variation in *Campylobacter fetus* Species

Annie Hass, CURO Research Assistant
Dr. Christine Szymanski, Microbiology, Franklin College of Arts and Sciences

The *Campylobacter* genus consists of species causing periodontitis, spontaneous abortions, and diarrhea. This research focuses on *Campylobacter fetus* species known to cause spontaneous abortions in livestock and recently associated with diarrheal disease and rare cases of human fatality. The N-linked protein glycosylation (Pgl) pathway is conserved among all campylobacters and influences a wide range of cellular functions. In *C. fetus*, the biosynthetic enzymes in this pathway create one major N-glycan structure, while the enzymes from a bacteriophage operon known as gtr create a second antigenic variant of the N-glycan. Normally the gtr operon is involved in O-antigen serotype conversion of lipopolysaccharide and prevention of superinfection. In *C. fetus*, the operon appears to be mobile in the genome resulting in mixed populations of gtr positive and negative cells. We hypothesize that the mobility of the operon may be dependent on stressors such as antibiotics and that the mixed antigenic population may be beneficial for pathogenesis. We will be testing different environmental conditions, such as antibiotic stress, to see what induces mobility of the gtr operon. In parallel we will be performing mutagenesis on putative mobility factors and pgl/gtr genes to assess pathogenesis in a wax moth larvae model.

Developing a Protocol for Large-Scale Toxicity Assays Using Flow Cytometry

Cord Helmken, CURO Research Assistant
Dr. Art Edison, Genetics, Franklin College of Arts and Sciences

Caenorhabditis elegans are nematodes that have the ability detoxify the environments in which they thrive through the employment of various mechanisms. In this study, I seek to develop a protocol for large-scale toxicity assays using the Union Biometrica BioSorter and to use this protocol to assay for the detoxification ability of *C. elegans* glycosyltransferase mutant strains in response to the toxin 1-hydroxyphenazine (1-HP). Because *C. elegans* utilize glycosylation in order to neutralize 1-HP, we hypothesize that some GT mutant strains will exhibit increased susceptibility to the toxin compared to the wild type N2 strain. In this study, wild type N2 and GT mutant strain *C. elegans* were exposed to a gradient of 1-HP concentrations then treated with a fluorescent nucleotide stain and analyzed using the Union Biometrica BioSorter, a large-particle flow cytometry device. Results from this experiment will be used to assess and improve current protocols and direct future experiments focused on the glycosylation ability of *C. elegans*.

Fifty Years In: Just Warming Up: How the Nuclear Nonproliferation Treaty Can Effectively Combat Global Warming

Cameron Ward Henderson, CURO Research Assistant

Dr. Sara Kutchesfahani, International Affairs, School of Public and International Affairs

As the Nuclear Nonproliferation Treaty (NPT) nears its fiftieth anniversary, now is a critical time to reflect on the success of the treaty and where it can find new relevance in the twenty-first century. At the same time, climate change presents a newfound necessity for clean energy and international coordination. The convergence of these two events is the focus of this research. This paper attempts to fill a gap in climate policy research by analyzing how Article IV (the pursuit of civilian nuclear energy) of the NPT contains sufficient language to allow the nuclear nonproliferation regime to encourage and provide safety and security measures to respond to the global call for nuclear energy as a low carbon alternative to traditional fossil fuel power generation. Considering the ecological imperative to expand civilian nuclear power generation, the NPT will need to play a critical role in ensuring the safe transport of fissile material and the implementation of relevant security measures. The growing role of nuclear energy will present both a challenge and an opportunity for nuclear nonproliferation, but by capitalizing on the opportunity, NPT signatory states can guarantee that the NPT will maintain relevance in the twenty-first century and provide a new, more benevolent, face to nuclear energy.

Assessing Toxicity and Contamination in Lake Herrick

Sarah Hensey, CURO Research Assistant
Dr. Susan Wilde, Forestry, Warnell School of Forestry and Natural Resources

Located on the University of Georgia campus, Lake Herrick serves as a valuable recreational and institutional resource. In recent years, use of the lake by the public has been restricted due to declining water quality. High nutrient levels in storm water runoff have been linked to seasonal toxic algal blooms. This study aimed to monitor these seasonal algal blooms and assess the present levels of contamination and toxicity in Lake Herrick in comparison to previously collected data. Weekly water parameters of temperature, dissolved oxygen, and pH were recorded and water samples were screened microscopically for potentially toxic cyanobacterial species. Fecal coliform were assessed from the water samples using petrifilm *E. coli*/coliform count plates to evaluate contamination levels. In addition, toxicity was assessed through chronic and acute reproduction and survival tests of *Ceriodaphnia dubia*. We anticipated the presence of a toxic algal bloom in the warmer months of August through October but there was no persistent bloom due to a lack of rainfall events. We recorded a small-scale bloom of *Aphanizomenon* cyanobacteria, of which most forms are toxic, during October 2016. A frozen water sample from an *Anabaena planctonica* bloom (157,000 cells/mL) during a similar time in 2015 resulted in significant reductions in *Ceriodaphnia dubia* reproduction and survival in both acute and chronic tests ($p<0.05$). Our current results suggest that Lake Herrick is continuing to experience infrequent seasonal algal blooms resulting in harmful levels of toxicity. The water quality data from this study can help guide future remediation plans.

Biochemical Investigations of Congenital Disorders of N-Linked Glycosylation

Laurel Hiatt, Foundation Fellow, CURO Research Assistant
Dr. Richard Steet, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Congenital Disorders of glycosylation are a group of rare inherited diseases caused by defects within the N-linked glycosylation pathway. Although decreased glycoprotein glycosylation is a common feature of these disorders, little is known about which proteins are most sensitive to loss of N-linked glycosylation and how the changes in glycosylation status affect their cellular function. These questions are being address utilizing new tools such CRISPR-Cas9 generated null cells for two subunits (STT3A and STT3B) of the OST complex, the enzyme complex responsible for adding N-glycans to newly synthesized glycoproteins. To profile how decreased N-glycosylation affects the cell surface abundance of glycoproteins, a new tagging methodology called SEEL (selective exo-enzymatic labeling) is being used. This method uses recombinant glycosyltransferases and biotin-modified nucleotide-sugars to tag cell surface glycoproteins via their terminal sugar chains. These glycoproteins can then be enriched, identified and

quantified to determine how impaired N-glycosylation affects their surface localization. Results to date demonstrate striking changes in the abundance of cell surface glycoproteins in the STT3A-null and STT3B-null cells. These data show that many of the sensitive glycoproteins that have been identified are involved in cell adhesion and migration including several integrins. Subsequent experiments involved performing scratch healing assays to determine whether the changes in cell surface integrins correlate with altered wound closure in the STT3A and STT3B cells. Surprisingly, it was observed that the motility of STT3A cells into the wounded area increased while the migration of the STT3B cells decreased in comparison to the wild type cells.

Investigating the Role of HPG27_395 in *Helicobacter pylori*

Jonathan David Hill, CURO Research Assistant
Dr. Timothy Hoover, Microbiology, Franklin College of Arts and Sciences

Helicobacter pylori is an Epsilon-proteobacterium that colonizes the human stomach and causes diseases such as peptic ulcers, gastritis, and gastric cancer. *H. pylori* synthesizes 2-6 flagella at a single cell pole and is necessary for colonization. In *H. pylori* strain G27, HPG27_395 is annotated as a hypothetical protein. In many Epsilon-proteobacteria, this gene is observed to be clustered with other flagella genes, and positioned immediately downstream of *flhF* and *flhG*. Both FlhF and FlhG have been identified in other model organisms to be involved in proper localization and numerical regulation of the flagellum. The role of HPG27_395 in flagella biosynthesis is currently unknown, but the relative position to *flhF* and *flhG* suggests this gene encodes a protein that is necessary for flagella biosynthesis. Therefore, I aim to identify the function of HPG27_395 during flagella biosynthesis. To begin our investigation, a counter selection method will be used to construct a HPG27_395 deletion mutant (ΔHPG27_395). Following the verification of the mutant, motility defects will be assessed using a semi-solid medium and flagella patterns will be visualized using Transmission Electron Microscopy. Subsequently, these two experiments will provide insight as to how HPG27_395 affects flagella biosynthesis and initiate future investigations.

The Necessity for Ethics in Developing Adaptive Management Strategies for Water Scarcity

Taylor Alicia Hill, CURO Honors Scholar, CURO Research Assistant
Dr. Don Nelson, Anthropology, Franklin College of Arts and Sciences

Water is a limited resource and, due to the accelerated impacts of climate change, is expected to become scarce in the near future. Adaptive management is an interdisciplinary set of guidelines that are instated to formulate solutions to multifaceted issues, such as that of sustainable water management. Moving beyond an economic efficiency approach, adaptive management promotes the importance of participation, learning, and ethics. Although the importance of ethics is acknowledged, there are few empirical examples of how they may be included in water management. This project, based in the Vale do Jaguaribe and Paraiba do Sul watersheds in Brazil, applies an ethical lens as a tool in the development of water governance strategies for the basins, which face drought risks due to climate change. The goal of the current portion of the project is to develop a conceptual framework for analyzing water ethics, which will include the categories of social, economic, and ecological values. This framework will be used to assess the management settings in the two watersheds. The significance of this project is, in part, making ethics in governance explicit, rather than implicit. By making ethics explicit, not only can they be used as a framework by which to compare values in governance and as a framework in future management decisions, it also opens a forum for discussion of water values such as quality, quantity, as well as risk management regarding people, environment, and economy.

Shoring Up Dam Safety: Risk Assessment Via Simplified Inundation Mapping

Robert Erwin Hines, CURO Research Assistant
Shana Jones, Carl Vinson Institute of Government, Public Service and Outreach

Dam break emergency action plans (EAP) are essential for dam break emergency response because they allow local authorities to issue warnings to at risk areas, identify infrastructure

which may be compromised by flooding, and prepare emergency services to respond to affected flood areas quickly. Nationally, the high cost of formal, unsteady state inundation mapping studies prevents dam owners with limited resources from preparing EAPs. This study aimed to assess the capacity of simplified inundation maps to inform EAP construction. Simplified inundation maps were expected to be accurate enough for EAP development when formal, unsteady state models are unavailable. To assess simplified map acceptability, this project first compiled simplified inundation mapping recommendations to prepare a dam break modeling method using Arc GIS mapping techniques and HEC-RAS powered steady state modeling. Second, Federal Emergency Management Agency recommendations for EAP development were assessed to identify road crossing and building structures as the most relevant point of practical interest on inundation maps for EAP implementation. Third, simplified maps were qualitatively compared to formal, unsteady state maps, kindly provided by the Georgia Soil and Water Commission, to identify differences in potential emergency response operations. Developed case studies indicated that simplified inundation mapping technologies either overpredicted or underpredicted the extent of the flooding and would either overly concentrate or disperse emergency resources. However, because these case studies do not formally assess risk, future research should consider assessing risk by comparing potential simplified inundation map EAPs to historic emergency response operations performed without prewritten EAPs.

Trilobite Coquina in Siliceous Concretions from the Middle Cambrian Conasauga Formation, Southeastern USA

Zaak Alvin Hinz
Dr. Sally Walker, Geology, Franklin College of Arts and Sciences

Before the Cambrian period, life on Earth was extremely different from life today. However, approximately 540 million years ago, rapid diversification of animal life took place. This Cambrian explosion led to the evolution of many different animal phyla, some of which are preserved within shales and siliceous concretions within the Conasauga Formation, southeastern USA. Previously, it was asserted that the concretions have abundant, diverse, and well-preserved skeletal and soft-bodied organisms in three-dimensional relief. However, there was little to no quantitative data to substantiate this claim. The purpose of my project is to collect quantitative data to determine whether the concretions contain diverse and well-preserved fossils. I examined 100 concretions, which yielded mostly trilobite fragments (99.3%, n=3356), and rarely brachiopod and hyolith fragments (0.4%, n=13 and 0.3%, n=9, respectively). Trilobite fragments were divided into categories based on morphology: complete skeleton, complete cephalon, crandium, glabella, fixigena, librigena, complete thorax, thorax segments, complete axial lobe, and pygidium. The most abundant type was cephalon (head) fragments (21% librigena, n=719, 12% cranidia, n=417). All brachiopod fragments were single valves and all hyolith fragments were portions of its conical shell. These concretions represent a low diversity assemblage of mostly epibenthic organisms, and not a highly diverse or well-preserved one as previously reported. I also anticipate results from stable oxygen isotope analysis to help determine if these concretions formed in seawater, which would be consistent with their formation Cambrian seas.

Development of a Droplet Digital PCR Assay for Pre-NGS Quality Assessment of DNA from FFPE Specimens

Jessica Ziling Ho, Foundation Fellow, CURO Research Assistant
Dr. Lance Wells, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Because formalin-fixed, paraffin-embedded (FFPE) tissue samples undergo a preservation process that damages nucleic acids, they are not ideal candidates for downstream molecular studies. However, DNA extracted from FFPE specimens is often screened for hotspot mutations in cancer-related genes via next-generation sequencing (NGS), which requires a substantial input of quality DNA and is resource-intensive. Our work focused on developing a dual size amplicon-based ddPCR assay that would serve as a pre-NGS quality control for FFPE sample-derived DNA. We employed two primer sets targeting non-overlapping sites on the *RPP30* gene and defined amplicons of 109 base pairs (bp) and 195 bp. DNA was extracted from 84 FFPE tumor

specimens, and ddPCR was accomplished with Bio-Rad's QX200 Droplet Digital System and C1000 Thermal Touch Cycler. Data were processed with QuantaSoft software. To verify that both primer sets' PCR efficiencies were close to 100%, the ddPCR assay was first run with placenta DNA. Analysis of the data revealed that for most FFPE specimens, 24 ng of DNA yielded enough amplifiable copies for amplicon-based NGS testing. We noted a positive correlation between the amount of amplifiable *RPP30*-195 bp targets and the amount of library generated for NGS. There was also a significant reduction in the quality of NGS results for DNA samples with a RPP30-195 bp:*RPP30*-190 bp ratio of less than 0.3. The preliminary data suggest that our *RPP30* ddPCR assay is an inexpensive and accurate way to assess the quality of FFPE sample-derived DNA and to predict the likelihood of amplicon-based NGS success.

Genotype-Phenotype Correlations for POMGNT1 and POMGNT2 in Dystroglycanopathies

Jessica Ziling Ho, Foundation Fellow, CURO Research Assistant
Dr. Lance Wells, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Dystroglycanopathies are a subtype of congenital muscular dystrophy that result from hypoglycosylation of α-dystroglycan (α-DG). POMGNT1 and POMGNT2 are glycosyltransferases involved in synthesizing O-mannosyl glycans on α-DG. Our work examines the role of the R311G, R605H, P303L, and D556N mutations in POMGNT1 and the R157H, G412V, and R445* mutations in POMGNT2 to define a genotype-phenotype correlation. The POMGNT2 mutations result in Walker Warburg Syndrome, the severest dystroglycanopathy. POMGNT1 mutations R311G, R605H, and P303L cause Muscle Eye Brain disease (MEB) and the D556N mutation causes limb-girdle muscular dystrophy (LGMD), a milder dystroglycanopathy with no neurological symptoms. The effects of those mutations on enzyme characteristics are not well established in the literature. To identify mutation-derived changes in enzyme kinetics and stability, HEK293F cells were transfected with mutant plasmids generated by QuikChange II Site-Directed mutagenesis. Preliminary data showed that POMGNT1 mutants maintained enzyme expression, but POMGNT2 mutants did not. Radiolabel transfer assays indicated that the two POMGNT1 mutants linked to MEB were kinetically dead while the one linked to LGMD was still kinetically active. Promega's UDP-GloTM assay was performed on the LGMD mutant, which exhibited decreased activity compared to wildtype POMGNT1. A SYPRO Orange thermal shift assay revealed the POMGNT1 mutants to be thermodynamically stable. We are currently investigating the ability of the mutants to rescue POMGNT1 or POMGNT2 knockout cell lines for IIH6 reactivity, laminin binding, and Lassa pseudovirus entry. Understanding genotype-phenotype correlations in those glycosyltransferases will facilitate the design of more targeted treatments for individuals based on the mutation(s) they carry.

Exploring Linkages between Environmental Degradation and Human Rights

Maggie Holland, CURO Research Assistant
Dr. Puneet Dwivedi, Forestry, Warnell School of Forestry and Natural Resources

Human rights are vital for ensuring sustainable development. A culture which emphasizes an integrated growth paradigm under the broad umbrella of sustainability principles must have a proper place for political and civil rights for ensuring equitable human development and transparent accounting of environmental impacts. However, the relationship between changes in the status of human rights over time on human development and environmental quality is poorly understood. A need exists to deliberate on these relationships for strengthening current policy prescriptions that will ultimately ensure simultaneous benefits to people and resources worldwide. This will also help ensure inclusivity of global sustainable development agenda. This study will ascertain changes in the status of human rights across countries and how these changes simultaneously correspond to any changes in environmental indicators and human development over time. For environmental indicators, I will focus on several factors including air quality. For human development, I will use UNDP's Human Development Indices. For human rights, I will use data from the Freedom House. By observing how

human development levels pair with the status of freedom within a country and how these variable together correlate with indicators of environmental degradation, I will establish a link between human advancement, human rights securities, and environmental degradation. An integration of human rights securities and environmental protection policies should be more congruent through policies which address both environmental sanctity and access to human rights and this study will demonstrate the importance of this overlap.

Protospacer Structure and Cas Protein Function in Adaptation of the *Streptococcus thermophilus* Type II-A CRISPR-Cas System

Erin Hollander, Foundation Fellow, CURO Summer Fellow, CURO Research Assistant
Dr. Michael Terns, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

The CRISPR-Cas system works through a three-stage process of adaptation, expression, and defense, in which a "spacer" from an invader is incorporated into the genome of the host organism, transcribed into CRISPR RNAs, and combined with Cas proteins to recognize and cleave the invader upon subsequent attack. My work focuses on the Type II-A CRISPR-Cas system of *S. thermophilus*, a key bacterium used in the dairy industry, which contains four Cas proteins: Cas1, Cas2, Csn2, and Cas9. My current research project focuses on determining how the Cas proteins, CRISPR array, and invading nucleic acid interact in vitro to accomplish adaptation. Four protospacers (precursors to spacers) were tested for their ability to integrate into a plasmid containing a basic CRISPR array using various combinations of Cas proteins to determine the minimum necessary for integration. After adaptation assays, bands of possible adaptation were amplified and sequenced to determine the orientation of their integration into the CRISPR array. Adaptation could be completed using only Cas1 and Cas2, with the addition of Csn2 and Cas9 not providing any significant benefit. All four protospacers were able to integrate into both the plasmid containing the CRISPR array and the empty vector, and all four possible half-site integration orientations were observed. The lack of specificity found in these assays indicates there may be additional factors in vivo. With only four proteins, this system has great potential for a broad range of applications. Better understanding of adaptation is a crucial step in making these applications a reality.

Nitric Oxide Releasing Urinary Catheters as a Method to Prevent Urinary Tract Infections

Katie Homeyer, CURO Research Assistant
Dr. Hitesh Handa, Chemical, Materials, and Biomedical Engineering, College of Engineering

The chance of bacterial infection in urinary catheters increases by 3-6% each day the catheter is in place, approximately 50% after ten days, and over 90% after 28 days. 500,000 to 700,000 catheter associated urinary tract infections (CAUTIs) occur each year. Treatment of these infections amounts to over $350 million each year; therefore, there is a dire need to decrease the risk of bacterial infection from the placement of urinary catheters. Nitric oxide (NO) is one of the body's natural defense mechanism against bacteria and has been proven to effectively inhibit biofilm formation, the principal cause of CAUTIs. Consequently, this project aimed to create urinary catheters impregnated with S-Nitroso-N-acetylpenicillamine (SNAP), a NO donor, to develop a NO-releasing catheter. Three concentrations of the NO donor were incorporated into commercial silicone catheters and evaluated for their NO releasing properties, leaching and antibacterial activity. These properties were measured using various methods, such as chemiluminescence, UV-Vis spectrophotometer, and bacteria studies, to identify the optimal concentration that demonstrated the greatest NO release and greatest reduction in viable bacteria. The prepared catheters produced NO surface-fluxes > 0.5 X 10^{-10} $mol\ min^{-1}cm^{-2}$ for over ten days under physiological conditions, with minimal SNAP leaching from the surface of the catheter. These devices are proven to significantly reduce biofilm formation on the surface of the catheter over a 72-hour period by CAUTI causing bacteria species. Thus, NO-releasing catheters provide a successful approach to significantly reduce biofilm formation on catheters, and decreasing the risk of CAUTIs.

Multi-Rotor Marsupial Drone System for Point Cloud Data Processing

Peter Hong, CURO Research Assistant
Michael Anthony Piseno
Dr. Adarsh Kumar Chaurasia, Engineering, College of Engineering

With autonomous and multirotor technology becoming increasingly developed, task-specific applications for these are becoming more relevant. However, there are also complications with time-efficiency and accuracy of modern drone systems. The Multirotor Marsupial Drone System (MMDS) utilizes algorithms to autonomously coordinate multiple drones using Point Cloud data to construct models of objects in 3-D space. We will be using a depth-sensing camera and Intel's RealSense software development kit to integrate 3-D mapping capabilities into our drone system. We will measure the effectiveness of the MMDS versus a single drone in a controlled environment, and compare the error of the Point Cloud 3-D model. This will allow us to refine our algorithm to more efficiently model 3-D space. We expect to find that the single drone will have more distortion in the 3-D model when compared with the MMDS. We also predict that the MMDS will be more cost-efficient in completing its task with respect to time. Possible applications of the MMDS include integrated multi-satellite communication in orbit, mapping ocean currents, mapping buildings in dangerous areas, and monitoring soil erosion in agriculture.

Analogies between Numbers and Polynomials

Jackson Hopper, CURO Research Assistant
Dr. Paul Pollack, Mathematics, Franklin College of Arts and Sciences

Polynomials have several properties in common with the more familiar natural numbers. One example is that both are unique products of prime divisors. An open question in algebraic number theory is to find the extent to which analogies hold between deeper number theoretic properties of the two sets. One such question asks about the digital representation of numbers, which is related to the natural structure of polynomials. We have previously strengthened a theorem about digitally delicate prime numbers, or numbers that become composite if any single digit is changed. We asked a similar question of polynomials, finding that infinitely many prime polynomials are digitally delicate. We also study the growth of the polynomial Carmichael function, which gives algebraic information about the polynomials, in analogy with the Carmichael function for natural numbers. We have found that the function grows much slower for some polynomials than it does for natural numbers. We are currently investigating the typical behavior, and expect it to grow slower as well.

Diachronic Perspectives on Human Diet Variation in Greek, Roman, and Medieval Albania

Rachel N Horton, CURO Research Assistant
Dr. Laurie Reitsema, Anthropology, Franklin College of Arts and Sciences

Carbon and nitrogen stable isotope analysis of skeletal remains offers information about past human diet, which may be unavailable or incomplete in historical accounts. We assess carbon ($\delta^{13}C$) and nitrogen ($\delta^{15}N$) stable isotope ratios from human bone collagen to interpret paleodiet from two sites in present-day Albania: a rural village neighboring the Greek colony Apollonia (~5^{th}-4^{th} century BC) (n=11) and a more urban settlement, Durres (n=30), occupied since its foundation (7^{th} century BC) to modern day. Four animal bones are used for comparison. We test the null hypotheses that there are no isotopic differences between sites during the Archaic-Hellenistic period, no differences between time periods at Durres, and no differences between sexes in individual sites/periods. Mean ($\pm$SD) $\delta^{13}C$ and $\delta^{15}N$ values are -18.7$\pm$1.3 and 9.1$\pm$1.6 respectively at Durres, -19.4$\pm$1.0 and 9.8$\pm$1.3 at Apollonia, and -20.9$\pm$1.0 and 6.7$\pm$1.5 among animals. Nonparametric Kruskal-Wallis tests show no significant sex-based differences at Durres ($\delta^{15}N$, p=0.201; $\delta^{13}C$, p=0.227), no differences between sites ($\delta^{15}N$, p=0.815; $\delta^{13}C$, p=0.212), and no differences between Durres time periods ($\delta^{15}N$, p=0.299; $\delta^{13}C$, p=0.426). Diet at both sites comprises terrestrial and marine protein. Two individuals at Durres show isotopic values similar to fauna, suggesting a vegan diet. Apollonian village data show potential intrasite variations, suggesting some individuals may have originated

from another region or cultural background. Reconstructing past human diet is necessary for understanding, at broad temporal and regional scales, how people are linked to their environment through culturally mediated foodways.

Effects of a PUFA-Rich Diet on Coagulation and Inflammation Markers in Healthy Adults

Megan Houston, CURO Research Assistant
Dr. Jamie A Cooper, Foods and Nutrition, College of Family and Consumer Sciences

Saturated fatty acids (SFA), in contrast to polyunsaturated fatty acids (PUFA), are associated with increased risk of chronic diseases by elevating blood pressure, cholesterol, and inflammation and coagulation potential. To test whether a diet rich in PUFAs can negate the potentially harmful health effects of eating occasional meals rich in SFAs. 25 sedentary, normal weight adults were randomized into a treatment or control group. All participants were put on the same 3-day lead-in diet followed by a pre-diet visit (v1) where they were given a high-fat meal rich in SFAs for breakfast and lunch. Fasting and postprandial blood draws were taken for 8h. Participants then completed a 7-day diet rich in PUFAs (21% of total energy) or a control diet (7% of total energy as PUFAs) followed by a post-diet visit (v2) identical to v1. Plasminogen Activator Inhibitor-1 (PAI-1) (coagulation marker) and Tumor Necrosis Factor Alpha (TNF-α) (inflammation marker) were measured at both visits. Average changes in fasting PAI-I from v1 to v2 were not different between the two groups (-1.69±4.37 vs. -3.88±11.71ng/mL for PUFA vs. control, respectively). However, there was a significant difference in the change in fasting TNF-α from v1 to v2 for PUFA vs. control (0.88±0.41 vs. -1.85±0.99pg/mL, respectively; p=0.01). Compared to a control diet, the PUFA-rich diet did not lead to changes in PAI-I, but did elevate TNF-α concentrations. Since we only measured one inflammatory marker, conclusions about compensatory effects of PUFA-rich diets need to be explored further.

Genetic Determinants of Intracellular Survival and Growth of *Bordetella pertussis*

Katie Howard, CURO Research Assistant
Dr. Eric T Harvill, Infectious Diseases, College of Veterinary Medicine

Bordetella pertussis is a respiratory pathogen associated with the infant disease whooping cough. Although vaccines are mostly effective, there is growing concern that *B. pertussis* is reemerging through unknown mechanisms, even in highly vaccinated populations. Due to this, there is an increasing need for novel treatment. Our preliminary results have shown that *Bordetella* species utilize intracellular survival within host immune cells as the mechanism for persisting at undetected levels. This could explain vaccine failure and the increased persistence of clinical disease. From our 20 candidate genes, 5 constructions have been finalized and 15 genes are half way completed. While constructing the clones, we studied 30 mutants to determine their ability to survive inside immune cells. The mutant that showed most promise was RB50Δ*bsr*, a strain of *Bordetella* species lacking the gene encoding for a small regulator. Preliminary results showed that the presence of this gene is required for persistence of *Bordetella bronchiseptica*, an established model organism for *B. pertussis*, in mice: RB50Δ*bsr* was completely cleared from all organs, while wildtype *B. bronchiseptica* colonized chronically. When studying the immune response, we detected that the strains evoked different immune responses. We hypothesized that as there is a difference in the adaptive immunity, challenging immunocompromised mice with RB50Δ*bsr* should lead to severe, systemic disease, which we have confirmed experimentally. The systemic dissemination can be explained by RB50Δ*bsr* having greater recovery from macrophages and using this as a method of transport throughout the body.

Characterization of Cas4 Activity in the CRISPR-Cas Systems of Pyrococcus furiosus

Jesse Hu, CURO Summer Fellow
Dr. Michael Terns, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Bacteria and archaea have evolved extensive protective systems to defend against genetic invaders. One component of this defense is

CRISPR-Cas (clustered regularly interspaced short palindromic repeats–CRISPR-associated), an adaptive prokaryotic immune system found in nearly all archaea and half of bacteria. This system is composed of a genomic CRISPR array and associated Cas proteins. The CRISPR array affords memory of past infections and contains identical repeats separated by variable sequences known as spacers, which are derived from foreign nucleic acids. CRISPR-Cas functions in three stages: adaptation, CRISPR RNA (crRNA) biogenesis, and crRNA-guided interference. During adaptation, new spacers are captured from the invader and incorporated into the CRISPR array. The CRISPR array is then transcribed during crRNA biogenesis, and the transcript is processed to generate small crRNAs complementary to invader DNA. Finally, during interference, the crRNA guides Cas proteins to the invader, cleaving foreign genetic materials. It has been previously demonstrated that two universally conserved proteins, Cas1 and Cas2, are necessary for the integration of spacers during adaptation. Recent unpublished work in the Terns lab using the model organism *Pyrococcus furiosus* (*Pfu*) has uncovered a requirement for a third, highly conserved Cas protein, (Cas4), in mediating adaptation. Through in vitro assays, we aim to elucidate the role of the *Pfu* Cas4 protein in spacer integration into CRISPR loci, thereby clarifying our understanding of prokaryotic adaptive immunity against viruses and other mobile genetic elements.

A Comparison of the Catalytic Activity of Tryptophan Synthase from *Salmonella* and *Photobacterium* at Various Temperatures and Pressures

Eric Wayne Hua, CURO Research Assistant
Devanshi Nayak
Dr. Robert S Phillips, Chemistry, Franklin College of Arts and Sciences

The purpose of this experiment is to determine the effect of various temperatures and pressures on activity of samples of the enzyme tryptophan synthase isolated from two different organisms, *Salmonella typhimurium* (PEBA) and *Photobacterium profundum* (Ppro). This significance of this research study lies in its capacity to enlighten our understanding of the structure and function of tryptophan synthase, which synthesizes an amino acid invaluable to the proteins and biochemical pathways essential for the sustenance of all living organisms. With increasing temperature, the catalytic properties of enzymes typically increase. However, since *Photobacterium* optimally grows in the cold depths of the sea, it is hypothesized that the optimal temperature range for the Ppro tryptophan synthase enzyme will be lower than expected. It is hypothesized that the optimal pressure for maximum enzyme activity should approximate the homeostatic pressure within the organism. Because *Photobacterium* is acclimated to extreme depths, the Ppro enzyme is hypothesized to maintain functionality at higher pressures, while maintaining sound function at normal atmospheric pressure. To conduct the experiment, first a sufficient amount of cells were cultivated from the cell culture. After cultivation, autoclaving, and sonication, the proteins were then purified through a phenyl sepharose column. A reagent solution and buffer were inserted in a spectrophotometer with the added enzyme, and the absorbance was measured over time to ascertain the enzyme's activity. Results at this time for enzymes from both organisms are congruent with those hypothesized. Tryptophan synthase activity peaks at the climate conditions that its organism is acclimated to.

Desires for Difference: Tastes and Collecting of Later Nineteenth-Century American Paintings

Catherine J Huff, CURO Research Assistant
Dr. Alisa Luxenberg, Art, Lamar Dodd School of Art, Franklin College of Arts and Sciences

During the latter half of the nineteenth century, the United States experienced unprecedented shifts into modernity as technology and industry expanded, resulting in changing lifestyles for many Americans. Collecting fine art became more desirable and accessible for the growing upper class, and American painting was especially sought. The evolution of taste during this period is thought to have responded to larger societal shifts, and is frequently reflected through the history of ownership of a single painting or the patronage of a single artist's production. Through new research on a small collection of little-studied American later 19th-century paintings recently gifted to a university museum, this paper will consider the

ways in which collectors of these paintings reflected evolving American tastes in fine art. It seeks to understand what type of collector was attracted to these kinds of paintings and how their interests might have differed over time. This new research includes formal analysis, provenance, market history, exhibition history and critical reception for these paintings. It will attend to similar qualities or evidentiary connections between them, as several of their artists knew each other and shared similar patrons. While the research primarily explores how preferences in American art collecting may have reflected the historical context of the 1880s-1900, this research also hopes to compare these paintings' later 20th-century collectors to their predecessors a century earlier.

Development of an Inducible Histone Methyltransferase System to Analyze Establishment of Repressed Chromatin Domains in *Neurospora crassa*

Mallorie Lee Huff, CURO Research Assistant
Dr. Zachary A Lewis, Microbiology, Franklin College of Arts and Sciences

H3K27me3 is a molecular hallmark of facultative heterochromatin and results in stable repression of silenced genes. Regulation of H3K27 plays an important role in X-chromosome inactivation and stem cell fate; alternatively, aberrant H3K27me3 is observed in certain types of cancer. Producing an effective model in which to study H3K27me3 deposition may provide insight into the activity of Polycomb Repressive Complex 2 (PRC2), a highly conserved histone H3 lysine 27 methyltransferase. Suz12, a component of PRC2, is essential for catalytic activity. Our method to study H3K27me3 in *Neurospora crassa* involves constructing a controlled system through inserting inducible promoters and a FLAG epitope tag in front of suz12 and transforming them into *Neurospora crassa* through linearized *E. coli* plasmids. Verification of the putative inducible systems will include western blotting with FLAG antibodies, ChIP with H3K27me3 antibodies followed by Illumina sequencing (ChIP-seq). The promoters undergoing transformation are Ptcu-1, Pccg-1, and Pqa-2. The aim of this project is to investigate currently uncharacterized H327me3 kinetics by controlling suz12 expression. Monitoring the spatial and temporal dynamics of H3K27me3 establishment will allow us to predict when PRC2 is recruited. Successful completion of this project will provide insights into a conserved enzymatic complex with important implications in human health and disease.

Genomic Editing of *Neurospora crassa* as a Tool for Studying Circadian Cycle Synchronization

Brooke Hull, CURO Research Assistant
Dr. Jonathan Arnold, Genetics, Franklin College of Arts and Sciences

Circadian rhythms are a well-characterized emergent property in *Neurospora crassa* with known responses to external factors, such as temperature and light, but the effect of intercellular communication on this system is not understood. Our group has recently demonstrated synchronicity of cells over time in interactive cell populations, but not in those which are physically barred from cell-to-cell interaction. We therefore hypothesize cells can communicate circadian time to each other, resulting in synchronization of cell clock phase. To directly measure the synchronicity of cells over time we have engineered a second construct with yellow fluorescence. Venus, a yellow fluorescent protein, was introduced into the genome in codon optimized form under the control of the promoter of the *clock controlled* gene 2 using CRISPR Cas9 guided homologous recombination. When used in tandem with an existing red fluorescence construct, this new strain allows visualization and direct study of circadian synchronicity in *N. crassa* on both a single cell and on a population scale.

Religion in Fantasy: Christian and Wiccan Protagonists as Vessels for Gendered Religious Ideals

Kate Huller, CURO Research Assistant
Dr. Robert Foster, Religion, Franklin College of Arts and Sciences

Wicca is often stereotyped as promoting strong, female individuals who value their connection to the land and rebel against certain common cultural beliefs. Fundamentalist Christianity is known for its stories of men redeemed from lives of sin by their belief in God who then fulfill their male role

by becoming leaders within society. Rather than rejecting these stereotypes, certain strains of religious fantasy instead employ them by proffering the protagonists of their novels as embodiments of each religion's stereotypically gendered values. This project proposes to examine Patrick W. Carr's Christian series *The Staff and the Sword* and Anne Bishop's Wicca *Tir Alainn* trilogy as reflections of this trend within Christian Fantasy and Wiccan Fantasy, respectively. The focus will be on analyzing the way that the authors' character choices tie into the overall ideological viewpoint on the path to power presented by their respective publishing houses, Baker Publishing and Penguin House Inc. It will be further supported by the examination of texts which have been previously published by the publishing houses in order to detail trends in their publication of modern Christian and Wiccan literature. The potential effect on the readership of the publishers will also be noted, particularly emphasizing situations were religious ideas are communicated indirectly within the texts as opposed to the more obviously religious or gendered books released by the two publishing houses.

The Accuracy of SfM-Generated Dense Point Clouds Given Varying Image Quality

Nirav Ilango, Foundation Fellow, CURO Research Assistant
Dr. Marguerite Madden, Geography, Franklin College of Arts and Sciences

Structure-from-Motion (SfM) is an increasingly popular 3D modeling technique that allows images captured at different angles to be synthesized into a full 360-degree view of an object. An undergraduate-led team has been formed at the University of Georgia, with funding from the Air Force Research Laboratory, to develop a new SfM technique that uses satellite imagery to create 3D models of coastal environments. Demonstration of SfM with space imagery could lead to more accurate large-scale ecological models and could allow a researcher to avoid the large investment of time and money that characterizes UAV-generated imagery. In order to develop new SfM software that operates on a large scale, the UGA CubeSat team must understand how current SfM software adjusts to decreases in image resolution, as the images captured by the UGA satellite will have a much lower quality than typical UAV-generated imagery. This experiment studied the rate at which the density of SfM-generated point clouds decreases as image quality also decreases using standard commercial SfM software and open-source image manipulation software. By recording the number of points generated in each SfM point cloud, the researcher hoped to quantify a decrease in quality for these models. The experiment did not yield conclusive results, although it did reveal an inconsistency in SfM processing software that will need to be modified by the researchers for the satellite project.

Sensitivity of Heterotrophic Soil Respiration (HSR) to Temperature as Mediated by Mycorrhizal Fungi

Grace Anne Ingham, CURO Honors Scholar, CURO Research Assistant
Dr. Nina Wurzburger, Ecology, Odum School of Ecology

Heterotrophic soil respiration (HSR) is the largest terrestrial, non-anthropogenic source of CO_2 entering Earth's atmosphere and contributing to global climate change. HSR increases with rising temperature, and thus contributes to rising atmospheric CO_2 concentrations as part of a positive feedback loop. The degree to which HSR is heightened by rising temperatures may however be mediated by the presence of mycorrhizal fungi. Ectomycorrhizal (EM) fungi may depress HSR by limiting nitrogen availability in soils, while arbuscular mycorrhizal (AM) fungi may heighten HSR by stimulating the metabolic activities of heterotrophs as a nutrient acquisition strategy. Therefore, we hypothesize that EM fungi will dampen the response of HSR to increasing temperatures, but that AM fungi will further stimulate carbon loss. To test this hypothesis, we will sample soils from Coweeta Hydrologic Laboratory, where mycorrhizal composition ranges from completely AM to completely EM. We will incubate soils from plots along the mycorrhizal gradient at four temperature regimes (5, 15, 22, and 30°C), and measure CO_2 loss through HSR over time. We expect that HSR will increase more dramatically with increasing temperature in soils from AM dominated areas, and that the rise in HSR is muted when soils come from EM dominated areas. Our results will inform

models of carbon budgets as climate changes by illuminating the way that mycorrhizal composition of an area mediates the response of HSR to changes in temperature.

Optimization of MATLAB Code for Faster and More Consistent Image Analysis

Jawad Iqbal, CURO Research Assistant
Dr. Eric Freeman, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

A Droplet Interface Bilayer (DIB for short) is a bilayer that is formed when two aqueous droplets dispersed in oil coated with lipid monolayers come in contact. Electrodes inserted within the droplets allow for characterization of the membrane properties by recording the current necessary for maintaining a prescribed transmembrane voltage. Combining these measurements with images of the droplets obtained through microscopy allows for measurements of secondary membrane properties such as thickness. My involvement was exploring how to best characterize the properties of a lipid membrane using this combination of microscopy and electrophysiology data. MATLAB is the primary tool used for DIB analysis. However, the existing code was cumbersome to use and involved many repetitive and time consuming tasks (i.e. manually changing the name of the file input for each image file to be analyzed; set of image files being 30+ images). Streamlining the process and assisting with the analysis was the primary focus of this work. Optimization of the code and process significantly reduced time on redundant tasks.

Determining the Development of the Parietal Eye in Brown Anoles

Katie Elyse Irwin, CURO Research Assistant
Dr. James D Lauderdale, Cellular Biology, Franklin College of Arts and Sciences

Circadian rhythmicity controls several physiological and behavioral responses in animals, and in people specifically, disturbances of circadian rhythms underlie mood disorders such as depression and seasonal affective disorder. The proper functioning of the circadian axis in humans and most other vertebrates is dependent on the pineal organ, a neuroendocrine gland that acts as the main synthesizer of melatonin, and the coordination of this hormone's production relies on perception of the photoperiod. However, the mechanisms governing this link between photoreception and melatonin production are not well understood. Because light is perceived in lizards through an additional parapineal structure that is not present in humans, the parietal eye, this extracranial organ offers a unique opportunity to study mechanisms of the pineal complex, as it is easily accessible and can be easily manipulated. As a first step toward better understanding these pineal processes, this project establishes *Anolis sagrei*, the brown anole lizard, as a new model organism by using a histological approach to characterize a timeline of parietal eye morphogenesis, providing a foundation for identifying molecular instrumentation mediating development. The expectation is that, because the parietal eye develops a cornea, lens, and retina similar to those of the lateral eye, the parietal eye and lateral eye will display similar molecular mechanisms of development that illuminate their relationships to the pineal gland.

The Prevalence of Science Misconceptions among the Human Body Systems: Understanding, Targeting, and Applying Misconception Findings to Effectively Teach Students about Diabetes

Stephanie Ann Jaipaul, CURO Research Assistant
Dr. Georgia W Hodges, Math and Science Education, College of Education

Research studies have repeatedly identified that students share consistent misconceptions regarding the human body systems individually and cooperatively. As part of a larger research project that addresses diabetes and obesity in humans, this literature review addresses misconceptions that students have about the musculoskeletal, cardiovascular, respiratory, endocrine, nervous, & digestive systems, which will inform the SYSTEMS team in the design of an educational game targeting diabetes and obesity learning objectives for elementary learners. This review began by identifying top misconceptions for each system separately as well as supportively, then conducting a thorough review on previous research regarding these misconceptions. Data

from the SYSTEMS project tested on students was analyzed for the misconception prevalence. The literature review and data analysis were used to prepare a full assessment on understanding, targeting, and reversing students' misconceptions of the body. I expected that I would find steady misconceptions across all grade levels, misconceptions built upon earlier misconceptions, and that misconceptions were due to a lack of science knowledge by both students and teachers along with methods of teaching that didn't incorporate misconception knowledge. The SYSTEMS project hopes to change the epidemic of obesity-related illnesses in the United States by teaching about pre-diabetic & diabetic conditions in a platform that concurrently teaches about body systems. This research is significant to the project by providing necessary resources used to understand and apply the way students think about and view the body systems, and to thus effectively teach about diabetes.

Depth Gradient Analysis of Potential *Vibrio* Pathogens in Subtropical Marine Water After the Arrival of Atmospheric Saharan Dust

Harris Jamal, CURO Research Assistant
Dr. Erin K Lipp, Environmental Health Science, College of Public Health

Every summer, Saharan dust is atmospherically transported to the waters of southeastern United States. Marine microbes, including *Vibrio*, have been shown to increase in response to the influx of iron found in desert dust, leading to blooms of potentially harmful bacteria. *Vibrio* is a genus of aquatic bacteria that can cause diseases in marine organisms and humans. The purpose of this project is to determine whether there are defined areas of enrichment of potential *Vibrio* pathogens in the water column after dust deposition. Water samples were collected from different depths at Looe Key Reef in Florida Keys, US, including the surface micro-layer (SML, top 1-1000 μm), sub-surface (~1 m below surface) and benthos (at reef depth, ~8 m). The SML is known to concentrate nutrients at the atmosphere-ocean interface, making it an important habitat for bacterial dynamics and nutrient exchange. We hypothesized that the increase in *Vibrio* population response would be greater at the SML and that the SML would be a hot-spot for potential *Vibrio* pathogens like *V. alginolyticus* that are highly responsive to Saharan dust. Species-specific PCR characterization of *Vibrio* pathogens was done on isolates collected from *Vibrio*-selective media for each depth, before, during and after a Saharan dust event in Florida. Discovery of high concentrations of *Vibrio* pathogens at the suggested depths would prove significant in that it would allow for predictive power over when and at what depth the risk of infection is higher in an effort to address increasing *Vibrio* infection rates in the US.

Mitochondrial Capacity in Young, Well-Controlled People with Type 1 Diabetes

Riley Jenkins, CURO Research Assistant
Dr. Kevin McCully, Kinesiology, College of Education

The role of mitochondrial capacity in the health consequences of type 1 diabetes (T1D) is not currently known. This study measured mitochondrial capacity of young people with T1D compared to controls. Participants with T1D (n=12) and controls (n=12) were tested for casual glucose, hemoglobin A1c (HbA1c), forearm adipose tissue thickness (ATT), and mitochondrial capacity. Mitochondrial capacity was measured in non-dominant forearm muscles using near-infrared spectroscopy as the rate constant of the rate of recovery of oxygen consumption after electrical stimulation exercise. T1D and control groups were similar in age, sex, height, weight, and race. T1D participants had a casual glucose of 133 $\pm$ 52 mg/dL, and the controls measured 93 $\pm$ 7 mg/dL, P= 0.06. HbA1c of T1D participants was 7.3 $\pm$ 0.8% versus 5.2 $\pm$ 0.4% for the controls, P<0.01. ATT was 0.6 $\pm$ 0.2cm for T1D and 0.4 $\pm$ 0.1cm for controls, P=0.03. There were no differences between groups in mitochondrial capacity (T1D= 2.0 $\pm$ 0.5min-1 and control= 1.8 $\pm$ 0.5min-1, P=0.24), or blood flow measured as the time to half magnitude of oxygen saturation (T1D= 8.8 $\pm$ 2.8s and control= 10.3 $\pm$ 3.0s, P=0.76). Young, relatively well-controlled people with T1D did not have reduced mitochondrial capacity or microvascular blood flow compared to controls. Future studies could evaluate poorly controlled or older participants with T1D to determine the effect of a longer history of T1D on mitochondrial capacity.

Bent and Broken: Debating China Beyond the Great Firewall

Amanda Molly Joffe
Dr. Rongbin Han, International Affairs, School of Public and International Affairs

The book *Bend Not Break: A Life in Two Worlds* by the Chinese-American entrepreneur Ping Fu stirred up much controversy in both China and America. In her memoir, Fu tells readers her stories, particularly her childhood experiences in the Chinese Cultural Revolution. While applauded by Western media and readers, the autobiography received polemic comments from Chinese audience. This paper explores how Chinese and non-Chinese nationals debated on this book by exploring the review/comments section on Amazon.com and other online platforms. We attempt to explain why there were such fervent and polarized outbursts, and why certain emotions are portrayed by certain nationalities. Why do Western and Chinese audiences have such polarized comments on the same book? In particular, why is there such a fervent outburst of online criticism towards Fu among Chinese in and outside China? And why do overseas Chinese that have been exposed to freer flow of information feel so strong about defending the communist China? Using the reviews on this book, our research seeks to fill the gap in the current understanding of the manifestation of Chinese cyber nationalism and how it interacts with Westerners on overseas cyberspace. We will use modern tangible examples and phenomena to gain a newer, deeper, and updated understanding.

Pressuring Playwrights: New Play Development for Contemporary Stages

Abraham Branch Johnson, CURO Research Assistant
Dr. John Patrick Bray, Theatre and Film Studies, Franklin College of Arts and Sciences

In contemporary theatre, there is an understood development process for the new script. The unprofessional reading leads to a staged reading, which leads to workshops and dramaturgy, which leads to the fluid definition of full "production." This process, however, affects the seriousness with which scripts are invested in. How do different developmental structures affect new scripts? How does producibility alter vision? I will be directly experiencing these processes in action by producing three scripts with three different intentions: a staged reading, a workshop, and a full production. I will measure dynamic pressures from writing to funding, while consulting texts and fellow playwrights in their processes. Along with this, I will keep all edits to these scripts in an effort to document changes and holistic pressures that alter and enhance my vision. This research is deeply necessary and valid in understanding the fields of professional dramaturgy, new play development, and playwriting in general. Alongside this, my work draws attention to the decline of live theatre in recent years, answering important questions like: How are theatres investing in new plays with ticket sales at risk? Where does the funding come from? Who has the most authority and how does this shape script editing? I expect to find that financing is the most tangible pressure in all of these endeavors, and that the tastes of those funding new play development have vast sway in editing new scripts for performance.

Newborn Hearing Screening and Follow-up in the Northeast Health District

Breana Johnson
MacKenzie McGraw, Anna Marie Fink, Brianna Kelley, Lauren Langan, Meredith Anne Towey, Alexis Pope, Jennifer Smith, Sherry Sayavongsa, Aleah Norton
Dr. Sandie Bass-Ringdahl, Communication Sciences and Special Education, College of Education

Newborn hearing screening is the standard of care for the early identification of infants who are deaf or hard-of-hearing. Studies investigating the outcomes of children who are deaf or hard-of-hearing continually identify early identification as a key factor in successful language development. The current project explores the state of newborn hearing screening in the Northeast Health District (encompassing Athens-Clarke County and many surrounding counties). Data obtained through the Georgia Department of Public Health for the years 2010-2016 will allow for a close investigation of the screening process including the rate of identification of hearing impairment. The data will be analyzed for demographic trends and screening

patterns with the goal of enhancing early identification and the follow-up in the District.

An Inquiry into the Role of SUT5 and SUT6 in the Release of Exudate at the Extrafloral Nectaries of *Populus tremula x alba*

Chandler Elizabeth Johnson
Dr. C. J. Tsai, Genetics, Franklin College of Arts and Sciences

The aim of this study is to evaluate the role of sucrose symporters (SUTs) in the release of extrafloral nectar (EFN) of *Populous tremula x alba*. The EFN is exuded from a small, node-like nectary gland located at the proximal end of the leaf petiole. EFN is rich in a variety of sugars, including sucrose, glucose, and fructose, as well as amino acids and various protective enzymes. EFN plays an important role in the indirect defense against insect herbivory: a mutualistic relationship is established with an EFN consumer that, in exchange, offers protection against pernicious herbivores. Previous studies have implicated a role of SUTs in regulating the release of exudate, but the exact mechanism is not very well understood. A better understanding of EFN regulation may give insight into areas as broad ranging as the evolutionary origins, food web interactions, and ecological interactions pertaining to the species in question: *Populous tremula x alba*. Over a period of nine months, the frequency and volume of exudate produced in a sample population of poplar trees, mainly SUT3-, SUT4-, or SUT5-silenced transgenic plants, and wild type, was monitored. SUT3, SUT4 and SUT5 belong to three subgroups of the SUT gene family with different functions. Results showed a marked increase in exudate production in the cool season spanning from November to February, whereas EFN production was poor during the warm season from June to October. In order to gain insight into the regulation of SUTs, in situ hybridization is undertaken. In this process, gene-specific, DIG labeled probes are prepared using in vitro transcription. Chemical analysis of exudate composition by means of gas chromatography, and signal detection via in situ hybridization are ongoing.

Fostering Productive Beliefs about Failure and Intelligence to Improve Learning in STEM

Elizabeth Cara Johnson, CURO Research Assistant
Dr. Logan Fiorella, Educational Psychology and Institutional Technology, College of Education

The demand for workers in STEM fields is increasing, yet the number of students choosing to pursue STEM educational and occupational goals does not match this demand. Women and minorities are especially underrepresented in STEM fields. Contributing to this misrepresentation and demand are unproductive beliefs that students hold about learning in STEM subjects. For example, many students believe that success is based on innate ability and that struggle and failure are signs of one's lack of ability. By challenging these notions of intelligence and success, we hope to improve student motivation and academic performance. Using story-based intervention, the current study asked 51 sixth-graders to read a story about a successful scientist that either emphasized her struggles and persistence in the face of challenges (struggle group), or that emphasized the role of her innate talent and ability (control group.) Students were assessed on beliefs and math ability before and after reading one of the two stories. We anticipate that participants assigned to the struggle condition will have improved beliefs and performance on math tests due to reading the story about struggle and overcoming challenges. Using stories as a method of instruction may be a promising tool for shaping student's beliefs about intelligence and failure. This may help more students persist in the face of challenges, ultimately expanding students' opportunities for success in STEM careers.

How Do Parental Practices Influence Adolescent Food Choices?

Evan Simone Johnson, CURO Research Assistant
Dr. Alex Kojo Anderson, Foods and Nutrition, College of Family and Consumer Sciences

We studied parental habits such as modeling, home food environment, and rules that impact eating behaviors during independent eating occasions among low-income, multi-ethnic adolescents between the ages of 10 and 13 years.

Family food practices are an influential component of developing lifelong healthy eating habits, and understanding which practices are most impactful among adolescents could help health practitioners better counsel their patients. This was a mixed-method design with parent-child pairs in the Athens area involving 2 study visits. On the first visit, the parent and child were interviewed, and the child was provided guidance to take photos of everything consumed in a chosen 24-hour period to send to the research team. On the second visit, adolescents were asked about independent eating environment, food choices and the role of their parents and peers in food selection. Parents were also asked about how they instill healthy eating habits in their household. Both completed a survey at the end of the interview. The interviews were transcribed verbatim and analyzed for themes. Anthropometric measurements of weight, height and waist circumference were conducted on both the parent and adolescent. Findings suggest that adolescents adapt similar food habits as their parents. They also lean towards ready-made, easily accessible foods that can be prepared without much supervision. To control eating habits, parents often utilize bargaining or do not purchase foods that they do not want their child to eat. Most parents wished their child would consume more fruits and vegetables. The findings have the potential to shape nutrition education targeting parents and adolescents.

Metacognitive Regulation in Undergraduate Biology Students

Me'Shae Johnson, CURO Research Assistant
Dr. Julie Dangremond Stanton, Cellular Biology, Franklin College of Arts and Sciences

Metacognition is what we know about our thinking and how we are able to regulate our thinking in order to facilitate our own learning. Metacognition positively correlates with learning outcomes, academic performance, and problem solving. This project centers on understanding metacognitive development among undergraduate students so that we can develop effective ways to stimulate metacognition. The long-term goal of this research is to use metacognition to enhance student learning in undergraduate biology courses. Our research question is: how does the use of the metacognitive skills (planning, monitoring, and evaluating) compare between first- and fourth-year undergraduate students? We will compare data from introductory biology students with data from upper-level biology students to see how metacognitive regulation might progress over time. We will collect data using two open-ended assignments given after the first and second exam in an introductory biology course and a senior-level cell biology course. We will use qualitative methods such as content analysis to find evidence of students' use of metacognitive skills. This analysis will allow us to identify those students who effectively use metacognition and those who are working to adjust their learning strategies. Our findings will be used to design research-based curriculum for improving student metacognition.

Mothers' Childhood Emotional Neglect as a Predictor of Child Behavior Problems

Sara Carroll Johnson
Amber Madden
Dr. Anne Shaffer, Psychology, Franklin College of Arts and Sciences

Childhood emotional neglect (CEN) is a specific form of child maltreatment in which caregivers fail to make a significant emotional connection with their child, thereby preventing the development of healthy attachment bonds. Individuals who have been emotionally neglected in childhood are more likely to experience later psychological distress when compared to those who were emotionally neglected by male caregivers. Mothers' experience of CEN has also been shown to be predictive of poor parenting outcomes, but less research has examined relations between maternal CEN and their children's behavior. Maternal emotion dysregulation, or difficulties in modulating emotional responses, is of particular concern since emotion dysregulation is a significant mediator of the relationship between childhood maltreatment and parenting stress. Based on these relations, we hypothesized that emotion dysregulation would mediate the relations between maternal CEN and the occurrence of internalizing and externalizing behaviors in their children. This study utilized data collected from a sample of 58 mothers and their children aged 8-11. Measures included a measure of maternal childhood emotional neglect (CTQ), emotion dysregulation (DERS), and mothers' reports of child behavior problems (CBCL). A multiple mediation model considered all of the

DERS subscales simultaneously as potential mediators. Results indicated that low emotional clarity, a component of emotion dysregulation, was a significant mediator of the relations between maternal childhood emotional neglect and the occurrence of behavior problems in their children (indirect effect=.17, SE=.11, 95% CI=0.2-.46). Future research might further examine the relationship between emotion dysregulation and other parenting behaviors that may predict child outcomes.

Household Production of Health: Cambodian Refugees' Health Strategies in the United States

Abby Carden Jones, CURO Research Assistant
Dr. Denise Clark Lewis, Child and Family Development, College of Family and Consumer Sciences

A life course theoretical perspective and multidisciplinary Household Production of Health (HHPH) conceptual model illustrate Cambodian refugee families' processes for acquiring and maintaining health. Life course perspective provides a dynamic view of refugees' pathways from fleeing their home nation to resettlement in the United States. Social ties, family relations, traditions, and immigration stressors contribute to refugees' experiences and influence culturally relevant health production. The HHPH model used in our analysis of 125 Cambodian refugees' narratives gathered during ethnographic research conducted between 1997 and 2014, includes multiple factors that influence refugees' ability to acquire and maintain well-being in the US. The HHPH conceptual model takes into account multiple elements associated with beliefs and behaviors surrounding decisions about the desire for culturally responsive health services. Life course perspective and the HHPH conceptual model combine to reveal how refugees' transition to the host country influences health trajectories, the significance of linkages between individuals, families and communities, and how historical context informs individual and collective actions. Ultimately each element shown in the HHPH model affects what is viewed as a culturally relevant health service, how refugees attain such service, and which services are suspect and not viewed as culturally responsive. The HHPH conceptual model is based on interviews and interactions with Cambodian refugees; however, the HHPH model can be applied across other refugee groups to understand transitions associated with their household projection of health. It can be used to inform US policy makers and service providers of culturally specific needs of refugee families.

The Suburbanization of Poverty in Metro Atlanta

Phillip Jones, CURO Research Assistant
Dr. Laura Zimmermann, Economics, Terry College of Business

Over the last decade, there has been a substantial increase in poverty rates in suburban counties surrounding cities across the country. The metro Atlanta region, with exponential growth in size and population in recent decades, has exhibited this same suburbanization of poverty. The dominant perception is often that poverty remains a uniquely urban problem, and therefore the problem of suburban poverty is often left unaddressed. Recently, the city of Atlanta has refocused on creating sustainable mixed income communities that will serve all Atlanta residents, regardless of socioeconomic status. An example if this is the developing Atlanta Beltline Project. However, the question remains of whether public services, including convenient public transit, affordable housing, sustainable economic opportunities, and other resources are being developed and readjusted to account for metro Atlanta's rise in suburban poverty. Research has suggested that the current public policy and nonprofit framework concerning poverty is too urban-oriented and therefore ill-equipped to deal with the new challenges of today's suburban poverty situation. This research project will begin by quantifying the change in poverty rates in nineteen metro Atlanta counties since the year 2000. Next, it will review literature and other resources that may help explain why there has been an increase in poverty in these counties. Lastly, this project will suggest actions that should be taken by the private, public, and nonprofit sectors in order to spur economic growth and opportunity for Atlanta's suburban poor.

PCR Detection of the SRY Gene of Male Dog Mesenchymal Stem Cells in Female

Dog Brains with Experimentally Induced Ischemic Stroke

Susie Jones, Foundation Fellow
Dr. Buffy Howerth, Pathology, College of Veterinary Medicine

Intra-carotid-delivered mesenchymal stem cells (MSCs) may improve functional neurological outcomes after acute ischemic stroke (AIS). However, a large animal model is essential before beginning human clinical trials for patients with AIS. This study uses a dog stroke model in which female dogs with experimentally induced AIS receive male-derived MSCs via intra-carotid injection. It is hypothesized that the MSCs will successfully move to the site of infarction and participate in repair of damaged tissue. The objective of the present study is to target the Y chromosome in order to track the migration of the male-dog derived MSCs to various locations by using PCR. To detect the MSCs, two techniques were developed or modified from those in the literature to amplify the SRY gene on the Y chromosome. A previously described PCR technique and an original quantitative PCR technique were then tested using fresh brain samples from female dogs with experimentally induced AIS that were subsequently injected with male MSCs on the side of the stroke. Both techniques were able to detect the Y chromosome in the brain samples and are suitable for tracking male-derived MSCs in this dog model of stroke. These techniques may have future applications in determining the sex of canine subjects in forensic cases.

Evaluation of Middle-Miocene Barnacles as High-Resolution Paleoclimate Proxies

Reid Jordan, CURO Research Assistant
Dr. Sally Walker, Geology, Franklin College of Arts and Sciences

The Miocene Epoch stands in stark contrast with the global climate trends of the Cenozoic Era. The Middle Miocene Climatic Optimum (MMCO) disrupted a ~50-million-year cooling trend with three million years of relative warmth. Characterizing the MMCO were elevated sea levels, increased global temperatures and oceanic stagnation. Increased scientific understanding of the MMCO will allow for parallels to be drawn between modern global climate change phenomena and past climate and oceanic conditions. Relatively little data exists for Middle-Miocene oceanic seasonality in the Atlantic Margin. For my research, the barnacle, *Balanus concavus*, of the Maryland Middle Miocene, is evaluated for suitability as a high-resolution paleoclimate proxy. These large Maryland fossil barnacles are suspected to have grown year-round while sequestering carbon and oxygen isotopes near equilibrium oceanic values. As these barnacles age, calcium carbonate is secreted via cuticle -like tissues along the base of the external shell. This process is nearly continuous excepting interruption from breeding or molting events and brief cessations due to lack of nutrients. These events result in distinct growth lines and molting ridges within the external parietal plates and results in a subannual to multiannual record of oceanographic conditions during the time the barnacle was living. This study involves gathering transects from the oldest to the youngest shell of *Balanus concavus* for stable oxygen isotopic analysis. We anticipate oxygen isotope data to reveal either oceanic seasonality within the MMCO or little seasonality if the waters were warm year round.

Mapping Near Misses in Athens-Clarke County

Stephen Benjamin Jordan, CURO Research Assistant
Dr. Jerry Shannon, Geography, Franklin College of Arts and Sciences

The Bike Master Plan (BMP) is a developing road biking plan for the use and implementation by the Athens Clarke County Planning Commission. A major point of interest and concern is a comprehensive source of spatial recognition of near misses of bike riders in Athens-Clarke County (ACC). In order to correctly gauge the intended spatial analysis, this research endeavor will take part with a series of interviews of persons who regularly ride for various reasons, such as work, exercise, and/or environmental concerns. Interviews will consist of both qualitative and quantitative data questions regarding each individual's experience bike riding in ACC. Moreover, a sketch map will be drawn by interviewees of their routes taken and information along with that. Methodologies include, but are not limited to, interview analyses, digitization of

routes drawn and discussed by interviewees, geospatial integrated tools to find, spatial clusters and heat indexed routes, and comparative data analysis which will aid in the pursuit to provide the BMP with a comprehensive idea of target areas to address in order to improve bike riding conditions. The latter portion explains a part of the significance from which this research will provide; furthermore this data will provide the ACC Planning Commission a valuable source of information pertaining to future development projects that will ensure the safety of both bike riders and drivers on ACC roadways.

Attachment Orientation and Career Goal Pursuit: The Effects of Relationship Commitment and Workaholism

Amita Joshua, CURO Research Assistant
Dr. Malissa Clark, Psychology, Franklin College of Arts and Sciences

The goal of this study is to examine the relationship between attachment orientation and career goal pursuit and the moderating effects of relationship commitment and workaholism. Specifically, we seek to understand whether attachment at infancy can affect goal pursuit in adulthood, which is defined as the active pursuit of career-related goals through spending time dedicated to goals and accomplishing measurable achievements. In attachment theory, anxious attachment refers to an obsessive approach to relationships that is associated with low self-esteem and fear. Avoidant attachment is associated with maintaining security by avoiding intimacy in social and romantic relationships. Attachment is more often studied in infants; however, recent studies have found the effects of attachment orientation carry past infancy and further into development. The following hypotheses will be tested: 1) Whether higher avoidant attachment predicts higher career goal pursuit, 2) Whether higher anxious attachment predicts lower career goal pursuit, 3) Whether relationship commitment moderates these relations and 4) Whether workaholism moderates these relationships. Nearly 400 participants will be recruited from Amazon Mechanical Turk. Participants will be asked to complete the Experiences in Close Relationships-Revised Questionnaire, the Tenacious Goal Pursuit scale, the Commitment Inventory and the Work Addiction Risk Test. Multiple regression analyses will be used to test these hypotheses. The findings from this study will help to elucidate the role of developmental psychology within the field of industrial-organizational psychology.

Depression and Risky Health Behaviors: The Moderating Effect of Coping Responses

Amita Joshua, CURO Research Assistant
Dr. Anne Shaffer, Psychology, Franklin College of Arts and Sciences

The goal of this study is to examine the relations between depression and risky behaviors and the moderating the effect of coping responses in college students. This research has important treatment implications for young adults experiencing depressive symptoms. This study examined risky behaviors including tobacco use, drug and alcohol use, risky sexual behaviors and safety-related behaviors. The following hypotheses were tested: 1) Whether higher levels of depressive symptoms predict higher levels of risky behaviors and 2) Whether positive coping responses moderate (i.e., buffer) these relations. Data was collected from 1561 participants from an undergraduate research pool. Participants completed the Center for Epidemiological Studies Depression Scale, the Youth Risk Behavior Survey and the BRIEF Cope Inventory. Bivariate correlations revealed that depressive symptoms were significantly correlated with risky behaviors ($r=.16$, $p<.01$). Additional regression analyses were performed to determine whether coping responses moderated the relations between depressive symptoms and risky behaviors. Results indicated that coping responses significantly buffered the relations between depressive symptoms and risky behaviors ($R^2=.03$, $F(3,1614) =11.70$, $p <.01$). Specifically, students who reported high usage of positive coping responses engaged in fewer risky behaviors ($\beta=.30$, $p<.01$). These findings highlight the importance of developing individual's adaptive coping responses in clinical applications. Given that this study was limited to college students, future studies should consider whether these findings generalize to other populations such as early adolescents and non-college samples, as well as consider analyzing the effects of depressive symptoms and coping

responses on specific categories of risky behaviors.

Turbulence at the Edges of Diffuse Molecular Clouds

Mackenzie Joy, Foundation Fellow
Dr. Loris Magnani, Physics and Astronomy, Franklin College of Arts and Sciences

Diffuse molecular clouds can be observed with carbon monoxide (CO) spectra obtained from radio spectroscopy. Though the clouds are mostly composed of molecular hydrogen, they are much more difficult to detect from ground-based telescopes, so the known correlation between the presence of CO and molecular hydrogen is utilized in the detection of clouds. This research seeks to better understand the behavior at the edges of diffuse molecular clouds. Because of the interactions between the molecular gas at the edge of the cloud and the surrounding atomic medium, one would expect the clouds' edges to be more turbulent than the insides of the cloud. Turbulence can be measured via the width of the CO spectral lines with broader lines indicating more turbulent clouds. Recent observations, however, have shown narrow spectral lines associated with CO at the edges of diffuse molecular clouds, contradicting the previous assumption. This research will compare the width of CO spectral lines with the area under the best-fit Gaussian curve, a measure of line strength, in order to determine the nature of the relationship between the edges of clouds and their surroundings. These relationships will be determined by compiling data from spectra detecting the 1-0 rotational transition of CO and graphing the line width versus the line strength. The results of this study will have consequences for understanding the behavior of molecular gas at the atomic/molecular interface and the nature of diffuse molecular clouds in general.

Examining the Entropic: Locating Modernity in the Writings of Jane Austen

Jianna Justice
Dr. Roxanne Eberle, English, Franklin College of Arts and Sciences

Jane Austen, often cast by critics as a conservative spinster writing novels of niceties stained with the scent of afternoon tea and crumpets, is rarely heralded for her radicalism or innovative experimentation. My paper addresses how we can locate Austen in her writings as a progressive author, incredibly intrigued with the prospect of radical modernity. I argue that Austen appears consciously caught at a point of dialectical antithesis between competing pressures of residual Georgian tradition, and pulsing modernity fueled by the mechanization of 19th century England. The crux of my justification hinges on textual evidence of the entropic, or the inclination towards chaos and disorder, as a peculiarly modern symptom. In tracing elements of the entropic throughout Austen's texts, I ultimately locate two salient phenomena, one phenomenological and one philological, that mark a pivotal shift towards the modern. The first, concerns a contextual renegotiation of masculinity; the grizzled, decorated war hero is favored over the passive, leisured gentleman. The landed gentry's way of life is ultimately revealed as outmoded and unsustainable in the changing climate. The second offers a formal dissection of the em-dash as a peculiarly entropic mark, insofar as it allows for increased disorder and a novel assemblage of disparate ideas within the confines of the sentence. In examining Austen's approach to the modern, specifically her promotion of agility in syntax and subject, I hope to express her attraction to both the precariousness and intensive possibility held in the notion of the new.

Significance of MARCO in *Mycobacterium tuberculosis* Resistance

Mevelyn Kaalla, CURO Research Assistant
Dr. Kaori Sakamoto, Pathology, College of Veterinary Medicine

A macrophage scavenger receptor, Macrophage Receptor with Collagenous Structure (MARCO), has been previously shown by the Sakamoto lab to be important in binding to a virulence factor, trehalose 6,6'-dimycolate (TDM), in the cell wall of *Mycobacterium tuberculosis* (*Mtb*), the causative agent of tuberculosis (TB). A single nucleotide polymorphism in the MARCO gene, rSNP, has been identified to be associated with resistance to TB. The rSNP is thought to introduce a DNA-binding site for the transcription factor, C/EBP (CAAT-enhancer binding protein). To test this hypothesis, biotinylated wildtype MARCO

(MARCO-WT) and rSNP MARCO (MARCO-R) probes were incubated with nuclear extract, applied to a neutravidin resin column, then eluted and subjected to gel electrophoresis. They were then transferred to a nitrocellulose membrane and probed for two forms of C/EBP, C/EBPα and C/EBPβ. Both forms demonstrated enhanced binding to the MARCO-R probe relative to the MARCO-WT probe. Next, a luciferase reporter assay was performed to examine transcriptional activity of MARCO-WT and MARCO-R in macrophages, revealing reduced transcription attributed to MARCO-R. Therefore, enhanced binding of C/EBP downregulates transcription of MARCO, as seen with the rSNP. By downregulating MARCO, the rSNP may allow for less MARCO-TDM interaction, which may be involved in arresting phagosomal-lysosomal fusion. Individuals with the rSNP would therefore exhibit increased control over the *Mtb* infection. This project studies the mechanism whereby the rSNP mediates resistance. Examining MARCO expression and interactions with TDM and *Mtb* infection will result in a better understanding of the role and mechanism of action of MARCO in TB pathogenesis.

Identification of MAb109 Epitope in Pancreatic Cancer Cells

Manasa Kadiyala, Ramsey Scholar, CURO Summer Fellow
Dr. Hawkeye Pierce, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Pancreatic adenocarcinoma (PDAC) is a lethal cancer with annual survival rates less than 25%. It currently lacks proper diagnosis and treatment, which leads to many patients being treated and screened after malignant tumorigenesis has already occurred. The progression of oncogenesis and tumor growth has been found to be linked to changes in glycan expression on the cell surface of pancreatic cells. These abnormal modifications can be specifically targeted, and their identification can serve as a potential therapeutic for the disease. Glycans and glycoproteins are useful objects of study as they are uniquely affected by changes in glycosylation that occur early on in oncogenesis. In order to identify the specific glycan target for pancreatic adenocarcinoma, researchers have identified a mouse monoclonal immunoglobin G (IgG) antibody (MAb109) that uniquely reacts with PDAC tissue but not normal, uninfected pancreatic tissue. The place where this antibody binds, its epitope, is N-glycan specific and is present on certain glycoproteins, one of which is CEACAM6 (Carcinoembryonic Antigen Related Cell Adhesion Molecule 6) in PDAC tissue. Identification of this MAb109 epitope using site-directed mutagenesis of N-glycosylation sites and truncation of CEACAM6 fragment 1 (C6f1) can set the stage for development of unique clinical screening and therapeutic tools and eventual treatment of pancreatic cancer.

How Does FoodCorps Contribute to the Pursuit of Farm to School Success?

Usha M Kaila
Dr. Jennifer Jo Thompson, Crop and Soil Sciences, College of Agricultural and Environmental Sciences

This project examines the impact of FoodCorps service members on the success of Farm to School programs in Georgia. Farm to School programs, which aims to bring healthy, locally grown foods, education about nutrition and agriculture, and school gardens to K-12 schools, are estimated to be in 42% of schools in the US. Nevertheless, Farm to School programs face a number of challenges, including cost and institutional support. FoodCorps is an Americorps service organization that aims to teach children about food and nutrition through hands-on experiences such as school gardens and culinary instruction. Since 2014, Georgia Organics has hosted FoodCorps service members placed in several school districts across the state. As part of an evaluation of Georgia Organics' farm to school programming, we conducted semi-structured interviews with FoodCorps members, their site supervisors, and school nutrition directors in their districts. We examine the data to determine how the presence of FoodCorps service members impacts student engagement and staff buy-in of Farm to School.

Characterizing the Ribonuclease Activity of *Staphylococcus epidermidis* Csm6

Joshua A Kalter, CURO Research Assistant
Dr. Michael Terns, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

CRISPR-Cas systems are adaptive immune responses that have emerged as powerful genomic editing tools to provide defense against foreign nucleic acids in prokaryotes. CRISPR-Cas systems have been categorized into several diverse groups but all function through specific interactions between a short RNA (crRNA) and CRISPR-associated (Cas) proteins. crRNA molecules provide specificity by base-pairing with foreign DNA and RNA molecules. Typically, several Cas proteins with varying structural and nuclease functions combine with the crRNA to form a CRISPR ribonucleoprotein complex, termed crRNP. In Type III-A (Csm) invader silencing, the crRNP contains five proteins (Csm1-5) with varying roles. Though it is not a member of the crRNP, invader silencing requires the presence and activity of an additional protein known as Csm6. Biochemical and structural data confirm the absence of Csm6 within the crRNP. Thus, understanding the contribution of Csm6 remains a major question. Studies have demonstrated that Csm6 is a single-stranded RNA-specific endoribonuclease that is necessary for anti-plasmid CRISPR-Cas immunity. We sought to characterize the ribonuclease activity of recombinant *Staphylococcus epidermidis* Csm6 in vitro, as well as to determine the presence of target specificity for this activity. We demonstrate that an introduced catalytic-site mutation results in diminished ribonuclease activity. We also demonstrate that *S. epidermidis* Csm6 degrades single-stranded RNA with a preference for purines. Not only is our work fundamentally important in determining the greater role of Csm6 in DNA targeting, but it will also lay the groundwork for the development of RNA-editing tools from the Type III-A CRISPR-Cas system.

The Effects of Two Different High-Fat Diets on Appetite Hormone Levels

Fatima Kamal, CURO Research Assistant
Dr. Jamie A Cooper, Foods and Nutrition, College of Family and Consumer Sciences

Eating a single meal rich in poly-unsaturated fats (PUFAs) results in greater suppression of the hunger hormone, ghrelin, and higher levels of the satiety hormone, PYY, vs. a meal rich in mono-unsaturated fats (MUFAs). We aim to determine the effect of a high-fat diet rich in MUFAs or PUFAs on ghrelin and PYY levels. Randomized, cross-over trails consisted of 2 trails that were each 10 days. Twelve adult males (ages 18-45) were recruited. Each 10 day trial consisted of a 3 day lead-in diet, two 9 hour testing visits (pre- and post-diet), and a 5 day intervention diet. During the 5 day diet, subjects received meals enriched with either cottonseed oil (high in PUFA) or olive oil (high in MUFA). The diets were 50% fat, 35% carbohydrates, and 15% protein. During each 9 hour testing visit, subjects received a breakfast and lunch meal, high in the fat designated for that trial. Blood was drawn every 30 minutes for 9 hours to measure appetite hormones. There was no difference in fasting ghrelin or PYY from pre to post diet in either PUFA or MUFA. Postprandial area under the curve was not different from pre- to post-diet for ghrelin in MUFA (pre: 518.6±145.8pg/ml, post: 505.3±182.7 pg/ml, p=0.7) or PUFA (pre: 499.3±113.0pg/ml, post: 541.6.±189.2pg/ml, p= 0.2). PYY was not different from pre- to post-diet in MUFA (pre: 1136.8±263.2pg/ml, post: 1085.0±208.0pg/ml, p=0.2) or PUFA (pre: 1064.4±197.0pg/ml, post: 1006.0±185.7pg/ml, p= 0.2). High fat diets rich in either MUFA or PUFA did not lead to changes ghrelin or PYY.

Are *Wolbachia* Co-Obligate Nutritional Symbionts in the Banana Aphid *Pentalonia*?

Bryan Kamalaker, CURO Research Assistant
Dr. Kerry Oliver, Entomology, College of Agricultural and Environmental Sciences

Many eukaryotes acquired ancient infections with microbial symbionts that allowed expansion onto novel feeding substrates. For example, the bacterium *Buchnera* colonized aphids 150 mya, and by providing essential nutrients, allowed aphids to exploit plant phloem resulting in more than 4500 extant aphid species. However, over time aphids and *Buchnera* became co-dependent resulting in major vulnerabilities to the partnership. The strict intracellular life and trans-generational bottlenecks of *Buchnera* resulted in small effective population sizes, which through relaxed selection have led to genome reduction and symbiont decay. Several processes potentially compensate for *Buchnera* decay. For instance, in a few aphid species, *Buchnera* has been replaced by other symbionts, while in other aphids, a normally facultative symbiont species, has joined the nutritional

partnership and become a co-obligate symbiont. Recently, a study suggested that *Wolbachia*, a ubiquitous heritable symbiont of arthropods, was a co-obligate symbiont in the banana aphid *Pentalonia*. In a small sample the authors found that all individual aphids were infected – a requirement for obligate status and unusual for *Wolbachia*, and that *Buchnera* had lost the ability to make Riboflavin while *Wolbachia* retained the missing components RibD and RibH. However, we screened diverse *Pentalonia* populations across the Pacific and found *Wolbachia* was not fixed (83% infected). Given its facultative status, we are conducted several assays reconsidering whether *Wolbachia* is genuinely a co-obligate partner. Early results indicate that in our non-fixed populations, *Buchnera* has indeed lost RibD & RibH, while *Wolbachia* retains them, which suggests that other compensatory mechanisms are operating.

Altered Neural Activity in the MCLS and NA linked to Alcohol Consumption

Aparna Kanjhlia, CURO Research Assistant
Dr. Lawrence Sweet, Psychology, Franklin College of Arts and Sciences

Alcohol use among adolescents and young adults has a significant impact on public health in the United States. Impulsivity has been linked with vulnerability to alcohol use and altered connectivity of the neural reward system. Several brain areas, such as the mesocorticolimbic reward system (MCLS) and nucleus accumbens (NA) have been associated with impulsive decision making. The present study aims to investigate whether neural activity in the MCLS and NA at rest is associated with risky alcohol related decisions through an analysis of functional connectivity. Nine healthy young adult participants from the rural southern United States participated in a functional MRI resting state scan using a 3T scanner as a part of a larger study conducted by the UGA Clinical Neuroscience (CNS) Laboratory. Alcohol use and associated behaviors were measured using the Alcohol Use Disorder Identification Test (AUDIT). Impulsivity was measured using the Monetary Choice Task (MCQ), a measure of delay discounting. Neuroimaging analyses will be conducted using Analysis of Functional Neuroimaging (AFNI) software and correlation and regression analyses will be conducted in SPSS. It is hypothesized that individuals with decreased connectivity of the MCLS and NA will report consuming alcohol at a higher frequency than those with higher connectivity. These findings may contribute to and extend the understanding of the link between alcohol and impulsivity in a yet unstudied population of emerging adults from rural communities.

Microaggression in the Eye of the Beholder: Perceiver Characteristics in the Detection of Microaggressions in the Workplace

Soundarya Kanthimathinathan, CURO Research Assistant
Dr. Brian Hoffman, Psychology, Franklin College of Arts and Sciences

Microaggressions are typically conceptualized as subjective and perceptual phenomena, defined as subtle verbal or behavioral discrimination based on the receiver's personal identity. Although much research has examined the impact of microaggressions on important work outcomes, scant attention has been paid to the characteristics of the perceiver of macroaggressions. To the extent microaggressions are believed to be subjective and perceptual phenomena, this study proposes that characteristics of the perceiver influence the likelihood that microaggressions will be perceived, specifically the perception of microaggressions by minority employees. Using Amazon's Mechanical Turk, data will be collected on the perceptions of microaggressions by minority employees working full time. Individual characteristics of the perceiver including personality, group identity, and familiarity with the microaggression paradigm will be examined as predictors of the perception of microaggressions. The association between perceiver characteristics and perceptions of microaggressions will be examined to shed light on the factors that contribute to the study of microaggressions. These findings will have important implications for the on-going debate as to how to address a subjective phenomenon such as microaggressions and thus, will provide insight for organizations seeking to reduce the harmful influence of microaggressions on employee outcomes through interventions or training.

Isolation of VAR2CSA DBL3x Binding Domains for Protein Expression

Rahul Katkar, CURO Research Assistant
Dr. David Peterson, Infectious Diseases, College of Veterinary Medicine

Placental malaria is contracted by pregnant mothers and latch onto the placenta, restricting nutrient delivery to the fetus causing premature birth and low birth weights. Whilst multigravid women develop immunity to Plasmodium falciparum, it seems that primigravid and secundigravid women struggle to combat the parasite. The parasite's genome has a semi-conserved var2csa gene which contains DBL domains which allow the protein to bind to chondroitin sulfate A receptors on the placenta, causing an accumulation of red blood cells thus disrupting the placental blood flow. Immune women have antibodies that restrict VAR2CSA, therefore it is hypothesized that the VAR2CSA found in immune women bind less well than VAR2CSA found in non-immune women. To study the binding domains encoded in the var2csa gene, the relevant regions of the gene must first be cloned. The cloning protocol uses vector plasmids, restriction enzymes and ligation to create plasmid constructs that are transfected into *E. coli* cells that clone enough of the gene to be sequenced and sent to be translated in wheat germ cell free protein synthesis. This protein synthesis technique was chosen for its high yield and quality of translated proteins. EBA-175 is a protein akin to VAR2CSA but is not involved in binding affinity to CSA, therefore is an excellent choice for a negative control. The proteins that are translated from these cloned genes can then be tested in binding affinity to CSA receptors, thus aiding in a possible vaccination development.

The Evolution of Religion in Africa: A Test of the Big God Hypothesis

Samantha Keating
Dr. Bram Tucker, Anthropology, Franklin College of Arts and Sciences

While throughout most of human history, people have lived in small-scale, hunter-gatherer societies, most people today live in large-scale, anonymous societies. Understanding why people cooperate in these large societies is a mystery that social scientists have attempted to solve. Psychologist Ara Norenzayan developed a cultural evolutionary hypothesis to explain this phenomenon, which states that the belief in moralizing high gods explains why people cooperate in large, anonymous societies. Therefore, the belief in moralizing high gods can universally be attributed to large-scale societies. However, this hypothesis is fundamentally flawed as it fails to take into account the diversity of humanity, and is therefore subject to testing. In order to test Norenzayan's hypothesis, data was collected on 11 African societies' sociopolitical structures and religious cosmologies, and statistical analysis was conducted on data from Murdock's Ethnographic Atlas on a global scale. Results show that Norenzayan's hypothesis is too simplistic and fails to account for human diversity. Of the sampled societies, belief in a moralizing high god was present in several small-scale, hunter-gatherer societies, while absent in some large-scale societies, thus falsifying the universality of Norenzayan's hypothesis. Due to the prevalence of claims of universal human nature in popular media, testing these widespread claims is critical as they perpetuate myths of human nature that are often untrue.

Environmental Consequences, Psychological Comorbidities, and Tic Symptom Severity in Children with Tourette Syndrome

Colleen Keeler, CURO Summer Fellow, CURO Research Assistant
Dr. Ronald L Blount, Psychology, Franklin College of Arts and Sciences

The present study evaluates the relationship between environmental factors (e.g., reactions to displaying tic symptoms [accommodation], family socioeconomic status [SES; as measured by parent income and education level]), tic symptom severity, and psychological comorbidities in children (aged 9-17 years) with Tourette syndrome (TS; n = 48). Caregivers (n = 48) reported on their children by completing the Tic Symptom Parent Report, Tic Accommodations and Reactions Scale, Behavioral Assessment System for Children – 2nd Edition, and Spence Child Anxiety Scale. Bivariate correlations were conducted to examine relationships between family SES, parent's accommodation behaviors for tics, tic symptom

severity, and comorbid psychological symptoms. Both family income level and parental education level were negatively correlated with children's social phobia symptoms. Separation anxiety was positively correlated with all other measured comorbidities. Children with TS whose parents reported higher accommodation of tic symptoms had higher parent-reported levels of separation anxiety, OCD, and hyperactivity than children of parents who reported less accommodation. Parents who reported higher accommodation of tic symptoms reported more severe tic symptoms than the children of parents who reported less accommodation. Findings indicate that parents of children with TS may benefit from behavioral interventions aimed at improving their responses to their child's tic symptoms, and that children with TS may benefit from family-focused interventions to increase positive coping strategies. Additionally, determining what factors associated with low SES that lead to the correlation between SES and symptom severity could help parents identify how they can alter their lifestyle in order to prevent the worsening of tic symptoms.

Functional Evaluation of Porcine Kidney: A Thorough PSF Organ Storage Study

Hannah Kemelmakher, CURO Research Assistant
Dr. John Peroni, Large Animal Medicine and Surgery, College of Veterinary Medicine

Organ persufflation (PSF), or gaseous oxygen perfusion is used to preserve organs outside of the body and has been studied in various tissues. Compared to the more universally accessible hypothermic storage method called Static Cold Storage (SCS), persufflation requires more characterization before it can be more widely accepted in the world of organ transplantation. There is promising evidence that PSF significantly improves tissue viability and survival rates of transplanted organs. Our goal is to compare the static cold storage method to organ persufflation in the kidney which is the most commonly transplanted organ. Our hypothesis is that persufflation will result in improved tissue viability than cold storage by preserving vascular and mitochondrial functions. We plan to harvest kidneys from pigs immediately after slaughter and preserving each for 24 hours with either PSF or SCS. Subsequently, renal parenchyma will be obtained to assess oxygen consumption rate, mitochondrial enzyme activity, endothelial dysfunction, spontaneous arterial tone development, and the presence of oxidative damage. To determine vascular function, renal vessels will be isolated while in a physiological salt solution using dissection microscopy. Their contractile function will then be measured using a small vessel wire myograph in a controlled temperature environment. We anticipate that organ persufflation will result in superior tissue respiration values and vascular contractility as assessed through measurements of mitochondrial and arterio-venous functions. This series of experiments will significantly impact the knowledge available regarding the effects of tissue persufflation of kidneys and may have a significant impact on the field of organ transplantation.

Electroformation of Giant Unilamellar Vesicles

Melanie Kemp, CURO Research Assistant
Dr. Eric Freeman, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

The intent of this research is to develop a protocol for the creation of "empty" model cells known as giant unilamellar vesicles (GUVs). GUVs are typically composed of an aqueous fluid encapsulated by a bare or unmodified lipid membrane. The content of the lipid membrane can be modified to measure the link between the membrane composition and its mechanical properties, such as the bending modulus and surface tension. The GUVs also allow for the observation of the membrane responses to environmental stresses, including varying osmotic pressures. For the purpose of this experiment, Diphytanoyl phosphatidylcholine (DPhPC), 1,2-Dioleoyl-*sn*-glycero-3-phosphocholine (DOPC), and asolectin (soybean) lipids were dissolved in chloroform and evaporated with nitrogen within a polydimethylsiloxane (PDMS) well secured on an indium-tin-oxide (ITO) slide. The evaporated lipids were then diluted in various concentrations of sucrose and underwent electroformation with varying voltages, frequencies, and times. It was determined that DPhPC diluted in 20 mM of sucrose under a sinusoidal voltage signal of 1.5 V at 10 Hz for two hours consistently yielded reasonably-sized liposomes useful for image

analysis of their surface undulations. Further experimentation is being conducted to characterize membrane responses to various osmotic shocks by the use of a perfusion chamber.

Elucidating the Function of GABAergic Signaling during Neural Development in Larval Zebrafish

Benjamin Martin Kidd, CURO Research Assistant
Dr. James D Lauderdale, Cellular Biology, Franklin College of Arts and Sciences

The goal of my research project is to determine functional consequences of alterations in GABA signaling on brain activity and seizure dynamics in larval zebrafish. In all vertebrates, the GAD genes encode for the enzymes that produce GABA, which is the major inhibitory neurotransmitter in the central nervous system. There are two GAD genes, GAD1 and GAD2, and both function in GABA synthesis. We created a line of fish with a mutation in the GAD1 gene gad1b, which has increased neural activity. This project utilizes light sheet microscopy and electrophysiology to address our research goals. We are generating different lines of zebrafish that combine two fluorescent transgenes with the gad1b mutants with the goal of being able to visualize and assess the neurological effects of a reduction in local GABA levels in generating seizure activity in the brain. I will also be performing these experiments on a zebrafish seizure model that utilizes an alternative mechanism of generating seizures for comparison and proof of principle. I hypothesize that in the gad1b mutant zebrafish, I will observe over-excitation in the optic tectum of the zebrafish and the excitation will spread across the brain during a seizure event. We suspect that the inhibitory neurons will then corral the excitation to restore the brain to a non-seizure like state. If this hypothesis is supported, it will help us better understand the mechanism behind how seizures occur which could have implications in the design of novel anti-epileptic drugs.

A Computer Program for Truss Design Optimization

Sokngim Kim, CURO Research Assistant
Dr. Siddharth Savadatti, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Trusses are some of the most efficient load carrying structures that are extensively used in the design and construction of physical infrastructure like bridges, housing and power transmission towers. The ultimate purpose of this project is to develop a computer program that can provide the optimum design of a truss for a given set of loads. A standard truss analysis program has already been developed and it will be used for topology optimization using the harmony search method. The resulting truss will be shape optimized and can be used to design a truss either manually or automatically.

Research and Development of Satellite Software and Electronics

Adam King, CURO Summer Fellow, CURO Research Assistant
Dustin Mizelle, Anurag Banerjee
Dr. Marguerite Madden, Geography, Franklin College of Arts and Sciences

Is there an optimal way to interface electronic components and software such that the satellite adheres to mission specifications while mitigating all possible failure? The answer will allow the Small Satellite Research Laboratory (SSRL) to have UGA's first satellite in orbit by 2019. The first SSRL mission, SPOC, will acquire moderate-resolution hyperspectral imagery of coastal ecosystems and ocean color to enable mitigation of environmental damage by means of conservation, recreation, and development. Though hyperspectral imagery has been gathered from Low-Earth Orbit before, it has never been launched on the Cube Satellite platform, a modular structure standard consisting of 10x10x11cm units. Throughout the project, the SSRL has continuously been involved in writing extensive documentation for NASA to review our progress. To complete this mission, the electronics team first had to understand mission objectives, work with the SSRL mission operations team to determine operational modes and needed tasks, and to begin developing software corresponding to these specifications. The challenge comes when understanding hardware architecture and interfacing said hardware. The electronics team

will work with our primary manufacturers to determine what is needed to fulfill the mission. Namely, the SPOC optical payload will interface with our on-board computer as well as our electrical ground support equipment, a challenging step in the development of this mission, as various electrical communication protocols will have to be mapped correctly in order for software to interface correctly among all hardware. Preliminary hardware will be tested throughout this semester, and final design decisions will be finalized by April. Preliminary results indicate that optimal electronics and software design is characterized by working with both concurrently and building towards the functional "middle" of these systems.

Mild Traumatic Brain Injury (mTBI) Moderates Protection of Cognitive Flexibility by Cognitive Reserve

Evan Knox, Ramsey Scholar
Dr. Steve Miller, Psychology, Franklin College of Arts and Sciences

Cognitive reserve (CR) protects various mental faculties, including cognitive flexibility, from damage. One common form of this damage is mild traumatic brain injury (mTBI), often termed concussion. However, the interaction between mTBI and CR in predicting cognitive flexibility has not been explored. Such a relationship or lack thereof could further understanding of how CR relates to mTBI. A sample of 40 adults (mean age = 51.5, ages 36-68), with half having experienced at least two mTBIs during high school sporting events and the other half having experienced none, were surveyed for number of mTBIs, cognitive flexibility, and a proxy measure of CR. Moderation analysis was performed to assess interactions for both a no-mTBI/mTBI dichotomy and for a no-mTBI/two-mTBI/greater-than-two-mTBI split. Dichotomous moderation demonstrated a beta of .839 ($p < .001$) for the mTBI group, versus a beta of .569 ($p = .006$) for the no-mTBI group. Furthermore, this model (also accounting for age) gave an adjusted R^2 of .652 in the mTBI group, versus .391 in the no-mTBI group. The three-way moderation demonstrated a beta of 1.061 ($p < .001$) for the greater-than-two-mTBI group, versus a beta of .498 ($p = .001$) in the no-mTBI group. This moderation model also accounted for significantly more variance than a no-moderation model ($p = .005$). These findings suggest that cognitive flexibility is well-protected from mTBIs by high CR, while it is disproportionately at-risk in individuals with low CR.

Georgia Social Workers and DACA

David Kobe, CURO Research Assistant
Dr. Jane McPherson, Social Work, School of Social Work

There are approximately 2 million undocumented students in the US, many of whom immigrated with their parents when they were too young to understand the educational implications. To help these students Obama created Deferred Action for Childhood Arrivals (DACA) allowing certain immigrants special status to attend public school, get drivers licenses, and get jobs. Georgia and two other states have additional policies banning undocumented immigrants from attending selected public state universities. This ban in Georgia directly opposes the Equal Protection Clause of the Fourteenth Amendment and legally segregates public universities. The problem these students face is worthy of social work consideration. The Georgia Chapter of the National Association of Social Workers (NASW) released a statement declaring it does not support the ban. The University of Georgia (UGA) has an interesting position as a public university selected in the ban, yet home to a strong Social Work program. To understand opinions of the students and faculty of the School of Social Work at UGA we created a survey focusing on the awareness participants have of current policies surrounding DACA and immigration in Georgia. Having an accurate idea of how social work students view current policies that directly affect their clients is vital. If our social workers disagree with the code of ethics how can it be expected to be implemented? If there is an overwhelming agreement with the current code of ethics then why do the policies for our state contrast them so sharply and what can we do about it?

Characterizing Ty1 Gag - CCT Complex Interactions in Budding Yeast Through Co-Immunoprecipitation and Mass Spectrometry

Ellen Grace Krall

Dr. David J Garfinkel, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Retrotransposons are mobile genetic elements that are able to actively replicate, reinsert into the host genome, and alter the expression of genes. Ty1 elements are the most abundant retrotransposon in the budding yeast *Saccharomyces* and represent a model for better understanding retroviruses like HIV as well as retrotransposons found in other organisms. Budding yeast lacks typical defense systems used to silence retroelements in other eukaryotes, and therefore has evolved a novel form of copy number control (CNC) to restrict Ty1 retrotransposition. Recent studies by Saha and Mitchell et al. in 2015 (*J. Virol.* 89:3922-38) show that an alternate Ty1 sense transcript (Ty1i RNA) encodes a 22-kDa protein which is necessary and sufficient for Ty1 CNC. It is likely that other cellular proteins associate with the Ty1 capsid protein (Gag) and influence virus-like-particle (VLP) assembly, Gag processing, and Gag-p22 interactions. Because systematic mutant screens are unable to identify essential or redundant gene products that associate with Gag, we have used proteomic analyses to characterize the Gag interactome. We have identified multiple subunits of the CCT complex, a conserved and essential protein chaperone that may interact with Ty1 Gag. Mutational analysis suggests that the CCT complex plays a role in Ty1 Gag processing and retrotransposition.

Tagging Fatty Acid Metabolism Proteins in *Trypanosoma cruzi*

Evelina Kravchuk
Dr. Rick Tarleton, Cellular Biology, Franklin College of Arts and Sciences

Trypanosoma cruzi infects millions of people worldwide, mostly in Latin America, causing potentially life-threatening sickness known as Chagas disease. This protozoan replicates within the cytoplasm of mammalian cells and persists in particular host tissues, especially muscle, leading to heart and gastrointestinal pathologies. There are currently no reliable drugs or vaccines for treatment or prevention of *T. cruzi* infection. An attractive target for new drugs is transporter proteins, enzymes, and molecules necessary for the pathogen to obtain energy from host cells. Previous investigations indicate that fatty acid (FA) transport and metabolism proteins are highly upregulated in intracellular amastigotes of *T. cruzi* and are essential for parasite survival. Interestingly, the genes encoding mitochondrial surface FA transporter proteins are duplicated in *T. cruzi* and modified, perhaps to allow localization to the parasite surface where they could compete with host cell mitochondria for FAs. We will use CRISPR/Cas9-mediated genome editing to tag the essential fatty acid transportation and metabolism genes in *T. cruzi* and thus document their cellular sublocalization. Homology directed repair will be used to insert a sequence encoding a fluorescent tag, which when incorporated into gene products can be visualized using fluorescence microscopy. We expect to find that *T. cruzi* has a duplicated set of FA transporters, one set that localizes to the parasite surface and another that localizes to the usual parasite mitochondrial surface membrane. If true, this will be the first reported example of a pathogen mitochondrial FA transporter being relocalized in order to scavage FA from host cells.

Understanding American and Cuban Perceptions of Migration to America

Mohammed Khalifa Kredan, CURO Research Assistant
Dr. Micah Gell-Redman, International Affairs, School of Public and International Affairs

More than 2 million Cubans currently reside in the United States, and roughly 60% are legal residents. Thanks in part to policies such as the Cuban Adjustment Act, Cuban migrants are able to secure a green card in just 1 year, and are more likely to be naturalized than immigrants from other nations. Major policy changes carried out by previous and incoming US administrations promise to impact all aspects of the relationship between the two nations, not least of which is the question of Cuban immigration to the US. Cuba promises to be an important case, answering many questions regarding immigrant motivations, and the perception of the effect of policy change. This is especially true, as other nations around the world send a mix of immigrant populations affected by similar political and economic motivations. We explore Cuba-US migration through a multi-method, binational approach. First, we conduct an electronic survey of Florida

voters to determine what qualities of Cuban immigrants are viewed as most "desirable." Second, through semi-structured interviews, we learn how Cuban nationals perceive the process of migrating to the US. By combining insights from these two lines of inquiry, we hope to identify gaps between US citizen beliefs about Cuban immigration, and the drivers that actually motivate potential migrants within Cuba.

The Role of LNFPIII-Dex on Cholesterol Efflux in Raw 264.7 Cells

Catrina Kure
Dr. Donald Harn, Infectious Diseases, College of Veterinary Medicine

Atherosclerosis is a major risk factor for cardiovascular diseases. Current means of prevention and treatment focus on lifestyle changes, including changing diets to include more anti-oxidants and anti-inflammatory foods and increasing physical activity when possible. In addition, statin therapy, to help control cholesterol levels. Each of these may help reduce plaques. In this regard, little research has been done examining potential immunotherapies related to plaque progression. LNFPIII is a biologically conserved human milk sugar, that when used as a conjugate, has been shown to function as therapeutic for treatment of several different inflammation based diseases, generally by activating anti-inflammatory (M2) macrophages. Gene arrays on cells stimulated in vitro along with analysis of cells from animals treated with LNFPIII-Dex conjugates both show an upregulatioin the transcription factor LxRα, which controls genes involved in cholesterol efflux. Thus, my research project asks if LNFPIII-Dex will induce cholesterol efflux from RAW 264.7 cells via downregulation of inflammatory genes and upregulation of mediators related to reverse cholesterol transport. This will be tested with RAW 264.7 macrophages that will be loaded with the fluor-tagged cholesterol (22-NBD-Cholesterol). We will first determine that we are able to successfully load the RAW cells with cholesterol by flow cytometry. Once we demonstrate we can load cholesterol into RAW cells, we will then stimulate the cells with positive and negative controls and LNFPIII-Dex for 3-12 hrs. We will then add the cholesterol acceptors HDL or ApoE, and allow efflux to occur. We will measure efflux in each well of cells using a plate reader. If we demonstrate that LNFPIII-Dex is able to induce cholesterol efflux from RAW 264 macrophages, we can propose LNFPII-Dex as a therapeutic to reduce plaque formation in vivo.

The Chromatin Remodeling Protein, ATRX, Regulates the Formation of Non-Canonical DNA/RNA G-Quadruplex Structures in Mammalian Oocytes

Ashley Elizabeth Lall
Dr. Rabindranath De La Fuente, Physiology and Pharmacology, College of Veterinary Medicine

One of the major chromatin remodeling proteins, alpha thalassemia mental retardation x-linked protein (ATRX) plays an important role in providing genomic stability that is essential for reproductive cells to successfully undergo cell division. The primary role of ATRX is to ensure proper heterochromatin formation in oocytes during meiosis. In transgenic (Tg) oocytes lacking ATRX, there are severe chromosomal abnormalities that often result in early loss of pregnancy. This experiment is aimed at elucidating the role of ATRX in the formation of non-canonical DNA/RNA quadruplex structures by using immunochemistry, epifluorescence microscopy, and super-resolution chromatin analysis of wild type (WT) and Tg oocytes. DNA G-quadruplex structures are associated with regions of guanine-rich DNA and cause genomic instability by affecting chromosome configuration. We hypothesized that Tg oocytes would have a higher prevalence of DNA/RNA quadruplexes as a result of the important role ATRX plays in regulation of these structures. Our results indicate that there is no statistically significant difference in the proportion of quadruplex formation between transcriptionally active WT (94%) and Tg (91%) oocytes. Notably, quadruplex RNA structure is resolved in 70% of transcriptionally inactive WT oocytes, while non-canonical RNA structure remains unresolved in 80% of Tg oocytes. These results suggests that ATRX deficient oocytes are unable to correctly remodel their chromosome configuration which results in a higher percentage of DNA/RNA quadruplexes and provides direct evidence that ATRX is necessary to resolve non-

canonical G-quadruplexe structures to maintain genome stability.

Retirement Planning Behavior and Retirement Plan Participation among Men and Women: An Examination of the Determining Factors

Sarah Landa
Dr. Swarn Chatterjee, Housing and Consumer Economics, College of Family and Consumer Sciences

As the largest cohort of the US population, the baby-boomers, continue to enter retirement, it is critical to examine the factors associated with better financial planning and investment participation decisions among households, and whether men and women differ in their approach to retirement planning. With this research objective in mind, our study uses a nationally representative dataset to examine whether men and women differ in their retirement planning behavior. This study also examines the factors that are associated with retirement plan participation among men and women. We use a multiple regression analyses to empirically test the key hypotheses of this study. Early findings reveal that a significant gender difference exists in the portfolio preferences and retirement planning behavior among households. Additionally, risk tolerance appears to affect retirement planning decision's differences for men and women. The implications of the key findings of our study will be discussed from a policy perspective.

Measuring the Expression Efficiency of Constructed Single Plasmid System in *Trypanosoma cruzi*

Tre Justin Landry, CURO Research Assistant
Dr. Rick Tarleton, Cellular Biology, Franklin College of Arts and Sciences

Our lab focuses on the host immune responses to infection with protozoan parasite *Trypanosoma cruzi*, the causative agent for Chagas disease, and how these responses may be modified or potentiated through genetic manipulation. My research addresses the technical obstacles to expressing multiple, potentially immune-modifying proteins in *T. cruzi*. In the past, this process has required the introduction of multiple plasmids encoding these genes and selection by multiple drug resistance markers. To make the process of genome modification more efficient, we have evaluated both viral-like 2A peptide sequences that induce a skip during translation, allowing for the production of two distinct proteins from a single gene transcript, and multiple head-to-tail expression cassettes that yield two separate mRNA transcripts from a single plasmid. We now show that both systems provide for the production of multiple protein products from a single plasmid but that different 2A-like sequences are differentially efficient in this process. Likewise, distinct intergenic regions impact on protein production from the expression cassettes. Future experiments will quantify the relative efficiency of the two systems, also comparing them to protein expression from multiple plasmids, and the positional impact (e.g. before or after the 2A skip sequence) on protein production. Additionally we plan to combine the 2 new systems in order to produce up to 4 different proteins from the same plasmid. These methods are facilitating the development of a conditional inducible expression system in *T. cruzi* that utilizes a tetracycline inducible ribosomal RNA (rRNA) promoter to control expression in transgenic parasites.

The Development of a Pathogen-Specific Diagnostic Device for Pneumonia

Laura Lanier
Dr. Ramana Pidaparti, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Pneumonia is one of the single largest infectious diseases in the world, affecting 450 million people globally and killing nearly 4 million people each year. More than 30 strains of bacterial and viral pathogens can cause this infection of the lungs—a fact that poses a significant challenge to improving accuracy in diagnostics for an appropriate pathogen-specific treatment. In this project, we are developing a pathogen-specific diagnostic device with the principles of Raleigh scattering. We are currently in the stage of proving this concept of particle-caused light scattering, with our experiments focused towards developing a forward scatter laser system where particles of known size and shape resembling the real pathogens are tested. The scattered beam

information from these particles is captured on a sensing device and this signal data, after noise removal, is processed for particle size range by applying various classifier algorithms. Identification of particle size range can provide baseline diagnostics for the disease, and further refinements for identifying pathogen types by their size are possible. After this proof of concept, we plan to embed this system into a portable, low cost mask, which can be integrated with a cell phone. It is our hope that patients can then breathe or cough into this mask, releasing particles for identification and diagnosis. This device, once realized, is expected to become a powerful diagnostic tool for the populations most affected by pneumonia, particularly in developing and underdeveloped countries.

Unlock the Vote: The Implications of Felon Disenfranchisement Laws on the Political Power of African Americans

Magali Lapu
Dr. Sarah Shannon, Sociology, Franklin College of Arts and Sciences

This policy paper seeks to answer why felon disenfranchisement has decreased civic participation among the African American community as a whole, examines literature on differing state-by-state laws, and offers policies to reverse and alleviate their disparate effect on that demographic. Per the ruling of the 1974 Supreme Court case *Richardson v. Ramirez*, there is a legal precedent that allows states to continue to restrict the voting rights of anyone who has served time for a felony. This includes non-incarcerated felons who have either completed their sentences or are on parole or probation. Because of disproportionate incarceration rates for convicts of color, a disproportionate number of minorities are barred from voting. Disenfranchisement laws have shut out minority demographics, given advantages to politicians in parties that do not have a large minority voter base, and affected law abiding citizens without a criminal record. After analyzing the effectiveness, cost, equity, public approval, and political feasibility of the three proposed policy alternatives against the status quo, this paper finds that the best option is to incentivize non-profits to mobilize voters in communities with large disenfranchised populations and low voter turnout of enfranchised community members.

Socioculturally Attuned Family Therapy: Guidelines for Equitable Theory and Practice

Lauren Jayne Lauterbach, CURO Research Assistant
Dr. J. Maria Bermudez, Child and Family Development, College of Family and Consumer Sciences

Family therapists practice based on diverse family models, but have recently lost sight of the social context in which families live. This scholarly book views a plethora of different models from a different perspective. This perspective is referred to as a socioculturally attuned lens. This lens strives to incorporate social context, power, and culture into the current family therapy models. The question we dive into in this text is, "How can practitioners integrate awareness of societal systems across models into their everyday work with individuals, couples, and families?" This question is addressed chapter-by-chapter, covering ten different family therapy models and intertwining third party change and a sociocultural lens with these models. There is a disconnection between family therapy models and the integration of social context, culture, and power, and this often leaves family therapists uncertain on how to use current family therapy models while supporting social equity. This book offers practical advice on incorporating sociocultural attunement into their everyday practice. We strive to educate family therapists on helpful ways to practically incorporate social context, power and culture through what we refer to as a sociocultural attuned lens. We believe that therapist can incorporate this lens with any type of family therapy practice, but in this text we focus specifically on ten different therapy models.

Blood Transfusion Related Zika Virus Transmission

Casey Lawrence, CURO Research Assistant
Dr. José F Cordero, Epidemiology and Biostatistics, College of Public Health

Zika Virus (ZIKV) is an arbovirus of the *Flaviveridae* family, transmitted primarily by *Aedes*

aegypti and *Aedes albopictus* mosquitos. ZIKV was first discovered in the Zika forest in Uganda in 1947 and has presented itself sporadically since then, with the most notable outbreaks occurring in Yap Island in 2007 and Brazil, likely beginning in 2014. ZIKV is roughly 80% asymptomatic, which could lead to major issues maintaining a safe blood supply. Many ZIKV infections go undiagnosed or misdiagnosed and evidence has emerged that blood donations have been compromised. The objective of this review is to examine past arbovirus outbreaks, and intervention and policies strategies that were used to protect blood donations. We searched PubMed, Google Scholar and Web of Science for literature related to blood and organ donation policy changes and interventions that were associated with outbreaks of dengue, chikungunya, West Nile virus, and other arboviruses. Our results focused on findings from the United States but also include relevant information from other countries. It is essential that blood and organ donation supplies are protected in during an infectious disease outbreak. This review presents recommendations for preventing ZIKV transmission from blood and organ transmission. Traditional blood donor screening and laboratory testing may not be sufficient prevention measures. Emerging detection strategies such as Nucleic Acid Testing (NAT) and pathogen inactivation techniques may be effective tools. Blood and organ donation safeguards must be flexible to the threats of emerging pathogens including but not limited to ZIKV.

Structural Design and Optimization of the SPOC Cube Satellite

Megan Le Corre, CURO Research Assistant
Graham Grable
Dr. Susanne Ullrich, Physics and Astronomy, Franklin College of Arts and Sciences

The primary purpose of a satellite's chassis or structure is to ensure that the satellite survives the rigors of launch, including dangers posed by the vibration and acceleration imposed by the launch vehicle. Launch is the first danger that a satellite faces once its mission begins. If the satellite structure fails in launch, the failure is irredeemable. The purpose of this research is to determine optimal structural design for the SPectral Ocean Color (SPOC) imaging satellite being built by the University of Georgia's Small Satellite Research Laboratory. Accomplishing this task requires several iterations of the engineering design process and conduction of analyses of increasing complexity. Structural analyses were primarily conducted in ANSYS; analyses conducted include modal analysis and inertial loading analysis. Two of the satellite subsystems, the payload and core avionics, were simulated as representative masses within the structure. It is important to recognize that this adds additional rigidity to the satellite, but is a necessary step to determine areas of optimization. First natural frequencies seemed to be nominal, ranging from 180.73 Hz to 246.94 Hz, depending on orientation during launch. Yield factors of safety ranged from 1.06 to 4.72 and ultimate factors of safety ranged 1.39 to 5.77. Though not indicative of failure, these values are uncomfortably low. Changes to be implemented as a result of this research include addition of stack interface ribs and an optimization of the payload structure in order to reduce inertial loading.

Determining Reoccurring Tick and Tick-Borne Disease Associations with Mammal Hosts

Jenna Kay Lea, CURO Research Assistant
Dr. William Park, Ecology, Odum School of Ecology

I am utilizing the Global Mammal Parasite Database to study associations between several species of ticks and parasites causing tick-borne diseases (TBD) on or in mammal hosts. I intend to find which hosts share ticks and TBDs, and identify common characteristics they have that make them more susceptible to the vector and/or pathogen. I will do this by creating two networks using R Studio: one describing the connections between hosts and ticks and the other comprised of connections between hosts and TBDs. This will not only create an easily interpretable visual representation of the data, but will build a foundation for further research to be done on parasite sharing. For instance, my preliminary data analysis will identify centralized hub host species that share ticks or TBDs with several other host species. This lays the groundwork to characterize common characteristics (e.g., body size, diet, and longevity) of hosts that play a disproportionate role in parasite sharing between species. The

extent to which the two networks are congruous is currently unknown, but I expect to find stronger associations between ticks, TBDs, and hosts that are herbivorous and long-lived. An herbivorous diet would result in a more frequent contact rate with vegetation containing ticks, and a long-lived host will have more opportunities to encounter ticks that transmit TBDs. Identifying which characteristics make hosts more susceptible to ticks and TBDs has the potential to help predict the risk of host-tick associations and TBD transmission, as well as identifying hotspots for risk of human-acquired TBDs.

From Trash to Fashion: Converting Polyethylene Terephthalate into Fabric

Cathy Lee, CURO Research Assistant
Dr. Suraj Sharma, Textiles and Merchandising, College of Family and Consumer Sciences

The impact of the clothing industry has been highly detrimental to the environment due to the overconsumption of resources and the increase of cheap, mass-produced garments that have short life spans. Plastic water bottles, made of polyethylene terephthalate, also accumulate waste, which can be combatted by creating a cradle-to-cradle life cycle in a sustainable way. This can be achieved by integrating the two polluting sources by converting the discarded polymers, found in local landfills or recycling facilities, into filament yarns than can be weaved into a wearable fabric. The developed process involves first the reduction of the recycled material into a pellet form that can then be extruded into filament fiber form. To do this I assembled and calibrated the dual-band extruder to the best temperature for the pellets and calculated the amount of yarn and fabric one bottle created. The yarn is extruded from a die with a 1/10,000-inch diameter and a round cross-sectional shape. The filaments are then subjected to standard textile testing methods outlined by the AATCC, and its performance characteristics is further compared to similar non-recycled synthetic fibers to determine qualities such as yarn strength. The results from the textile testing processes are forthcoming but when released I will also compare the statistical performance data of standard fibers, yarns, and fabrics and the recycled synthetic material to measure the wearability of the new fabric. These studies will aid sustainability efforts in the fashion industry through this developed process and compilation of testing data and analysis.

Interactive Animatronics in Consumer Environments

Christina Lee, Foundation Fellow
Dr. David Z Saltz, Theatre and Film Studies, Franklin College of Arts and Sciences

Entertainment and consumer industries around the world are striving for innovative yet economical ways to interact with consumers and craft more personalized and unique experiences. In this project, I am fabricating an interactive animatronic puppeteered through radio-transmittance. The trans-locational motion of the form is controlled with medium-range radio frequencies and is separate from the rest of the system. The input sensory devices, such as the microphone, and the output sensory devices, such as the voice modulation and nontrans-locational motion, are integrated into a singular system and run from a programmed microcontroller housed within the unit. Some challenging aspects of this project are ensuring that the input and output devices are strong enough to provide a suitable range for interaction while providing sufficient power to necessary motors without surpassing weight parameters of the figure. The project includes the design, fabrication, and optimization of the movement, sensory input, voice modulation, and sensory output of the figure. I will be comparing the final project with interactive animatronics currently in use in industry environments such as theme parks and haunted attractions.

A Preliminary Evaluation of Supplemental Vitamin E Form on Serum α-Tocopherol Levels and Oxidative Stress Parameters Measured in Response to a Novel Exercise Challenge

Kendall Lee
Dr. Kylee Duberstein, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Vitamin E is a component of the antioxidant system and is commonly included in commercial horse feeds in the form of synthetic α-tocopherol acetate. The purpose of this research was to assess

the effect of supplemental vitamin E form on serum α-tocopherol levels and oxidative parameters in mature horses at rest and in response to an exercise challenge. Sixteen horses first underwent a 2wk low vitamin E wash-out period and were then randomly assigned to one of four treatment groups, each receiving the control diet plus 4000 IU/day of vitamin E for 14 days: (1) synthetic all rac-α-tocopherol acetate powder, (2) natural RRR-α-tocopherol acetate powder, (3) micellized RRR-α-tocopherol liquid, (4) micellized RRR-α-tocopherol powder. At the completion of the feeding trial, horses began a two day standard exercise test. Blood was collected at days 0, 7, 14 of the feeding trial and pre and post exercise. Serum α-tocopherol was higher on days 7 and 14 as compared to day 0 in all treatment groups with no differences between treatment groups. Average serum α-tocopherol levels were higher in horses supplemented micellized forms as compared to synthetic and natural acetate powder over the three exercise time point sampled ($P<0.05$). Additionally, horses fed micellized RRR-α-tocopherol maintained whole blood GSH-T levels following exercise, whereas horses receiving acetate bound forms showed a post exercise decrease in whole blood GSH-T ($P=0.03$). Findings of this study indicate that micellized RRR-α-tocopherol is superior to other vitamin E forms in maintaining serum α-tocopherol and antioxidant status in response to a novel exercise test.

All Things in Moderation: The Effect of Moderation Messages on Food Perceptions

Mitchell Lee
Dr. Michelle R vanDellen, Psychology, Franklin College of Arts and Sciences

Heart disease is the number one cause of death in the United States and obesity has been increasingly linked to being a cause of it. Although it is easy to point to overeating as the cause of obesity, there is no clear explanation for why people overeat. The purpose of the present study was to study the effect of how different messages on consumption habits impact people's perceptions of food. We hypothesized that exposing people to different messages about healthy eating habits would change how healthy they thought certain foods were. In order to test this hypothesis, participants came to the lab and saw one of four different messages regarding how to maintain healthy eating habits. Participants then saw images of various foods and asked to rate how healthy they perceived those foods. Results found that telling people that eating foods in moderation is okay results in people considering more foods as healthy than they would otherwise. This suggests that one reason for overeating is that when people are told that eating unhealthy foods in moderation is acceptable they are more comfortable with the idea of eating them. A study examining consumption is testing this idea.

The Effect of Lutein and Zeaxanthin Supplementation on Emotional Well Being

Paul Lee, CURO Research Assistant
Dr. Lisa Renzi Hammond, Psychology, Franklin College of Arts and Sciences

Dietary carotenoids lutein (L) and zeaxanthin (Z) are the only carotenoids in the neural retina and are the dominant carotenoids in the neocortex. Here, L in particular is thought to directly influence neural communication. Past research suggests that supplementation with L and Z can improve visual processing speed, reaction times and cognitive function across the adult lifespan. Despite the fact that L is widespread in the neocortex, past research has focused predominantly on only one output of a healthy brain: cognitive function. If L influences neural communication throughout the brain, other behavioral outputs of a healthy brain should also be observable, such as emotional processing. The purpose of this study was to test this hypothesis in 51 healthy older adults and 51 healthy young adults from the UGA and surrounding Athens-Clarke County community. Participants were randomized into two groups, one that received 12 mg / day L+Z, and one that received a visually identical placebo. Emotional processing data were collected using the CNS Vital Signs computerized testing platform at baseline, 4-months, 8-months and 12-months of intervention. L+Z status was measured in the neural retina as macular pigment optical density (MPOD). Analyses are ongoing, and results will be presented at the symposium.

Current Investigations of Chromium Photocatalyzed [4+2] Cycloadditions

Sang M Lee, CURO Research Assistant
Dr. Eric M Ferreira, Chemistry, Franklin College of Arts and Sciences

Photoredox catalysis is an emerging field in modern organic chemistry with visible light as the source of energy to enable transformations previously inaccessible by traditional means. Recently, earth-abundant photocatalysts have been employed in a radical cation Diels-Alder cycloaddition of electron-rich dienophiles. Current literature suggests that the electron-rich alkene is rendered electron-poor after single electron oxidation by the catalyst, allowing it to cyclize with the diene. Electron-poor dienophiles have also been employed in this net [4+2] reaction, but because the Cr complexes themselves are not strong enough to oxidize electron-poor olefins, current research in the lab promotes the idea that it reacts with the diene through an alternative pathway. Experimental evidence suggests a light-mediated [2+2]-cycloaddition, followed by a Cr-catalyzed vinylcyclobutane rearrangement. This rearrangement yields the net [4+2] product with reversed Diels-Alder regioselectivity. Current understanding of the cycloaddition requires further studies on the effects of electronics and sterics in order to elucidate the mechanism. For this study, dienophiles of various steric bulk and electronics were used to determine the efficiency of the cycloadditions based on these criteria to assess π-π stacking interactions in a putative catalyst-substrate association complex.

Effect of Reproductive State on Parasite Infection in Wild Rodents

Soo Min Lee
Dr. Vanessa Ezenwa, Ecology, Odum School of Ecology

Sex steroid hormones are known to have strong effects on the mammalian immune system. Testosterone has been shown to suppress immune function in males, while estrogen can enhance certain mechanisms of the immune system in females. Importantly, these hormone-associated changes in immunity can affect parasite susceptibility. Since rodents tend to shift in and out of actively reproductive states on relatively short time scales, changing their hormone levels, this study focused on wild cotton mice (*Peromyscus gossypinus*) and hispid cotton rats (*Sigmodon hispidus*) in Georgia. We will test to see whether the reproductive and non-reproductive states alter the intensity of parasite infection. Additionally, we will examine the number of parasite species between males and females. To assess differences in parasite infection, we will use fecal samples collected from each species during non-reproductive and reproductive periods to measure the intensity of the gastrointestinal parasites. We expect reproductively active individuals to be infected with a higher intensity of parasites and a greater number of parasite species. Additionally, the reproductive males are expected to be more infected than the reproductive females. This study will reveal the effect of reproductive state on the parasitic infection.

Off-Target Effects of the Inhibitor MRS2578 on the Formation of Neutrophil Extracellular Traps

Tae-In Lee, CURO Research Assistant
Dr. Balazs Rada, Infectious Diseases, College of Veterinary Medicine

Within the joints of patients with gout, the deposition of monosodium urate crystal drives the accumulation of polymorphonuclear leukocytes. At the site of infection, neutrophils primarily engulf pathogens exposing them to antimicrobial compounds such reactive oxygen species produced by the NADPH oxidase. However, in gout in response to monosodium urate crystal deposition, PMNs undergo another antimicrobial activity called NETosis which is the release of chromatins, granule proteins and DNA into the extracellular space to form neutrophil extracellular traps. NETs immobilize pathogens preventing further dispersal, but uncontrolled formation of NETs also leads to several diseases such as gout. Previously found, MRS2578 inhibits a purinergic P2Y6 receptor in THP1 macrophages and keratinocytes yet at a higher level than the inhibitor's IC_{50} value. Therefore, MRS2578 loses its inhibitory effect around its IC_{50} value proposing potential off-target effect. Here, we examined the effect of MRS2578 at much lower concentrations and of zinc—an inhibitor of proton channels—on NET formation. Zinc reduces NET formation stimulated by MSU crystals suggesting the involvement of the proton channel. Since NETosis is dependent on NADPH

oxidase and phorbol-12-myristate-13-acetate (PMA) triggers NETosis by activating protein kinase C, which activates NADPH oxidase, PMA was used for positive control of NET formation. Our data indicate that the purinergic MRS2578 inhibitor can have off-target effects, likely inhibiting the NADPH oxidase or its associated proton channel, which sheds novel light on its potential use for inhibiting neutrophil activation in diseases including gout.

A Study of Interstellar Intermediate Velocity Gas Clouds

Bjorn Leicher, CURO Research Assistant
Dr. Robin Shelton, Physics and Astronomy, Franklin College of Arts and Sciences

Intermediate Velocity Gas clouds (~80 km/s) are enormous clouds of neutral atomic Hydrogen that travel throughout the galactic halo; the area of dust and gas surrounding our galaxy. As a result, the gas clouds experience numerous changes in their characteristics. In this research, we use hydrodynamical simulations to analyze the changes in these characteristics over the duration of its lifetime (~5-10Myr). Three different simulations are run for three different speeds of the cloud (60, 80, and 100km/s). By using speed as a control variable, we can see how it affects the other aspects of the cloud. Through the analysis of IVCs, we attempt to answer questions such as where these clouds come from and how they play a role in the galactic fountain process, if any. Because IVCs have not yet been extensively studied, the primary focus of this study is to gain a better understanding of the clouds holistically.

Competing Pressures: Tipping the Scales in the Prosecution of Rape and Sexual Violence

Zoe Li, Foundation Fellow
Dr. Maryann Gallagher, International Affairs, School of Public and International Affairs

The treatment of the issue of rape and other forms of sexual violence in international law is continually evolving. Prosecutors are coming across increased cases of rape and sexual violence crimes that can potentially be brought to trial. Of those that could be brought forth, however, only a fraction of them actually pursue the charges. This begs the question, why? This paper presents a potential explanation involving opposing pressures that prosecutors in the international criminal courts face when choosing which cases to take on: "win" pressure and "outsider" pressure. In this argument, "win" pressure refers to the internal pressure applied by prosecutors upon themselves to "get the win" or take on cases they deem most likely to garner a conviction. On the challenging side, there is "outsider" pressure, which refers to the influence of any other actors outside the Office of the Prosecutor, including judges, non-governmental organizations, international organizations, and individuals outside the court. Inner "win" pressure usually acts as a discourager for rape and sexual violence cases, while "outsiders" are usually sources that push for increased rape and sexual violence indictments. It is in the way that these two competing pressures are reconciled that determines whether or not rape/gender-based violence crimes are charged against perpetrators in the international courts. The study of these prosecutorial motivations can enhance our understanding of international humanitarian law and contribute to the development of the most effective ways to reform and ameliorate it.

Nanofibrous Pectin Scaffolds for Biomedical Applications

Nathan Likens, CURO Research Assistant
Dr. Sergiy Minko, Chemistry, Franklin College of Arts and Sciences

In today's rapidly growing field of biomedical applications, biocompatible materials are increasingly sought after. Pectin, a polysaccharide found in plant cell walls, is one such material. This heteropolysaccharide is composed of homogalacturonans, rhamnogalacturonans, and substituted galacturonans. The goal of this experiment is to create scaffolding from crosslinked pectin nanofibers for tissue engineering and drug delivery use. Many previous attempts at creating nanofibrous scaffolding involved the use of toxic or flammable solvents which is not conducive for a biocompatible application. The process of elecrospinning the pectin polymer into nanofibers creates a high surface area to volume ratio which is ideal for cell adhesion, proliferation and differentiation. Previous experiments have been conducted with

chitin, which produced promising results; however, the addition of pectin enhanced the mechanical structure of the scaffold. Our goal is to find an ideal concentration of pectin to optimize the tensile strength, cell viability, and ultimate decomposition of the nanofibrous scaffold.

Sensitive Liquid Chromatography/Tandem Mass Spectrometry Method for the Determination of a Novel Highly Lipophilic Anti-Cancer drug Candidate in Rat Plasma and Kidney Tissue

Michael Linzey, CURO Research Assistant
Dr. Michael Bartlett, Pharmaceutical and Biomedical Sciences, College of Pharmacy

Prostate cancer (PCa) is the second leading cause of cancer related deaths in males. When PCa forms metastasis they develop onto the bone and it is these migratory tumor cells that cause most morbidity and mortality. There are currently no satisfactory treatment options for bone metastatic PCa. There is a great need to further develop treatments that will fill this need. There is a group called amino-bisphosphonate derivatives that have shown promise in targeting bone metastatic PCa. These compounds have been shown to be highly lipophilic so understanding where they partition is extremely important. LG1980 is a representative molecule of this class. It selectively induces apoptosis in aggressive PCa cells. This particular candidate is in pre-clinical studies to test its toxicity and pharmacokinetic properties in animals. There needs to be an accurate and reproducible method for quantifying the drug concentrations in various organs. The purpose of this investigation was to develop and validate a selective, sensitive, and robust LC-MS/MS method for quantification of this highly lipophilic anti-cancer drug candidate in rat plasma and kidney tissue. This bioanalytical method was validated in accordance with current FDA guidelines including accuracy and precision of inter- and intra-batch variation, specificity, linearity, limit of detection, limit of quantitation, recovery, and stability. While this specific drug candidate may fail, it is worth noting that this method could be applicable for the quantifications of other amino-bisphosphonate derivatives in biological samples with minor modifications to the method.

Consumers as Curators: Brand Use in Social Media

Lydia Liu, CURO Research Assistant
Dr. John Hulland, Marketing, Terry College of Business

Online consumer curation describes the behavior of gathering, selecting, and assembling online content into a display. Consumers may use art, photos, text, product images, and brands in their curation efforts. This behavior is an understudied way in which consumers are engaging with brands online, and thus is important for marketers to understand. The current research is focused on uncovering what information about curated brands is related to the popularity of an online display, in order to understand what characterizes an influential display. To address this question, data were collected from a social media site centered on the creation of curated displays. A regression analysis will uncover what information about the curated brands (e.g., the general popularity of the items, price statistics, and the number of unique brands) is related to the popularity of the curated display. Further, results will be compared across two groups on the social media site in order to address the generalizability of our findings. This research will move our knowledge of online consumer behavior forward and provide important information for managers about how consumers are using brands online.

Distribution of Ticks on Cervids and Prevalence of Selected Tick-Borne Pathogens in These Ticks from Kentucky

Bessie Lockwood, CURO Research Assistant
Dr. Michael Yabsley, Forestry, Warnell School of Forestry and Natural Resources

In recent decades, white-tailed deer (*Odocoileus virginianus*) populations have increased dramatically, partially due to the conversion of farmland to forests. Furthermore, more people have moved to areas adjacent to woodland habitats. Thus, vector-borne diseases are becoming increasingly more prevalent in humans and domestic animals. Vector-borne pathogens can also cause disease in various wildlife species.

In this study, ticks were collected from cervids in Kentucky, identified to species, and selected species tested for causative agents of Lyme disease (*Borrelia burgdorferi*) and spotted fever (*Rickettsia parkeri*). Four different tick species were collected including the winter tick (*Dermacentor albpictus*), lone star tick (*Amblyomma americanum*), black-legged tick (*Ixodes scapularis*), and the Gulf coast tick (*Amblyomma maculatum*). *D.albipictus* was detected in 42 counties, *I.scapularis* was detected in 41 counties, *A.americanum* was detected in 16 counties, and *A.maculatum* was detected in 7 counties. These four tick species were detected throughout Kentucky indicating the risk of tick-borne pathogens statewide. Of 173 *I. scapularis* ticks tested for *B. burgdorferi*, 11% were positive. Of 43 *A. maculatum* ticks tested for *Rickettsia sp.*, 19% were positive and sequence analysis indicated several *Rickettsia spp.* were detected. Further research will be done to determine the exact species of *Rickettsia* present. The data provides important data on the current distribution of tick species present in Kentucky and their associated pathogens.

Investigating the Role of Cyanogenic Glycosides as a Potential Defense for *Passiflora incarnata* against *Agraulis vanillae*

Atul Lodh, CURO Research Assistant
Dr. Rodney Mauricio, Genetics, Franklin College of Arts and Sciences

Plants produce the largest variety of secondary metabolites of any organism on the planet. However, the evolutionary forces that generate this diversity are still unknown. A leading hypothesis is that these metabolites serve as defenses against insect herbivores that utilize plants as a food source and that herbivores evolve to combat these defenses in response. To test the hypothesis that cyanogenic glycoside is a defensive metabolite and therefore is under natural selection by insect herbivores, a common garden experiment was conducted using the plant species *Passiflora incarnata*. Furthermore, a second experiment looking into *Agraulis vanillae* (Gulf Fritillary) performance on *P. incarnata* plants from different regions of the United States was conducted. The results of the common garden experiment suggested that a relationship between cyanogenic glycoside production and fitness was unable to be determined. Furthermore, from the herbivore performance experiment, a significant interaction between toughness and cyanogenic glycoside production on female pupae weight was observed. This work provides further insight into the importance of metabolites in mediating plant-herbivore coevolutionary interactions.

Evaluating Woody Tissue in Chicken Breast Samples with X-Ray, CT, and MR Imaging – A Pilot Study

Mary Catherine Lollis, CURO Research Assistant
Dr. Mark A Haidekker, Electrical and Computer Engineering, College of Engineering

The trend to grow larger chickens has posed a problem to the quality of meat, a muscle condition known as Woody Breast. The affected muscle tissue is characterized by the presence of hardened fibers, which affect the texture and can be tough to chew. Methods are sought to help identify the affected tissue to prevent it from consumer consumption and to analyze the factors involved in the hardening of the tissue. Using x-ray imaging, computed tomography (CT), and magnetic resonance imaging (MRI), absorption values of healthy muscle tissue and woody breast were examined for significant differences. The guiding hypothesis was that there is a difference in radiological absorption between healthy and diseased tissue. Using CT, the healthy tissue was found to be in the expected range of about 45 to 60 Hounsfield units, but the woody tissue showed an approximate 18.5% decrease in density compared to healthy tissue ($P<0.01$). A lower density was also found in x-ray imaging, dependent on the density ratios between 25 and 30 kVp and 25 and 35 kVp. The trend was not statistically significant. The variability in x-ray values can be explained by the variations in sample thickness. MRI relaxation times were not found to relate to the disease, but MR images served as a visual control to eliminate low-density samples caused by fatty striations. While this pilot study established the principal benefit of dual energy imaging, a larger study is needed to obtain more representative values and to eliminate unrelated influences.

Tail Ischemia Associated with Arterial Catheters in the Coccygeal Artery: A Case Series

Daiannette Lopez, CURO Research Assistant
Dr. Jane Quandt, Small Animal Medicine and Surgery, College of Veterinary Medicine

A case series study is intended in order to detail the presence of tail ischemia as a complication after an arterial catheter has been placed on the coccygeal artery of a cat or dog prior and during surgery. The study is limited to cases presented at the College of Veterinary Medicine (CVM) at the University of Georgia. Dog and cat cases presented at the Soft Tissue Surgery service with tail necrosis and/or amputation will be reviewed to see if it was subsequent to a surgery where an arterial catheter was placed in the coccygeal artery. Although correlation does not indicate causation, it is possible that the arterial catheter created blood clots that could have caused the tail ischemia, which could end in amputation. Another possible cause of tail ischemia is the occlusion of blood flow to vessels near the arterial catheter, or proximal to it, due to the catheter's size. The standard gauge of the catheter placed in the artery on the ventrum of the tail is twenty-two gauge and one-inch long. It is of importance that these cases are reported since no articles reporting cases of cat's or dog's tail ischemia caused by arterial catheters placed in the coccygeal artery have been published.

The Sustainability and Performance of Metakaolin and Blast Furnace Slag in Mass Concrete Production

Victor Lopez, CURO Research Assistant
Dr. Mi Chorzepa, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

The search for sustainable concrete mixtures has been on the rise in recent times. Cement binds four other constituents together to create concrete, but is also the constituent that requires the most energy to be produced and must be manufactured separately in a cement plant. As a result, the entire concrete mixing process is unsustainable. Substituting cement with certain materials will not only produce a more sustainable mixture, but improve performance. This study involves researching viable cementitious materials, materials that exhibit properties similar to cement, and substituting a percentage of cement with these materials. The cementitious materials observed in this study are metakaolin and blast furnace slag (BFS). In terms of performance, metakaolin possesses specific qualities that contribute to long-term concrete strength as well as reduction of shrinkage, an issue involving reduced volume due to water loss. Alternatively, BFS can also replace a percentage of cement. Along with being recyclable, BFS is also used to increase concrete durability. Several concrete mixtures will be produced and tested for strength and durability, then compared to control specimens. 9 tests will be conducted on the specimens. Stength tests include Compression, Split Tension, Modulus of Rupture (MOR), and Modulus of Elasticity (MOE), and durability tests include Rapid Chloride Permeability (RCP), Alkali-Silica Reaction (ASR), Dry Shrinkage, Sulfate Resistance, and Coefficient of Thermal Expansion (CTE). These tests will determine the benefits of these cementitious materials based on environmental impact and performance.

Investigating Diet and Stress in Medieval Polish Individuals Using the Bone Density Fractionation Method

Janae Marie Lunsford, CURO Research Assistant
Dr. Laurie Reitsema, Anthropology, Franklin College of Arts and Sciences

Stable isotope analysis is well-established method for reconstructing diet and stress in past populations. However, the relative inertness of bone presents a challenge for reconstructing diet and stress during the last years and months of life. The bone density fractionation method offers a means to overcome this problem. As it allows one to see the changes in diet and stress over time in a person's life, the bone density fractionation method was used in order to better understand the diet and stress of a Medieval Polish sample. Using the ribs of three Medieval Polish adults and one subadult, the cortical bone was separated into different densities prior to undergoing stable carbon and nitrogen isotope ratio analysis. Stable isotope ratios of carbon can show whether or not a person was eating more C3 or C4 plants. Stable isotope ratios of nitrogen can demonstrate where a person was eating on the food chain and can

signal weaning in subadults. Through stable isotope analysis of the different densities, one can reconstruct patterns in diet and nutritional stress in the final years and months prior to death in adults and can test for patterns of weaning in subadults. This research allowed the application of the bone density fractionation method to a Medieval Polish sample in order to explore the changes in health and stress in those individuals until their deaths.

Forensically Influential Beetle Fauna in the Fall of 2016

Alexandria Lushaj, CURO Research Assistant
Dr. Marianne Shockley, Entomology, College of Agricultural and Environmental Sciences

What beetle fauna colonize carrion in the fall, and at what stage of decay do we find each of the different beetle families? Forensic entomology is very influential in urban and criminal court cases. Insects are the keys to unlocking hidden truths behind investigations that may otherwise not be discovered without their aid. Unfortunately, there is not much information about beetle fauna found in Georgia and much of the south so that is why the interest in conducting this experiment is so great and influential. For my experiment, I will be examining beetle fauna that colonize carrion during the fall of 2016. The point of this research is to compare what I and several other researchers collected in the spring of 2016. The continuation of this experiment is crucial in creating a substantial and solid database. The trial conducted in the spring of 2016 was very successful and helped guide the continuation of research on beetle fauna in the fall of 2016. As mentioned, there has not been much exploration behind beetle fauna research and its importance. The science we will uncover will aid investigators in estimating a post-mortem interval in potential homicide cases. In starting my quest in my experiment, a pig that is killed by a single gunshot to the head will be obtained. Next, the pig will be placed in a cage to be protected by scavengers. After the stimulation of a crime scene, pitfall traps will be placed around the cage to obtain the beetle fauna necessary to properly examine. The data from spring 2016 will be used as a comparison so a clear correlation and trend is visible.

Mechanical Characterization of Lipid Membranes Using Micropipette Aspiration

Katherine MacManus, CURO Research Assistant
Dr. Eric Freeman, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

The study of the mechanical properties of liposomes will provide further insight to cell membrane fusion events such as endocytosis and exocytosis. The purpose of this experiment is to measure the mechanical characteristics of liposome membranes by using the micropipette suction technique. With this technique, data will be collected that can measure the membrane area expansion modulus and the in-plane Young's modulus, allowing for the mechanical characterization of the liposomes. The experiment is divided into two parts: the creation of the liposomes through electroformation, and the study of their membrane properties using a pressure clamp. The pressure clamp allows for the aspiration of the electroformed liposomes within a micropipette through maintaining a holding pressure. The data collected from the pressure clamp is then combined with the measured curvature of the deformed liposome using a MATLAB script, and the membrane resistance to mechanical deformation is calculated. This technique can be used for various kinds of lipids, developing the knowledge and understanding of the complex structures and properties of the lipid membrane.

A Correlational Study: The Relationship between Critical Flicker Fusion Thresholds of Postpartum Women and Infants

Neha Arun Madangarli
Dr. Janet Frick, Psychology, Franklin College of Arts and Sciences

Macular pigment, found in the center of the retina, is composed of the carotenoids lutein (L), zeaxanthin (Z), and meso-zeaxanthin. Studies by Hammond, Bovier, and Renzi (2013) and by Hammond and Renzi (2010) have shown that macular pigment optical density (MPOD) correlates negatively with visual motor response times (shorter response times indicate better performance) and positively with visual temporal

processing speed, quantified via measurement of critical flicker fusion thresholds (CFF), in adults. CFF thresholds represent the fastest frequency of a flickering light that an individual can discriminate as flickering; lights flickering at speeds above an individual's CFF will appear solid. The present study investigates the relationship between the MPOD of 20 postpartum women and the CFF thresholds of their 4.5-month-old infants. Customized heterochromatic flicker photometry was used to test the women's MPOD with a 1° 460nm and 570nm stimulus flickering in counter phase. Infant CFF was measured using a forced-choice preferential looking (FPL) paradigm in which the infant was presented with two stimuli (one solid and one flickering at a particular frequency) on either side of their midline and a naïve observer judged the side with the flickering stimulus based on the infant's looking behavior. This was repeated until a threshold estimation could be made by the second experimenter. Based on the previous research outlined above, it was hypothesized that the MPOD of postpartum women would positively correlate with their 4.5-month-old infants' CFF thresholds, meaning that women with higher MPOD should have infants with faster visual temporal processing speeds. Data collection is ongoing.

Effect of Invasive Macroalgae *Gracilaria vermiculophylla* on Feeding Behavior of *Callinectes sapidus*

Katie Maddox, CURO Summer Fellow
Dr. James E Byers, Ecology, Odum School of Ecology

Within the past decade the invasion of southeastern estuaries by a non-native seaweed, *Gracilaria vermiculophylla*, has greatly altered the physical structure of previously bare mudflats. With the creation of novel habitat, this invader could have major impacts on the trophic relationships of Georgia's estuarine communities. *Callinectes sapidus*, or the Atlantic blue crab, is a common intermediate predator found on the mudflats along the southeastern United States. Blue crabs feed on a wide range of invertebrates such as worms and clams, which are some of the species that proliferate in mudflats where *G. vermiculophylla* is often present. My study aims to quantify the effect of the emergence of this landscape-altering seaweed on the foraging behavior of *C. sapidus*. To study this effect, I conducted feeding trials in which *C. sapidus* had the option of feeding in the presence or absence of *G. vermiculophylla*. We found that blue crabs showed no preference for foraging in areas with *G. vermiculophylla* versus without the invasive seaweed. A tethering experiment was conducted in order to study predation on the mudflats. We quantified the foraging pressure on *Mercenaria mercenaria*, a clam commonly found on the mudflats where *G. vermiculophylla* is present. Again, we found that there was no significant difference in foraging pressure within *G. vermiculophylla* mats versus on bare mudflats. We also conducted a long-term predator exclusion experiment to quantify the effect *G. vermiculophylla* has on invertebrate diversity. We expect our results to show that *G. vermiculophylla* has no effect on invertebrate diversity.

The Effect of ePortfolio Use on Real-World Application of Classroom Skills

Carter Patrick Maguire III
Dr. Leslie Gordon, Institute of Higher Education, Senior Vice President of Academic Affairs

The introductory linguistics class is often more difficult than students expect, due in large part to its emphasis on active analysis of language over simple memorization of facts. Under the experiential pedagogy of ePortfolio, the abstract concepts students encounter become more accessible. Undertaken in an introductory Spanish linguistics class, the project studied the implementation of ePortfolio, a web-based collection of student work and reflections that provides evidence of learning. The ePortfolio is a unique way for students to personalize learning, encouraging the application of concepts and skills outside of the classroom. Two Honors students were used as peer tutors, reviewers of ePortfolio construction, and collectors of formative classroom data on the project's effectiveness. Three surveys taken at the beginning, middle, and end of the semester gauged variables such as the effectiveness of peer tutoring and the pace of progress through the assignment, among others. The two Honors students wrote blogs describing the experience of acting as a peer tutor, and provided accounts of the project from the student perspective. The data from the surveys and the

Honors students' blogs demonstrate that students engaged in critical observation of language use and applied course concepts to these observations. Analysis of the project shows that one semester of ePortfolio use increases the likelihood that students will apply course concepts to their observations of real world language use.

Effect of Polarization on Hierarchies of Committee-Representative Networks: Social Network Analysis

Emily Maloney, Foundation Fellow
Dr. Dawn T Robinson, Sociology, Franklin College of Arts and Sciences

The dramatic increase in party polarization within the United States Congress over the past decade has logically been linked to the government shutdown in 2012, general gridlock, increased filibustering, and an overall decline in productivity. The mechanism by which polarization plays out within US legislative bodies may be the practice of "rewarding" partisan members of Congress with preferential committee positions, because this allows the majority party to design and prioritize influential ideological legislation. Since committees originate new legislation, they are substantial actors in the production of new laws that guide the nation. This research aims to answer the question, "Does polarization and majority party control in state Houses of Representatives have an effect on the hierarchy and extremism of committee-Representative networks?" To analyze this question, datasets of Representative – Committee relationships will be constructed, along with matrices of roll call voting data. Next, a myriad of social network analysis methods will be conducted on this data, such as centrality to identify key legislators, singular value decomposition to measure partisanship, and hierarchical clustering to show cohesive subgroups. The research questions answered through this analysis are important because they can explain how polarization of parties has affected the structure of state legislative bodies and thus legislation produced, and it can begin to identify the link between polarization of parties and intentional actions in order to maintain power within the legislative body.

Local Perceptions of Wildlife in Samburu, Kenya

Erin Malsbury
Dr. Vanessa Ezenwa, Ecology, Odum School of Ecology

Wildlife conservation initiatives, guided by threat classification systems such as the IUCN red list, often focus their work on rare species with a high risk of extinction. These threat classifications are largely produced by international organizations that may be geographically and culturally distant from the area of implementation. Local people, who are critical to the success of conservation programs, may have different perceptions of wildlife in their region, and disconnect between local communities and conservation organizations has been implicated as a factor in conservation success. Thus, to improve conservation initiatives, it is imperative to understand local human-wildlife relationships and the level of awareness surrounding endangered wildlife. We conducted one-on-one interviews with members of communities in Samburu, a northern region of Kenya which harbors 51 species of large and mid-sized mammals, many of which are threatened, in order to assess local perceptions of wildlife abundance and diversity, extinction threats, and why people believe wildlife should be valued. Our results indicate that people are more likely to care about a species if it is rare but generally lack awareness about the rarity of Samburu's wildlife. Almost all participants indicated that wildlife abundance and diversity have decreased over their lifetime; however, the majority of interviewees felt that extinction is not possible. This view was largely attributed to the protection of local wildlife by recently established community-led conservancies. These results have implications for the design of conservation narratives.

The Effectiveness of Music Therapy Techniques for Improving Second Language Acquisition in Adult ESL Students

Aisling Mohini Manison, CURO Research Assistant
Dr. John Roy Kennedy, Music, Hugh Hodgson School of Music, Franklin College of Arts and Sciences

ESL teachers are always exploring creative methods for increasing second language acquisition (SLA) in their students. Music has long been recognized as a close relative of language and an effective tool for teaching. However, while music is frequently used in elementary schools, it is less popular with adults, who struggle the most with language learning. Is music just play? Or can it be just as useful for adults? The purpose of this study is to investigate the effectiveness of music therapy techniques for SLA compared with traditional classroom methods alone. Participants will be composed of adult non-native speakers with starting L2 acquisition levels spanning early beginner to mid-intermediate. The control group will be taught with traditional ESL classroom methods, while the experimental group will receive 30 minutes of supplemental instruction with music therapy techniques at the end of their traditional class once per week. Each group will take the BEST Literacy test and a Writing/Story Retelling checklist as a pre- and post-test at the beginning and end of the study. It is anticipated that students who receive music as a supplemental portion of their ESL classes will progress more quickly through their ESL levels than students without supplemental music. This study is especially significant for ESL programs whose funding is determined by their retention and graduation of students the program. In accord with Krashen's hypotheses, music therapy techniques can facilitate and expedite SLA, development of fluency, and overcoming student's affective filters by making the learning experience more authentic and enjoyable.

The Effects of Salinity on *Helianthus*

Grace Manning
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts and Sciences

Food scarcity has become a growing problem as the Earth's population increases while global food production has remained relatively stagnant. In addition to this, the locations where population growth is projected to be largest are also the parts of the world that are expected to be influenced greatest by climate change. A major effect of climate change is drought along with rising seawaters. These changes will have an adverse effect on soil salinization and agriculture production. In this experiment we will be assessing the effects of salinity on 11 genotypes of *Helianthus*. Each of these genotypes will be undergoing four treatments 0mM NaCl, 100mM NaCl, 200mM NaCl and 300mM NaCl, where the treatment will initially start at 0mM and will be slowly ramped up over the course of 30 days to their final concentrations. Plants of each genotype will be harvested at the 10, 20 and 30-day marks of treatment and will be analyzed for relative growth rate (RGR), dry biomass (roots, stems and leaves), as well as the ion concentration in the leaves. We have two hypotheses: If the plant has been previously found to have salinity tolerance there will be a higher ion concentration in the leaves at higher salinity concentrations than there will be in the less tolerant genotypes; and there will be a maximum limit for the ion concentration, which will be higher in the genotypes that are previously found to be tolerant and lower in the susceptible genotypes.

Decoding Higher-Order Relations in Biological Data by Learning Markov Networks

Aaron Martinez
Dr. Liming Cai, Computer Science, Franklin College of Arts and Sciences

With the exponential growth of the amount of biological data, there is a rapidly growing need for machine learning and data mining methods that can comb through massive data repositories to answer important biomedical research questions. In particular, learning of Markov networks is viable for discovery of correlations and causality networks among biomedical entities/processes based on observed phenomena/data. The central task of learning is to compute the optimal topology of such networks through optimization computation of the joint probability distribution function, a task that in general is computationally intractable. However, recent breakthrough by the RNA Informatics Lab at UGA proves that Markov networks for tree-like (i.e., k-tree) topologies can be learned efficiently from biological sequence data, leading to successful applications such as bio-molecular structure prediction. Based on this work, the current project is progressing toward the goal of decoding higher-order relationships crossing two or more molecules with significant applications, for example, in RNA-RNA and RNA-protein 3D

structure complex predictions. Specifically, we have developed two optimization algorithms for Markov k-tree learning, for variable k, on both one and two-backbone graphs. The algorithms, which were implemented into software packages OSkT1 and OSkT2 in Java language, have already been applied to Markov network learning from miRNA-target duplex data, which can be effectively used for miRNA target prediction. To make the software scalable to larger biological sequences, our on-going research is improving the computation efficiency, including deploying the packages on parallel computers.

Bone Characterization in the Treatment of Hypophosphatasia with Mesenchymal Stem Cells

Ana Maslesa, CURO Research Assistant
Dr. Luke Mortensen, Animal and Dairy Science, College of Agricultural and Environmental Sciences

We present the use of second-harmonic generation (SHG) images produced by two-photon microscopy to characterize bone morphology using Hypophosphatasia (HPP) as a model. Hypophosphatasia (HPP) is a rare genetic disorder caused by mutations to the tissue-non-specific alkaline phosphatase (ALP) gene. Diminished ALP activity prevents the enzyme from dephosphorylating inorganic pyrophosphate (PP_i), a potent inhibitor of mineralization, resulting in disarticulated collagen and porous bones. Current treatments only alleviate symptoms in the long bones of patients with HPP and do not address premature loss of teeth and craniosynostosis. A promising treatment is mesenchymal stem cell (MSC) therapy, which has been used in clinical studies along with myeloablation and full bone marrow transplants. However, many patients in need do not qualify for bone marrow transplants as they are too sick for such a harsh, risky procedure. The impact of MSCs on bone structure has yet to be described due to the limitations of current technologies, microCT and DEXA. Image J will be used to analyze characteristics of bone such as pore size, number, and spacing along with collagen fiber density. We will use SHG images to examine the collagen microstructure in cranial bones to assess the impact of MSCs in their local environment. We predict that bones will have smaller, fewer pores and denser collagen fibers when the mouse is treated with MSC therapy. This data will be used to determine the effectiveness of MSC therapy for HPP and will establish SHG as a means for characterizing bone morphology for bone diseases.

Is Serum Bacteria-Killing Ability in the African Bush Rat Driven by Complement?

Isabella Mateu
Dr. Vanessa Ezenwa, Ecology, Odum School of Ecology

Vertebrate innate immunity provides a rapid and nonspecific response to invading pathogens. This form of immunity consists of anatomical barriers, phagocytes, natural antibodies, and opsonizing proteins. The complement system is a vital component of the innate immune response. Its enzyme cascade lyses targeted pathogen cells through either direct-attack or by marking them for subsequent phagocytosis. Previous work has suggested that wild African bush rat (*Aethomys spp.*) possess a highly robust innate immune response that destroys pathogenic bacteria significantly more effectively than the response of laboratory mice. The primary objective of this project is to test whether complement activity plays a key role in driving this robust response. To explore this issue, the bacteria (*E. coli*) killing ability of bush rat serum exposed to the complement inhibitor, 6-amidino-2-naphthyl p-guanidinobenzoate dimethanesulfonate (futhan) will be compared against untreated and heat-inactivated serum. We anticipate that, if complement is the major driver of bacteria killing in bush rats, that the futhan and heat-treated samples will exhibit very low killing compared to untreated samples, due to the inactivation of complement in these samples. This study will provide insight into precisely which aspect of innate immunity wild bush rats use to fight off bacterial infection.

Perceived Severity of Conditions Related to Obstructive Sleep Apnea among At-Risk College Students: Consequences That May Influence Academic Performance

Jamarcus Gregory Mathis, CURO Honors Scholar, CURO Research Assistant

Dr. Matthew Lee Smith, Health Promotion and Behavior, College of Public Health

Obstructive sleep apnea (OSA) is a condition that typically impacts middle-aged and older adults. However, with the rise in obesity nationwide, OSA and other forms of disordered breathing are increasing among younger populations. The ramifications of OSA among college-aged students may impact their academic performance due to inadequate oxygen intake and reduced sleep quality. The purposes of this study were to: identify familial risk factors for OSA among at-risk college students; and compare severity perceptions about OSA-related conditions that may influence academic performance. An internet-delivered survey was used to collect data from 334 overweight (57.5%) and obese (42.5%) college students who snored. Pearson correlations were performed to assess the strength and direction of severity perception associations between OSA-related conditions. Then, a series of paired *t*-tests were used to compare perceived severity levels between OSA-related conditions. Compared to overweight participants, obese participants reported their mothers had significantly more OSA-related risk factors. On average, the OSA-related conditions perceived to be most severe was cardiovascular disease (CVD) followed by depression, decreased memory, decreased concentration, daytime sleepiness, and low sex drive. Strong positive correlations were observed between the majority of severity perceptions about OSA-related conditions ($P<0.01$). In paired *t*-tests, severity perceptions were consistent for overweight and obese participants. On average, CVD and depression were perceived to be significantly more severe than other OSA-related conditions ($P<0.01$). Understanding at-risk college students' OSA-related severity perceptions can inform interventions about the importance of OSA screening and obtaining one's family health history.

Bioactive Scaffold Design for Bone Tissue Engineering

Ridge Maxson, CURO Research Assistant
Dr. Cheryl Gomillion, Chemical, Materials, and Biomedical Engineering, College of Engineering

A significant number of bone grafting procedures are performed annually in the United States. Autografts and allografts have historically been used to repair fractured bone; however, they present myriad complications, including limited tissue availability and rejection of allograft donor tissues. Advances in tissue engineering hold the promise of providing an improved mode of treatment that will expedite the formation of new bone and eliminate the possibility of rejection. Biomaterial scaffolds provide the foundational support for cell attachment and subsequent tissue formation, and are therefore a key area of interest in tissue engineering. In this work, we aimed to fabricate polymer scaffolds to include a combination of natural and bioactive molecules, and then assess various formulations to identify the optimal bone supporting scaffold. Scaffolds were fabricated using poly (lactic-co-glycolic) acid) (PLGA), a synthetic biodegradable copolymer consisting of lactic and glycolic acid. Varying combinations of tricalcium phosphate, a ceramic component associated with osteoconductivity, was blended with the polymer to improve the mechanical strength and cell supporting potential of these scaffolds. Scaffolds were prepared using a porogen leaching method, and characterized using a variety of techniques, including mechanical testing, in vitro degradation tests, and swelling studies. In addition, an in vitro cell study to examine the interaction of bone cells with these materials was used to evaluate bone cell attachment, proliferation, and mineralization. The long-term goal of this work is to develop a composite, multi-functional scaffold that addresses current limitations, mimics the properties of native bone, and supports the creation of new bone.

Communicating the Importance of Microbial Symbionts to the Public

Johnathan Martin Mayfield, CURO Research Assistant
Dr. Gaelen Burke, Entomology, College of Agricultural and Environmental Sciences

Spanning across the eastern seaboard from Maine to our own state of Georgia are Hemlocks (*Tsuga canadensis* and *T. caroliniana*) as well as the invasive and destructive sap-feeding insect Hemlock Woolly Adelgid (HWA). The successful management of this species will require the public

and its support as well as continued research by professionals into both management policies and the basic biology of the HWA. The University's mission, "to teach, to serve, and to inquire into the nature of things," serves as the foundation for this research project that aims to understand the interplay between adelgid life cycles and their microbial symbionts, and how to relay this to the public. We intend to survey community members in Athens-Clarke County about their knowledge of adelgids, their life cycles, and their symbionts before and after a program designed to simulate aspects of and increase understanding of HWA biology. Specifically, we have designed an activity to demonstrate the life cycles of adelgids and the importance of the nutritional benefits that their microbial symbionts provide. Anticipated results include increased expressed appreciation for research on insects and their impact upon the environment. Furthermore, we intend to publish the activity and other resources online for use by educators outside of the UGA community. Through our various outreach methods we believe that we can both inform the public about a research project being actively conducted in the Entomology department at UGA and the impact of adelgids and other invasive insect pests upon our environment.

Primordial Chemical Composition Through the Reionization Period

Ryan McArdle
Dr. Phillip C Stancil, Physics and Astronomy, Franklin College of Arts and Sciences

The focus of this research is to model and explore the chemical evolution of the primordial universe, from the Big Bang through the reionization period. We use code developed by Christopher Gay for his dissertation, which models the chemistry of the universe from its beginnings through the recombination period under the effect of the CMBR. The goal of our project is to further develop this code in order to extend the model through the end of the reionization period, in which primordial gas clouds collapse into the first stars and radiate their surroundings. The radiation released by the newly formed stars results in a shift in compositional evolution that differs from the evolution produced by the CMBR alone, and an accurate modeling of the influence of these stars is necessary for a proper model of chemical composition through the early period of the universe. Our current model provides data that largely indicates a dying out of activity following the recombination period, in which the abundances of the different compounds remain at rather stagnant values. However, with an appropriate model of stellar influence, one would expect another period of compositional evolution to coincide with the existence of these primordial stars, and we hope to accurately model these changes in development.

Improved Nitric Oxide-Releasing Polymer with Surface Exposed and Crosslinked Zwitterionic Polymer for Antimicrobial Applications

Jennifer McCarty, CURO Research Assistant
Dr. Hitesh Handa, Chemical, Materials, and Biomedical Engineering, College of Engineering

Accumulation of bacteria, proteins, and platelets on medical device surfaces is a leading cause of nosocomial infections and device failure. If this fouling of medical device coatings could be eliminated, then the safety of implantations, catheters, and stents would increase exponentially. By applying a zwitterionic polymer topcoat (antifouling agent) to a nitric oxide (antimicrobial agent) releasing medical grade polymer, we can dramatically decrease protein adhesion and reduce bacterial attachment synchronously. The zwitterionic polymer (2-methacryloyloxyethl phosphorylcholine- co-benzophenone, BPMPC) was tested for protein adhesion by analyzing its surface properties using ellipsometry and contact angle measurements. This zwitterionic polymer was then crosslinked to the surface of the NO releasing polymer that contains NO donor molecules. The test samples containing the NO donor with the zwitterionic topcoat were tested for NO release behavior to ensure sustained drug release. This combination was tested with *Staphylococcus aureus*, a common pathogen detected in nosocomial infections, for its antimicrobial efficacy. This study aimed to prove that a zwitterionic antifouling topcoat, when paired with a nitric oxide donor, could significantly decrease microbial adhesion. This coating has significant antifouling benefits, allowing for many applications in the biomedical field.

Insects as a Nutritional Source in Horse Feed

Jacki McCollum, CURO Research Assistant
Dr. Marianne Shockley, Entomology, College of Agricultural and Environmental Sciences

There has been a rise in Entomophagy lately as it is a more sustainable food source for both people and animals. It is both nutritional and sustainable, so I decided to research insects as a feed source for horses. I set out to find, based on what is already known, if the nutritional content in insects seems to correlate with what horses need in their diets, and also what people who buy horse feed would think of such a feed. I began by getting as much information as I could about the nutritional needs of horses compared to the nutritional content that insects contain. This proved to be difficult, as I found that insects as a food source for horses has not been studied before, but based on what is known, insects should be able to fill many nutritional requirements of horses. After drawing conclusions from my findings, I created a survey that I have sent out to people that ride horses in order to understand what the public's opinion on such a feed would be. Based on the responses, the people that buy horse feed would be open to trying an insect based feed if it were proven to be beneficial to the horse.

The Conservation of Allostery in *C. Elegans* UDP-Glucose Dehydrogenase

Weston Ellis McDonald, CURO Research Assistant
Dr. Zachary Wood, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

The human enzyme UDP-Glucose Dehydrogenase (hUGDH) catalyzes the NAD+ - dependent reaction of UDP-Glucose to UDP-Glucuronic acid. The product is essential to glucuronidation, a detoxification pathway of drugs in the human body. This process enhances the rate at which drugs are excreted, and leads to many drugs failing clinical trials. hUGDH catalysis is dependent on its hexameric structure, which is allosterically regulated by a downstream feedback inhibitor, UDP-Xylose. The binding of UDP-Xylose in the active site induces the formation of a distinct inactive conformation of the enzyme through the translation of a conserved allosteric switch. Identifying ways to inhibit UGDH by studying the evolution of this switch and the cavities it occupies could provide ways to influence glucuronidation. Bioinformatics studies identified *C. elegans* UGDH (cUGDH) to be one of the more divergent versions of UGDH that still conserve the allosteric switch. Structural studies with cUGDH show that UDP-Xylose induces the same conformational change in the enzyme. Sedimentation velocity studies show that UDP-Xylose stabilizes the cUGDH hexamer in solution. These results suggest that the allosteric mechanism is preserved between the divergent enzymes. However, steady-state kinetic studies show that the affinity for UDP-Xylose in cUGDH is reduced by more than an order of magnitude. Future studies will aim at solving which structural changes in the functional allosteric switch causes a lesser affinity in cUGDH. I am currently refining the X-Ray crystallographic data of UDP-Xylose-bound cUGDH, and will overlay the refined structure to discover any observable differences.

Rapid Control of New Infections with *Trypanosoma cruzi* in Previously Infected Mice

Caroline McElhannon
Dr. Rick Tarleton, Cellular Biology, Franklin College of Arts and Sciences

Chagas disease, caused by infection of the protozoan parasite *Trypanosoma cruzi*, remains the leading cause of human congestive heart failure worldwide. Particularly prevalent in South America, recognition and treatment are limited, and prevention relies primarily on control of the insect vector. In this study, whole mouse imaging and transgenic parasites expressing luciferase were used to monitor control of parasites at the initial site of infection. Unsurprisingly, previously infected mice controlled skin-introduced parasites more effectively than naïve animals. Mice with a chronic infection, though, had significantly greater control of reinfection than mice with an active acute infection. Additionally, this control in chronically infected mice occurred much faster than expected: within 3-4 days post-challenge. This result suggests that a resident population of T cells may be providing early recognition of challenge parasites. However, experiments to test the requirement for resident memory T cells in this rapid control have so far not supported this

hypothesis, and attempts to transfer this phenotype through T cells of chronically infected mice have failed. This early control also does not appear to be dependent on type I interferon, as mice lacking type I IFN receptors exhibit the same patterns as wild-type mice. Future experiments will use T cell depleting and migration inhibiting treatments to determine the role of non-tissue-resident T cells in the very early control of *T. cruzi* infection in chronically infected mice. These results and future studies will inform on mechanisms that may be required for effective vaccination against *T. cruzi* infection.

Fluidity of Identity among Older Gay Men

Maddie McGarrah, CURO Research Assistant
Jacklyn J Byrd
Dr. Denise Clark Lewis, Child and Family Development, College of Family and Consumer Sciences

Using case study analysis, we will explore how two cisgender gay men reach their decision to "come out," revealing their sexual identity. Otis and Harley (2016) propose that identity is constructed by three fundamental components. Identity is (1) socially constructed, (2) fluid, and (3) continuously evolving through social interaction and meaning-making. Using these three components, we consider various individual factors that form one's identity in later life. Possible factors include age, social & community support and values, as well as race or ethnicity. We recognize that it is not feasible to generalize findings from singular case studies to an entire population; however, case study analysis allows us to identify and generalize theoretical positions. In addition to our findings, we will also discuss whether factors identified in these case studies coincide with broader LGBT literature, particularly addressing additional contributing factors in accepting or rejecting one's sexual identity and the pathways that lead these men to revealing their identity to those around them.

Endurance Training in Patients with Friedrich's Ataxia

Nicole McGarrell, CURO Research Assistant
Dr. Kevin McCully, Kinesiology, College of Education

Friedrich's Ataxia (FRDA) is a rare autosomal recessive disease that results from a faulty mitochondrial protein known as Frataxin. Patients with FRDA have progressive loss of motor function. This case report evaluated muscle adaptation to neuromuscular electrical stimulation (NMES) training. A 36-year-old female with FRDA completed twelve 30-minute training sessions using NMES over 30 days. Pre and post measurements of muscle specific endurance and oxidative capacity were taken. Oxidative capacity was measured using near infrared spectroscopy and muscle specific endurance was measured using twitch stimulations and an accelerometer and recorded as an endurance index. Training sessions started with 4,200 contractions and progressed to 9,420 contractions. Muscle-specific endurance increased by 14% at 2 Hz, 17% at 4Hz, and 51% at 6 Hz. No measurable quantitative difference was observed in the patient's mitochondrial capacity. Patients with FRDA are able to be trained via NMES to improve muscle-specific endurance indicated by increases in training volume and endurance index values. It is not certain if mitochondrial capacity in these patients is able to be improved significantly within a measurable range. This study supports the use of the mitochondrial and endurance tests as a way of obtaining outcome measures for clinical trials for people with FRDA.

An Analysis of Early Vocalization Development from the Natural Environment of Two Young Children with Autism Spectrum Disorder

MacKenzie McGraw
Anna Marie Fink, Brianna Kelley, Lauren Langan , Meredith Anne Towey, Alexis Pope, Jennifer Smith, Sherry Sayavongsa
Dr. Sandie Bass-Ringdahl, Communication Sciences and Special Education, College of Education

Autism Spectrum Disorder (ASD) is a diagnosis that includes a wide range of symptoms and levels of impairment. The most common symptom that prompts parental concern is the delay in onset of spoken words, including delayed or disrupted onset of babbling (beyond the typical 6-10 months of age) and gesture usage (Baranek, 1999; Mitchell et al., 2006). Early identification and intervention

are widely recognized as critical to language development and are significant variables in the development of communication (Yoshinaga-Itano, 1998). Children with ASD who have undergone early intervention demonstrate gains in verbal and nonverbal communication, intelligence test scores, and peer interaction (Wiggins et al., 2006). Unfortunately, the diagnosis of ASD often occurs well past the first year of life often, in part, due to the failure of a child to develop spoken language. The current study is an analysis of data from two young participants with ASD. A 12-16 hour vocalization recording was collected in the home using the LENA device. The recording was analyzed to determine the degree of vocalization development and for the presence of canonical babble, a milestone for first word production. In addition, the recordings were analyzed for the presence of background noise, and its impact on each child's productions. The results of this analysis may provide insight into the early vocalizations of children with ASD thus allowing for earlier identification and intervention. The results may also have implications for maximizing learning in the home by modifying the environment.

Effects of 25-Hydroxycholecalciferol on Bone Growth and Development in Laying Pullets

Luke McGrory
Dr. Woo Kyun Kim, Poultry Sciences, College of Agricultural and Environmental Sciences

Avian osteoporosis leads to serious economic and welfare issues in the laying hen industry. Avian osteoporosis, which is very similar to osteoporosis in humans, is described as the reduced activity of osteoblasts with increased activity of osteoclasts. Osteoblasts build bone to be stronger and osteoclasts break down bone. As a result, this leads to a lack of bone density and increased fractures. In order to counteract these issues in laying hens, it is vital to promote proper bone health prior to onset of egg production. One method of fighting osteoporosis in laying hens is through the use of pro-osteogenic agents. 25-Hydroxycholecalciferol (25-OH VitD3), an intermediate of active VitD3, is hypothesized to be a more potent stimulating agent to increase bone density and prevent bone degradation in layers than normal VitD3. The main objective is to evaluate the effects of 25-OH VitD3 on laying pullets. This will be done by introducing the 25-OH VitD3 and normal VitD3 into the diets of two different groups of layers as well as a third control group. From here, bone samples will be collected and analyzed using micro-CT and UV injection dye technologies. We expect that the 25-OH VitD3 will be more effective than both the VitD3 and control groups in promoting bone growth and development. The overall goal is that this study will introduce an effective strategy in allowing for optimal egg production by reducing osteoporosis in laying hens.

A Comparison of Muslim and Jewish Cultural Impacts on Spanish Society in Relation to Punishments for Practicing These Religions during the Spanish Inquisition

Anna Kay McKenzie
Dr. Dana Bultman, Romance Languages, Franklin College of Arts and Sciences

Spanish culture displays a profound Muslim inheritance due to the Islamic kingdoms of the Iberian Peninsula that reigned from 711 to roughly 1492. This influence is seen in the architecture, language, customs, and clothes. Despite the impact on the nation, Muslims within Spain were persecuted greatly during the Spanish Inquisition, which lasted from 1478 to 1834. The persecution, which began under the reign of Ferdinand and Isabel, most famously affected Spanish Jews. The punishment mandated to Spanish Jews was much more severe than that mandated to the Muslims. Interestingly, Jews inhabited Spanish lands for much of Spain's history, yet there does not appear to be as strong a lasting cultural impact from their presence. Due to persecution during the Inquisition, many Muslims and Jews practiced crypto-Islam and crypto-Judaism, respectively. This practice entailed public devotion to Catholicism even though the new converts continued to practice their original religions secretly within their homes. Despite the secrecy, the Catholic rulers discovered these practices and began persecuting those who performed them by holding trials. By examining records of trials during the Inquisition and books discussing the cultural impacts of these minorities on Spain, I aim to find a correlation between the

impact on Spanish culture from the Jews and Muslims with regard to their relative punishment during the Inquisition. Through preliminary investigation, I believe that those who practiced crypto-Islam were persecuted less than those who practiced crypto-Judaism because of the kinds of cultural impacts each group had on Spanish society.

Climate Change and Gene Flow Rates in *Boechera stricta*

Kathryn McKibben, CURO Research Assistant
Dr. Jill Anderson, Genetics, Franklin College of Arts and Sciences

Climate change affects plant populations by altering natural selection on traits and changing the fitness values of current adaptive traits. The research investigates the evolutionary effects of climate change in plants by conducting field and lab studies of the ecological model species *Boechera strica*, a mustard plant native to the Rocky Mountains. To distinguish whether traits are caused by genetic and/or environmental factors and to determine the extent of phenotypic plasticity, we quantify traits of individuals transplanted in five common gardens at varying elevations in the Rocky Mountains. At each elevation, half of the plants were exposed to current climate conditions and the other half were exposed to early snow removal which effectively simulates future climates in this region. I have examined traits such as stomatal density, epidermal cell density, and leaf area. Extensive phenotypic plasticity was found which I will present. We are about to begin a study to determine gene flow rates across populations and ultimately to map quantitative trait loci for traits and fitness using genome-wide association studies. We predict that the amount of gene flow in the populations will not be sufficient to keep pace with climate change. We will collect data on several thousand single nucleotide polymorphisms across the genome to quantify gene flow and allelic turnover. By integrating genotypic and fitness data from the same plant families, we can predict whether gene flow facilitates adaptive response to climate change. Results of this genotyping work may not be available for the CURO presentation.

Testicular Toxicity of Bisphenol AF: Induction of Multinucleation of Spermatogonia

Emily Measel, CURO Research Assistant
Dr. John Yu, Environmental Health Science, College of Public Health

Bisphenol A (BPA) is a widely studied endocrine-disrupting chemical (EDC) due to its potential adverse effects on animals and humans. Many BPA analogs such as BPAF have been synthesized and are now used as substitutes for BPA. However, there is a paucity of information available on the effects of these substitutes on human health and the environment. Using an automated multi-parametric high-content analysis (HCA) in spermatogonial cells, we compared these effects on nuclear morphology, DNA content, cell cycle, cytoskeleton integrity, and DNA damage responses. BPAF exhibited higher testicular toxicities, especially the formation of multinucleation (MNG) of spermatogonia as compared to BPA. Induction of MNGs has been reported following gestational exposure EDC, and may link to the testicular dysgenesis syndrome (TDS). However, the molecular mechanism is still unclear. In this study, we tested the hypothesis that the formation of MNGs is due to the failure of cytokinesis after exposure to BPAF, resulting from alterations of mechantransduction pathways such as Src, p190, RhoA, lamin A/C, and LINC complex. Dose and time-dependent alterations of these proteins were examined using Western blot analysis. Furthermore, we developed a single cell based HCA to examine the temporal and dose-dependent alteration of protein expression of lamins, LINC complex components SUN1, SUN2, as well as p190. We found alterations of lamin A/C and p190 were associated with nuclear morphology, cell cycle progression, and cytoskeleton integrity. Understanding the mode of action of BPAF induced MNGs will provide essential information for the risk assessment for the safety of the public.

Admit One: Analyzing the Myriad Pathways into the Design Industry

Reilly Megee, Foundation Fellow, CURO Research Assistant
John Weatherford, New Media Institute, Grady College of Journalism and Mass Communication

This research will dive into the ever-evolving industry of design. In today's professional climate, design is becoming increasingly recognized as pivotal, as efficiency and aesthetics become paramount to survival in the business world. As all eyes turn towards design, the field and the people within it are being put under the microscope. This research will examine how design professionals, with their myriad skills and backgrounds, find their way into the industry. It will focus on the path designers take to enter the field and the challenges they face while doing so. How do people become aware of different design-centric career paths, and how do they know when or how to choose those paths? In addition, this research will look into whether the gender, race, and sexual orientation of designers present additional challenges to entering the field. Primarily, data will be gained through in-depth interviews with current design professionals. This data will be analyzed, supplemented with outside data, and presented in a public, online format. In examining this topic, this research hopes to uncover places where design education and awareness could be improved, including, but not limited to, secondary education, higher learning, and specific geographic areas of the US. It contends that there are large gaps in education and awareness about design-based careers and seeks to draw attention to this deficiency, should one be found.

Trait Activation Theory and Academic Performance: Does Academic Major Moderate the Relationship between Personality and Academic Performance

Arturia T Melson-Silimon, CURO Research Assistant
Dr. Nathan Carter, Psychology, Franklin College of Arts and Sciences

Within the field of personality psychology, researchers have long been engaged in the debate regarding the relative influence of personal attributes and situational features on human behavior known as the "person-situation debate." In recent years, interactionist perspectives such as trait activation theory (TAT) have been suggested as a possible solution to this debate. TAT posits that situational cues serve to strengthen or weaken the influence of personality on behavior. TAT has been mostly explored in the workplace, but seen little attention in the academic setting. The purpose of this study is to explore TAT in academic settings by studying how the situational cues associated with one's major influences the relationship between personality and academic performance. It is predicted that the relationship between personality and academic performance, as measured by GPA in the major, will depend on the correspondence between the cues by different academic majors and the personality trait studied. For example, although openness to experience may have little influence on performance in engineering courses, it may have strong influence on performance in visual arts. To test this hypothesis, 300 undergraduates of various majors will be randomly selected to participate in this study. Participants will complete an online self-report survey measuring personality and academic performance. Regression analyses will be conducted to evaluate the relationship between personality and academic achievement by major. Results of this study will further advance the field by leading to a better understanding of the relationship between personality and academic achievement.

Glycome Profiling of Medaka Exposed to Chronic, Low Level Ionization Radiation

Olivia Mendel
Dr. Carl Bergmann, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Within the United States there are over 1000 locations that are contaminated with radiation. Although this ionizing radiation (IR) can have beneficial applications, the long-term health implications are still unknown. Using medaka fish as the model organism, the overall aims of the project are to quantify proteomic and glycomic responses of medaka across varying levels of chronic doses of IR. This project focuses specifically on N-linked glycosylation in the intestines of medaka. N-linked glycosylation occurs through a highly conserved process, and affects many properties of proteins including conformation, solubility, and antigenicity. N-glycans play important roles in cell signaling and the immune response. At the Savannah River Ecology Lab, medaka fish were irradiated with 0.1 mGy, 2mGy, 20mGy and 200 mGy IR for 6 months to allow for chronic accumulation. They were then dissected into carcass (including eyes

and brain), organs, and intestines. N-glycans were obtained by enzymatic hydrolysis using PNGase F followed by MALDI-TOF and ESI-MS and bioinformatic analysis. Thus far, glycome analysis has revealed significant differences in the glycan composition and abundance of the control intestine as compared to the treated samples. There are also notable differences between the glycan composition in the intestine and carcass samples. Identification of the glycan structures is still in progress. These findings will aid in elucidating the physiological responses of organisms to chronic, low dose IR.

Evaluation of Residential Basement Wall Concrete Mixtures for Water-Tightness and Reduction in Traditional Reinforcing Steel

Jake Michael, CURO Research Assistant
Dr. Stephan A Durham, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

The Atlanta housing market is expected to grow 7% in total households during the next five years. With this potential economic opportunity, it is advantageous to develop innovative methods of constructing more economical homes. Ready Mix USA is interested in evaluating concrete mixtures for basement walls that provide equivalent water-tightness to that of current installation methods and have the potential to decrease the required area of temperature and shrinkage steel. The 2015 International Residential Code (IRC) requires foundation walls that retain earth and enclose interior spaces and floors below grade to be dampproofed. This study evaluated novel concrete mixtures for use in basement walls that satisfy the IRC without having to provide an exterior damproof/waterproof membrane and the novel mixture that utilized a permeability reducing admixture was found to reduce the seepage through concrete specimens. This study also examined the use of macrofibers and shrinkage reducing admixtures to potentially reduce the reinforcement required in the basement wall. This allows for a quicker and more economical installation of residential basement walls. The study was completed in three phases (1) establishing the property characteristics of novel concrete mixtures, (2) modeling and analyzing basement walls with the novel concrete mixture using Finite Element Analysis, and (3) constructing a full-scale basement wall to demonstrate the placeability of the novel concrete mixture.

Nanocellulose Based Drug Loaded Micro/Nanoparticluate for Therapeutic and Drug Fate Analysis

Betsi Micholas
Dr. Jaya Sundaram, Chemical, Materials, and Biomedical Engineering, College of Engineering

Nanoparticles provide massive advantages regarding controlled and targeted delivery with their potential to combine diagnosis and therapy, emerge as one of the major tools in nano-medicine. Curcumin has anti-cancerous and anti-inflammatory benefits, specifically for the colon. The main issue with drug delivery to the colon is that the drug often degrades in the gastrointestinal tract before reaching the colon. Encapsulation of drug into bio-based polymer is a common practice in pharmaceutical industries. Nanocellulose is classified as a biopolymer and has unique properties allowing it to be a good candidate for site-specific drug delivery through nano-encapsulation. This project is proposed to make nanocellulose encapsulated curcumin nanoparticles to have site-specific controlled delivery at the colon. Cellulose nanocrystal (CNC) was dispersed in water and used to encapsulate curcumin. A measured amount of curcumin was dissolved in the required amount of ethanol, and added slowly to CNC solution by continuously stirring the mixture. Once the mixture was homogeneous, it aged for 24 hours and curcumin encapsulated CNC particles were separated using vacuum filtration. The filtered cake was dried at low temperature in a vacuum dryer and stored for further analysis. Analysis of curcumin-loaded nanoparticles follows surface morphology analysis, physicochemical analysis, bioavailability, biodegradability and in vitro release study using artificially simulated intestinal and stomach fluids. The specific aims are to have a controlled delivery of the drug in the intestinal fluid and to increase the bioavailability of curcumin. The developed nanoceullose encapsulated curcumin will improve the current drug delivery methods of colon cancer treatments.

The Call of the Crypt Keeper: E.C. Influences in the Films of George A. Romero

Audrey Miller, CURO Research Assistant
Dr. Christopher Sieving, Theatre and Film Studies, Franklin College of Arts and Sciences

When discussing the foundations of his style, George A. Romero, like many 'Horror New Wave' directors of the 1960s and 70s, frequently and unapologetically points to the early influence of popular 1950s titles from the notorious Entertaining Comics (E.C.) over the horror films of his childhood. While this nod to comics is reasonably well documented—he felt indebted enough to direct an explicit homage in 1982's *Creepshow*—few studies have attempted any closer interpretation of the kinships between the two horror mediums. This paper will ask more explicitly what it means for a film or director to claim a distinctly comics-inspired style. Grounded in discussions of the visual, narrative, and thematic connections between E.C. stories and Romero's film texts, this paper argues that Romero's comics-inspired style, more than constituting a passing anecdote, can be precisely articulated and its functionality as a means by which Romero broke from previous cinematic horror traditions explained. This paper will further demonstrate how a film like Romero's 1968 *Night of the Living Dead*, through its more adept integration of a comics visual style into a language coherent as film, represents a more compelling application than *Creepshow*, which insistently, though arguably superficially models itself after E.C. anthology comics. Though much of the discussion surrounding film and comics is about the incommensurable differences of language that often give rise to ineffective adaptations, this paper argues that Night represents a site for considering how the two mediums can be used productively together.

Self-Assembled Chitosan Nanoparticles for Breast Cancer Therapy

Jeremy Miller
Dr. Cheryl Gomillion, Chemical, Materials, and Biomedical Engineering, College of Engineering

Breast cancer is among the most common causes of death among women in the United States, with a mortality rate slightly less than the second most common cancer, lung cancer. Typically, breast cancer therapies target hormone receptors for estrogen, progesterone, and HER2 for delivering the drugs to the tumor cells; however, triple-negative breast cancer cells lack all three receptors, and thus cannot be treated with conventional therapies. These commonly used drug therapies are unable to permeate into the tumor cells without a receptor to mediate drug uptake. To circumvent this, drugs can be loaded into nanoparticles small enough to permeate freely through the membrane without the use of the hormone receptors. Therefore, the objective of this work was to fabricate and characterize polymeric nanoparticles useful for treating these specific tumor cells. Chitosan was selected as the biopolymer of choice for this application. Chitosan, a polysaccharide derived from the deacetylation of the chitin, has multiple unique properties that make it ideal for drug delivery. Specifically, it is biocompatible, maintains antimicrobial and analgesic properties, and its positive charge allows it to act with the negative part of cells' membranes. Chitosan nanoparticles were successfully prepared via self-assembly with tripolyphosphate (TPP). Current and future work includes determining the viability of these particles as a drug delivery vehicle for cancer therapy. Fabricated particles will be characterized to assess drug loading capacity, drug encapsulation efficiency, etc. The particle shelf-life and batch reproducibility will be important factors for determining the efficacy of these particles for cancer therapy.

Refugee Health and Migration

Prabhjot K Minhas, Ramsey Scholar
Dr. Susan Tanner, Anthropology, Franklin College of Arts and Sciences

In today's globalizing world, migrant and refugee health has become an increasingly important topic in public health, medicine, and anthropology. Research suggests that understanding the backgrounds of migrants helps in the delivery of high quality healthcare. This research focuses on nutrition and health within refugee populations and is part of a larger, ongoing project designed to understand the relationship between acculturation and maternal-child health in the US. Specifically, I conducted a literature review to examine

healthcare experiences among US refugees. Research themes concerning refugee health and migration were traditional medicine, nutrition and health, obstacles to healthcare, and the effect of language and culture on the healthcare experience. The literature suggested that health and nutrition changes in resettled migrants, and the next generations, are influenced by interactions of culture, history, language, ethnicity, and social relationships. A second literature review focused on the Karen refugee community, diet, and nutrition. Overall, both literature reviews showed that much research has been conducted on diet and nutrition change among refugees and migrants; however, little has investigated refugees' and migrants' perceptions of these changes. To study the perception of food and diet changes, I have developed a set of nutrition and diet-related questions to be included in a questionnaire exploring maternal-child health. Throughout the semester, I will investigate the role of perceived quality of diet and nutrition among refugees and migrants in the Athens area. The information gathered with this research has the potential to help healthcare professionals better understand and work with patients.

Employer Expectations and Experiences of Gratitude

Molly Eleanor Minnen, CURO Research Assistant
Dr. Michelle R vanDellen, Psychology, Franklin College of Arts and Sciences

Gratitude—recognition of goodness outside the self—is a positive emotion often experienced in close relationships. Research has not yet examined how work-related traits (e.g., self-control) affect experiences of gratitude at work. We expect employers may feel more grateful when a low self-control employee performs an organizational citizenship behavior (OCB) or resists a counterproductive work behavior (CWB) than when a high self-control employee performs or resists the same behavior. In prior work, we observed employers to be habitually grateful for high self-control employees. Thus positive extra-role behaviors or resisted missteps may not produce a material increase in gratitude. When a low self-control employee exceeds expectations, employers may experience noticeably more gratitude. The goal of this study was to assess both trait and state gratitude for employees. Specifically, we examined how employers react to employee work behaviors. Participants imagined they were a supervisor in a company and were randomly assigned to read about either a high or low self-control employee. They were additionally randomly assigned to read a report of an OCB or a CWB taking place at the office. Participants learned the target employee either committed the OCB or did not commit the CWB. We assessed their reactions. We found that participants expressed more trait gratitude for high self-control employees but more state gratitude for low self-control employees. Results from this study could provide novel insight into why low self-control employees might receive more recognition for positive behaviors than high self-control employees.

Redefining the Boundaries of Healthcare Technology Policy

Simran Modi, CURO Research Assistant
Dr. R. Vincent Pohl, Economics, Terry College of Business

In recent years, the rise of healthcare technology such as mobile applications, telemedicine, and remote patient monitoring systems has become more prominent. However, the regulations that govern these devices and applications are not clear and do not serve to benefit the patient population. In 2011, Teladoc, a telemedicine company, filed a suit against a Texas Medical Board for limiting the scope of telemedicine practice. Other cases and lack of clear definition call for a meta-analysis to assess these policies. This study examines several state policies that can be expanded to the federal sphere in order to benefit the patient population. The purpose of this study is to identify policy initiatives that will provide clarity for the scope of practice and use of medical technology. The effectiveness of the healthcare technology policies will be analyzed using three criteria: cost of policy implementation, economic benefits, and expanded accessibility to healthcare. The analysis will point towards extended benefits and appropriate implementation techniques.

The Language of Leadership: Investigating Speech as a Predictor of Leadership Capacity

Amanda Moeller

Dr. Karl Kuhnert, Psychology, Franklin College of Arts and Sciences

Previous research done on leadership indicates that there are four distinct levels of leadership maturity that individuals can possess, each of which are characterized by distinct behavioral patterns, perceptions, and priorities (Kegan, 1982; 1994; Kegan & Lahey, 2009; Eigel & Kuhnert, 2016). These four Leadership Development Levels (LDLs) are appraised to individuals by multiple raters who conduct and evaluate their in-person interviews and assess according to criteria outlined by Lahey, L., Souvaine, E., Kegan, R., Goodman, R., & Felix, S. (1988). LDLs have been found to be predictive of job performance, even surpassing the predictive ability of the Big 5 personality assessment and 360-degree performance feedback ratings. (Strang & Kuhnert, 2009). Using transcribed in-person interview text as well as language and text-processing software, such as the Linguistic Inquiry and Word Count (LIWC) software developed by Pennebaker & Francis (1996) and The University of Cambridge Psychometrics Centre's Apply Magic Sauce (AMS) word processing engine, this study will aim to analyze the language of leadership by seeking out differences in speech indicative of emotional state, personal concerns and priorities, and different thinking styles between LDLs. Our sample consists of nine Fortune 50 executive leaders' transcribed interviews that span across each of the four LDLs. Each transcription ranges between 3436 and 9685 assessable words. If significant language-based differences between LDLs are found, it may result in a new quantitative method being applied to judge potential employees' leadership capacity.

Small Molecule-Stimulated MSC Adhesion to Enhance Atopic Dermatitis Therapy in Companion Animals

Adir Mohaban, CURO Research Assistant
Dr. Luke Mortensen, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Decades of research have shown the potential of stem cells therapies as a remedy for chronic illnesses due to their anti-inflammatory and immunomodulation capabilities. While there is much hope for viable stem cell therapies, a major limitation can be linked to inefficient cell homing due to poor expression of surface adhesion receptors. Could surface modification of MSCs allow for more efficient homing? In a previous study, pretreating MSCs with Ro-31-8425, a molecule shown to upregulate the *CD11a* gene which codes for surface receptors, led to an increase in static adhesion to plates coated in intercellular adhesion molecule 1 (ICAM-1). ICAM-1 is expressed in increased levels by endothelial cells at sites of inflammation. In this study, we hope to expand on this by observing static and shear adhesion levels of pretreated MSCs to canine endothelial cells expressing ICAM-1. This will be accomplished by inducing shear stress over MSCs firmly adhered to endothelial cells (static adhesion) or by flowing MSCs over an endothelial cell monolayer (flowing adhesion) at measured levels of shear stress, using a syringe pump and a parallel plate flow chamber. White blood cells will be used as a positive control for comparison. We expect to observe increased adhesion of pretreated MSCs to the endothelial cells. This would indicate the possibility of using MSCs pretreated in Ro-31-8425 as a viable therapy for diseases causing inflammation, such as atopic dermatitis. We hope to move on to clinical trials with diseased canines once we determine the efficiency of pretreated MSC homing.

The Difference Between Men and Women in the Effects of Exercise on Circulating Angiogenic Cells

Sydney Michelle Mohr, CURO Research Assistant
Dr. Nathan T Jenkins, Kinesiology, College of Education

Physical activity reduces the rates of cardiovascular mortality by several mechanisms including promoting angiogenesis and increasing shear stress. Previous research has shown circulating angiogenic cells (CACs) are affected by exercise. CACs are specialized white blood cells, more specifically peripheral blood mononuclear cells (PBMCs), which can maintain vascular homeostasis, repair the injured vascular endothelium, and promote angiogenesis. We hypothesize that women, especially those in the luteal phase, will experience greater exercise induced increases in the number and function of CAC compared to men. Thus far 4 men have had

a body composition test and performed a graded maximal energy test on a stationary bike. Cell isolation and flow cytometry were performed on blood drawn from participants at baseline and post exercise. The results showed an increase in CD16+, CD14+CD16+ and CD14-CD16+ cells and a decrease in CD3+, CD14+, CD14+CD16- and CD34+ cells. The decreases in CD14+ and CD14+CD16- were expected due to their pro inflammatory affects but the other results were not. These results were inconclusive due to the small sample size and lack of women participants and will be continued in the spring.

Comparing Activity Budgets between Adult and Juvenile Asian Elephants

Nam Money, CURO Research Assistant
Dr. Vanessa Ezenwa, Ecology, Odum School of Ecology

The slow growth and development rate of Asian elephants (*Elaphus maximus*) is directly linked to the length of their lifespan, which can be as long as 70 years in the wild. This suggests that behavioral differences between juvenile and adult elephants can be very prominent. However, there has been limited research on differences in elephant behaviors based on age. In this study, the behavioral activity budgets of six semi-wild elephants were observed at the GVI Thai Elephant Project in Northern Thailand. Since half of the elephants were juveniles and the other half adults, the objective of the study was to discern if knowledge and learning causes older elephants to perform activities indicating a higher understanding of environment. This main hypothesis was tested by investigating four specific hypotheses: (1) The activity budgets of adult elephants will be less diverse than those of juvenile elephants (2) Adult elephants will be more sedentary (3) Juvenile elephants will exhibit more exploratory behaviors, and (4) Adult elephants will walk more, as they are more familiar with the area and have more experience. Behavioral differences between adult and juvenile elephants did not appear to differ significantly for any of the hypotheses. Thus, none of the hypotheses were supported by the data. By better understanding age related behavioral differences in elephants, conservation measures can be tailored to specific populations of elephants based on their ages. More thorough and comprehensive research should be conducted on this topic to better test the hypotheses.

Double-Deficit Hypothesis for Dyslexia: A Meta-Analysis

Mary Elizabeth Moody, CURO Research Assistant
Dr. Jason Nelson, Psychology, Franklin College of Arts and Sciences

Although the phonological theory of dyslexia has dominated the research literature over the past several decades, a more recent theory – the double-deficit hypothesis (DDH) – has received increased attention and has potentially significant implications for the identification and treatment of individuals with dyslexia. Three subtypes are purported within the DDH model, including a phonological deficit (PA) subtype, naming speed deficit (NS) subtype, and double-deficit (DD) subtype. The purpose of this study was to conduct a meta-analysis to determine if those with the different deficit subtypes differed in their reading skills in the way predicted by the DDH. Inclusion criteria were that studies (a) used a group design, (b) categorized groups according to the DDH subtypes, (c) compared at least two of the subtypes on a reading measure, and (d) reported statistics necessary for calculating effect size. Of the 193 studies reviewed, 22 met these criteria. The hypothesis that the DD subtype experiences more impaired reading skills than the other subtypes was confirmed. The DD subtype had lower reading skills than both the PA and NS subtypes, with effect sizes in the medium range for both comparisons. The PA subtype had lower reading accuracy than did the NS subtype, and the NS subtype had lower reading fluency than did the PA subtype. However, each of these effect sizes was in the small range. The hypotheses of the DDH were confirmed, although the effect sizes were substantial only for the hypothesis that the DD subtype has more impaired reading skills than the PA and NS subtypes.

Likely Leaders: The Influence of Big Five Personality Traits on Leadership Dynamics

Alex Moore, CURO Research Assistant
Gabrielle Moriah Richie, Carissa Urrea, Diana Enriquez, David Wyrembelski

Dr. Dorothy Carter, Psychology, Franklin College of Arts and Sciences

Leadership theorists are increasingly conceptualizing leadership as a relationship that is co-constructed as two or more people 'claim' and 'grant' influence (DeRue & Ashford, 2010). Although certain individuals may be motivated to influence others, the endorsement of followers (i.e. granting) is necessary for leadership to occur. The purpose of the present study is to test two hypotheses. First, we expect that an individual's levels of Big Five personality traits of (H1a) extraversion and (H1b) conscientiousness will positively predict the likelihood that they are granted leadership influence by their teammates. Second, we hypothesize that the Big Five trait of agreeableness (H2) will positively predict the likelihood that individuals will grant leadership to others. We test our hypotheses in a sample of 240 undergraduate participants assembled into 20 unique 12-member teams that were tasked with combining disciplinary knowledge in a complex problem-solving task. Participants responded to self-report sociometric measures of leadership claiming and granting in relation to their teammates. We test our hypotheses using a class of inferential models of network emergence called exponential random graph models, which identify key predictors of networked relationships.

The Effect of Galanin on Stress Resilience in Rats and the Relationship between Stress and Inflammation

Emily Stewart Moore, CURO Research Assistant
Dr. Philip Holmes, Psychology, Franklin College of Arts and Sciences

Galanin is a neuropeptide that modulates the actions of classic neurotransmitters in the central and peripheral nervous system. It has three G-protein coupled receptors, GALR1-GALR3, that have been shown to influence depression and anxiety disorders. Several studies have been done on galanin's effects on anxiety-like behavior in different animals, with variable findings depending on animal species, injection site, and behavioral models used. This study focuses on the effects of galanin on stress resilience in male Sprague-Dawley rats, as well as the relationship between stress and inflammation, which has been shown to induce anxiety-like behavior in animal models. Complete Freund's adjuvant (CFA) was injected into the back-left paw of rats to induce chronic inflammation in the area, then galnon, a galanin receptor agonist, was injected into the peritoneum for the following nine days. Control rats were injected with saline. Following injections, rats were exposed to stress via the forced swim test, then underwent a series of behavioral tests (sucrose preference, open field, and elevated plus maze) to test for anxiety-like behavior, exploratory behavior, and locomotor activity. Brain tissues were processed using ELISAs and HPLC for galanin and monoamine content. CFA is expected to increase anxiety-like behavior in the elevated plus maze, open field, and sucrose preference tests, while galanin is expected to block the effects of CFA. Dopamine is expected to decrease in the ventral striatum as an effect of CFA and galanin is expected to decrease in the ventral tegmental area.

Development of an Indoor Guidance System for Unmanned Aerial Vehicles with Power Industry Applications

Julian Moore, CURO Research Assistant
Dr. Zion Tse, Electrical and Computer Engineering, College of Engineering

Unmanned aerial vehicle (UAV) systems are experiencing a period of rapid growth as the constituent technologies are reaching maturity and the potential for industrial and commercial applications are arising. Conventional UAV technologies focus on outdoor large area navigation, utilizing GPS, which has proven to be less effective in enclosed environments. We aim to develop an indoor navigation system, specifically designed for these industrial applications which require custom sensing technologies to aid in pilot navigation. A custom sensing array, featuring ultrasonic transceivers used to measure displacement and a hardware angle correction system, was developed to localize drone position in an enclosed known environment and provide pilot feedback during navigation. Six subjects were recruited to pilot the drone with and without the navigation system in an enclosed room to a preset target at a known location in two cases: (1) with a clear line of sight, and (2) without line of sight. Flight duration, number of collisions, and distance from target were recorded and used to quantify performance of the navigation system. Upon using

the navigation system, subjects were able to reduce their flight duration on average by 19.7% during an obstructed line of sight, illustrating the increased ability and confidence in piloting the drone using the navigation system. This study serves to prove the potential of this device as an essential tool for indoor drone localization and commercial inspections.

Effect of Heliox through Airflow and Aerosol Deposition in Oral Airway

Miranda Moore, CURO Research Assistant
Dr. JongWon Kim, Engineering, College of Engineering

It is feasible, in principle, to treat breathing difficulty using Heliox (rather than air). The main effect of Heliox usage is to transform turbulent flows into laminar flows. Heliox (20% Oxygen, 80% Helium) has approximately five times lower kinematic viscosity. For a given inhalation velocity, the Reynolds number is five times less than air. The objective of this study is to investigate the effect of Heliox flow in an oral airway through airflow characteristics and particle deposition with an oral airway model. Specifically, one normal condition with air is simulated, and this is compared using Heliox. Lagrangian tracking models were used to simulate the respiratory airflow and aerosol dynamics. Apparent discrepancies in airflow characteristics and aerosol distributions were observed by Heliox transport. Furthermore, Heliox flow compared to airflow gave a different aerosol pattern that was clearly suggestive to treat breathing problems. For any given breathing problem, Heliox persists for different particle sizes considered, even though their detailed distributions vary. Results of this study indicate that the use of Heliox led to less particles deposition due to the intrinsic properties of the gas phase. Heliox with inhaled aerosols appears to be non-invasive enough to be a practical tool for respiratory system, which may disclose clinically relevant clues about the severity of respiratory disease.

Are Urban Birds in South Florida Reservoirs of *Salmonella spp*. for the American White Ibis (*Eudocimus albus*)?

Tyler Moore
Dr. Sonia Hernandez, Forestry, Warnell School of Forestry and Natural Resources

In the last two decades, populations of the American White Ibis (*Eudocimus albus*) have become increasingly more urbanized in South Florida. This sudden urbanization has given rise to an increase in contact between the White Ibis, various other species of urban birds, and people. Urban birds (e.g. wading birds, waterfowl) with which White Ibis come into direct, frequent contact may be reservoirs for *Salmonella spp*. and may play a role in the infection rate of white ibis. In previous studies, the prevalence rate of *Salmonella* of white ibis averaged 13%. Due to increased contact, we predict that the prevalence of *Salmonella spp*. will correlate and, as potential reservoirs, might be higher than the White Ibis. In order to discover if urbanized birds are reservoirs of *Salmonella spp*. for the American White Ibis, fecal samples were collected from waterfowl and wading birds from four urban sites in Palm Beach County, Florida. Simultaneously, we collected feces from white ibis at the same sites. *Salmonella spp*. was isolated from various species, including Muscovy ducks (*Cairina moschata*) and Mottled ducks (*Anas fulvigula*), at a prevalence of 19.1%, at four urban sites. *Salmonella* isolates were submitted to the National Veterinary Laboratory to determine serotype and strain type, allowing us to further understand the relationship between *Salmonella* isolated from ibis and other birds at these sites. Overall, understanding the mechanistic effects of wildlife interactions due to human-dominated landscapes will help us to better control our impacts on wildlife ecosystems and the spread of pathogens among them.

Development of a Novel Three-Dimensional Model to Study Breast Cancer Metastasis

Bryanna Moppins
Dr. Cheryl Gomillion, Chemical, Materials, and Biomedical Engineering, College of Engineering

The mechanism behind breast cancer metastasis, or spreading, to patient bones is poorly understood. This may be attributed to the usage of traditional two-dimensional (2D) culture surfaces to study breast cancer cells, which lack structural properties of native tissues in the body. Tissues of

the body are composed of multiple layers of cells, forming three-dimensional (3D) structures. In addition, breast cancer cells secrete signals to neighboring cells that stimulates migration to other regions of the body, so utilizing a 2D surface limits the actual amount of signaling that takes place. Therefore, we aim to study breast cancer cells on a 3D surface because they will ideally behave more closely to how they would in the body. Our 3D system for modeling breast cancer metastasis to bone will be composed of chitosan-based hydrogel scaffolds that will be modified to mimic two different tissue types (soft breast tissue and hard bone tissue). Preliminary studies to evaluate breast cancer cell viability on plain chitosan scaffolds were performed using three breast cancer cell lines of varying subtype, including MCF-7, MDA-MB-231, and HCC1806 cells. Results from the preliminary studies indicated that the chitosan-based scaffolds were able to support breast cancer cell growth. Current and future work will include development of protocols for fabricating and characterizing the composite bone scaffold consisting of varying concentrations of chitosan and calcium phosphate to help answer the question of how the degree of stiffness of bone affects tumor cell behavior.

Clay Mineral Concentration with Depth and Land Use History in the Critical Zone in Calhoun, South Carolina

Tony Moraes, CURO Research Assistant
Dr. Paul A Schroeder, Geology, Franklin College of Arts and Sciences

History of land use at the Critical Zone Observatory (CZO) in Calhoun, South Carolina has been well documented and studied. Land use, climate, biotic factors and topography all contribute to rates of chemical denudation (mass loss) and chemical weathering (mineral transformations). This comparative study contrasts clay mineral assemblages in a hardwood plot, which has not had recent anthropogenic influence, and an adjacent reforested pine plot that has been historically farmed. Methods used to characterize the soil cores taken from the respective plots include X-ray diffraction of oriented clay fraction with treatments of K-, Mg-, and Na- saturation in the air-dried, ethylene glycol (EG), and heated (100O, 330O, and 550OC) states. Based on weathering intensities, early end member minerals with little weathering are biotite and muscovite, while the other end member is thoroughly weathered kaolinite soils. Bedrock at the Calhoun Experimental Forest is Neoproterozoic gneiss, which shows a progression of micas, interlayered vermiculite, vermiculite, smectite, interlayered kaolin-smectite, and kaolin with increasing depth. In shallow depths of older profiles, kaolin-smectite interlayering should be apparent due to the long time for weathering and erosion. Smectite should be seen at greater depths of younger profiles using the same reasoning. From 240 XRD patterns of varying depths and methods, smectite interlayering begins at 40 centimeters at the hardwood site and at 100 centimeters at the pine site. This data is consistent with the predictions of where smectite interlayering should be found.

Identifying Novel CAAX Motifs Using YDJ1 as a Reporter

Michael Christian Morgan, CURO Summer Fellow
Dr. Walter K Schmidt, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

CAAX proteins are commonly involved in carcinogenesis and many are targets of therapeutic strategies. Mutations in Ras GTPase proteins- a subset of CAAX proteins- cause roughly a third of all human cancers and 95% of all pancreatic cancer. To better understand the signal transduction pathways that involve CAAX proteins, the Schmidt lab investigates the post-translational modifications (PTMs) that regulate the activities of CAAX proteins. CAAX proteins receive three distinct modifications at their C-terminus: isoprenylation, proteolysis and carboxylmethylation. Using the yeast model, the Schmidt lab has recently discovered a novel branch to the standard PTM pathway herein referred to as the shunt pathway. In this pathway, CAAX proteins complete isoprenylation but are not subsequently modified. Ydj1 is a heat-shock protein that uses the shunt pathway. This project takes advantage of Ydj1p to identify CAAX motifs that promote isoprenylation. A plasmid library encoding Ydj1 CAAX mutants was created by standard molecular biology techniques (e.g. PCR), transformed into yeast, and screened for motifs that promote isoprenylation using a Ydj1-

dependent thermotolerance growth assay; shunted motifs allow growth at high temperature. The Ydj1-endoding plasmids were isolated and sequenced, yielding 123 novel CaaX motifs that allowed for strong isoprenylation of Ydj1. Analysis of these sequences is being used to determine a set of rules that can predict isoprenylation better than current prediction methods, and to determine whether all or part of the sequences promote shunting.

An Analytical Evaluation of the Compounding Skills of Pharmacy Students

Kyana Breche' Morris
Dr. Deborah Lester Elder, Pharmaceutical and Biomedical Sciences, College of Pharmacy

According to the FDA, compounding pharmacy is a specialty in which a pharmacist "alters drug ingredients to create a medication tailored to… a patient." The American Association of Colleges of Pharmacy (ACCP) assembled a committee that offered its member institutions recommendations on their compounding curriculum. This study evaluates the compounding techniques of pharmacy students at the University of Georgia's College of Pharmacy based on the guidelines set forth by ACCP. The analysis included, second year pharmacy students (n=137) who compounded a 1mg/mL aqueous solution using salicylic acid powder, USP 99.5% purity and a 1mg/mL aqueous suspension from prepared 10mg salicylic acid tablets. After being stored at -2°C, suspension samples were thawed at room temperature and centrifuged at 5,000 RPM for 10 minutes. Solution samples were not centrifuged following thawing. To acquire the theoretical concentration of 0.01mg/mL, 0.25mL of each sample was transferred to a 25mL volumetric flask and diluted with distilled water. The dilutions were thoroughly mixed before transferring 8mL to test tubes and adding one drop of ferric nitrate reagent. Ultraviolet spectroscopy was used to determine the concentrations of each sample. Sample concentrations were compared to linear concentration curve made from a 1% salicylic acid stock solution. The results displayed that roughly 30% of students were able to compound within the deviations set by ACCP. This proves that quantitative analysis is indeed a useful way to measure the compounding skills of pharmacy students. Further continuation of this study will hopefully show that students can improve their skills over time.

Pregnancy Planning and Prevention

Andrea L Morrison, CURO Research Assistant
Dr. Kathrin F Stanger-Hall, Plant Biology, Franklin College of Arts and Sciences

Unintended pregnancies and the results of those pregnancies are important and pertinent issues in modern society. By analyzing the effectiveness of current education strategies and examining their shortcomings, researchers can improve upon those strategies in order to best prevent unintended pregnancies. The purpose of this research study is to analyze and evaluate the knowledge of UGA students regarding sexual health topics. In particular, this study focuses on the data analysis of pregnancy planning and prevention. The data were obtained via an anonymous, online survey sent out to all UGA undergraduate students in spring 2015. I quantified and analyzed all answers to the survey questions on sexual health, pregnancy prevention, and fertility awareness. The results demonstrate what information UGA students do and do not know about reproductive health, and also reflect the students' opinion on topics such as sex education and family planning. These topics are often under-discussed and under-reported for young adults, making an accurate account of their knowledge and a concrete plan for improvement difficult. This study will be a first step to changing this lack of knowledge by sharing the results with the University Health Center as well as opening a door to collaboration with the Health Center to develop educational materials.

Discovery of Foliar Endophytic Nitrogen Fixation in *Pinus palustris*

Kelsey Morton, CURO Research Assistant
Dr. Nina Wurzburger, Ecology, Odum School of Ecology

Longleaf pine (*Pinus palustris*) savannas are highly diverse ecosystems that once dominated the Southeastern United States, covering 94 million acres. The distribution of this ecosystem has been greatly reduced due to land-use change, but recent restoration efforts have increased its coverage to 4.3 million acres. Therefore, many longleaf pine

savannas are in early stages of development and require a substantial amount of nitrogen (N) to grow. Longleaf pine savannas are N-limited and known inputs of N (from herbaceous N-fixing legumes) do not account for N demand by growing pines. Here, we investigated whether longleaf pine foliage contains bacterial endophytes that fix N, and whether the rate of endophytic fixation differs across stand age and site. We collected foliage from plots along an age gradient at two sites in GA and FL. We used acetylene reduction assays on surface-sterilized foliage samples to quantify N fixation. We detected significant fixation activity in foliage from both study sites. We found that fixation rate did not differ by stand age but was greater at our FL site than our GA site. This finding suggests that heterogeneity in soil nutrients, climate, or other factors may affect the capacity of endophytes to fix N. Our future work will explore these possibilities. Endophytic N fixation is thus a newly discovered source of N to longleaf pine savannas, and determining the factors that control this biotic process will improve our resolution of the nitrogen budget of these ecosystems.

Comparing the Incomparable: A Methodological Investigation of Water Limitation Treatments

Liana Mosley, CURO Research Assistant
Dr. John Burke, Plant Biology, Franklin College of Arts and Sciences

As climate change progresses, environmental conditions will become increasingly unpredictable, burdening Earth's fragile resource supply. Agricultural crops are no exception to this trend, specifically considering the resource of water. Agricultural drought, or water limitation stress, has been shown to negatively affect crop productivity, reducing crop yield necessary for human consumption. To mediate the effects of drought, plant scientists aim to develop methods that increase water use efficiency across crop species. While there are many valid ways to implement water limitation stress in a laboratory setting, often times, results gathered utilizing one method are compared with results using a different method. To determine the comparability of water limitation methods in cultivated sunflower, we established seedlings of three diverse genotypes for 25 days followed by a 10 day water limitation stress. Water limitation was simulated with four treatments: two osmotic stresses, polyethylene glycol (PEG-6000) and salt (NaCl; 100mM), as well as a 20% maintained dry down and a three day repeated dry down, all of which were compared to a well watered control. Phenotypic results, such as above and below ground biomass, specific leaf area, and stem height and diameter, were measured. Experimentation is ongoing; however, we do expect to find significant differences in phenotypic variation across water limitation treatments that outweigh phenotypic variation by genotype. This methodological study not only highlights the issue of equating water limitation treatments, but also provides a basis for further study into the optimal design of water limitation implementation.

Updates on Current Circumscribed Interest Object Categories of Children with ASD and Accuracy of Parent Reports

Sanjida Jahan Mowla
Dr. Ashley Johnson Harrison, Educational Psychology and Institutional Technology, College of Education

The present study aims to examine previously defined categories of circumscribed interest (CI) objects among children with ASD to determine if updates are warranted. To further aid in this investigation, the study will also consider the convergent validity between parent reports of CI objects and children's gaze allocation to these objects. Seventy two CI object pictures were obtained from parents of both typically developing children and children with ASD. Using operational definitions, these objects were compared across categories of CI objects from other studies (Baron-Cohen & Wheelwright, 1999; Sasson & Touchstone, 2014; South, Ozonoff, & McMahon, 2005) and coded by multiple raters to determine whether the categories identified in past studies adequately represented the objects provided by parents in this study. Parents were asked to rate children's preferred items using a visual analogue scale. In order to establish the validity of parent reports, these ratings were compared to eye tracking data of children's gaze allocation to their ideographic CI objects. The goal of the study is to identify a more inclusive and relevant way to categorize CI objects for

children with ASD as well as establish the accuracy of parent reports of their children's CI objects.

Adaptation of a DNA Purification Protocol for 3rd Generation Sequencing of *Eimeria* Species

Adrea Mueller, CURO Honors Scholar, CURO Research Assistant
Dr. Brian Jordan, Population Health, College of Veterinary Medicine

Coccidiosis is an economically significant enteric disease in chicken that is caused by several *Eimeria* species parasites. Among the different species of *Eimeria* that infect chickens, the independence of the species' *E. mitis* and *E. mivati* is controversial. Previously, *Eimeria* have been speciated based on gross morphology, pre-patent period, and region of the gut parasitized. More recently, molecular identification has been used to identify species. Full genomes of 7 *Eimeria* species have been published, but no molecular genomic data is present for *E. mivati*. The purpose of this study is to use genomic sequencing of a pure strain of *E. mivati* from a vaccine stock to determine similarities and/or differences between it and published *E. mitis* genomic sequence. For this, a DNA purification protocol that can isolate large fragment genomic DNA will be established. The genomic DNA will then be sequenced using next generation sequencing. The previously published genomes of other *Eimeria* species will be used to align the genomic sequences into a functional genome, and then specific genome markers will be compared. Understanding the similarities and differences in the genomic structure of this contested *Eimeria* will allow us to accurately determine its relatedness to other *Eimeria* and, ultimately, determine if it is truly a separate species.

Application of Heel Lift during Squat Task Decreases Trunk Flexion Overcompensation

Chandler Mulford
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Trunk flexion is an important characteristic of an overhead squat, and may change depending on heel height. The purpose of this study was to determine if differences in trunk flexion existed during assisted and unassisted squats in university club athletes. Eighteen ultimate frisbee players (14 males, 4 females; age=20.1±1.8yrs; height=185.7±25.7cm; weight=75.4±8.8kg) completed informed consent and underwent infrared camera motion analysis while wearing fifty-nine reflective markers. Participants were instructed to perform the unassisted squats while holding a bar directly overhead along the frontal plane of the body and lowering the pelvis to the lowest point possible. For the assisted squats a 2"x4" plank was placed under participants' heels to relieve gastrocnemius tightness and followed the same procedure as the unassisted squats. Trunk flexion was defined as anterior movement of the trunk along the sagittal plane as displacement from vertical. Overcompensation of trunk flexion during a squat was qualitatively measured and defined as the wrist markers passing a longitudinal reference line from the marker placed on the tibial tuberosity. The frequency of overcompensation for each condition was determined. A paired t-test was used to compare differences in frequency means between the two conditions ($\alpha<0.05$). The frequency of overcompensation in assisted squats (3.8±4.1) was significantly less than in unassisted squats (8.0±3.2) ($t(17)= 4.42$, $p<.001$). The lifted platform placed under the participants heels during the assisted squats resulted in increased ankle mobility and less trunk flexion overcompensation. Gastrocnemius stretching should be considered to decrease trunk flexion overcompensation and increase depth of bodyweight squats.

Meat Consumption as an Indicator of the Near Term Stability of Each Country's Food Supply in the Global Marketplace

Dylan Munn, CURO Research Assistant
Dr. John R Schramski, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Trends show that as countries inevitably become more urban, incomes will increase, but more importantly more meat is consumed. The human diet has been profoundly affected by globalization throughout the past half century. Research into the energetics of the food system and the

increasing urbanization of the world shows that the increased percent urbanization and per capita gross domestic product of a country is negatively and predictably affecting the per capita dietary energy production (per capita food calories grown decreasing) while the percent meat in citizens' diets is increasing. Because of the large energetic inefficiencies and water needs attributed to meat production, an increased strain will likely occur on national dietary energy production (calories grown in country), perpetuating an ever increasing reliance on international trade while simultaneously enhancing unsustainable practices within national borders, thus creating a self-enhancing feedback loop towards failure of the global food supply system. The over-reliance on global food trade to accommodate an increased focus on the production of meat is a dangerous position in the face of unstable geopolitics. International trade has provided food security to many countries enabling meat to become a larger source of calories for diets around the world, but data shows this is enhancing an unsustainable food supply in the near future. We provide an easy four quadrant metric to assess each country's trajectory in this cycle over the period of 1965 and 2005.

Non-Vocal Sounds in a Group of Western Lowland Gorillas

Maria Munoz, CURO Research Assistant
Dr. Roberta Salmi, Anthropology, Franklin College of Arts and Sciences

Previous studies in non-human primate communication have focused on vocalizations as a way to bridge the gap to understand the origins of language in humans. This study aims to investigate the use of non-vocal sounds (i.e., chest beating and hand clapping) in one group of habituated western lowland gorillas (*Gorilla gorilla gorilla*) at Mondika Research Center. Given that western gorilla habitat is dense, auditory gestures become important for understanding the communicative repertoire of the western gorilla. Focal and ad libitum samplings were used to collect behavioral data during two study periods (June - August 2007 and May 2009 - May 2010). Ten behavioral categories were identified, including: foraging, resting, playing, travelling, travel-pose, aggression, display extra-group, display within-group, vigilance and mating. Hand clapping, which has been observed with rarity in the wild, was observed during both study periods and was only observed in adult females, juveniles and infants. Its absence in adult males provides a good argument for intentionality and flexibility. In adult females, the majority of observances of hand clapping occurred during vigilance to alert individuals to potential threats. Hand clapping during play is predominantly done by infants, though females were observed to hand clap during play with infants. Chest beating occurs across age-sex classes in contexts of displays, within- and extra-group and in play. Auditory gestures, like chest beating are recognized as species-typical signals which are termed inflexible, but these findings suggest that western gorillas use gestures flexibly and differently depending on age-sex class.

The Effect of Aerobic Exercise on White Matter in Overweight Children: Studying the Effect of an 8-Month Exercise Program

Megan Murphy, Ramsey Scholar, CURO Research Assistant
Dr. Jennifer McDowell, Psychology, Franklin College of Arts and Sciences

Obesity has become an epidemic in America, with rates increasing dramatically over the past decade. Obesity is associated with multiple physiological problems but also causes deficits at the level of neural white matter (WM). Lowered integrity of WM is associated with deficits in cognitive control (CC), and these deficits are evident in obese children as they exhibit lowered academic performance and worse classroom behavior than their healthy-weight counterparts. However, aerobic exercise is shown to improve cognitive functioning and integrity of WM. This study sought to investigate the link between obesity, WM, CC, and aerobic exercise by comparing diffusion tensor imaging (DTI) brain scans before and after children participated in an 8-month program, in which they were assigned to either an aerobic exercise group (n=14) or sedentary group (n=9). The results showed decreased WM integrity in both groups over time in the left and right cingulate gyrus, the forceps major, and the right inferior longitudinal fasciculus. There was no significant interaction detected between groups as a function of exercise.

Novel Object Recognition: A Promising Approach to the Comparative Study of Memory in Porcine Vascular Cognitive Impairment Studies

Richard Dunstan Murray, CURO Research Assistant
Dr. Franklin Delano West, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Dementia is a major threat to public health. The National Institute of Neurological Disorders and Stroke Progress Review Group recently cited "prevention of vascular cognitive impairment (VCI)" as a major research priority. Numerous therapies for dementia have failed in human clinical trials indicating a clear need for rigorous testing in a translational large animal model with brain anatomy and physiology more comparable to humans. Therefore, we are developing a novel VCI pig model in order to test an inexpensive treatment method known as remote ischemic conditioning (RIC). One of the major assessment tools used to determine if a potential VCI treatment is effective is by observing changes in cognitive function, specifically learning and memory. In the present study we evaluated the cognitive ability of normal six month-old male pigs via novel object recognition testing (NORT). The animals tested in this study will serve as a baseline for normal pig cognition and their performance will be compared to non-treated and RIC treated VCI pigs in the next phase of the study. NORT showed no significant difference in exploration time between similar objects during the sample trial, but a significant difference in exploration time between the familiar and novel objects during the test trial. There was also a significant difference in exploration time of the familiar objects between the sample and test trials. This data demonstrates pigs are capable of forming memories and the efficacy of a potential VCI treatment such as RIC can be evaluated using NORT in future VCI studies.

Biocompatible, Biodegradable and Antimicrobial Skin Substitute with Nitric Oxide Release for Instant Burn Wound Treatments

Sai Nagula, CURO Research Assistant
Dr. Hitesh Handa, Chemical, Materials, and Biomedical Engineering, College of Engineering

Severe skin injuries, some of the most common non-chronic medical conditions, require hospitalization to heal completely. Annually, over 100,000 patients die due to infection of these wounds during the skin healing process. We explored the potential clinical application of combining a biodegradable skin substitute with an antimicrobial agent to serve the dual purpose of effectively regenerating skin tissue, while also preventing pathogenic infection. After background research of various polymers commonly used for skin healing, we pursued a novel combination of hyaluronic acid, a naturally occurring polymer in humans, and alginate, a biodegradable polymer derived from algae. As an antimicrobial agent, we added GSNO (G-nitrosoglutathione) to this polymer combination. GSNO releases nitric oxide, a natural antimicrobial mechanism found in our bodies. After performing nitric oxide release kinetics, an optimal skin substitute composed of 1:1 of 2%(wt/v) hyaluronic acid to 2%(wt/v) alginate with 20% (wt) of GSNO was found. Various physical characterization experiments were performed, including contact angle, moisture content, SEM, degradation studies, as well as biological characterizations, including cytotoxicity studies and zone of inhibition with *S. aureus* and *P. aeruginosa*. From the results, we observed data that were consistent with currently available skin substitutes. The cytotoxicity results indicated that the GSNO levels were not toxic to mammalian cell types, and the zone of inhibition studies showed inhibited growth of both bacteria types. Overall, these results demonstrate the potential for the novel combination of hyaluronic acid, alginate, and GSNO for future clinical studies in preventing death from infection of severe skin wounds.

Investigation of Nap1 as Reporter for CaaX Protein Post-Translational Modification Shunt Pathway

Christina Marie Najjar, CURO Research Assistant
Dr. Walter K Schmidt, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

All DNA genetic material in eukaryotes is packaged into nucleosomes, a process necessary for modulating gene expression. The nucleosome is composed of several histone proteins. Assembly of the histone 2A and 2B heterodimer requires a chaperone protein, the nucleosome assembly protein 1 (Nap1p) that is encoded by the *NAP1* gene. Limited evidence suggests that Nap1p can be categorized as a CaaX protein and thus potentially subject to the 3-step post-translational modification pathway typically associated with CaaX proteins: isoprenylation, proteolysis, and carboxylmethylation. In plants, AtNap1p is known to be farnesylated, a modification associated with CaaX proteins. It is unclear whether proteolysis and carboxylmethylation occur. In humans, HsNap1 appears to be farnesylated, but the presence of farnesylation is inferred. This study investigates the post-translational modification of yeast and human Nap1, especially in light of the recent discovery that some CaaX proteins avoid the second and third post-translational modification events after initial isoprenylation. This project explores the potential use of Nap1 as a reporter for this alternative pathway (i.e. shunt pathway). Plasmid constructs encoding wildtype and mutant versions of Nap1 were designed as experimental tools to determine the post-translational modification status of Nap1. Constructs contain various CaaX combinations (CKQS, SKQS, CTLM, CVIA, CASQ) and affinity / localization tags (i.e. His8, GFP) for use in biochemical, genetic, and cell-based assays. Thus far, farnesylation in human and yeast homologs have been confirmed and current studies are underway to establish the impact of mutations on function and localization of Nap1.

Glycosylation in Spores

Sholeh Namdari
Dr. Maor Bar-Peled, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Endospore forming bacteria produce a dormant spore that is resistant to harsh environmental conditions. We examined the function and role of rare carbohydrate produced during spore formation in pathogenic bacteria belonging to Bacillus cereus group. We identified an operon encoding several enzymes that are involved in nucleotide-sugar synthesis. Purified recombinant enzymes were tested for their specific activities by LC-MS/MS. In addition, the use of in microbe approach helped to identify the enzymatic products produced by the four different genes. Using LC-MS/MS and HPLC, I have determined the initial function of each of the enzymes and helped elucidating an unknown metabolic pathway in this group of bacterial strains. I was able to trace the biochemical changes that form and transform a simple sugar-phosphate to three different activated nucleotide-sugar forms. Furthermore, I am working on the molecular mechanisms that facilitate the incorporation of these sugars into surface glycoproteins that are displayed on the outermost surface of spores of *Bacillus cereus* and examined their potential role in biofilm formation and or host recognition.

Examining Stigma and Social Functioning in Young Adults with Autism

Maggie Naughton, CURO Research Assistant
Dr. Ashley Johnson Harrison, Educational Psychology and Institutional Technology, College of Education

There is mounting evidence demonstrating the negative impact of stigma experienced by parents of children with autism spectrum disorder (ASD; Gray, 2002; Farrugia, 2009; Mak & Kwok, 2010). Little research has investigated the consequences stigma has on the diagnosed individual, particularly adults. The current study assesses the relationship between stigma (with subscales measuring discrimination, positive aspects of the disorder, and disclosure) and social variables, including self-esteem, self-efficacy, and social satisfaction in adults with ASD. Participants (n = 20) were recruited from university disability resource centers, autism-related events, and other support services. Participants (M = 26.77 years, range = 18.59-57.94) completed psychometrically supported measures to assess stigma, self-esteem, self-efficacy, and social satisfaction. Results showed that adults experiencing more self-reported stigma have lower self-efficacy and lower overall social satisfaction. Additionally, those who experience more discrimination have lower social satisfaction, and those who express more positive aspects of their diagnosis have higher self-esteem. As rates of ASD continue to rise, more individuals with ASD will likely enter post-secondary education or professional settings; therefore, exploring variables that impact adaptive social

function among young adults has increasing importance. More specifically, examining how stigma affects the social outcomes of adults, such as self-esteem, social competence, and social satisfaction, may provide educational institutions or workplaces with information that is necessary to develop and implement more appropriate support structures for students or employees with ASD.

Implementation of Structure from Motion from a Cube Satellite in Low Earth Orbit

Hollis Neel, CURO Summer Fellow, CURO Research Assistant
Dr. Marguerite Madden, Geography, Franklin College of Arts and Sciences

The UGA Small Satellite research laboratory's mapping and ocean color imager mission utilizes an algorithm known as structure from motion (SfM) which recreates 3D maps of a surface. In order to achieve this we have to consider factors such as computational complexity, hardware constraints, atmospheric distortion, and orbital optimization. To maximize the effectiveness, we will attempt to write custom SfM software specifically for our system using the Scale Invariant Feature Transform algorithm. This algorithm creates thousands of key points in any image and if two images have the same key point it is then possible to tie them together. This allows us to calculate the geometry of the object we are imaging. This is calculated by knowing where the cameras precise position was at the time of each picture and then using epipolar geometry to triangulate the location for the rest of the tied points. To optimize this for in orbit applications, we will be able to make estimations on where the tied points should occur in each image. This paired with the near constant attitude to reduce computing camera position shows promise to greatly reduce the computational complexity of the algorithm. We also plan to implement our algorithm in software from either a field programmable gate array or a graphical processing unit. This shows promise to also reducing the computation time even farther due to SfM's computationally greedy past. Pairing all of this with a custom SfM testing suite in blender has allowed us to simulate these scenarios on a to-scale model.

The Effects of Aging on Neuroblast Proliferation in the Pivotal Lateral Ventricle Region: A Canine Model

John Newman
Dr. Buffy Howerth, Pathology, College of Veterinary Medicine

Through the studies of legendary neuroscientist Santiago Ramón y Cajal, it was previously thought that the adult brain lacks the ability to regenerate neurons. In modern science, adult neurogenesis has been well established in the hippocampal region of rodents. Since this landmark, many studies of adult neurogenesis in the hippocampus of gyrencephalic species, such as bovine, have been conducted. However, the ontogeny of neurogenesis in the canine brain, particularly in the lateral ventricle region, is poorly understood. Data concerning the importance of the lateral ventricle and its accompanying cerebrospinal fluid in trauma repair, nutrient delivery and waste removal is burgeoning. Therefore, it is vital to elucidate the neurogenic properties of this region, and the tissue surrounding it. Here, we evaluate the relationship between age and proliferation of neuroblasts, or immature neuronal precursors, in the Subventricular Zone (SVZ) of the lateral ventricle region of the canine brain. The SVZ is a proven hotspot for robust neuroblast proliferation, and thus an excellent target for evaluation. Also, considering the canine brain is similar to humans in that it contains many gyri, there is ample opportunity for neuroblasts to migrate through the SVZ via the Rostral Migratory Stream (RMS). We hypothesize that as age increases, the robustness of neurogenesis in the canine brain will decrease, as indicated by decreasing numbers of DCX and Ki67 immunopositive cells. To address this, formalin fixed brains from dogs of various ages submitted for postmortem examination and with known pathologies were evaluated. Immunohistochemical staining of transverse sections of forebrain for doublecortin protein (DCX) and Ki67 were performed in order to assess the density of migrating neuroblasts, and general cell proliferation, respectively.

Simulation of Small Satellite Photovoltaic Power Generation System

Khoa Minh Ngo, CURO Research Assistant

Dr. Marguerite Madden, Geography, Franklin College of Arts and Sciences

A satellite is artificial body placed in orbit around the earth or moon or another planet in order to collect information or for communication. One example of a satellite is a retroreflector sphere. A retroreflector is a small spherical object that has retroreflector built across its outer surface area to directly reflect any laser back to its origin. This type of satellite does not require a power system and it is use to study geo-referencing methods in orbit. However, many satellites require a power system in order to power its payload and transmit data to ground. Typically, powered satellites will be equipped solar panels for Earth orbiting mission. Solar panels, also known as solar powered photovoltaic (PV) panels, convert the sun's rays into electricity by exciting electrons in silicon cells using photons of light in the sun. This electricity can then be used to give an energy supply of electricity or used to charge a battery. Because the amount of electricity generated from photovoltaic cells are tied to the amount of photons hitting the cells, we can estimate a satellite's solar power generation by estimating the amount of sun light shining on the solar panels. This research focuses on estimating the power generation of a CubeSat in orbit using rough order-of-magnitude (ROOM) predictions and complex orbital simulation analysis. The result of this research will allow us to better understand how satellite power generation potential is affected by orientation, seasons, and orbital parameters.

Evolution of Body Size in *Drosophila subquinaria*

Amy Nguyen
Dr. Kelly Dyer, Genetics, Franklin College of Arts and Sciences

Selection can shape trait variation and can be studied by examining the interplay between genes and environment in natural populations of *Drosophila*. *Drosophila subquinaria* occurs throughout western North America. Initial observations indicate that coastal populations have a substantially larger body size than inland populations despite extensive gene flow across the range. It can then be hypothesized that large body size in coastal populations of *D. subquinaria* is a derived trait and due to differences in selection. To better understand the role life history evolution has played in populations of *D. subquinaria*, questions regarding if coastal (large) females are more fecund and lay larger eggs than inland (small) females. Egg size is an important life-history character that is positively associated with offspring fitness and affects development rate (egg-larva and egg-adult). Likewise, fecundity is a critical life-history character in that the more fecund a female is the more opportunity she has to spread her genes to the next generation and beyond. This will be examined by measuring female wing size and oriole size in different iso-female lines and its correlation with the number of eggs laid and the size of the eggs laid. By understanding the variation in egg size/number in populations of *D. subquinaria*, determination of the sources of selection acting on body size and the benefits to maintaining a larger body in coastal populations can be achieved.

Investigation of Antimicrobial Resistance in *Salmonella* and *Escherichia coli* isolated from the Upper Oconee Watershed

Anh Hoang Thi Nguyen
Dr. Jonathan G Frye, Microbiology, Franklin College of Arts and Sciences

Bacterial contamination of surface water from agricultural runoffs, sewage drainage, and natural sources can contribute to disease transmission. This is concerning due to increasing antimicrobial resistance (AR) in bacteria. Overuse of antibiotics and the spread of mobile genetic elements (MGEs) encoding AR has contributed to the emergence and dissemination of resistant bacteria. Pathogens, like *Salmonella* and *Escherichia coli*, can acquire AR through MGEs such as plasmids. To determine if bacteria in surface water were resistant to antimicrobials or carried MGEs, water samples were collected from the Upper Oconee Watershed in Georgia; *Salmonella* and *E. coli* were isolated from the samples and characterized. Fifty-four *Salmonella* and *E. coli* isolates were resistant to the antimicrobials tested. Resistant isolates were assayed for the presence of plasmids and were genetically fingerprinted using Pulsed-field Gel Electrophoresis (PFGE). Plasmids were detected

in 7/22 *Salmonella* including the IncN and IncA/C plasmids. One *S. Newport* isolate contained an IncA/C plasmid and was resistant to 10/14 antimicrobials tested, including tetracycline, ceftriaxone, and streptomycin. This resistance profile matched *S.* Newport strains associated with foodborne outbreaks. *Salmonella* isolates containing the IncN plasmid were resistant to tetracycline and trimethoprim and/or sulfamethoxazole. Approximately 69% of PFGE profiles determined for the *Salmonella* isolates were identical or similar to PFGE profiles of clinical isolates from the Centers for Disease Control and Prevention PulseNet database. Approximately 78% of the *E. coli* isolates contained at least one plasmid. These results show the potential role of surface water in harboring antimicrobial resistant bacteria that may cause human infection.

Instant Clotting Patch to Prevent Excessive Bleeding during Emergency Injuries

Dieu Thao Nguyen, CURO Research Assistant
Dr. Hitesh Handa, Chemical, Materials, and Biomedical Engineering, College of Engineering

Excessive blood loss continues to be one of the leading causes of death at in war fields, road accidents, surgeries, and other emergency situations. In addition, the presence of common bacteria exacerbates the wound by diverting the inflammatory response away from healing the injury and toward eradicating the infection. The objective of this research is to fabricate a bio-inspired wound dressing which can form instant blood clot and also minimize bacterial reduction. The internal layer of the bilayer wound dressing is composed of an adhesive suspension of propolis, fibrin, and Tranexamic acid. Propolis, a natural antimicrobial agent, prevents bacteria from adhering and proliferating on wounded areas, reducing the susceptibility to infection. Fibrin provides a platform onto which platelets and blood cells can attach, forming blood clots. Tranexamic Acid, an antifibrinolytic, reduces the degradation of blood clots, thus stabilizing them. The external layer consists of a nitric oxide (NO) releasing agent. NO is a crucial cellular signaling molecule which has a proven role in wound healing process via regulation of cell proliferation, angiogenesis, inflammation and prevent of infection. The wound dressing will be characterized for antibacterial potential, biocompatibility, mechanical testing, surface properties, NO flux analysis, hemocompatibility, gene expression and in vivo animal studies. The preliminary tests have shown promising results and the novelty of the wound dressing provides an innovative approach to ensure a greater promise for recovery from injuries.

Using Serological Tools to Measure the Prevalence of Filarial Infection after Mass Drug Administration

Stephanie Nguyen, CURO Research Assistant
Dr. Patrick J Lammie, Cellular Biology, Franklin College of Arts and Sciences

Evaluating the success of mass drug administration (MDA) programs to eliminate lymphatic filariasis (LF) requires monitoring of infection in sentinel communities. At the beginning of MDA, LF programs monitor the levels of parasites in the blood stream, but as infection levels decline, parasite antigen and antifilarial antibody prevalence are used to assess progress. In this study, I will analyze blood serum samples by using serological tools to determine the status of LF infection in the community of Saut D'eau, Haiti. Serological tools, such as Immunochromatographic Card (ICT) tests and Multiplex assays, will provide a comprehensive evaluation of LF antigen and antibody prevalence, respectively. Participants were tested for LF antigen by ICT and dried blood spots (DBS) were collected for assessment of antibodies to LF and other infections by Multiplex. By evaluating other other parasitic antibodies, such as Malaria, Tetanus, Measles, Cysticerosis, and Toxoplasma, I will achieve a greater understanding of the overall health status of the community. After data collection, I will create age prevalence curves via Excel® to determine the presence of particular antibodies in respect to aging. In addition, I will compare the percentage of individuals positive for LF antigen in ICT versus LF antibodies in Multiplex to assess which assay is more sensitive to the presence of infection. Conducting these experiments will allow me to determine the status of particular infections and the progress of the MDA LF program in Saut D'eau.

Examining the Arrhythmogenicity of Dobutamine When Used in Conjunction with Isoflurane or Sevoflurane

Emily Nieves, CURO Research Assistant
Dr. Rachel Reed, Large Animal Medicine and Surgery, College of Veterinary Medicine

Dobutamine is an inoptric agent typically administered to counteract the low cardiac output associated with isoflurane, sevoflurane, and other types of anesthesia, but has been known to cause arrhythmias as well. The increased risk of arrhythmias during surgery may lead to an increase of complications during surgery, as irregular heartbeats can mean decreased blood flow to vital organs. Previously, halothane was administered to maintain anesthesia, and was found to cause a significant number of arrhythmias when coupled with dobutamine. Since isoflurane and sevoflurane replaced halothane as a means of maintaining anesthesia, there have been few studies investigating the occurrence of arrhythmias when dobutamine is used in conjunction with isoflurane or sevoflurane. This experiment serves to bridge that gap in knowledge by examining the arrhythmogenicity of dobutamine when given to horses that have been anesthetized with either isoflurane or sevoflurane. This experiment was conducted as a retrospective study. The data was collected using anesthesia records from the UGA Veterinary Teaching Hospital. 200 horses were studied and variations in heart rate and other variables were recorded as well as any documentation of arrhythmias. It is expected that the occurrence of arrhythmias will be much lower in the horses studied than in the horses that were administered halothane in previous studies.

Facilitating the Continuous Expression and Secretion of the Influenza Surface Glycoprotein, Hemagglutinin, within Human Cells

Santosh Nimkar, CURO Research Assistant
Dr. Ted M Ross, Infectious Diseases, College of Veterinary Medicine

Influenza is a viral infection that causes severe respiratory illnesses and, during epidemics, is responsible for 250,000 to 300,000 deaths per year worldwide (WHO). Due to antigenic shift and drift, many different antigenic combinations occur resulting in pandemics and seasonal epidemic infections. Hemagglutinin (HA), a surface glycoprotein on influenza virions, initiates the viral binding to human host cells, thereby initiating the infection. One of the major mechanisms of protection from influenza infection is the ability of specific antibodies to bind to the viral surface of, particularly, the HA glycoprotein. Given the central role of HA in influenza infections due to it being a major target of the humoral immune response, study of this protein is critical to understand, not only, the immune response to the virus but also the biology of the virus, itself. Therefore, the goal of my project is to clone HA genes of various pandemic and seasonal influenza viruses and insert them in mammalian expression vectors for the stable transfection of human embryonic kidney (HEK)-293T cells. Ideally, this will allow for continuous expression and secretion of this protein for purification. Up to this point, through polymerase chain-reaction (PCR), restriction enzyme (RE) digestion and ligation followed by transformation and mini-prep purification, I have successfully obtained the ideal DNA plasmids for transfection. Later on, positively-transfected HEK-293T cells will be evaluated for HA expression and subjected to antibiotic (Zeocin) selection from which resistance is conferred by the transfecting plasmids.

Archaeometry of Argentinean Rock Art

Autumn Nobles, CURO Research Assistant
Dr. Tina Salguero, Chemistry, Franklin College of Arts and Sciences

From the famous Lascaux cave paintings in France to Cueva de las Manos in Argentina, naturally occurring pigments have been used as colorants since antiquity. The pigments used were typically composed of common minerals found in the region of the artist. The high availability of these inorganic compounds coupled with their high resistance against weathering made them a key ingredient in early artwork. The primary goal of this project is to identify the mineral composition of the pigments used in cave art samples from Santa Cruz, Patagonia and to compare them to local mineral sources. Studies on rock art pigments have been conducted in Argentina, but there have been few studies comparing these samples to the natural pigments to minerals found in the surrounding region. The

beginning stages of this project focused on analyzing ~20 soil samples from the Southern Deseado Massif region of Patagonia with X-ray Diffraction (XRD), Electron Dispersive Spectroscopy (EDS), and Raman Spectroscopy. The chemical composition and structural information gathered from these techniques were then used to compile a database of possible pigment sources. For the second part of this project, Patagonian cave art samples were analyzed with Scanning Electron Microscopy (SEM) and EDS. In order to achieve high quality images and data, each sample was embedded in epoxy, polished and carbon-coated. The elemental data from the cave art samples was then compared to that of the soil samples, in order to search for a link between pigment and source.

The Effect of Macrocyclic Lactones on the Canine Immune Response towards the Heartworm Parasite *Dirofilaria immitis*

Connor Matthew O'Neill, CURO Summer Fellow, CURO Research Assistant
Dr. Adrian Wolstenholme, Infectious Diseases, College of Veterinary Medicine

Dirofilaria immitis is a parasitic nematode that causes heartworm disease in cats and dogs. To prevent *D. immitis* infections, which primarily occur in the pulmonary arteries of an infected dog or cat, macrocyclic lactone (ML) drugs – like ivermectin (IVM) and moxidectin (MOX) – are typically administered to healthy animals each month. In the last 10-15 years, loss of efficacy (LOE) cases have been reported where IVM treatments appeared not to have worked, primarily in the Mississippi Delta Region of the United States. Previous work at UGA has resulted in the isolation of *D. immitis* isolates that have been confirmed to be resistant to IVM in vivo. Work in our laboratory has shown that, in vitro, the drug increases recognition of IVM-susceptible larval worms by cells of the dog innate immune system, neutrophils and mononuclear cells. Therefore, the end goal of this project is to answer whether or not there is a correlation between the effects of different MLs at various concentrations on cellular recognition of parasite larvae in vitro and the ML resistance of the *D. immitis* strain being tested. To date, MOX has been found to significantly increase PBMC binding to susceptible strains of *D. immitis* at concentrations above 0.1 μM while IVM has done so above 1 μM. Likewise, MOX has significantly increased PBMC binding to resistant strains of *D. immitis* at 0.1 μM, while IVM did not do so at any concentration. We are currently examining two other strains of *D. immitis* for resistance towards ML drugs.

Attention-Deficit/Hyperactivity Disorder (ADHD) Subtypes: Cross-Informant Agreement and Stability from Childhood to Adulthood

Selin Odman
Dr. Jason Nelson, Psychology, Franklin College of Arts and Sciences

Attention Deficit Hyperactivity Disorder (ADHD) is a complex disorder that is challenging to accurately identify. When clinicians diagnose ADHD, they assign a specific subtype to their patients. Minimal research has investigated the reliability of these subtype designations. The purpose of this study was to investigate the reliability of assigning ADHD subtypes across time and informants within the following ADHD subtypes: inattentive, hyperactive-impulsive, combined (inattentive and hyperactive-impulsive), and other specified. Participants (N = 634) were individuals who were diagnosed with ADHD via a neuropsychological evaluation at a university-based clinic. Participants and their parents completed measures of childhood and current ADHD symptoms using the 18 DSM symptoms of ADHD. Kappa values measuring agreement across time and informant ranged from slight agreement to fair agreement for all subtypes. In addition, preliminary analysis shows a 59% agreement for child subtype rating between raters, a 45% agreement for current subtype rating between raters, a 68% agreement for self subtype rating across time, and a 53% agreement for other subtype rating across time. In conclusion, the currently accepted and wide-spread ADHD subtype assignments show low agreement across time and informants. This ultimately causes challenges for clinicians, who have to assign labels to their patients using contradicting information from different sources.

Characterization of Genes Predicted to Function in Signaling for Expression of RNA Repair Operon in *Salmonella*

enterica serovar Typhimurium

Obi Okafor, CURO Research Assistant
Dr. Anna Karls, Microbiology, Franklin College of Arts and Sciences

Salmonella enterica serovar Typhimurium, a food-borne human pathogen, must survive an arsenal of host defenses during infection. Understanding pathogen survival strategies facilitates the design of antimicrobials and vaccines. Our laboratory has previously shown that the RNA repair operon of Salmonella increases survival of the pathogen under conditions that damage nucleic acids, such as exposure to the antibiotic mitomycin C (MMC). The purpose of this project is to identify the genes that are involved in generating the signal that activates RtcR, a transcriptional regulator of the RNA repair operon. A reporter strain for quantitating transcription of the RNA repair operon was created in *S*. Typhimurium by replacing the first gene of the operon with *xylE*; the gene product of *xylE* converts catechol to a quantifiable yellow compound. The BEI Resources collection of *S*. Typhimurium deletion mutants, which has nonessential genes replaced individually with kanamycin- or chloramphenicol-resistance cassettes, is a source for deletions/substitutions of genes that are predicted to play a role in generating signaling molecules. Initially focusing on the *rna* (RNase I) or *rpoS* (sigma factor S) genes, I used PCR to confirm the Δ*rna*::Kan^R and Δ*rpoS*::Kan^R mutations in the BEI resource mutants and P22 transduction to move the mutations into the *xylE*-reporter strain. MMC treatment will be used to induce RtcR-dependent expression of the RNA repair operon and the level of *xylE* expression will be measured in the wildtype and mutant strains to determine whether *rna* or *rpoS* are required for generating the signal that activates RtcR.

Justice for All: Addressing Codified Discrimination in the Georgia Justice System

Nanma Okeani
Dr. Susan Haire, Political Science, School of Public and International Affairs

This policy research investigates the troubling prevalence of codified discrimination within the judicial system of Georgia, particularly within the jury selection process and against the state's public defense system. Discriminatory practices widen the division between minority members and law enforcement, and increase the skepticism many groups harbor about the equity of the justice system as a whole. The overworking and underpayment of state public defenders undermine the constitutional rights of Georgia citizens, while also exacerbating the issue by deterring potential law students from careers in public interest, like public defense. Leniency against attorneys who use peremptory challenges to stack juries through the elimination of minority groups result in cursory decision-making within juries, a lack of diversity in race and perspective, and wasted court time. To address these issues, three policy alternatives were formulated: a reduction in peremptory challenges, third party presiding sources for Batson challenge reviews, and pay parity for prosecutors and public defenders. After analyzing the effectiveness, cost-benefit, and feasibility of each alternative, this policy paper asserts that the third party presiding source is the best option.

Majority Party Factionalism and Gridlock in State Legislatures

Rob Oldham, CURO Summer Fellow, CURO Research Assistant
Dr. Anthony Madonna, Political Science, School of Public and International Affairs

Congressional gridlock is often blamed on majority party factionalism. After the 2010 elections, a group of strongly conservative Republicans, sometimes referred to as the Tea Party or the Freedom Caucus, prevented Congress from passing legislation on salient issues even when there was a bipartisan majority that supported it. Conservatives took advantage of institutional rules and a polarized electorate to obstruct legislation with majority support such as government funding bills and comprehensive immigration reform. Although obstructionism has been well documented at the national level, there have not been similar studies at the state level. I attempt to fill this gap by examining the relationship between majority party factionalism and gridlock in state legislatures from 2001 to 2013. Using McCarty and Shor's (2015) ideological scores for state legislators, I calculate a measure of factionalism in majority party caucuses. I examine

the effect of factionalism on legislative output and on the enactment of major policy items. I hypothesize that increased majority party factionalism will lead to heightened levels of gridlock, especially when supermajoritarian rules facilitate obstructionism.

Examining Younger Age at Menarche in Mexican-American Girls

Ginny Lee Olivier
Virginia Olivier
Dr. Jennifer L Gay, Health Promotion and Behavior, College of Public Health

During the past century girls have been having their first menstrual period (attaining menarche) at younger ages. This may be due in part to increased body fat in childhood and adolescence. Previous studies also have found a correlation between girls' age at menarche and mothers' age at menarche, although this may be moderated by overweight or obesity. Because prior research has mainly studied Caucasian populations, the aim of this study was to determine if the relationship between daughter's age at menarche with mother's age at menarche varied by body composition in a sample of Mexican-American girls. Data were obtained from 446 girls from a larger cross-sectional survey of Mexican-American students in grades 4-12 in south Texas. Height, weight, BMI, and body fat percent were measured. Girls and their mothers self-reported age at menarche. A general linear model was tested with age at menarche as the dependent variable. Interestingly, girls in this sample attained menarche at a significantly younger age than their mothers by 1.5 years ($p=0.000$). The relationship between mother's and daughter's age at menarche approached significance ($p=0.082$) in the general linear model. This relationship did not vary by body fat percentage. Because of this study's cross-sectional nature, a future longitudinal study of Mexican-American girls could determine if there is an association between childhood body fat and age at menarche. As earlier age at menarche has been shown to be associated with greater cardiovascular disease risk, this factor may be considered in prevention efforts.

The Effect of High-Fat Diet in Altering the Metabolism of Mice with Differing Expressions of RGS10

Erik Olsen
Dr. Jae-Kyung Lee, Physiology and Pharmacology, College of Veterinary Medicine

Regulator of G-Protein signaling protein (RGS) 10 has shown to negatively modulate levels of inflammation by inhibiting macrophages and microglial activation. Although immune response is an important part of brain health when functioning normally, abnormal or chronic inflammation is known to be a risk factor not only in brain health but also in peripheral system. The mechanism of RGS10 in immune cells and other cell types has not identified, yet. Interestingly, when RGS10 knockout mice were characterized by Jackson Laboratory, they reported RGS10 knockout (KO) mice displayed impaired glucose tolerance. We also observed that RGS10 knockout mice gained more weight with aging (unpublished observation). These imply its role in metabolism and/or obesity. To better understand the role of RGS10 in metabolism and obesity, we have conducted a study that investigates the effect of high fat diet on RGS10 KO mice. RGS10 KO mice and wild type (WT) control mice were fed a diet of low fat (LF) or high fat (HF) for 8 weeks. At week 8, HF-fed RGS10 KO mice displayed significantly increased body weight compared to HF-fed WT mice. HF-fed RGS10KO mice displayed significantly increased retroperitoneal adipose tissue and liver weights. Especially, HF-fed RGS10 KO mice displayed insulin resistance which implicates in metabolic disregulation in these mice. This study is the first time one has investigated the role of RGS10 in metabolism and obesity. With further research, this understanding can be used to search for a deeper understanding of the biochemical regulation pathways that play large roles in both metabolic disorders and neurodegenerative disease.

The Rules Change the Game: Delegate Allocation Variations and Presidential Primary Season Length

Paul DuPont Oshinski, CURO Research Assistant
Dr. Joshua Tyler Putnam, Political Science, School of Public and International Affairs

Scholars examining presidential primaries have long-discussed how the primary rules that govern

the allocation of delegates in each state play significant roles in the primary process as a whole. As there are myriad primary rules that alter delegate allocation methods, this research argues that different rules favor different candidates, depending on a candidate's positioning in the primary race. This paper finds that candidates leading in the primary race (i.e. frontrunners) receive more delegates in winner-take-all primaries than in any other delegate allocation method, including proportional representation, winner-take-most, or any hybrid delegate allocation method. The success of front-runners in winner-take-all primary states yields a shorter primary season for both the Republican and Democratic parties. Variables such as momentum, frontloading, primary contest type, and electorate preferences are controlled for in a regression analysis examining the effect of delegate allocation methods on presidential primary length. The study uses delegate count data from Republican and Democratic primaries in the 2008 and 2012 presidential elections and analyzes which delegate allocation methods produce a quicker primary victor. By examining delegate counts in these two elections, this study uncovers which delegate allocation methods both offer the front-runner the greatest delegate payoff and lead to a quicker primary season for both Republican and Democratic parties.

Introductory Biochemistry Students' Use of Learning Objectives

Bethany Osueke, CURO Research Assistant
Dr. Julie Dangremond Stanton, Cellular Biology, Franklin College of Arts and Sciences

Learning objectives are tools used to articulate the knowledge and skills instructors intend their students to acquire by the end of a particular section of material or an entire course. Learning objectives make goals and expectations clear while providing organization for teaching and learning. By aligning course instruction and assessment, learning objectives have been shown to enhance student performance. There have been many studies on how faculty should write and use learning objectives in the classroom. Yet little attention has been given to understanding how students use learning objectives in order to study effectively. Academic faculty should be invested in engaging with learning objectives from a student-centered perspective. This study employed two open-ended surveys to explore students' perceptions and uses of learning objectives. Participants were undergraduate students taking Introductory Biochemistry at one institution (n=185). The surveys were completed after the students' first and second exams. We used content analysis to identify key ideas within students' answers. Most participants used learning objectives by answering them as if they were questions. Students perceived the purposes of learning objectives to be showing them what is important to learn, providing organization, and helping them meet their instructors' expectations. Students also reported that the learning objectives helped focus their study for exams and for learning purposes. Ongoing research is centered on how students' use of learning objectives affects their exam and course grades.

Investigating a Potentially Novel Cache Valley Virus Variant in a Clinical Case in Missouri

Isabel Ott, CURO Honors Scholar, CURO Research Assistant
Dr. Daniel Mead, Population Health, College of Veterinary Medicine

The Southeastern Cooperative Wildlife Disease Study (SCWDS) investigates wildlife mortality events in the southeastern United States. In July of 2015, the Missouri Department of Conservation submitted samples from a white-tailed deer (*Odocoileus virginianus*) euthanized after showing signs of hemorrhagic disease. Submitted samples tested negative for hemorrhagic disease viruses and other major viruses of white-tailed deer using reverse transcriptase polymerase chain reaction (RT-PCR). Further tests detected an *Orthobunyavirus*, a genus of arthropod-borne RNA viruses distributed worldwide, showing highest similarity to Cache Valley virus (CVV). CVV, better known as a cause of severe neurological birth defects in sheep, has previously been isolated from asymptomatic deer. The deer's unusual clinical profile suggested the potential presence of a genetically variant strain. Variant or novel orthobunyaviruses emerge relatively frequently, as they lack replication proofreading mechanisms and frequently exchange genetic material between species. To explore this possibility, partial segments of the isolate's genome were amplified

and sequenced using RT-PCR and short-read Sanger sequencing. Sequence data analysis showed a high similarity between the isolate and two different lineages of CVV, suggesting that genetic exchange between traditional Continental US and Mexico lineages had occurred. The Mexico lineage, introduced to the Northeastern US in 2010, has caused more severe birth defects than previous strains. Further genetic characterization of the clinical isolate, along with analysis of historical Georgia isolates, should better define the virus's ancestry and potential causes for its unusual pathogenicity.

From Ancient Artifacts to 3D Printers: Using Modern Engineering Tools to Enhance Our Understanding of Classical Athenian Elections

Chris W Overbaugh, CURO Research Assistant
Dr. Naomi Norman, Classics, Franklin College of Arts and Sciences

This project is an interdisciplinary effort between UGA's departments of Civil Engineering and Classics. To better serve the nationwide classics pedagogy developed in part by Dr. Naomi Norman, Reacting to the Past, 3D modelling and additive manufacturing are employed to create high-fidelity, low-cost replicas of artifacts pertaining to Athenian Democracy. By using information found from excavations at the Athenian Agora in Greece, models of ballots and other artifacts were created in AutoCAD. Pictures were analyzed to develop fonts representative of inscriptions on the ballots, and a trial and error process varying the weight, size, and style of the font (2D characteristics) and depth and shape of inscription (3D characteristics) were used to select the most legible representation. The models were refined for more efficient and higher-quality 3D printing by breaking the artifacts in to various pieces to be joined in post-processing. Replicas were printed on Makerbot Replicator+ machines using PLA filament and models will be shared via an online community for universities using Reacting to the Past to print. The use of the replicas in Dr. Norman's FYOS seminar will be observed to assess impact. The design process will be presented as findings alongside all existing artifact replicas. Additive manufacturing is becoming commonplace in educational systems to create effective hands-on teaching tools. The replicas created in this research/design process are both effective tools and highlight the benefits that an engineering perspective and expertise can bring when applied to other disciplines. This project will set precedence for future collaboration at UGA.

Exploring Uncertainty in Models of Mosquito Vector-Borne Disease

Jack Owen, CURO Research Assistant
Dr. Courtney Murdock, Infectious Diseases, College of Veterinary Medicine

Understanding the dynamics of the spread of mosquito-borne diseases such as malaria and dengue virus are important public health challenges, as these diseases affect millions of people around the world. Mosquitos, like most ectotherms, are heavily influenced by the temperature of their environment. Recent work suggests that mosquito traits and thermal performance follow a unimodal response to temperature, with an "optimal range" in the middle that decreases as the temperature moves in either direction. Global climate change data indicate that different parts of the world may move into the mosquitos' optimal range in the coming years, changing the prevalence of mosquito-borne illnesses in those areas. Little empirical work, however, has been done to validate data gathered from metadata studies from which the unimodal thermal performance was generated. This experiment monitored mosquito mortality, bite rate, and fecundity across a range of temperature points in laboratory incubators. From the results, we will be able to further specify which variable is the most important driver of mosquito transmission potential.

The Effects of Temperatures on the Stability and Infectivity of Arboviruses

Hannah Packiam, CURO Research Assistant
Dr. Melinda Brindley, Infectious Diseases, College of Veterinary Medicine

Viral stability can affect how long viral particles remain infectious in the environment. In addition, the stability, or lack of stability, of viral particles may impact experimental outcomes if particles are easily inactivated. In this study, we investigate the effects of temperatures on the stability and

infectivity of arboviruses. Understanding how both high and low temperature treatments alter particle infectivity may enable us to design better experiments concerning chikungunya virus, dengue virus, and Zika virus in our lab. To specifically examine the stability of the arboviral particles, I determined the temperature that inactivated particle infectivity as well as examined how freezing affects the viral titers. Dengue virus was less thermally stable than attenuated chikungunya virus and Zika virus, and was inactivated at a lower temperature. To determine if freezing viral stock alters the titer, I produced viral stocks and titered them immediately, as well as after short freezing periods (4 and 24 hours) and compared to a full-week time period. Preliminary results suggest that the viral titers remained similar to unfrozen material when frozen for short periods, but decreased significantly after being frozen for 7 days. Thorough understanding of viral particle stability and how infectivity can change due to temperature exposures will be informative as the lab undertakes additional experiments comparing how arbovirus infectivity and transmission potential changes over a range of temperatures.

South African Wineries and the US Wine Market

Kavi Pandian, Foundation Fellow, CURO Research Assistant
Dr. William Finlay, Sociology, Franklin College of Arts and Sciences

This research investigates the presence of South African wineries in US wine markets as well as what factors may influence that presence. Using a dataset consisting of stores in the US that sell different wines from South Africa, my research mentor and I analyzed the market presence of the different wineries. Initial results appear to indicate that the US market for South African wines is a "winner-take-all" market in which a few wineries vastly outweigh the other wineries both in market presence as well as volume of wine sold. Unlike many other "winner-take-all" markets, this one does not consist of a few large wineries dominating the smaller ones; instead, it consists of many small wineries competing against other small wineries. Our research seeks to explain why such a market exists. We also use data about wine quality, as established by *Platter's Wine Guide*, to argue that quality ratings have a negligible impact on market presence. Initial results of our analysis appear to indicate that the most important factor in winery market presence is what distributor each winery is connected to.

Reducing School Discipline Disparities and Excesses in K-12 Education in the State of Georgia

Kavi Pandian, Foundation Fellow, CURO Research Assistant
Dr. Sarah Shannon, Sociology, Franklin College of Arts and Sciences

This policy research investigates the high rates of discipline in public schools in Georgia as well as the ways in which this discipline is administered unequally based on characteristics such as race, gender, and ability status. After conducting a review and analysis of relevant literature and research, some root causes have been identified for why these rates of discipline are so high and disproportionately affect students of color and students with disabilities. These include implicit biases from teachers who do not understand the culture of their students, undiagnosed medical issues, undiagnosed behavioral issues, and psychological characteristics inherent in developing children. To address these causes, three policy alternatives were developed: a policy proposing the implementation of restorative justice practices in schools and school districts throughout Georgia, an optical health medical intervention policy modeled after one which has been implemented in Florida, and a policy calling for changes in record-keeping and other bureaucratic measures to increase accountability and reduce rates of discipline for vague, undefined offenses. After analyzing effectiveness, feasibility, and the costs and benefits of each policy, this policy paper asserts that working to implement restorative justice in districts and schools throughout the state is the best option to reduce school discipline disparities and excesses in the state of Georgia.

Identity, Cosmology, and Subsistence in Madagascar

Rose Parham, CURO Research Assistant
Dr. Bram Tucker, Anthropology, Franklin College of Arts and Sciences

Southwestern Madagascar is characterized by one of the most inconsistent and variable climates in the world. This high degree of unpredictability would seemingly indicate a need for humans living in the area to reduce subsistence risks associated with high variability by diversifying subsistence strategies and increasing mobility, but in this region of Madagascar, ethnic identity relates to subsistence strategies, which limits economic diversification, and religious cosmology involves ancestor reverence, which limits mobility. These limiting cultural traits seem as if they would be maladaptive due to the high subsistence risk associated with this region. This research will explore whether these cultural traits are most likely regional adaptations versus traditions shared widely throughout Madagascar. This will be accomplished using a cross-cultural dataset of cultural groups throughout Madagascar. The research will compile previously published data from various cultural groups across Madagascar, which will then be compared using frequency statistics such as chi-squared analysis. Findings are suspected to suggest that while there is some cosmological variability across Madagascar, it stays fairly consistent across the island. Ethnic identity is expected to be more variable, especially with the unique trait of identity being related to subsistence strategy in southwestern Madagascar. On a broader scale, this research explores different ways in which humans can adapt to various environments, as well as how culture and socioreligious institutions affect the ways that people interact with their environment.

Effect of Different Concentrations of 25-Hydroxycholestrol on Osteogenic Differentiation of Mesenchymal Stem Cells (MSC) from Broiler Compact Bone

Diane Park, CURO Research Assistant
Dr. Woo Kyun Kim, Poultry Sciences, College of Agricultural and Environmental Sciences

MSC are multipotent progenitors that can differentiate into various tissue cells. The objectives of the study were to 1) isolate MSC from broiler compact bone and 2) study the effects of 25-hydroxycholestrol on osteogenic differentiation of MSC. This is important for the production and welfare facets of the poultry industry as chickens develop orthopedic problems such as lameness, tibial dyschondroplasia, and osteoporosis. MSC were isolated from the femurs and tibia of day-old chicks and left to confluent, with the media changed every 2-3 days. The cells were passaged until P4 and plated in 24 well plates at density of 20,000 cells/cm^2. Upon confluency, cells were treated with the following treatment: control, osteogenic media (OM), and OM with 0.5, 1, and 2 uM 25-hydroxycholesterol. Cytochemistry conducted on day 7 and 14 to detect osteogenesis. Cells treated with OM, and 25-hydroxycholestrol induced higher proportion of Alizarin Red and Von Kossa stain (mineralization), and Alkaline Phosphatase (early osteogenic marker) compared to control cells. However, 2uM 25-hydroxycholesterol was toxic to cells, causing cell death. Results indicated that 25-hydroxycholesterol has a stimulatory effect on MSC ostegenesis. Current results provide rationale for further study on regulatory mechanisms of 25-hydroxycholesterol on MSC which can help to address skeletal problems in poultry. RNA extraction then RTPCR will be conducted at 7 and 14 days to analyze gene expression and obtain a broader understanding of the effects of 25-hydroxycholesterol on MSC. A positive result will show a significant expression of pathways activated by osteogenesis such as BMP and BGP.

The Isolation of *C. elegans* Germ Cell Line

Yeonsoo Park, CURO Research Assistant
Dr. Edward Kipreos, Cellular Biology, Franklin College of Arts and Sciences

The nematode *Caenorhabditis elegans* is one of the most important model systems for biological research. Despite many advantages of *C. elegans*, it lacks a critical tool - there are no *C. elegans* cell lines. Germ cells that are isolated from tumorous germline mutants can be maintained in a tissue culture media that was created by the Kipreos laboratory. However, the germ cells do not divide continuously, which is a requirement for generating an immortal cell line. This study focused on testing different mutant combinations in order to isolate a continuously-dividing germ cell line. We tested two different combinations of tumorous *C. elegans* mutants: glp-1(ts/gf); cki-2(lf); daf-16(lf); and glp-1(ts/gf); cki-2(lf); daf-16(lf); let-60(gf). We compared how effectively germ cells from these two different mutants can proliferate

in the tissue culture media. To carry out the experiments, the mutant strains were disrupted to release their germ cells, and then the germ cells were transferred to tissue culture media. The ability of the cells to proliferate was followed by measuring the level of DNA in the culture over time. To measure DNA levels, we set up a DNA quantitation assay using the fluorescent DNA stain Hoechst 33342, which was analyzed with a fluorometer. The level of DNA in the culture was measured as the cells were incubated over several days. The study also tested the effect of bacterial folates, which are a germ cell stimulatory signal, on the ability of the cells to replicate over time.

Implicit Subjectivity Assessment and Guilt-Shame Proneness in Work-Family Conflict, Family-Work Conflict and Workaholism

Dillon Patel, CURO Research Assistant
Dr. Malissa Clark, Psychology, Franklin College of Arts and Sciences

Workaholism, work-family conflict, and family-work conflict are emerging topics of profound interest and endless possibilities. Current studies on these topics have been largely limited to studying a small number of antecedents and the reliance on assessing self-reported perceptions of work-family conflict and family-work conflict. Though these forms of study have been able to yield interesting and powerful results, there is an implicit subjectivity in assessing one's own perception of workaholism, work-family conflict or family-work conflict. As such, this study aims to evaluate the validity of a behavioral checklist assessment, which would mitigate subjectivity, in relation to the pre-existing subjective work-family conflict, and family-work conflict measures. In addition, this study aims to investigate guilt/shame proneness, an antecedent that has yet to be investigated in consideration with workaholism, work-family conflict, or family-work conflict. Data collection has been completed through a Qualtrics questionnaire with a sample size of 300 working class adults. We anticipate that the behavioral work-family and family-work checklists will be positively related to self-perceptions of work-family and family-work conflicts. Additionally, we anticipate that guilt/shame proneness will be positively correlated with workaholism, in that individuals that feel a higher degree of guilt or shame are more likely to feel guilty for not devoting themselves to work enough.

Task Allocation between Established and Impromptu Dyads: A Test of the Transactive Goal Dynamics Theory

Divya Patel
Lindsay Burr, Grant Butschek
Dr. Michelle R vanDellen, Psychology, Franklin College of Arts and Sciences

The transactive goal dynamics theory suggests that the compatibility of a couple is characterized by their ability to allocate tasks when pursuing their goals, rather than by having similar traits or values. More compatible couples should have higher efficiency in task allocation, resulting in better goal outcomes and higher relationship satisfaction. In our research, we examine how relationship partners and random pairs of individuals allocate tasks when pursuing a shared goal. In the experiment, researchers invite two couples to each session and inform them that they are to complete a series of tasks as well as a questionnaire about the nature of the couple's relationship. This experiment is a 2x2 design in which researchers randomly assign participants, firstly, to be either on a team with their relationship partner or with an impromptu partner from the other couple, and secondly, to choose their own tasks to complete or receive designated task assignments from the researchers. In the free choice condition, participants allocate sixteen tasks, including darts, dancing, anagrams, and mental math between themselves and their partner in an attempt to maximize their total score. Tasks in assigned conditions are yoked on basis of previous participant choices. Data collection is ongoing and predicted results will be presented. We hypothesize that established relationship partners will be able to allocate tasks more effectively and efficiently than random pairs of individuals and this superior performance will be dampened when the tasks are assigned (i.e., not chosen by participants).

Cytotoxic Effects of Novel Compounds on Clinically Challenging Cancer Cell Lines

Hiral Patel, CURO Research Assistant

Dr. Mandi M Murph, Pharmaceutical and Biomedical Sciences, College of Pharmacy

Current therapeutic options aimed at cancer diagnoses include targeted therapy, immunotherapy, surgery, chemotherapy, and radiation to eliminate the present tumors. Each class of drugs strives to combat the cancer cell's ability to hijack their surrounding healthy systems, and therefore, a multifactorial approach to patient therapy is often ideal. However, 70% of patients do not respond to initial chemotherapy and the five-year survival rate for patients who display resistant behavior ranges from 10 to 30%. Cancer cells are able to prevent drug influx and therefore, buildup of chemoresistance often results in therapeutic failure. In this study, the cytotoxic effects of the provided compounds on are observed. We hypothesize that exposure of various melanoma and ovarian cancer cell lines to these potential cytotoxic compounds will greatly reduce cell viability, and possibly yield a novel therapeutic agent to combat malignant tumor growth. Alterations of functional groups on the original set of compounds may also enhance or decrease cytotoxic effects and is currently being explored through creating variations of successfully tested candidates. We utilized cytotoxicity assays depicted as dose response curves to represent our results and determine IC_{50} and statistical values. The three most effective compounds were D5, D9 and C2 as a majority of their IC_{50} values fell under the ideal 10 μM across the different cell lines. For future work, we plan to continue testing variations of the three successful compounds to yield the most potent candidate for in vivo testing.

Building the Genetic Tools to Make *Methanococcus Maripaludis* the Next-Generation Model Chassis for Biochemical Production

Hirel B Patel, CURO Research Assistant
Ben Park, Kyler Herrington, Ghazal Motakef
Dr. William Whitman, Microbiology, Franklin College of Arts and Sciences

Current bacterial chassis use expensive sugars as feedstocks, which limits profitability. Using the archaeal model *Methanococcus*, we are developing an archaeal chassis that feeds on inexpensive CO_2 and H_2 or formate instead of sugars, for next-generation biochemical productions. Our team is developing tools and methods for modulating protein expression in *M. maripaludis*, an archaeal model. Our focus is engineering the Ribosomal Binding Site (RBS). We use a mCherry reporter developed by our team previously to measure protein expression levels in a library of RBS mutants. We are now working to (1) determine the effects of mutations in the spacer region and the role of mRNA secondary structure, (2) expand our Archaeal Interlab study to encourage more iGEM teams to collaborate with us and standardize our fluorescence measurement protocol, and (3) continue metabolic modeling to evaluate the effect of alternate carbon sources on cell growth and geraniol production in *M. maripaludis*.

A Method for Enrichment of Maize Stem Cells and Leaf Primordia

Krishna Patel
Eva Lauren Rodriguez
Dr. Xiaoyu Zhang, Plant Biology, Franklin College of Arts and Sciences

Plant development is characterized by continuous organ formation and growth throughout the life cycle. This is primarily achieved via two small groups of self-renewing stem cells at the shoot and root apical meristems (SAM and RAM, respectively). In the SAM, stem cells are maintained in a central zone and daughter cells move laterally to peripheral zones where they differentiate into lateral organs, such as leaves. Despite the biological importance of plant stem cell maintenance and differentiation, the underlying mechanisms of stem cell self-maintenance and differentiation remain outstanding questions in plant biology. This gap in our understanding derives largely from the technical difficulty of performing chromatin analyses on the small number of cells in the SAM. To resolve this gap, we will use cell-type specific fluorescent lines, coupled with fluorescence-activated cell sorting, to acquire homogenous samples of stem cells and cells of young leaf primordia. We plan to use the Assay for Transposase-Accessible Chromatin (ATAC) to map accessible chromatin and transcription factor binding sites genome-wide. The ATAC-seq uses a hyperactive Tn5 transposase to insert Illumina sequencing adapters into sterically accessible

DNA, which will provide a genome-wide map of open chromatin. We have confirmed the presence of SAM- and leaf primordia-specific fluorescence in transgenic maize lines and we are optimizing a method for dissecting SAMs and processing for fluorescence-activated cell sorting.

Substrate Specificity of the Lactoperoxidase/Thiocyanate/Hydrogen Peroxide Cell-Free System to Inactivate Influenza Virus

Urmi Patel, CURO Research Assistant
Dr. Balazs Rada, Infectious Diseases, College of Veterinary Medicine

Influenza virus (IV) is a deadly pathogen that has the ability to affect large populations by infecting the airways. NADPH oxidase family's Dual Oxidase 1 has shown to play a role in antiviral defense through the production of hydrogen peroxide (H_2O_2) in tracheal airways. Lactoperoxidase (LPO), an enzyme present in tracheal airways, uses H_2O_2 to oxidize thiocyanate ions (SCN^-) into antimicrobial hypothiocyanite ($OSCN^-$). A similar reaction is seen in the formation of hypoiodous acid (HOI). Our previous work has shown that $OSCN^-$ inactivates Influenza A virus (IAV) H1N2 strain in a cell-free system where H_2O_2 is not generated by Duox1 but by the glucose/glucose oxidase system. To further confirm the hypothesis, rat tracheal cells were infected with different strains of IAV and Influenza B virus (IBV) in combination with SCN^-, I^- and LPO. Once the supernatants were collected, they were used to perform plaque assays. These antimicrobials resulted in viral inactivation of both IAV and IBV. The data obtained indicated several log reductions of infective virus via inactivation in the 3 component systems (LPO, I^- and SCN^-). Per the comparisons between I^- and SCN^-, in the cell-free system, IAV strains, such as H1N1 and H1N2 displayed higher susceptibility to HOI than $OSCN^-$ substrate. However, IBV displayed a greater inactivation by the $OSCN^-$ substrate compared to the HOI substrate system. These differences seen could lead to future studies that would develop our knowledge of the Duox1 system and enhance applied research in the direction of possible treatments of IAV and IBV.

Photodissociation of Carbon Monosulfide in Interstellar Environments

Ryan Pattillo, CURO Research Assistant
Dr. Phillip C Stancil, Physics and Astronomy, Franklin College of Arts and Sciences

Photodissociation occurs when a molecule absorbs a photon of light and breaks apart into separate atoms or molecules. The molecule is initially rotating and vibrating at a certain energy level, and it transitions to an excited, unbound state upon absorbing the photon. This process is a major source of molecular destruction in a variety of interstellar environments with a strong radiation field such as circumstellar disks, protoplanetary disks, and diffuse and translucent clouds. To reliably estimate the abundances of molecules in these regions, it is important to have accurate photodissociation rates. Typically, photodissociation rates for a molecule are computed for transitions from only its ground rotational-vibrational level. For the carbon monosulfide (CS) molecule, we instead compute photodissociation cross sections for transitions from several thousand rotational-vibrational levels to six excited molecular states. This yields comprehensive cross sections which can be applied to calculate accurate photodissociation rates in a wide range of interstellar environments. We achieve this computationally using a two-state quantum perturbation approach. A detailed look into the modeling of this process, as well as some example applications of the cross sections, is presented.

Cambodian Mental Health Therapists' Experience in Clinical Supervision: A Phenomenological Exploration

Amanda Peclat-Begin, CURO Research Assistant
Dr. Desiree M Seponski, Child and Family Development, College of Family and Consumer Sciences

Decades after the Khmer Rouge genocide in Cambodia, the country is still continuing to develop and rebuild, including mental health treatment services. While there is extensive research on mental health attitudes, practices, and treatments with Cambodian refugees around the world, there has been a lack of focus on the effectiveness of therapies in native Cambodia or

Cambodian therapist's personal experiences in providing mental health treatment. Psychotherapy is a field that is highly stigmatized, unregulated, underfunded, and still developing in Cambodia. In 2011, the first cohort of therapists graduated from the Royal University of Phnom Penh's Master's program in clinical and counseling psychology, which is currently the only program of its kind in the country. Given the influx of newly trained therapists and implementation of mental health treatments, it is important to understand their experiences of psychotherapy and how treatments can be made more culturally responsive. This study explores the psychotherapy practice experiences of Cambodian therapists, and their utilization of clinical supervision. Thirteen practicing therapists were interviewed in the winter of 2015-2016 and asked about their experiences practicing therapy and receiving supervision, usually from a supervisor not native to Cambodia. Preliminary analysis of the data show that while supervision is usually regarded as a positive experience for therapists, there are some difficulties that commonly arise. Issues understanding one another (as sessions are conducted in English) and a lack of cultural understanding of Cambodian culture could lead to discouragement among the therapists. As the first ever certification course for clinical supervision in Cambodia is currently in progress of development, data driven suggestions for a culturally responsive approach to supervision for non-Cambodian supervisors are explored.

Variation in Egg Development in Deceased *Extatosoma tiratum* Females

Linden Pederson, CURO Research Assistant
Dr. Marianne Shockley, Entomology, College of Agricultural and Environmental Sciences

Through the dissection of a deceased female *Extatosoma tiratum* (a large species of phasmid endemic to Australia) it became apparent that the specimen has a multitude of eggs in her ovarioles and ovipositor that had yet to be laid, and presumably would have been laid had the female not died. In this study ten deceased female *Extatosoma tiratum* will be dissected in order to examine their ovarioles and the eggs arranged in their ovipositor. Previous research shows that there is considerable variation in the developmental rates of embryos in eggs that have already been laid. Despite this, I anticipate a distinct level of internal development of the eggs in the females' ovipositors — that there is a certain developmental point eggs must reach before being laid. The internal structure of the eggs in the ovipositor will also be compared to the eggs which are of similar exterior development located in the females' ovarioles. This comparison will be used to discern if there is a difference between the development of eggs that would have been laid imminently and those that would have been laid at a later date had the female not died. Better understanding the nature of reproduction of this species will hopefully maximize their fecundity as well as promote the health of colonies reared in labs and zoos.

Do Changes in the Quality and Quantity of Leaf Litter Inputs Affect Growth Rates and Emergence of Stream Macroinvertebrate Consumers Following Reach-Scale Removal of Rhododendron?

Reed Peloquin, CURO Research Assistant
Dr. Catherine Pringle, Ecology, Odum School of Ecology

Rhododendron is a locally invasive shrub that grows along small southern Appalachian streams that inhibits the growth of other riparian vegetation. The USDA Forest Service is experimenting with removing this shrub along several streams in the Wine Springs watershed in the Nantahala National Forest of North Carolina in order to promote the growth of hardwoods. This study focused on two second-order steams, Kit Springs and Holloway. Kit Springs was treated as a reference stream, while Rhododendron at Holloway was cut and piled away from the bank and herbicide was used to inhibit growth of Rhododendron stumps. Rhododendron leaves are of lower quality than hardwood litter, and removal of this riparian shrub could affect the quality of leaf litter resources in streams, affecting stream macroinvertebrates that feed on leaf litter. When stream insects metamorphose into their adult winged forms to reproduce, they also provide an important food source for terrestrial predators. Removing Rhododendron from the riparian zone could have several effects on stream insects that consume leaf litter. Low-quality Rhododendron leaves have been shown to reduce the growth

rates of insect consumers, while high-quality litter (contributed by hardwood trees recruited after Rhododendron removal) may increase growth rate of insects that consume leaf litter. Excessively high growth rates have been shown to cause insects to develop faster and emerge at smaller sizes. This could cause a desynchronized emergence, with a portion of the population emerging before the rest of the population does in a usual mass emergence. Other studies of desynchronized emergence have observed that early emergence is dominated by males, potentially interfering with later-emerging females finding mates and affecting reproductive success. The potential for these effects will be explored by examining the size distribution of populations of two different insect taxa: *Tallaperla maria* and *Pycnopsyche sp*. in stream reaches where Rhododendron has been experimentally removed. We hypothesize that desynchronized emergence will occur in the Rhododendron removal reach, with individuals emerging early in the emergence window at a smaller size than individuals from the reference stream.

Using Syndemics Theory to Examine the Correlation between Wealth, Disease Knowledge, and Zoonotic Diseases in Panama

Kara Pemberton, CURO Research Assistant
Dr. Susan Tanner, Anthropology, Franklin College of Arts and Sciences

Syndemics are defined as "two or more afflictions acting synergistically, contributing to excess burden of disease in a population" (Merrill Singer. 2009. *Intro to Syndemics*.) Historically the term has been used to describe interactions of diseases and social conditions such as Substance Abuse, Violence, and AIDS (SAVA), but syndemics may also be a useful framework to examine synergistic interactions between wealth, humans, and zoonotic diseases. This paper draws on previously collected data from a collaborative project in Panama that investigated two zoonotic diseases (Chagas disease and American leishmaniasis) in six rural communities. Data analysis will examine correlations between a person's knowledge of zoonotic diseases, socioeconomic condition, and access to health care infrastructure. This will involve several measures of household economic status, results from a knowledge test of zoonotic disease, and the presence of a community health post. Preliminary analysis suggests an association between household wealth and disease knowledge. Health is a holistic thing that extends beyond the body, to the physical, social and economic environment in which we live. Syndemics are a starting point for understanding how that environment affects the body. Negative social conditions can weaken our bodies and exacerbate disease, and treatment should involve preventative care of conditions making our bodies vulnerable. Further research into how a government can manage syndemics, through funding policies, health care resources, or other methods, will help inform global health policy.

Parental Support for Autonomy as a Predictor of Anxious and Depressed Behaviors in Elementary School Children

Julia Marie Petros
Chantal Van Landeghem
Dr. Anne Shaffer, Psychology, Franklin College of Arts and Sciences

Previous research has consistently demonstrated the positive influence of parental support for autonomy on children's psychosocial development. Findings are mixed regarding the relationship between support for autonomy and child internalizing problems, however. For the current study, we hypothesized that parental support for autonomy would be negatively correlated with child internalizing problems, and this relation would be mediated by the child's emotion regulation. The study used a diverse community-based sample of 64 children, ages 8-11, and their mothers. Measures of autonomy support were obtained through observations during a series of interaction tasks, child anxious/depressed behaviors and emotion regulation were assessed via parent report (CBCL, ERC). Multiple regression analyses were used to test the mediation model. Partially consistent with the hypotheses, maternal support for autonomy did not directly predict internalizing problems (B=.39, SE=.35, CI =-.30 to 1.09), but it did have a significant indirect effect, with child emotion regulation acting as a significant mediator (B=-.20, SE=.13, 95% CI =-.56 to -.01). The mediation model was not significant when child gender and maternal education were included as covariates,

however. Because maternal support for autonomy does not appear to be a direct predictor of young children's internalizing problems but still plays a role in child outcomes, future studies should analyze related maternal behaviors that may interact with support for autonomy to impact child development. It may also be that support for autonomy is more relevant at older ages, such as adolescence, suggesting a need for longitudinal research.

Mechanisms of Drug Resistance Based on Computational Studies of Taxol

Amanda Pham, CURO Research Assistant
Darby Lyle Woodling, Marisa Stewart
Dr. Paul Xie, Electrical and Computer Engineering, College of Engineering

Microtubules are known to have a dynamic intracellular structure that is involved in a variety of cellular mechanisms including intracellular transportation, structure stability and cell division. From previous research on this important molecule, microtubules have been found to be primarily correlated with developments of cancer and chemotherapy resistance. Further studies have found a breakthrough anticancer drug, Paclitaxel, which targets to the "Taxane site," on the β-tubulin heterodimer structure that aids in creating the overall microtubule structure. As a result, this has provided multiple advancements for treatment of several tumor cancers. However, drug resistance is a major challenge associated with Paclitaxel and for the overall response and survival of cancer patients. Microtubules play a major role as drug targets in cancer treatment due to their key role in cell division. Understanding the binding of Paclitaxel and the interactions between Paclitaxel and its binding residues is important for revealing the mechanisms of drug resistances and identifying new drugs. However, the determined structures have bad resolution which caused arguments to the overall "binding pattern." In this research through computer drug discovery, we have applied ligand docking on tubulin proteins through a specialized program, Schrodinger, and will compare the docking structures from our projected list of tubulin proteins. Our predicted results will provide new evidences for the disagreement of binding conformations and the mechanisms of observed drug resistances.

A Look into the Contents of Faculty Learning Community Meetings of STEM Professors

Jamie Pham
Dr. Paula Lemons, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

US policy makers and education researchers are calling for college biology professors to adopt new teaching strategies that include the use of assessment data in teaching decisions. To do so, a number of biology professors have joined a project called Automated Analysis of Constructed Responses (AACR). In this project, the professors incorporate pre-made AACR questions into their classroom. AACR questions are constructed-response questions focused on key concepts in biology that can be analyzed by a computer. After sending off their students' results, faculty receive an AACR report that shows them the student misconceptions. Seeing these data allows faculty to modify their teaching in order to address the misconceptions. In order to learn to use AACR, these faculties participate in faculty learning communities (FLCs), where they have the opportunity to discuss various topics related to the project with their colleagues. This paper reports on the investigation of AACR FLCs at six institutions and focuses on the research question, "How is time utilized during AACR FLC meetings?" FLC meetings are studied from transcripts of audio recordings. The transcripts are analyzed using qualitative content analysis to identify meeting topics and emphases. These analyses reveal that each AACR FLC spends their meeting times differently to accommodate the group's needs. This new knowledge is important because it allows greater insights into faculty teaching obstacles, their thoughts on teaching and learning, and their motivations for changing their teaching style. This knowledge will assist in the development of future professional development opportunities.

Animism and Foraging Economies

Matt Pieper
Dr. Bram Tucker, Anthropology, Franklin College of Arts and Sciences

This research will test recent anthropological claims that "animism" or "perspective cosmology"

(in which humans, animals, and plants have similar souls) is either an adaptation to a foraging economy or a cultural tradition shared amongst Native American societies. The hypothesis will be tested through cross-cultural analysis of indigenous North American cultures and foragers from Africa. The research will use existing published data as well as data collected from individual research participants. Participatory data collection was deemed necessary as preexisting ethnographic information proved to be insufficient. Africa was chosen as a cross-cultural reference point due to a comparable presence of foraging economies; an imperative parallel in identifying potential cross-cultural patterns. These patterns, if observed, have the ability to further contribute to substantive discussion regarding the topic of psychic unity v. cultural relativism in regards to human behavior. I anticipate that the data will reflect a trend in which animism is shown to be associated with foraging economies and not a cultural adaption unique to the indigenous peoples of North America.

Effect of Sample Collection at Various Collection Sites on the Detection of *Mycoplasma synoviae* by Real-Time PCR

Stephanie Alexandra Pierre
Dr. Naola M Ferguson-Noel, Population Health, College of Veterinary Medicine

Mycoplasma synoviae (*MS*) is a prevalent and economically significant poultry pathogen, causing respiratory tract infections and infectious synovitis. Tracheal swabs are considered the standard collection site for sampling to detect *MS* by culture or PCR but various sites in the upper respiratory tract have been used to detect avian *Mycoplasma spp.* and other respiratory pathogens in commercial poultry. It is important to identify which of the collection sites produces optimal PCR results when performing diagnostic tests, to ensure that *MS* is rapidly and correctly identified for the protection of poultry breeding flocks. The objective of this study was to compare the detection of *MS* by quantitative real-time PCR (qPCR) from three collection sites (trachea, choanal cleft and ororphaynx). Two groups of broiler-type chickens were inoculated with different strains of *MS* (a virulent strain and a potential vaccine strain) and sampled. The qPCR results (mean Ct values and MCNlog10) showed that all three of the sampling sites were appropriate for PCR, as there were no significant differences ($P< 0.05$) with respect to percent positives or MCNlog10 among the sites. Overall the tracheal swabs had the stronger PCR results leading to the conclusion that it should remain the standard for research purposes.

Promotion, Patronage and Merit in the Royal Navy during the Napoleonic Wars

Stephen Robert Pokowitz, CURO Research Assistant
Dr. Jennifer Palmer, History, Franklin College of Arts and Sciences

Naval promotion during the Napoleonic Wars in the Royal Navy started shift away from the Captain's List towards more merit based promotions that allowed the Royal Navy to maintain naval superiority against other European powers. An analysis of how prevalent merit based promotions were, along with an analysis on the success of these early promotions, will be based on a collection of primary and secondary sources. The primary sources will consist of letters and dispatches from leading figures within the Admiralty and publications such as the *Naval Chronicle* and the *London Gazette*, which had a large impact on public opinion and advancement. The secondary sources will be drawn from academic books and will allow for a more broad analysis on specific cases and the overall impact of merit promotion. The research has shown that merit promotions were a mixed bag, with the Captain's list becoming more irrelevant in favor of merit promotion, but also that merit promotion wasn't always used on deserving Commanders. This shift might also be seen as a response to the individualism of the French Revolution. The shift more toward merit promotion was the start of more professional modern militaries that placed less emphasis on social status and more on ability.

Investigating the Use of mRNA Transfection to Treat Hypophosphatasia

Trey Powell, CURO Honors Scholar, CURO Research Assistant, CURO Summer Fellow
Dr. Luke Mortensen, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Hypophosphatasia (HPP) is a rare genetic disease that impairs the process of bone mineralization due to low activity of tissue-nonspecific alkaline phosphatase (TNAP). Severe hypophosphatasia also manifests with complications including hypercalcemia, vitamin B6-dependent seizures, and craniosynostosis. Many patients suffering from these symptoms die from respiratory failure. Other forms of HPP include perinatal, childhood, adult, and odonto-HPP with symptoms ranging from stillbirth to loss of teeth. Current treatment for HPP, enzyme replacement therapy, hinders the livelihood of HPP patients, as it requires daily intravenous treatment, and does not impact craniofacial or tooth defects. Mesenchymal stem cells derived from bone tissue have shown promise to treat HPP with a low allogenic transplantation rejection rate, and yield increased bone mineralization and muscle mass in patients. To enhance mesenchymal stem cell (MSC) therapy as a treatment for HPP, I studied the application of mRNA transfection in MSCs using the CRE lox system. The transfection of mRNA may be used to alter protein expression in therapeutic MSCs to increase cell production of alkaline phosphatase or enhance transplanted cell engraftment. Here, mRNA transfection was used to express fluorescent proteins. Three experiments analyzed the transfection optimization and indicated that 1:3 and 1:5 mRNA to transfection reagent ratios produced the greatest overall cell fluorescence. Our results indicate the power of mRNA transfection to alter MSC behavior, which will be useful for in vitro and in vivo studies.

An Investigation into the Dynamics of Faculty Learning Communities

Briel Power, CURO Research Assistant
Dr. Paula Lemons, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

A growing emphasis on reform in US higher education has led many college faculty members to consider changing their teaching strategies. In particular, many are now implementing active learning, which consists of teaching methods that encourage students to cognitively engage with the material during class. Research focuses on the dynamics of Faculty Learning Communities (FLCs) and their use as professional support for the implementation of active learning strategies in undergraduate science courses. The FLCs under investigation arose through a multi-institutional project known as Automated Analysis of Constructed Response (AACR). AACR provides data to faculty about their students' thinking. AACR FLCs support faculty in understanding the data-heavy AACR reports and how to modify teaching accordingly. Transcripts of FLC meetings from multiple institutions are analyzed by qualitative content analysis, which involves exploring the transcripts for thematic patterns. These data reveal the interests and perceptions of AACR FLC participants. This knowledge will lead to improved professional support for faculty groups and should and may improve the implementation of active learning strategies in the undergraduate classroom.

The Persistence of Small Pollen Grains in Populations of *Ipomoea purpurea*

Darien Power, CURO Research Assistant
Dr. Shu-Mei Chang, Plant Biology, Franklin College of Arts and Sciences

This research project uses the common morning glory flower, *Ipomoea purpurea*, to examine how different pollen grain sizes contribute to male reproductive success. This is important since most studies examine female fitness only. The Chang laboratory found previously that when large and small pollen grains are in direct competition in greenhouse experiments, large pollen grains fertilize more ovules than small ones. The current project investigates whether or not this remains true when the flowers are exposed to natural pollinators. The plants used in this study were from artificially selected lines that diverge in pollen size and were naturally pollinated by bees. These samples were allowed to flower naturally so that the flower number represented the normal display size. The seeds produced from this pollination array study were collected and planted in the greenhouse. Once these seeds grew, I collected leaf tissue samples from 84 individuals and extracted their DNA using a modified CTAB protocol. Polymerase Chain Reactions for seven different microsatellite loci were run on each individual. I conducted paternity analyses on the computer to determine whether the paternal parent was a large- or small-pollen parent. Contrary to the greenhouse results, I found that small pollen grains were more reproductively successful than large ones. This result points to

the importance of understanding why we see different patterns in greenhouse experiments and field studies. It also contributes to our understanding of why both large- and small-pollen grains are produced in natural populations.

Chikungunya Virus-Like Particles Vaccine Formulations that Elicit Balanced Th1/Th2 Response in Mice

Matthew Prellberg, CURO Research Assistant
Dr. Ted M Ross, Infectious Diseases, College of Veterinary Medicine

Chikungunya virus (CHIKV) is a mosquito-borne alphavirus that is responsible for large epidemic outbreaks in South-East Asia, India, Europe, and recently the Americas. CHIKV causes severe fever, rash, and joint pain, and represents a serious public health threat in countries where *Aedes spp.* mosquitoes are present. Vaccination remains the best strategy to prevent most vector-borne diseases, as they offer means to induce rapid and long-lived immunity with negligible risk of serious adverse reactions. In order to develop such a vaccine to protect against CHIKV infection, we developed CHIKV virus-like particles (VLPs) produced in insect cells by recombinant baculoviruses. We then paired them with different adjuvants aimed at modifying VLP's T-helper (Th) cell polarization to induce a balanced Th1/Th2 response, which is believed to be productive against chronic infection. Vaccine candidates will be tested in mouse models of CHIK infection and will be evaluated for immunogenicity and protection. CHIKV antigen-specific antibody responses in immunized C57BL/6 mice were determined using ELISA. We are interested in measuring mouse total IgG, IgG2c, and IgG1 antibody responses against CHIK VLP antigens paired with differing adjuvants. Measured IgG2c and IgG1 antibody ratios will be used to evaluate Th1 vs. Th2 response for vaccine candidates respectively. The final vaccination-challenge in mice against wild type CHIK infection will be done to examine vaccine efficacy. Vaccines displaying balanced IgG2c and IgG1 antibody ratios are hypothesized to stimulate superior protection.

Metabolic Responses to Diets of Varying Fatty Acid Saturation

Leah Nicole Prine , CURO Research Assistant
Dr. Jamie A Cooper, Foods and Nutrition, College of Family and Consumer Sciences

Studies show that composition of dietary fats has differential influences on fat oxidation, playing a role in obesity. Determine the effects of a high-fat (HF) diet rich in either poly-unsaturated fatty acids (PUFAs) or mono-unsaturated fatty acids (MUFAs) on fat oxidation. Fifteen normal weight men (18-45 years) completed a randomized, cross-over design of 2 feeding trials. Each trial included a 3 day lead-in diet, pre- and post-diet study visits, and a 5 day HF diet. 5 day diets were rich in either cottonseed oil (PUFA) or olive oil (MUFA). During the 2 study visits (before and after the 5 day diet), indirect calorimetry was used to measure fasting respiratory exchange ratio (RER) and substrate oxidation. There was a two week washout period between trials. Area under the curve (AUC) was calculated and used to assess differences within groups. RER AUC decreased significantly from pre to post in the PUFA-rich diet (pre=0.85 ±0.06units/h, post= 0.83 ±0.03units/h), but not in the MUFA-rich diet (pre= 0.84 ±0.06units/h, post=0.83 ±0.05 units/h). Fat oxidation AUC increased significantly from pre to post in the PUFA-rich diet (pre= 8.9±0.7 g/8h, post= 10.5 ±0.4 g/8h), but not in the MUFA-rich diet (pre= 10.0 ±0.7 g/8h, post=10.5 ±0.7 g/8h). Significance was expected at $P< 0.05$. Chronic ingestion of a PUFA-rich HF diet may decrease RER (indicating higher fat oxidation) in normal weight men whereas a MUFA-rich diet does not have the same effect.

In Vitro Activity of Gallium Maltolate against Drug-Resistant *Rhodococcus equi*

Maggie Pritchett
Dr. Steeve Giguere, Large Animal Medicine and Surgery, College of Veterinary Medicine

Rhodococcus equi is a Gram-positive bacterial pathogen causing severe pneumonia in foals. Recently, emergence widespread resistance to macrolides and rifampin, the two types of antibiotics currently used to treat infection caused by *R. equi*, has become a major problem facing the horse industry. The only viable long-term approach to prevent emergence of resistant *R. equi*

will be to decrease widespread use of commonly used antibiotics in foals. Gallium maltolate (GaM) is a semi-metal that is active against many types of Gram-positive bacteria. If GaM proves to be active against *R. equi*, its use in infected foals might be a way of decreasing selection pressure for antibiotic resistance. The objectives of this study were to compare the in vitro activity of GaM to that of other antimicrobial agents against R. equi and to determine if exposure of *R. equi* to GaM in vitro will select for resistance. The minimum inhibitory concentration (MIC) and the mutant prevention concentration (MPC) of GaM, macrolides, and rifampin were determined for both antibiotic susceptible (n= 30) ant antibiotic resistant (n=30) isolates of *R. equi*. Gallium was active in vitro against all isolates of *R. equi* with a median MIC of 8 μg/mL (range 4 to 32 μg/mL). However, the MPC was ≥ 512 μg/mL, indicating that resistance to GaM occurs readily in vitro. Additional in vivo studies will be required before GaM can be used for the treatment of pneumonia caused by *R. equi* in foals.

No Longer Used: Designing Non-Exploitative Communication for Organizations Seeking to End Human Trafficking

Emma Katherine Protis, CURO Research Assistant
Dr. Maria Len-Rios, Journalism, Grady College of Journalism and Mass Communication

A common approach nonprofits use in developing external communication to publics is to stress emotional detail and capture the intense circumstances of the people they serve. At times, this results in over-portraying elements of pity and helplessness regarding these circumstances. This can be an effort to generate funds or support from the general public. Even so, when this is the predominant tone for all storytelling, it can exploit the survivors, even if unintentional. This research seeks to answer how to effectively conduct external communications for nonprofits seeking to end human trafficking without exploiting the survivors. This study takes a novel approach using theory to design ethically responsible communication. It focuses primarily on representing the trafficked person with dignity in communication materials calling for support to end human trafficking. In-depth interviews with professionals at organizations who advocate for an end to human trafficking will be synthesized into a qualitative study from which I will create a guide of best communicative practices to achieve non-exploitative storytelling. The guide will provide recommendations for nonprofits practicing advocacy work, ultimately strengthening efforts to bring justice to the estimated 20-30 million humans held captive in slavery today.

Persistence of Extractive Foraging in Humans and Wild Tufted Capuchins (*Sapajus libidinosus*) Abstract

Mackenzie Rose Pryor, CURO Research Assistant
Nam Money, Jessica C Respress
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts and Sciences

Wild tufted capuchin monkeys (*Sapajus libidinosus*) are the only New World primates that use stone tools for extractive foraging. Stone tool use is an extremely energy intensive practice for these monkeys, and their behavior has been described as persistent in nature. This study examined persistence of humans during an extractive foraging task and compared it to footage of wild capuchin monkeys practicing extractive foraging by cracking nuts with stone tools. Thirty human participants were provided a choice of ten tools to open a pomegranate, extract each seed, and deposit them individually into a receptacle. Foraging behavior frequency, variability, and task length for both humans and capuchins were coded and collated. Preliminary analysis suggests that capuchins will be more persistent than humans and it appears that capuchins tend to spend more time foraging, and use less diverse foraging techniques than humans. This implies that monkeys can maintain focused attention on an extraction problem for as long as humans. We discuss the hypothesis that working with a tool can promote the development of sustained attention.

Effects of Form and Level of Vitamin E Supplementation on Kinematic and Physiological Measures of Muscle Damage Following Intense Exercise in Horses

Lauren A Purvis
Dr. Kylee Duberstein, Animal and Dairy Science,

College of Agricultural and Environmental Sciences

Vitamin E is an essential dietary antioxidant thought to have a role in preventing delayed onset muscle soreness in exercising subjects. Previous research has shown that horses supplemented with natural α-tocopherol are able to achieve higher blood α-tocopherol levels as compared to those supplemented with the more commonly used synthetic acetate form. The purpose of this study is to determine if this confers any physiological advantage to the exercising horse. Eighteen horses will be placed on one of three diets for a seven week feeding trial: control diet fed 1000 IU α-tocopherol acetate; control diet plus 3000 IU supplemental α-tocopherol acetate; or control diet plus 3000 IU natural α-tocopherol. Horses underwent a 6 week exercise program of increasing intensity following one full week of supplementation. A standard exercise test (SET) was performed immediately before and immediately after the 6 week program. Blood was drawn pre- and 2 hours post-SET and analyzed for creatine kinase and aspartate aminotranserase (measures of muscle damage). Additionally, horses were filmed trotting (4 mps) in hand using high speed cameras. Filming was conducted immediately prior to each SET, and 24 hours post-SET to assess kinematic changes to the gait that may be induced by muscle soreness. Physiological measures of muscle damage were correlated to stride parameters such as swing and stance times as well as suspension of the gait. Findings from this study should show whether higher blood levels of α-tocopherol confer a physiological advantage to the performance horse.

Early Rehabilitation to Augment Skeletal Muscle Function Following Volumetric Muscle Loss Injury

Anita Qualls, CURO Research Assistant
Dr. Jarrod A Call, Kinesiology, College of Education

Significant loss of skeletal muscle tissue from severe trauma or surgical removal is known as a volumetric muscle loss (VML) injury. Muscle repair following VML injury is attenuated due to prolonged inflammation, increased fibrosis, and poor muscle regeneration, which results in extensive skeletal muscle function impairments and mitochondrial dysfunction. The purpose of this study was to implement early rehabilitation strategies that augment muscle function and mitochondrial capacity via range of motion, intermittent electrical stimulation, and supplementation with guanidionpropionic acid (GPA) (a drug to enhance mitochondria). Surgical VML injury was performed on the hind limb of male C57/B6 mice. Mice were randomized into three rehabilitation intervention groups: passive ankle range of motion (ROM), range of motion with intermittent electrical stimulation (ROM-E), and ROM-E with addition of 1% GPA mixed in standard chow (ROM-E-GPA). All groups performed two 30-minute rehabilitation therapy sessions per week beginning 72 hours post VML injury. Passive isometric torque, a measure of muscle stiffness, was recorded from each therapy session. Prior to sacrifice, peak isometric torque was assessed via an in vivo contractile test. Mitochondrial content and function were analyzed via citrate synthase activity and state three mitochondrial respiration rates from permeabilized muscle fibers, respectively. Following two months of rehabilitation, peak isometric torque was significantly greater in both ROM-E and ROM-E-GPA groups compared to ROM ($p=.0212$). Passive isometric torque decreased during individual therapy session in all groups (~15-40%). Preliminary muscle torque data indicates that early rehabilitation intervention techniques improve functional recovery and regeneration following VML injury.

Time is Brain: Expanding Access to Stroke Care in Rural Georgia Communities

Anita Qualls, CURO Research Assistant
Dr. Pamela Whitten, Communication Studies, Franklin College of Arts and Sciences

There is a lack of access to acute stroke care in rural Georgia, particularly with respect to the absence of neurological expertise and appropriate infrastructure, such as "stroke-ready facilities" to accurately identify and treat stroke victims. This issue stems from the extremely common and serious nature of stroke, the time-sensitive delivery for the treatment, and an underlying poor health condition correlated with a significantly higher incidence of stroke mortality in Georgia. Regional disparities in quality of healthcare services and

funding have been sustained through history and continue to create detrimental symptoms, including increased chance of death from stroke in rural areas and excessive spending to cover the expenses of stroke and disability throughout the nation. An analysis of root causes and symptoms was conducted to gain a better understanding of why these issues persist after multiple policies have been instituted to ameliorate these issues. To address these causes, three policy alternatives were developed: continued stroke education for physicians, community based stroke prevention coalitions, and state-wide implementation of telemedicine services. After analyzing the effectiveness, cost-benefit, and feasibility of each alternative against the status quo, it was determined that the best option for short-term implementation is continued stroke education for rural emergency physicians and the best long-term goal is state-wide implementation of telemedicine services.

Applications to Prolonging Data Collection Efficiency in Stream Channels

Matthew Quinn, CURO Research Assistant
Dr. John Dowd, Geology, Franklin College of Arts and Sciences

Within small first- and second-order streams, such as tributaries of the North Oconee River watershed, the response time to precipitation is fast. This response makes repetitive measurement of discharge and water chemistry necessary. Continual data collection in streams can be more efficiently measured with an automated system. The discharge of a stream is easily determined by a pressure transducer, but water chemistry proves to be more problematic. Probe calibration is prone to drift if continually left in the water. Three electrical conductivity systems are compared in this study. One system is a probe that remains in the stream taking measurements every five minutes. The second system is driven by peristaltic pumps that draw from the stream in order to fill a reservoir for measurement. The system measures conductivity every hour. The last system is a track that lowers a probe into the water on the hour and then raises it. The anticipated result is that the peristaltic pump apparatus will be the most efficient system due to more isolated measurement and greater protection from the stream. However, early failures have occurred when the air temperature drops below freezing or the intake is buried under shifting sands of the channel. The submerged probe has also failed from burial. When operating properly both systems have shown similar results, however the probe that stays submerged displays more drift in calibration over time. This research exhibits how reliable chemical data can be collected in remote areas where field visits are infrequent.

Investigations on the Distinct Isoforms of Duffy Antigen Receptor for Chemokines

Zehra Rahman
Dr. Melissa B Davis, Genetics, Franklin College of Arts and Sciences

The Duffy Antigen Receptor for Chemokines, also known as DARC, is a promiscuous chemokine receptor encoded by the DARC gene. This receptor protein is found, along with other cell types, on the surface of erythrocytes and helps to maintain chemokine homeostasis. DARC accomplishes this by sequestering chemokine activity, which indirectly helps to control the movement of immune cells to or away from the site of inflammation via a chemokine gradient. DARC has seven transmembrane domains with the extracellular binding region localized at the amino terminus. It is considered a promiscuous receptor because it can bind two structurally distinct classes of chemokines. The DARC gene also has two isoforms, A and B. These two isoforms are a result of two distinct promoters producing alternative transcripts. They are co-expressed in many tissues, but the functional differences between them have not been well-characterized. Using breast cancer cells that have been transiently overexpressed with both isoforms separately, our research seeks to investigate the functional roles of these isoforms. This will allow us to determine any distinct chemokine binding profiles between the two isoforms. We will accomplish this by using downstream applications such as co-immunoprecipitation and western blotting to validate overexpression and determine any protein-protein binding interactions. We will also perform ELISA assays to quantitate differences in chemokine concentrations in the media of the transfected cells. Our investigations will aid in the determination of any distinct chemokine binding between the isoforms, in

addition to better characterizing their role in a breast cancer context.

Branched-Chain Amino Acid (BCAA) Transporters: Mechanism, Physiological Function and Roles in Cancer

Simran Rajput, CURO Research Assistant
Dr. Takahiro Ito, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Branched-Chain Amino Acids (BCAA) are amino acids with aliphatic side chains. Valine, leucine, and isoleucine are the three proteinogenic BCAA among the nine essential amino acids in humans. Besides their importance in nutrition, recent studies have shown the utilization of BCAA in cancer. Because cancer cells proliferate more rapidly than normal cells, they rely more on nutrients such as glucose and amino acids. In order to be used in cellular processes, BCAA need to be transported into cells. Therefore, the role of BCAA transporters is essential to understanding how they contribute to cancer growth. In this study, we used previous scientific literature and human gene expression databases to focus on the three BCAA transporter protein families expressed in various types of tumors, namely SLC6, SLC7, and SLC3 families, and discuss their mechanistic functions in cancer development. The gene expression of the solute carrier family 6 member (SLC6 family) transporters is upregulated in tumors of epithelial origin, such as cervical, pancreatic, breast, and colon cancer. BCAAs are highly enriched in lung tumor cell lines as a result of overexpression of SLC6A15. The SLC7 family members are highly expressed in nine different cancer types including endocrine lung carcinomas and pancreatic cancer. Our research guided us to look deeper into a SLC3 transporter (SLC3A2), because SLC3A2 is involved in guiding and targeting SLC7A5 and SLC7A8 in the plasma membrane. The identification of specific BCAA transporters that are essential for growth or survival of cancer cells may reveal a therapeutic target.

Healthcare for All: A Roadmap for a Healthier Georgia

Vineet S Raman, Ramsey Scholar, CURO Summer Fellow, CURO Research Assistant
Dr. Barbara Schuster, Clinical and Administrative Pharmacy, College of Pharmacy

The Patient Protection and Affordable Care Act (ACA) signed into law on March 23, 2010 is the most significant attempt to overhaul the American healthcare system since the creation of Medicare and Medicaid under the Great Society of President Lyndon B. Johnson. The ACA stopped short of reforming the multiple different systems of healthcare provision in the US. Instead, it focused on outlawing less consumer-friendly insurer practices and expanding insurance coverage by widening the definition of "low-income" to include childless adults under 138 percent of the Federal Poverty Level (FPL). The passage of the ACA was quickly followed by a June 2012 case in the Supreme Court that largely upheld the ACA, but struck down the stipulation requiring states to expand Medicaid to remain eligible for federal funds. Despite this overhaul, almost one in seven Georgians is uninsured, and over 300,000 Georgians have fallen into a coverage gap created due to the failure of Georgia to expand Medicaid. Rural and urban health facilities struggle to maintain their services and remain viable, causing their surrounding communities to suffer. Thirty-two states have expanded Medicaid, with seven of these expanding their Medicaid programs through non-traditional methods using Section 1115 waivers which allow for flexibility with federal funds. This policy paper asserts that the best option for Georgia is to expand Medicaid to 138 percent FPL, as originally mandated by the Patient Protection and Affordable Care Act (ACA).

Tablet-Based Data Collection for Leprosy Field Surveys

Vineet S Raman, Ramsey Scholar, CURO Summer Fellow, CURO Research Assistant
Dr. Corrie Brown, Pathology, College of Veterinary Medicine

Though previously rare, leprosy surveys have seen a recurrence as public health organizations seek to gauge the increase in leprosy prevalence in South Asia. All of these surveys are conducted mainly using paper-based methods. With the recurrence of leprosy surveys and the popularity of tablet-based data collection, this study seeks to implement a tablet-based form created using

Open Data Kit Software functioning on an Android operating system for a leprosy survey, and gauge the initial experiences of veteran paramedical field workers. The experiences of the field personnel were recorded through an interview and subsequently analyzed. The objectives of this study and paper therefore, are to assess the experiences of paramedical field workers with a novel survey tool, describe the tool, and evaluate its efficacy.

Incorporating Individual Consumer Physiology into Our Current Understanding of *Littoraria-Spartina* Interactions within Southeastern US Salt Marshes

Hend Rasheed, CURO Research Assistant
Dr. Craig W Osenberg, Ecology, Odum School of Ecology

Salt marshes are some of the most productive ecosystems on the planet. In the Southeastern US, this high productivity results from the seasonal turnover of a highly productive grass, *Spartina alterniflora*. A ubiquitous grazer in these marshes, the snail *Littoraria irrorata*, has been shown to exert varying degrees of top-down control on *Spartina* in marshes spanning Florida to New England. Variability in *Littoraria-Spartina* interactions can be linked with population biomass of *Littoraria*, which in turn is a function of population size structure and density. To date, however, no previous studies have disentangled the direct effect of *Littoraria* body size on feeding rates. Furthermore, the potential for the effect of body size on feeding rates to vary across a gradient in temperature has yet to be explored. To investigate the effects of temperature and *Littoraria* body size on feeding rates, we will conduct laboratory based feeding assays along a temperature gradient. We will then construct thermal response curves to better visualize this relationship and to directly parse out the effect of body size. We expect that temperature will be positively related to feeding rates up to a thermal optimum, after which feeding rates will decline. Furthermore, we anticipate that smaller individuals will respond more strongly to temperature changes than larger individuals owing to their metabolic demand. Knowledge of feeding rates across a range of temperatures will yield valuable insight into grazer physiology, their interactions with plant resources, and the potential for these interactions to shift with climate change.

Biophysical Characterization of Human Transketolase (TKT) and Transketolase-Like Protein (TKTL-1) Interactions with the Thiamine Diphosphate Cofactor

Aamanya Raval, CURO Research Assistant
Dr. Scott Pegan, Pharmaceutical and Biomedical Sciences, College of Pharmacy

Transketolase is a ubiquitous thiamine pyrophosphate (TPP) and Ca^{2+} dependent enzyme in both the glycolytic and pentose phosphate pathways (PPP). TKT catalyzes the reversible transfer of a ketose phosphate to an aldose phosphate, thus providing a reversible link between the PPP and glycolysis. A variant of TKT, known as TKTL-1 (Transketolase-like protein 1), is highly expressed in malignant tumors indicating its potential role in the phosphoketolase pathway analogous to TKT. However, the exact physiological role of TKTL-1 is yet to be identified. If TKTL-1 requires TPP as a cofactor for its catalysis, then it will be involved in pathways similar to TKT. The expression and purification of TKT and TKTL-1 from *E. coli* extracts as His6-tagged proteins. This process uses protein isolation procedures, nickel affinity chromatography, and isothermal titration calorimetry (ITC). ITC displays the initial binding titrations of thiamine and interactions with its phosphate linked analogues. Exothermic values should indicate that there are two possible binding sites within the enzyme and a high KD shows a weak binding affinity of TKT for the TPP cofactor. The information provides us with greater understanding about the physiological role of TKT-L and designing inhibitors for the enzyme which can later be used for anticancer drug development.

Variant Identification Using RNA-Seq Data for Improvement of CRISPR gRNA Design in Hybrid *Populus*

Jacob Reeves, CURO Research Assistant
Dr. C. J. Tsai, Genetics, Franklin College of Arts and Sciences

CRISPR is a powerful tool for genome editing; however, designing CRISPR guide RNAs (gRNAs) is more challenging for outcrossing species such as *Populus* because of sequence heterozygosity. Though many programs have been borne in hopes of facilitating gRNA design for CRISPR experiments across a variety of genome-sequenced organisms, none of them have yet considered SNPs. Our research aims to incorporate sequence variants into existing gRNA design programs, thereby improving the gRNA specificity and CRISPR editing success rates. Our lab has previously developed a web-based tool that allows users to query the *Populus tremula* × *alba* 717-1B4 (Pta717) genome for SNPs and indels in custom gRNA sequences based on genome re-sequencing data. However, some genomic regions have less than 5 times the coverage due to shallow sequencing. To address this issue, we exploited deep genome sequencing data of Pta717 from the Department of Energy's Joint Genome Institute to obtain high-confidence SNP and/or indel calls with an average of 576 reads per nucleotide. The completion of this version is expected to improve CRISPR editing reliability for *Populus* researchers engaged in genome editing experiments.

African Agency in Policy and Project Autonomy: An Analysis of Investment Promotion Centres in Rwanda, Botswana, and Lesotho

Rara Reines, CURO Honors Scholar, CURO Research Assistant
Dr. David O Okech, Social Work, School of Social Work

African agency is a relatively new concept in the field of International Relations. This idea insists on viewing African states and actors as serious, real subjects in their own right rather than as non-participants in International Relations or as passive actors. The dominant focus of the African agency literature has been on relations between states and the collective impact of African groupings of states in international fora. Thus, the current literature on African agency is limited in two major ways: the literature is state-centric in a world where non-state groups and organizations exert increasing influence; and the literature has neglected the role of the private sector as a major driver of development processes on the continent. This research posits Branding Agency as the term for understanding agency in the context of the private sector, which can be analyzed through the activities of Investment Promotion Centres. Branding Agency concerns how domestic and international actors, be they individuals, institutions, or private sector firms, are actively pursued to invest in and contribute to a nation's prospective and ongoing development projects. The research methodology includes a literature review of African agency, comparative analysis of major development projects' leadership, funding, and ownership, and case studies of development projects exerting strong agency. This research aims to develop a framework for a holistic conceptualization of agency, including Branding Agency, and impact how the reality of development is viewed in Africa regarding the relationship between African governments and the private sector.

Lassa Virus GP1 Glycoprotein Receptor Binding Site Characterization

Hayley Reynolds, CURO Research Assistant
Dr. Melinda Brindley, Infectious Diseases, College of Veterinary Medicine

Lassa virus (LASV) is an Old World arenavirus endemic to West Africa. It is responsible for severe cases of hemorrhagic fever and is the cause of 5,000 deaths per year. No effective human vaccine currently exists and the only treatment available is ribavirin, which is costly, must be administered early after infection to be effective, and has many side effects. LASV infection is initiated by the viral glycoprotein complex (GPC), which binds to the cellular receptor, facilitating viral entry and fusion with the target cell. Our project's goal was to define the receptor binding site(s) in the LASV GPC. Structurally defining the receptor binding site will provide targets for new entry inhibitors and vaccines. Site-directed mutagenesis was implemented on charged, hydrophobic, and glycosylation site residues in order to functionally characterize domains in the GP1 subunit of LASV GPC. Constructs were first evaluated for cleavage efficiency and fusion activity, and then for transduction efficiency. In general, there was observed high correlation between cleavage efficiency and cell-to-cell fusion activity, demonstrating that properly processed GPC was able to mediate cell-to-cell fusion. Due

to the BSL4 classification of LASV, vesicular stomatitis virus (VSV) pseudotyped particles were utilized to display LASV GPC's and mimic viral entry in HAP1, HAP1-ΔDAG1, and Vero cells. By using cell types with differential production of cellular receptors, we compared transduction efficiencies and were able to identify several residues that potentially play a role in alpha dystroglycan (a-DG) and lysosomal associated membrane protein 1 (LAMP1) interactions.

Assessment of Spatial Distributions of Sea Turtle Nests In Relation to Artificial Lighting in St. Kitts, West Indies

Jessica Lauren Reynolds
Dr. John Maerz, Forestry, Warnell School of Forestry and Natural Resources

Light pollution associated with coastal development is a widely recognized threat to sea turtle populations. In addition to causing disorientation in hatchlings, artificial lighting poses a threat to sea turtles because it can deter females from nesting in suitable areas and increases nesting in less-suitable but unlit habitats. St. Kitts in the northeastern Caribbean Sea is an important nesting area for the endangered green (*Chelonia mydas*) and critically endangered hawksbill (*Eretmochelys imbricata*) sea turtles and St. Kitts has had a significant rise in tourism-related development. Our goals are to determine whether: light pollution levels on St. Kitts beaches are positively correlated with the probability of a false crawl and are negatively correlated with sea turtle nest density; there is a threshold level of artificial light pollution above which no sea turtle nesting is observed; and there are longer-term spatial trends indicating effects of coastal development on the number of sea turtle nests. In 2016, we used GIS data to quantify development along coastal beaches and we measured light pollution using a Unihedron Sky Quality Meter. We are modeling beach light levels as a function of development and correlating those measurements with nest survey data from the St. Kitts Sea Turtle Monitoring Network (SKSTMN) for hawksbill and green adult female emergence events collected from 2010 to present. Our ultimate goal is to inform management decisions, minimizing coastal light pollution and development impacts on sea turtle nesting.

Neuroanatomical Correlates of Functional Decline during Normal Aging

Joshua Reynolds, CURO Research Assistant
Dr. Steve Miller, Psychology, Franklin College of Arts and Sciences

Previous research has shown that age-related neural atrophy and cognitive decline predicts declines in functional independence (FI), or the ability to perform daily activities. The current study aimed to test whether volumetric brain differences predict FI in a sample of community-dwelling older adults, whose data was drawn from two neuroimaging studies of brain changes in aging (N=109, mean age=73.4 years, 63% female, 98% Caucasian). We additionally aimed to determine whether cognition mediates the relationship between brain volume and FI. Cognition was measured using the Repeatable Battery for Assessment of Neuropsychological Status (RBANS; Study 1, N = 48) and the CNS Vital Signs (Study 2, N = 61). FI was measured using the Direct Assessment of Functional Status (DAFS). Analyses were conducted for total gray matter volume (GM) and five regions of interest: dorsal-lateral prefrontal cortex (PFC-DL), orbitofrontal cortex (PFC-OF), primary motor cortex (MC), and dorsal (DS) and ventral (VS) visual processing streams. All brain volumes were corrected for intracranial volume (ICV). Initial regression analyses using the combined sample confirmed that GM (r^2=0.175, p=0.000), PFC-DL (r^2=0.085, p=0.002), MC (r^2=0.092, p=0.001), and VS (r^2=0.135, p=0.000) volumes predict FI. Mediation was tested separately in the two samples using bootstrapping analysis. Results showed that cognition partially mediated the relationship between GM, PFC-DL, MC, and VS and FI. These findings provide support for the hypothesized model of brain structural, cognitive, and functional decline in aging and suggest that improving cognition in older adulthood may mitigate the negative effects of brain atrophy on FI.

Rare Earth Elements Distributions in the Critical Zone: Possible Roles of Pine Versus Hardwood Vegetative Covers

David Forest Richards IV
Dr. Paul A Schroeder, Geology, Franklin College of Arts and Sciences

Rare Earth Elements (REE) are metals used in technology that enable global economic growth. Though these elements are titled as rare, they are only rare in abundance. Soil-forming processes can concentrate REE. This study hypothesizes that modern surface biogeochemical weathering in the Critical Zone redistributes the concentrations of REE. Furthermore, vegetative cover controls relative pH, redox, and hydrologic flux conditions, which can affect REE mobility. The study site is in Calhoun, South Carolina on a degraded landscape due to farming. The samples were collected from 0 to 350 cm depth at proximal sites, including a hardwood forest and a site extensively farmed until the 1950s cultivated as pine forest. All REE's were measured by Induction Coupled Plasma Mass Spectrometry (ICPMS), enriched relative to normalized chondrite values. Both sites are mostly concentrated in REE. The B-horizon is enriched in Ce relative to La for both pine and hardwood; however, Ce is enriched at depth in the hardwood. The mobility of Ce^{3+} under reduced conditions versus Ce^{4+} under oxidized conditions could occur by lessivage, soil organic matter complexation, leaching percolating water, and adsorption by iron-, aluminum-oxides and clay minerals. Ce enrichment correlates with goethite in the profile, suggesting that pine vegetative cover and active agricultural land management may differently mobilize REE. If compared to erosional histories and conditions of vegetation cover, REE may be a record of land use history. The REE patterns developed in saprolite offer great potential in understanding environments responsible for saprolite formation rates and insight to sustainability of land resources.

Digital Timeline of Mina Loy's New York Years 1937-1953

Jesse Riley, CURO Research Assistant
Dr. Susan Rosenbaum, English, Franklin College of Arts and Sciences

I am creating a digital timeline of poet and visual artist Mina Loy's life and work in New York during the years 1937-1953. This timeline is a part of a larger digital platform project *Mina Loy: Navigating the Avant-Garde*, which is in the process of being approved for an NEH Digital Humanities Advancement Grant. The timeline will be placed on the platform's website (mina-loy.com) with a goal of creating multimodal access to Mina Loy's life and work. The timeline was created digitally using a variety of sources, including Loy's biography and archives. The project hopes to develop a theory of *en dehors garde* that accounts for the contributions of women and people of color to the historical avant garde. We expect to find that en dehors garde is not a supplement for or plea for inclusion in the *avant-garde*, but rather a marginalized movement of women and people of color creating their own artistic spaces to drive change '*en dehors*,' or 'coming from the outside.' Through the timeline of her New York years, we ask how Mina Loy's life and poetry in New York contributed to or provided for *en dehors garde*? Much of Loy's work is presently buried in archives, and we hope through the timeline and larger digital platform to create accessibility to her life and work.

The Role of Histone Modification in Splicing and the Tethering of ps-mRNA

Lexi Blue Ritter, CURO Research Assistant
Dr. Xiaoyu Zhang, Plant Biology, Franklin College of Arts and Sciences

There is a dearth of knowledge surrounding the mechanisms by which post-splicing RNA (ps-RNA)—which is completely transcribed but incompletely spliced—becomes fully spliced. Additionally, there is growing interest in the study of histone covalent modifications and their interactions with chromatin and other proteins. Different histone modifications, as well as the degree of modification, may change the activity of gene expression. The *Arabidopsis* double-mutant *sdg7 sdg8* eliminates the trimethylation of lysine 36 on histone 3 (H3K36me3), which plays a key role in regulating gene expression. Elimination of trimethylated H3K36 causes severe developmental phenotypes; furthermore, H3K36me3 plays a role in the splicing of RNA. While typically thought of as a co-transcriptional process, splicing may occur post-transcriptionally, creating partially-spliced RNA (ps-RNA); the post-transcriptional model of splicing is hypothesized to be related to the interaction between HUA2, H3K36me3, and ps-RNA. Double and triple mutants for the genes HUA2, HULK2, and HULK3 (HUA2-like genes) were identified and genotyped. Many of the plants sowed were fully or partially unable to grow, indicating the important role that these genes play

in development. Four of the plants grown were identified as triple mutants, lacking all three of the genes. Further experimentation will be performed to determine the enrichment of these genes for certain histones and the modifications of those histones, as well as the levels different RNA fragments (ps-RNA and m-RNA) in the chromatin and nuclear environments. The model of post-transcriptional splicing will give insight into the machinations of DNA formatting and gene expression.

Laboratory Operations Support for Small Satellite Research Laboratory

James Hugh Roach, CURO Research Assistant
Paul Hwang
Dr. Marguerite Madden, Geography, Franklin College of Arts and Sciences

As members of the laboratory operations team for the Small Satellite Research Laboratory (SSRL), we provide a wide array of support services and provide necessary infrastructure to ensure mission success. One such vital service is the community outreach and graphics resources provided by our team lead Paul Hwang. Through a process of intensive design, Paul ensures that things like our mission patches and website meet the high levels of aesthetic quality necessary to attract the highest levels of student ability here at the University of Georgia. We also handle the organization of internal lab structure, to include onboarding, leadership hierarchy, internal clearance levels, and more, all of which are vital to smooth operation of the lab. On the technical side, our backend developer, James Roach, ensures all software infrastructure needed by our team is both available and at an acceptable level of stability so our labmates can proceed with their workflows in the most efficient way possible. This software architecture includes, but is not limited to: computational servers, our public website, version control systems, and the digital security of our lab. Our team mission is to provide whatever is needed for the success of our colleagues and the overall SSRL mission objectives.

Propagation of Errors in Single Cell Oscillatory Time Series to the Periodogram

Sarah Robinson, CURO Research Assistant
Dr. Jonathan Arnold, Genetics, Franklin College of Arts and Sciences

The biological clock in an organism controls the timing of biological processes from development to behavior. Single cell measurements are taken to determine if genes that are synchronized have the same oscillation frequency in different cells. These gene expression measurements are typically noisy due to two sources of error: the stochastic noise from the cell itself and the detector noise for cell fluorescence. A model has been proposed to propagate the errors of the single cell gene expression measurements to the periodogram and phase distribution. To verify the method, three different sinusoid models were simulated, in which the amplitude, period, or phase was randomized individually. Randomly generated data was used in the simulations of the original experiment, as well as a reconstructed model which mimics an experiment without noise in the measurements. Comparison of the reconstructed model to the propagation model showed that the propagation model estimates the true proportions of variance in the gene expression measurements accurately. This is useful for all gene expression measurements in single cells that possess an oscillatory behavior.

Analysis of Different Methods for Quantitative Western Blot Analysis in the Avian Model System

Logan Ruiz, CURO Research Assistant
Dr. Andrew Benson, Poultry Sciences, College of Agricultural and Environmental Sciences

Western blotting is a commonly used laboratory practice that can be used to quantify protein levels in samples. One essential consideration for quantitative Western analysis is the amount of protein in each lane, which may vary due to inaccuracies with protein concentration determination, loading volume, or differences in transfer efficiency. To account for these potential differences, the amount of target protein is normalized to the amount of protein present in each lane by using a loading control. A good loading control is one that is co-expressed with target protein within the same sample and consistently expressed between samples. Tubulin, beta-actin and GAPDH have

traditionally served as loading controls. Unfortunately, very little research in the avian model has employed quantitative Western analysis, thus little is known about good loading controls for use in the chicken. Bio-Rad has recently developed Stain-free technology, a new method that allows for total protein quantification and normalization using haloalkylated tryptophan fluorescence. We recently compared this stain-free technology to the standard practice of using loading controls, chicken anti-beta-actin and GAPDH, for quantitative Western analysis in the avian model system. Our results show that the stain-free technology was superior for quantitative comparison of protein expression between different chicken tissues (liver, heart, muscle, kidney, spleen, lung) and within the same tissue.

Books for Keeps' "Stop Summer Slide!" Program and its Impact on Literacy Levels in Clarke County Schools

Miranda Russell
Dr. David B Mustard, Economics, Terry College of Business

I aim to answer the question "Does Books for Keeps' 'Stop Summer Slide!' program increase literacy levels for elementary students in the Clarke County School District (CCSD)?" Books for Keeps is a 501(c)3 non-profit founded in Athens, GA that works to improve childrens' reading achievement. Books for Keeps' signature program "Stop Summer Slide!" provides each child with 12 new books of their choosing at the end of the school year. The Clarke County School District supports the "Stop Summer Slide!" program and believes that it has had positive effect on their students' reading levels since the program began 7 years ago in 2009. This research is significant because an empirical analysis will allow Books for Keeps and the CCSD to determine where the program is succeeding and where changes could be made to better support the students. I will answer my question by comparing the students' spring and fall SRI Lexile levels, a metric that determines the reading level of a student. My thesis is that schools without Books for Keeps' intervention program will demonstrate the expected "summer slide"—that is, that students will "slide back" and decrease their reading levels during the summer. I believe that students that do participate in the intervention program, however, will demonstrate either a constant reading level or even a slight increase. Using econometric tools, I will also control for the variables of gender, socioeconomic status, race, special education status, gifted status, English fluency, number of yearly behavior referrals, and number of yearly absences.

An African American Oral History: Historic and Contemporary Experiences of Gentrification in the Hancock Corridor

Adam Salway, CURO Research Assistant
Dr. Jerry Shannon, Geography, Franklin College of Arts and Sciences

This research considers the risk of displacement due to gentrification experienced by residents of the Hancock Corridor, a historic African-American neighborhood in Athens, Georgia. In this project, we are working alongside neighborhood residents, UGA archival librarians and a team of community researchers to synthesize archival, interview, and geospatial data in order to create a robust digital story mapping platform that reflects the historical and cultural importance of the Hancock Corridor. We seek to create this online digital experience in a way that documents the important voices of the Hancock Corridor residents, while showing their contemporary experiences with displacement pressure in the face of ongoing development that threatens the identity of their community. This participatory approach enables community-based researchers to conduct oral history-style interviews with residents directly affected by urban development. Upon synthesizing these data, narratives of contemporary displacement based upon continued disinvestment in the Hancock Corridor are elucidated. We argue that there is a considerable disparity between the local knowledge of African-American history in the Hancock Corridor and the diligence with which it is and has been documented. Further, contemporary knowledge about resident experiences of displacement pressure are lacking from important discussions on future development decisions by city officials. By collecting available sources of data pertinent to this history and present, this project will reveal both the cultural and historical value of the Hancock Corridor and its current vulnerability to on-going and unchecked urban development.

All-Source Fusion in Combatting The Global Terrorist Threat

Peyton Sammons
Dr. Loch Johnson, International Affairs, School of Public and International Affairs

The technology of the 21st century has created a set of unique challenges for the intelligence community, in that it is easier than ever before for terrorists and other transnational criminals to coordinate on a global scale. The purpose of this research is to examine the role of all-source fusion as a tool by which intelligence communities in the US, the UK, Canada, and Australia counter terrorist threats within their borders, and how each respective intelligence community uses all-source fusion to protect the civil liberties of their populations. By examining quantitative and qualitative data to identify the elements of all-source fusion that have been successful in countering terrorism, I have conducted a comprehensive literature review on all-source fusion with a specific focus on the four aforementioned case studies. Through my research, I have found that all-source fusion is by far the most effective intelligence collection method that allows intelligence officers to provide policymakers with the most comprehensive picture of the "who, what, when, where, and how" of each issue area. By combining all of the INT's means that the weaker links, such as HUMINT, in the collection process are accounted for and counteracted.

Legislative Complexity in an Increasingly Competitive Electoral Environment

Adrien Sandercock, CURO Research Assistant
Dr. Anthony Madonna, Political Science, School of Public and International Affairs

I hypothesize that as electoral competitiveness has increased over time, legislation has gotten more complex due to both the majority parties' use of procedural methods to control the legislative process, increased minority party leverage, and an overall desire to make opaque an increasingly transparent legislative process. This is criticized as being potentially harmful, but there is little documentation of this phenomenon. I will model the relationship between electoral competitiveness and legislative complexity by building on data already collected as part of the University of Georgia Amending Process Project. Specifically, I will take data on landmark bills and add additional variables related to their consideration and passage. Electoral competitiveness will be measured as the average margin of victory in House and Senate races in a particular year; legislative complexity will be defined by a multi-variate measure that includes factors such as bill length, number of companion bills, whether or not a bill is an omnibus, how frequently a bill references other bills, and how much time was spent discussing the bill.
I anticipate that as elections have grown more competitive, legislation has grown more complex. In cycles with higher competition (lower average margin of victory), there will be more complex legislation, while less competitive electoral cycles will have less complex legislation. This research is significant because there is not a comprehensive measure of how complex legislation is; creating one will contribute to research in this field substantially. This relationship could provide new insight into the legislative process and its motives.

Utilizing Cultural Advisors in Marriage and Family Therapy Practice

Emily Sands, CURO Research Assistant
Dr. Desiree M Seponski, Child and Family Development, College of Family and Consumer Sciences

Mental health practitioners assist ethnically and linguistically diverse clients, a portion of which are refugees who have experienced trauma, as they have a heightened risk of mental illness compared to the overall population (Fazel, Wheeler, & Danesh, 2005; Porter & Haslam, 2005). Despite the increase in client diversity, research is lacking on cross-cultural psychotherapy and in particular with marriage and family therapy and trauma treatment of refugee populations. The purpose of this study is to explore cross-cultural clinical practices by North American marriage and family therapists and advocate for the use of cultural brokers. This study is driven by the following research question: How can North American marriage and family therapists' use of cultural brokers enhance refugees' therapy experiences. In this qualitative study, data were collected through open-ended interviews to gain detailed and thick transcriptions of the data. Thematic analysis was

utilized to identify emerging themes. This study's preliminary findings support the use of cultural brokers in culturally responsive therapy.

United States Corporate Tax Reform: Keeping Capital within US Borders

Nancy Saucedo, CURO Research Assistant
Dr. Chris Pope, Banking and Finance, Terry College of Business

Since the 1980s, the United States has seen an increase in the number of corporate tax inversions. A corporate tax inversion is a strategy that companies employ to reduce their tax payments. This typically occurs when a domestic company changes its domicile to a country with lower taxes while maintaining the same level of operations in its country of origin. This practice has brought about much debate regarding what should be done to reform current corporate tax law. With one of the highest foreign corporate income taxes in the world at 35%, the US has struggled to keep corporations on American soil. Many US companies manage to keep trillions overseas using inversions and tax loopholes. Despite Congress and the US Treasury implementing laws to stifle tax evasion, the US still fails to compete with tax havens around the world. We will begin by taking a closer look at the intricate history of International tax law, analyze the worldwide system implemented by the US, and examine the shortcomings of using this tax system instead of a territorial tax system. From there, we will evaluate proposed solutions from the Trump Administration, GOP, and various tax experts, evaluating the advantages and disadvantages of each proposal. Finally, our quantitative case study will analyze a US company's failed attempt at inverting. We will evaluate and compare the company's taxes under various tax reform proposals to determine which would have the most positive effect on taxes.

Nanoparticles Transport of FDA-Approved Drugs Across the Blood Brain Barrier in a Porcine Stroke Model

Kelly Marie Scheulin, CURO Research Assistant
Dr. Franklin Delano West, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Stroke is the leading cause of disability and the fourth leading cause of death amongst adults in the United States. Despite the devastating effects of stroke, there is only one FDA-approved treatment, which in itself is only advantageous in a small fraction of strokes. Our research team has developed two enabling technologies 1) a highly lipophilic, biodegradable nanoparticle (NP) delivery platform that has a high zeta potential and the novel ability to cross the blood brain barrier (BBB) and 2) a novel translational pig stroke model. We hypothesize that this novel NP technology will be able to deliver FDA-approved, hydrophilic drugs past the BBB into the damaged brain tissue in our pig model, which will help reduce the cytotoxic environment for future stem cell transplant therapy. In preliminary studies, we have determined the FDA-approved drugs, Co-Q-10 and Tetracycline, can be successfully incorporated into our novel NP vehicle (at concentrations of 304.92 ug/mL and 186.24 ug/mL, respectively). To trace NPs delivered into the injured brain tissue, we successfully incorporated the fluorescent Cyanine 5.5 dye into NPs. We have demonstrated that intravenous injection of NPs leads to high Cyanine 5.5 fluorescence concentrations in the brain, heart, lungs, kidneys, liver and spleen in a piglet neural injury model. These results suggest that NPs can cross the BBB and transport FDA-approved drugs to the injured site of our novel pig model. This study will provide a novel approach to stroke treatment and will likely lead to more success in human clinical trials.

Investigation of Visual Event Related Potentials in Schizophrenia, Schizoaffective, Psychotic and Non-Psychotic Bipolar Disorders

Zoe Schneider, Ramsey Scholar
Dr. Brett Clementz, Psychology, Franklin College of Arts and Sciences

Event related potentials (ERPs) are electrophysical responses to stimuli that can be measured non-invasively in electroencephalographic (EEG) studies. Previous studies have used ERPs to evaluate early processing deficits present in individuals with schizophrenia. The goal of this research is to compare early visual processing over time across five diagnosis groups (Healthy

Control: HC, Schizophrenia: SZ, Schizoaffective disorder: SAD, Bipolar disorder with psychosis: BD-WP, and Bipolar without psychosis: BD-NP) using four different visual tasks. 407 individuals (HC = 153, SZ = 64, SZAFF = 79, BD-WP = 65, BD-NP = 46) completed each task at five BSNIP2 sites while 64 sensor EEG data was recorded. A black square was placed in the subject's central, left, right, or bilateral visual field. Grand average ERPs identified peak sensors across all groups. One-way ANOVAS were run on each 10ms time bins for each visual task to identify group differences. We hypothesized that all three psychosis groups would show a reduced response to the visual stimuli in the first 500 ms, and the BP-NP and HC groups would display similar responses. These tasks will allow us to test central visual processing, interhemispheric visual processing, and contralateral visual processing in all diagnosis groups. These results give insight into the dysfunction of common neural paths and the pathophysiology of psychotic groups. They may also provide greater understanding of the causes and mechanisms of early visual deficits in individuals with psychosis.

Intersectional Failure: The Effect of Zero-Tolerance Policy on Girls of Color

Chloe Schrader
Dr. Nichole Ray, Communication Studies, Franklin College of Arts and Sciences

This exploratory research investigates how the lack of intersectional theory in education practices prevents students, especially girls of color, from getting an equal education and therefore the validation and empowerment education can provide. This research is important because intersectional failure starts in elementary school and creates a cyclical pattern of poverty; it has long lasting effects on students' educational outcomes. I will be analyzing the ways in which zero-tolerance policy affects girls of color and contributes to the school to prison pipeline in order to examine the structures of domination that cause this intersectional failure. I will then use this analysis to inform further research in the Athens-Clarke County school district and ultimately create policy to institutionalize solutions and better practices. This is crucial to breaking the cycle of poverty and incarceration of women of color and providing an equal education to all students.

Filipino Immigrant Social Networks and Their Influence on Settlement Experience

Anna Schramski, CURO Research Assistant
Dr. Denise Clark Lewis, Child and Family Development, College of Family and Consumer Sciences

Findings from a qualitative study with 14 mid-life Filipino immigrants residing in the United States revealed that work settings, existing familial structures in the US, religious settings (largely Catholic due to the influence of home country), and the Filipino immigrant community allowed for the formation of new social networks. Individual and dyadic interviews were conducted and analyzed using Berry's theory of acculturation, which defines four acculturative strategies by the relationships between host culture and immigrant group; and the maintenance of home culture by the immigrant group in the new environment. These strategies are integration, assimilation, separation, and marginalization. We sought to determine where Filipino immigrants find their social networks, the influence of social networks on adjustment and well-being during settlement, and how those influences led immigrants to adopt one of Berry's strategies of acculturation. Some individuals sought interactions similar to those found in the Philippines and preferred to surround themselves with the familiarity of Filipino cultural practices. This reflects the strategy defined as separation. Others expressed the desire to establish a new community, actively seeking the strategy of assimilation into the host environment. Fascinated with the fast-paced, work-oriented culture of the US, these individuals often found social networks through their occupations. Many participants stressed the importance of engagement while adjusting to a new environment; those who did not have an active social network expressed feelings of depression and loneliness, which Berry describes as marginalization. This research adds to the existing literature on the settlement of mid-life Filipino immigrants in the US. Additionally, it could be used modify existing and create new culturally responsive programs serving Filipino

immigrants by providing contextualization of the acculturative process.

Understanding Toxicity of *Botrytis cinerea* Mutant

Patrick Thomas Seethaler, CURO Research Assistant
Dr. Maor Bar-Peled, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

Botrytis cinerea is a devastating pathogenic fungi that affects the yield of over 100 crops. It causes a gray mold and rot disease that drastically damages important agricultural crops. Previous work in the lab found that a mutation in the nucleotide-sugar metabolism leading to UDP-rhamnose gave rise to fungi that are unable to effectively infect plants. This research also helped to identify the potential toxic intermediate UDP-KDG. The exact mechanism for toxicity remains elusive. To identify the toxicity, we mutate the enzyme involved in the conversion of UDP-galacto-pyranose to UDP-galacto-furanose (UDP-galactomutase) so as to mimic and intensify the toxicity pathway. In doing so, we can compare the initial substrates to the end products to determine the pathways of metabolism. Through the use of alditol acetate and analysis through LC/MS and GC/MS, we hope to see differences in the final concentrations of water-soluble metabolites inside the cells and the glycans in the cell wall when the wildtype and knockout gene strains are compared. This will show us the specific pathway that the toxicity occurs through.

Saharan Dust Increases Amount of Vibrio Pathogens in the Florida Keys

Roland Francis Seim, CURO Research Assistant
Dr. Erin K Lipp, Environmental Health Science, College of Public Health

Vibrio is a genus of bacteria found in marine habitats world-wide but usually represents a minor portion of the microbial community. Previous studies show that *Vibrio* populations can grow explosively in response to annual Saharan Dust events. While *Vibrio* has been shown to increase in response to dust-associated nutrients, e.g. iron, species-specific characterization is not known. This information is important to determine if dust deposition leads to an increase in pathogenic species. Here, using species specific PCR we examined the presence of *Vibrio* pathogens among isolates cultured at Looe Key Reef in the Florida Keys, US before, during, and after a Saharan dust event. Specifically, we determined if dust was associated with the presence of human pathogens such as *V. alginolyticus*, *V. cholerae*, and the coral pathogen *V. coralliilyticus*. *V. cholerae* is known to cause cholera; *V. alginolyticus* can cause wound and ear infections. Data collected to date indicated that the abundance of pathogenic *Vibrio* species increased in response to these dust events. We collected approximately 300 isolates over a four-day period during a Saharan Dust event during the summer of 2016 and extracted DNA for PCR and gel electrophoresis to identify the *Vibrio* species present. This research has broader implications in public health, environmental health, and microbiology. It is important to understand the *Vibrio* response to these dust events and the impact it might have on the health of residents living in the Florida Keys.

Characterizing the Species Distributions of North American *Pyractomena* Fireflies

Pearl Shah, CURO Research Assistant
Dr. Kathrin F Stanger-Hall, Plant Biology, Franklin College of Arts and Sciences

Different *Pyractomena* species differ greatly in the biogeographic distribution across the United States. Extensive research has been done on the distribution patterns of birds, mammals, and plants and the relationship, but what determines the spatial distribution of *Pyractomena* fireflies is currently unknown. We investigated the impacts of environmental variables, including average precipitation, average temperature, elevation, and soil characteristics on the distribution of the 16 species of North American *Pyractomena* fireflies, using field records from the past 50 years, national data bases and ArcGIS mapping software. Soil was tested because the vast majority of a firefly's life is spent during the larval stage, where these insects largely prey upon gastropod mollusks and other semiaquatic invertebrates. Understanding the biogeographical patterns of species distributions will ultimately contribute to habitat and species conservation.

Using Electrical Stimulation to Lower Post-Prandial Blood Sugar in People with SCI

Nivita Sharma, CURO Honors Scholar, CURO Research Assistant, CURO Summer Fellow
Rachel Aldridge
Dr. Kevin McCully, Kinesiology, College of Education

Type II Diabetes is prevalent among individuals with spinal cord injuries (SCI) because of their limited mobility. Exercise has been shown to lower post-prandial blood glucose levels in able-bodied people. Electrical stimulation of the muscles causes similar muscle contractions that occur when an individual exercises. Muscle contractions act like insulin to allow cells to consume glucose from the blood. We aim to observe changes in blood glucose levels when six muscle groups (quadriceps, hamstrings, and calves of both legs) are electrically stimulated after the consumption of a carbohydrate rich meal in able-bodied and individuals with SCI. We hypothesize that electrical stimulation will cause a clinically relevant decrease in post-prandial blood glucose levels. Continuous glucose monitors (CGM) will be used to measure the blood glucose levels throughout the three-day experiment. Electrical stimulation will be performed using a medical grade electrical stimulator (Theratouch 4.7, Rich-Mar). The first day will include insertion of the CGM, the second day will involve sedentary conditions after the consumption of a carbohydrate-rich meal, and the third day will involve 60 minutes of electrical stimulation after the consumption of a carbohydrate-rich meal. All meals provided to the participants will be established using their estimated caloric intake and physical activity. CGM data on the sedentary day will be compared to the electrical stimulation day to test for effects of stimulation. Significance: If effective, post-prandial electrical stimulation can be a simple method to decrease the risk of Type II Diabetes in individuals with SCI.

Unalterable Roots

Sachi Shastri, CURO Honors Scholar, CURO Research Assistant
Dr. Christopher R Lawton, History, Franklin College of Arts and Sciences

The history of Putnam County, Georgia, has long been told through a biased, whitewashed perspective that completely neglected the relevance of African Americans in Putnam's development. Historical markers posted at antebellum mansions celebrate the achievements of white planters, while ignoring that their houses, their lives, and the county of Putnam, itself, was built upon the labor of slaves. Ignorance of black contributions is a common characteristic of small Southern towns, but Putnam is unique in that both Alice Walker, author of *The Color Purple*, and Joel Chandler Harris, teller of the *Uncle Remus* tales, grew up in the same Putnam neighborhood nearly a century apart. More remarkable is that both internationally famous authors, in their own way, chronicled the lives of Putnam's African American communities that historical markers still miss. The project has been to begin developing a book proposal for UGA Press that will expand the history of Putnam with an eye towards making visible the intersectionality and inclusivity recognized by both Harris and Walker. The work began with a literature review on the relevance of geographical locations to history, and will soon progress to setting up community events that will allow local people to tell their personal stories. By understanding the history of Putnam as told by a diverse group of people, and using those histories to create context for narrative elements from both Harris and Walker, the book proposal will create a space for telling Putnam's more authentic, more inclusive, more complicated history.

Infant Sleep Duration among White Breastfed and Black Formula Fed Infants at 16 Weeks

Olivia Shealy
Dr. Leann Birch, Foods and Nutrition, College of Family and Consumer Sciences

The National Sleep Foundation recommends daily sleep duration of 12-15 hours for infants (4-11 mo) as appropriate for health and well-being. Insufficient sleep and poor sleep quality have been linked to adverse effects on development and behavior, as well as increased risk of obesity. Both race and feeding mode have been examined as possible factors affecting infant sleep patterns, with variable results. Further research is needed to clarify these associations. This study examines the differences in infant nighttime sleep duration, and

total sleep over a 24-hour period at 16 weeks among a sample of black formula fed (BFF) and white breastfed (WBF) infants. Black and white mothers (n=44) participating in the Maternal and Infant Growth Study reported infant sleep duration (hrs) via self-completed questionnaire at a 16-week postpartum study visit. Infant feeding mode (>80% of intake), breastfed (n=23) or formula fed (n=21), was determined using mother-provided bi-monthly feeding logs. WBF infants slept longer than BFF infants over a 24-hour period (p=.047) and overnight (p= .000). These results suggest a difference in infant sleep duration between groups. BFF infants' shorter overall sleep duration could play a role in increasing the risk of obesity among African American children.

Parasite Infection, Group Size, and Feeding Behavior in Grant's Gazelle

Caroline Shearer, Foundation Fellow
Dr. Vanessa Ezenwa, Ecology, Odum School of Ecology

Group size is known to affect feeding behavior in animals because individuals living in larger groups benefit from the vigilance of others which frees up more time for feeding. Thus, group size influences the way animals distribute their time among various behaviors, and typically the time spent by animals feeding increases with group size. This study examines whether parasite infection modifies the relationship between group size and feeding behavior. Female Grant's gazelles (*Nanger granti*) were treated with an anti-parasitic drug to reduce their nematode parasite burdens, and the feeding behavior of treated and untreated individuals was tracked through time. Using data on the duration and occurrence of feeding behavior, we tested the hypothesis that parasite treatment eliminates the relationship between group size and feeding. Results of this study will increase our understanding of the factors that determine group size in wildlife.

Proteomics of CBL0137-Treated *Trypanosoma brucei*

Shanlin Shoemaker, CURO Research Assistant
Dr. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts and Sciences

Human African Trypanosomiasis (HAT) is a parasitic disease endemic to parts of sub-Saharan Africa. The disease-causing protozoan, *Trypanosoma brucei*, proliferates in the blood, lymph, and ultimately the central nervous system of both humans and cattle. Nearly 70 million people are at risk of contracting HAT, which is fatal without treatment. Drugs currently used to treat HAT are toxic and difficult to administer, highlighting a need for the discovery of safer and more effective drugs. We identified Curaxin-137 (CBL0137) as a lead anti-HAT drug. This orally bioavailable drug cures mice infected with *T. brucei* and has completed phase I clinical trials for other indications, making it an excellent "drug repurposing" candidate for treating HAT. A 6-hour CBL0137 treatment of *T. brucei* in vitro followed by a 48-hour incubation in drug-free media revealed a "delayed killing" effect, suggesting that *T. brucei* commits irreversibly to death within the first few hours of exposure. In this study, we aim to understand why this drug is successful in killing *T. brucei* by identifying changes in the proteome of CBL0137-treated trypanosomes compared to untreated trypanosomes. We will first compare the protein profiles of treated and untreated trypanosomes using a combination of silver staining and phosphoprotein staining. Then, we will identify specific proteins affected by CBL0137 treatment through mass spectrometry. Determining the possible protein effectors of CBL0137 may reveal essential proteins in the trypanosome that may be tested genetically, thereby validating new targets for drug development to cure HAT.

Formation of Natural Product Glucosides by *Escherichia coli* in Controlled Conditions

Kimberly Mercedes Shumaker, CURO Research Assistant
Dr. Mark A Eiteman, Chemical, Materials, and Biomedical Engineering, College of Engineering

Flavonoids consist of a large group of natural polyphenols found in fruits, vegetables and cereals. Many possess anti-oxidative and vasodilation effects. Many flavonoids are water insoluble, and bioavailability can be increased through O-glucosylation of flavonoids by the action of enzymes called glycosyltransferases. This research describes the conversion of a model

compound, maltol, into its O-glucoside using UGT73B3 by *E. coli* strains under various fermentation conditions. We compared the production of maltol-O-glucoside by *E. coli* with and without a deletion in the pgi gene coding phosphoglucose isomerase. We also compared the formation of maltol-O-glucoside under nutrient limited growth conditions.

An In Vitro Model Demonstrating the Direct Current Stimulation Mediated Recovery from Neuronal Injury

Naomi Afnan Siddiquee, CURO Research Assistant
Noah Goldstein
Dr. Lohitash Karumbaiah, Animal and Dairy Science, College of Agricultural and Environmental Sciences

The goal of this study is to create an in vitro model of Traumatic Brain Injury (TBI) in order to assess treatments targeted to help repair disrupted neural networks and return lost function. Since moderate-to-severe TBI can cause a surge in glutamate, leaving behind damaged neurons, mouse embryonic stem cell derived neurons were exposed to 100 μM of L-glutamate to mimic the excitotoxicity after a moderate-to-severe TBI. Utilizing a high density Multi-Electrode Array (MEA) recording system, we recorded neuronal activity in a 12 well plate equipped with 64 recording electrodes per well used to record extracellular action potentials (EAP). We then assessed the whole well and electrode specific spiking activity over a period of four weeks. L-glutamate exposure at a concentration of 100 μM two weeks post-seeding resulted in a high Mean Firing Rate (MFR) that sharply declined ($P < 0.001$) and dysregulation of neural networks demonstrated by lower synchrony ($P < 0.01$) by week 4 and less frequent and shorter bursts ($P < 0.001$) by week 3. These electrophysiological changes were accompanied by a subsequent decrease in Beta-3 Tubulin+ neurons ($P < 0.001$) and oligodendrocytes ($P < 0.01$). We propose that the evaluation of these parameters followed by the immunocytochemical evaluation of motor neuron cultures will allow for a robust assessment of the effects of excitotoxicity on neurons, glia, and neuronal network repair in vitro.

Plasma Purification Method for Agglutination Assays in White Ibis

Olivia Lauren Sieverts, CURO Research Assistant
Dr. Sonia Hernandez, Forestry, Warnell School of Forestry and Natural Resources

As the everglades continue to disappear, many species of animals, including the American white ibis (*Eudocimus albus*) are being forced to urbanize. Urbanization may affect pathogen prevalence as these ibis aggregate in large densities, and mixed species flocks for food. Many of these birds are hand fed by people providing an opportunity for pathogen transmission between birds and humans. We used the Elementary Body Agglutination (EBA) assay to determine if the ibis in this study were infected by the zoonotic pathogen, *Chlamydia psittaci*. We used banked plasma for this assay as available; however, the preferred sample for this assay is serum. We obtained a prevalence of infection of X (n=X), which was unexpected. We suspected that the positive results were a result of cross-reactivity between proteins in the plasma and the antigen. Thus, we tested a method to purify immunoglobulin from the plasma. We used an ammonium sulfate solution to precipitate and remove nonspecific proteins present in plasma, to determine if they were interference with our assay. In order to test that we had in fact preserved and concentrated immunoglobulin in our purified sample, the sample was run through a protein gel and transferred onto a cellulose membrane, where it reacted with anti-bird antibodies. Our validation method confirmed successful recovery of immunoglobulins from the plasma. The purified samples were re-tested using the EBA assay—all were negative. Based on these findings we theorize that the initial results were false positives as the purified immunoglobulin samples tested negative.

Fatigue, Executive Functioning, and Activities of Daily Living in Older Adults

Shivani Singh
Dr. Steve Miller, Psychology, Franklin College of Arts and Sciences

Fatigue is a common symptom in a wide cross-section of elderly patients, caused by a myriad of reasons. The purpose of this study was to evaluate how fatigue, a physiological measure, may mediate

the relationship between declining executive functioning (EFs) and activities of daily living (ADLs). The current sample consisted of 189 community-dwelling older adults (ages 54-101, M= 77.94, SD= 8.717). Participants completed the Neurobehavioral Cognitive Status Examination (NCSE), an ADLs Checklist, as well as a Physical Symptoms Checklist. The assessed EF domains included judgment, similarities, and attention. Based on our mediation model, we hypothesized that fatigue would mediate the negative effect of declining EF on functional outcomes (ADLs). Results showed a significant R^2 change when fatigue was included in the model, R^2= .021, F_{change} (2, 187) = 4.765, p= .03, however, there was no significant relationship between fatigue and EF, making it difficult to conclude significant mediation is occurring, r= .059, p= .325. Further exploratory moderation analysis showed that there was no significant interaction effect between EF and fatigue, indicating that the relationship between the EF and ADLs did not change at the level of fatigue, R^2 = .194, F_{change} (3, 186) = .093, p= .760. There was a significant correlation between EF and ADLs, which supports existing literature on functional independence and EF in late life. However, the absence of an effect of fatigue on this relationship may be due to the restricted range of fatigue symptoms in our sample, and limitations of our fatigue measure.

The Chthonic Elements of Mithraic Worship

Michael Sloman
Dr. Charles Platter, Classics, Franklin College of Arts and Sciences

My paper examines how traditionally chthonic elements exist in Mithraism, a Roman cult dedicated to a sun god. It will isolate the specific symbols and practices that are associated with chthonic worship in the scene and examine their role in the Mithraic context as well as the greater religious context of the time period. This paper proposes that these elements are remnants of hero cult, standard across mystery cults in the Greco-Roman world. The Eleusinian Mysteries and the cult of Cybele share similar tropes and scenes and serve as an example for the possible development of this iconography. This question is important because a cosmological interpretation of the Mithraic cult, and therefore its symbols and iconography, has become more widely accepted. Although Mithras is worshipped as the Unconquered Sun, this cosmological interpretation denies half of his divine heritage. We must ask why chthonic elements are so prevalent in the worship of this cult. This paper will argue that these chthonic elements of Mithraism must have grounding in previous religious practice. The notion that they could have spontaneously arisen from nothing is doubtful given the long tradition of religion and cult in the ancient Mediterranean world. More reasonably, they exemplify traditional ritual of mystery cults which mix the heavenly origins of gods with the earthly works of heroes. Although perhaps a product of celestial worship, Mithraism is indebted in its practices to the worship of predecessor deities in Middle Eastern culture.

Phosphorous Efficiency in Cultivated Sunflower

Alex Morgan Smith, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts and Sciences

Cultivated sunflower, *Helianthus annuus L.*, is an important global oilseed crop. Phosphorus is needed for the normal growth and maturity of this commercial crop, and has been shown to affect yield quality/quantity in sunflower. Historically, breeders prefer sunflowers that have high phosphorous acquisition efficiency (plant uptake per nutrients available in the soil). Unfortunately, global sources of phosphorous are rapidly depleting, which makes genotypes with both high phosphorus utilization efficiency (yield per gram tissue phosphorous content) and high overall yield highly desirable. Furthermore, phosphorous can be allotted differently above than below ground. To get a better understanding of the link between overall yield and phosphorus use efficiency, we measured phosphorus concentrations of 12 diverse lines of sunflower grown under 4 different nutrient treatments. To account for the effect of organ type, we analyzed above and below ground tissue separately. We hypothesized that roots contain more phosphorous than shoots under high-fertility conditions; phosphorous allocation between above ground and below ground matter shift with low-nutrient stress, such that the proportion of root: shoot phosphorous increases

(i.e., more phosphorous will be allocated to roots relative to control); and genotypes with higher phosphorous utilization efficiency: phosphorous acquisition efficiency ratio preform best under low-nutrient conditions. Our results will better inform genetic breeding efforts in cultivated sunflower.

Effects of Vegetation Structure on Nest Predation of Artificial Diamondback Terrapin Nests

Kayla Jordan Smith, CURO Research Assistant
Dr. John Maerz, Forestry, Warnell School of Forestry and Natural Resources

Nesting is an important component in animal life cycles. Human activities often interrupt nesting behavior by degrading nesting habitats. For turtles, altering vegetation structure can increase predation rates. Diamondback terrapins (*Malaclemys terrapin*) occupy salt marshes, nesting in sparsely vegetated areas above high tide. Terrapin females show nest-site fidelity, and may continue nesting in human-degraded areas. My objectives are to: evaluate the effect of shrub habitat maintenance on terrapin nest predation; determine whether spatial patterns of vegetation-driven nest predation contributes to terrapin population decline; and evaluate whether vegetation management improves terrapin nest survival. Building off of long-term terrapin studies on the Jekyll Island Causeway (JIC) and a dieback of Northern raccoons (*Procyon lotor*), I measured predation rates using artificial nests in hedgerow, cleared hedgerow, and open, sparse vegetation. Using the results, spatial patterns of nest mortality along the JIC were used in a population viability analysis to estimate terrapin population persistence. I found predation rate on nests in hedgerows (62.5% of nests) was double that of nests in open sites (31.7%), while rates in cleared hedgerow remained high (71.5%). Nest predation was 39% lower (45.7% of nests) compared to a 2013 study at the same locations (75.4%), consistent with local raccoon dieback. These results confirm vegetation structure as a driver of unsustainable predation, and natural raccoon dieback or culling can significantly improve nest survival. Despite effects of vegetation on nest predation, vegetation removal may not immediately reduce predation. Future research is needed to determine long-term benefits of vegetation management.

Affect of Capsiate on Perirenal and Epididymal Fat in Rats Fed a High Fat Diet

Sierra Megan Smith
Dr. Buffy Howerth, Pathology, College of Veterinary Medicine

Obesity has become an epidemic in many parts of the developed world. Because of its relatively recent emergence, scientists have been looking for a remedy to help people who are suffering from the disease. This project aims to evaluate whether oral capsiate can ameliorate the effects of a high fat diet. The specific objective in this project was to evaluate the size and number of fat cells in epididymal fat and perirenal fat of rats on a high fat diet supplemented with capsiate. The anticipated findings are that capsiate will reduce the size and number of fat cells in rats on a high fat diet. Fat cells were evaluated in epididymal and perirenal fat in fixed tissue that was paraffin embedded, sectioned and stained with hematoxylin and eosin. Digital images from three fields were captured, and the total number of fat cells and cell area were determined. Results will be compared to rats fed a low fat diet and a high fat diet without capsiate.

The Novel Function of RGS10 in Obesity

Isabelle Veigh Snider, CURO Research Assistant
Dr. Jae-Kyung Lee, Physiology and Pharmacology, College of Veterinary Medicine

In previous research exploring the relationship between neuroinflammation and neurogenerative diseases, the Regulator of G-protein Signaling (RGS10) gene was found to negatively regulate microglial activation. In addition to neuroinflammation and damage to their dopaminergic neurons in response to systemic inflammation, RGS10 knockout (KO) mice showed lower levels of glucose in serum and gained more weight while aging. Although there's enough evidence to support a relationship between inflammation and metabolic diseases, detailed mechanisms are still unclear. Our objective is to investigate the role of RGS10 in this relationship. RGS10 KO and wild type (WT)

mice were fed a low fat (LF) diet and a high fat (HF) diet for eight weeks. We performed glucose tolerance and insulin sensitivity tests along with monitoring their weight and collecting serums and tissues at the end of 8 weeks. On both diets, the RGS10 KO mice displayed impaired glucose tolerance. On the HF diet, the KO mice displayed impaired insulin tolerance and higher body weights than WT mice, implicating that the RGS10 plays a role in metabolism and obesity. We're currently processing adipose and liver tissues and extracting the RNA in order to perform quantitative real-time PCR to determine the detailed mechanisms. We'll compare the mRNA expression of metabolism-related genes including sterol receptor element binding protein 1c (srebp1c), peroxisome proliferator-activated receptor-gamma (PPAR-g), fatty acid synthase, adiponectin, and leptin. We hope to gain a better understanding of the mechanism of metabolic disorders so that a treatment can be created to prevent or mitigate the disease.

Designing Relevant In Vitro Models of Muscle Metabolism with Inclusion of Energy Expenditure

Madeleine Holden Snidow, CURO Research Assistant
Dr. Chad M Paton, Foods and Nutrition, College of Family and Consumer Sciences

Typical protocols for in vitro studies of lipid metabolism use free fatty acids (FFA's) as the lipid source, whereas in vivo, triglycerides (TG) are the predominant lipid. In the absence of increased energy expenditure (EE), the study of lipid metabolism in vitro is unlikely to reflect in vivo metabolism. We hypothesized that a more realistic replication of in vivo metabolism should use TG and not FFA and incorporate EE. C2C12 muscle-like cells were used to assess differences in response to FFA versus TG. Cells were treated for 4h with either 16:0, 18:1, 18:2n6, or 18:3n3 as FFA or TG alone or in the presence of AICAR (an adenosine monophosphate mimicking molecule). Total mRNA and protein were collected to assess changes in gene and protein expression respectively. Studies are ongoing, however preliminary results suggest that FFA's produce numerous changes in C2C12 cell functions including inflammation, cell stress, and oxidation with only minor changes associated with TG's. In the presence of AICAR, TG effects are noted and FFA's are somewhat blunted. These results suggest that EE may drive metabolic function in vitro and may provide a more realistic foundation for assessing lipid metabolism compared to simple addition of FFA's. This in vitro discovery plays an essential role in better understanding metabolism and the way human muscle processes lipids. The study of TG's impact on muscle cells provides a better reflection on the true physiological response of FFA metabolism and helps to refine procedures for in vitro models of discovery.

Automatic Recognition of Periocular Facial Alterations

Ryan Snowden, CURO Research Assistant
Erica Anstey
Dr. Larry Hornak, Electrical and Computer Engineering, College of Engineering

Currently, there is no rapid, automated, repeatable method to detect and quantify periocular changes from chemodenervation. Multi-spectral imaging, including the visible, near and short-wave infrared spectrum, may provide novel information. We aim to detect and quantify periocular change, including position and texture changes, over time in participants who underwent periocular rejuvenation with BOTOX injection. Using eye location algorithms developed in MATLAB, face images of subjects are registered and cropped to the periocular region. These face images were captured immediately before and after injection, then at 1 day, 1 week, 1 month, 3 months, and 6 months. Different camera sensors were used to collect the aforementioned data including the visible, near and short-wave infrared bands. The individual regions where BOTOX was injected (corrugator supersilii, procerus, and orbicularis oculi muscles) are extracted and geometrically normalized via a set of algorithms. The normalized regions are processed using an algorithm that compares the extent of texture-based facial alterations before and after treatment. It is expected that most change will occur along the upper brow in the furrow region and in the crow's feet region, although the extent of these texture changes will continue being analyzed through the usage of more sophisticated image processing algorithms. The ability to objectively quantify subtle position and textural changes in

the periocular region in an automated, reliable way has vast potential. For example, detection of subtle change may lead to earlier cancer diagnosis, or even guide cancer resection.

Investigating CRISPR/Cas9 as a System for Gene Editing in *Trypanosoma cruzi*

Lilith Renae South, CURO Research Assistant
Dr. Rick Tarleton, Cellular Biology, Franklin College of Arts and Sciences

Trypanosoma cruzi is the protozoan responsible for human Chagas Disease. This disease is prevalent in Latin America and has no vaccine or effective drug treatment. Development of new drugs and vaccines has been hobbled by the difficulties of genetic manipulation which could lead to better understanding of the complex parasite biology. CRISPR (clustered regularly interspaced short palindromic repeats)/Cas9 (CRISPR associated gene 9) is a useful gene editing system recently borrowed from bacteria and widely applied to efficiently manipulate the genomes of many diverse species. The system utilizes a nuclease Cas9 protein and a guide RNA which directs Cas9 to cut a target gene. We have previously shown that SpCas9 protein, derived from *S. pyogenes*, can be expressed by *T. cruzi* and used to target parasite genes for editing. Although this method is relatively effective, expression of SpCas9 is somewhat toxic to *T. cruzi*. Here we show that the smaller recombinant SaCas9 protein from *Staphylococcus aureus*, but not SpCas9, can be electroporated into *T. cruzi* for effective gene editing. This procedure has shown nearly 100% knockout (KO) efficiency using a fluorescent reporter protein. SaCas9 fused to GFP – thus creating a protein comparable in size to SpCas9 – also fails to achieve reporter gene KO. These experiments demonstrate a new and highly efficient gene editing protocol for *T. cruzi* that depends on the ability of the smaller SaCas9 protein to traverse the *T. cruzi* cell membrane that appears impermeable to the larger SpCas9 protein.

ROS-Responsive and pH Inhibiting Polymer Nanoparticle Platform for Cancer Treatment

Jonathan Spagnoli, CURO Research Assistant
Dr. Jin Xie, Chemistry, Franklin College of Arts and Sciences

Cancer is a deadly disease ravaging the lives of many people around the world. As a result, there is a significant need for new research and treatment methods aimed at inhibiting the growth of cancer cells while maintaining as much healthy tissue as possible. This study aims to determine the anticancer activity of intracellular pH change by utilizing the higher hydrogen peroxide levels in cancer cells as a substrate in a reaction including ethanol and $FeCl_2$, which react to form acetic acid in the cellular environment. Ethanol, ferric chloride, and PVA (an emulsifier) will be loaded into poly(lactic-co-glycolic acid) (PLGA), which is FDA approved, to generate nanoparticles small enough to diffuse through the cellular membrane of cancer cells. Experiments will be performed to design an optimized synthesis protocol with the aim of loading the maximum amount of substrate and generating nanoparticles at about 200nm or less. Size and morphology of the synthesized nanoparticles will be determined by dynamic light scattering (DLS) analysis and a scanning electron microscope (SEM), respectively. Cell viability studies will be performed on glioma and hepatoma cells to determine the anticancer effect of the designed system. Overall, our work suggests that the resulting nanoparticle platform is a promising tool for uniquely exploiting biologically relevant concentrations of H_2O_2, and thus can be used as a new platform for cancer treatment.

Morphological Attributes Underlying Feeding Ability in Burying Beetles

Madeline Sparks
Dr. Allen J Moore, Genetics, Franklin College of Arts and Sciences

Adaptive evolution leads to differences in morphology and behavior between species. During development, the differences that arise in behavior are often accompanied by morphological differences, creating unique functional phenotypes. In this study, we look at a behavioral and morphological disparity between the larvae of two species of burying beetles (*Nicrophorus*). *Nicrophorus vespilloides* possess the ability to self-feed in the first instar, while *Nicrophorus orbicollis* do not until the second instar. We examine differences in mouthpart morphology to account for this difference in behavior. We find that *N. vespilloides* larvae have serrations on the inner edge of their mandibles at the first instar, while *N.*

orbicollis larvae do not. *N. Orbicollis* larvae have smooth mandibles, and do not develop the serrations until the second instar. There are no allometric differences in the mandibles between species. Therefore, we suggest that heterochrony in the development of mandibular serrations is directly correlated with the ability to self-feed.

Homeschooling and Its Effect on the Parent-Child Relationship

Maggie Spears, CURO Research Assistant
Dr. Jennifer L George, Child and Family Development, College of Family and Consumer Sciences

Homeschooling offers families a diverse and flexible option when it comes to educating their children. It also creates a unique familial situation in which one or both parents act as both guardian and teacher, facilitating, and personally guiding their child's education. Considering the unique challenges and benefits that homeschooling seems to offer families and individuals it remains largely unstudied. This exploratory study aims to examine homeschooling and how it affects parent-child relationships. Parent-child relationships will be assessed by interviewing emerging adults, between the ages of 18-25, who were homeschooled, to answer broad questions about homeschooling and their relationship with their parents. Qualitative data will be gathered from personal interviews with the research team. Once data from interviewees is gathered it will be analyzed using themed coding. Results will be discussed based on themes found in the data. This study aims to shine a light onto the understudied homeschooling population and contribute to the scientific communities' understand of how homeschooling effects individuals, families, and communities.

Standards for Metakaolin Supplementation into Georgia DOT Concrete

Kevin Elliott Spicer, CURO Research Assistant
Dr. Mi Chorzepa, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

This research seeks to find standards for the incorporation of metakaolin as a supplementary cementitious material (SCM) in concrete mixtures. Ultimately the standards should show conclusive proof that metakaolin can be adapted to the Georgia Department of Transportation (GDOT) Standard Specifications. In the past, the demand for metakaolin as a SCM was low because other SCM like fly ash and blast furnace slag were widely available and useful in Georgia. However, with the way the energy sector is transitioning, the availability of fly ash (a byproduct of coal combustion) has drastically decreased. Fly ash is important because, when added to the concrete mixture in certain amounts, it reduces heat of hydration leading to fewer cracks and higher ultimate strength. The GDOT seeks to catch up to current research that is evaluating the use of metakaolin as a SCM so that they can have a stronger, more cost effective, and more durable concrete. Metakaolin contributes to concrete properties in different ways than fly ash. This study is important so that thresholds and controlled standards for the incorporation of metakaolin as an SCM can be evaluated and declared. The successful completion of this research will provide an economical and widely available alternative to the current SCMs being used in the state of Georgia.

Limb Elevation as a Model of Peripheral Arterial Disease

Diana Springer, CURO Research Assistant
Dr. Kevin McCully, Kinesiology, College of Education

Peripheral arterial disease (PAD) is an age-associated condition that limits blood flow primarily in the legs. The influence of restricted blood flow can be difficult to study in PAD due to comorbidities. Limb elevation has been proposed as an alternative method of studying the effects of PAD on muscular function. This study evaluates the medial head of the gastrocnemius muscle in young, healthy adults with the leg in three different elevations above the heart (2, 30, and 60cm). Blood flow and oxygen saturation during exercise via electrical stimulation is measured using near-infrared spectroscopy (NIRS). Using surface mechanomyography, muscular endurance is measured at 2, 4, and 6 Hz of electrical stimulation. Comparisons are then made between the measurements at each elevation as well as correlations between perfusion and muscle endurance. We hypothesize that limb elevation

will reduce muscle blood flow and reduce oxygen levels during electrical stimulation. With lower oxygen levels, we hypothesize that muscle endurance will be reduced. Our primary aim is to test the influence of reduced blood flow (due to elevation) on the measurement of muscle endurance. In addition, if limb elevation does provide a good model of PAD, future experiments evaluating treatments (including exercise training) for reduced blood flow and PAD will be possible. Limb elevation experiments could then be performed on older adults with comorbidities and intact circulation to better understand PAD.

Mentoring as a Protective Factor of the Association between Child Maltreatment and Substance Use in Adolescence

Jordan Srochi, CURO Research Assistant
Dr. Assaf Oshri, Child and Family Development, College of Family and Consumer Sciences

Maltreated youth are at significant risk for substance use behaviors in adolescence. Although role models have been shown to facilitate positive youth development (PYD) among at-risk and maltreated youth, less is known about what types of adult mentorship can buffer the link between child maltreatment and adolescent drug use. In this research study, a secondary data analysis will be conducted to examine how mentors or role models buffer the relationship between adverse childhood experiences, such as maltreatment, and substance use behaviors in adolescence. The present study will utilize three time points from the LONGSCAN study, which includes data from maltreated and non-maltreated youth and their caretakers (N = 1,354). A structural equation model will be used to compare protective effects of different mentoring experiences (i.e., natural mentors, program mentors, or both). I hypothesize that utilization of any type of mentor would lower substance use for children who experienced maltreatment, and that natural mentors would have more of a protective effect than program mentors. Preliminary results indicate that both natural and programmatic mentors buffer the relationship between maltreatment experiences and substance use. This study is important in order to target appropriate interventions aimed at reducing substance use and promoting resilience among at-risk youth.

A Movie without a Hero: Casting Becky Sharp in Early Hollywood Cinema

Gabrielle Stecher, CURO Research Assistant
Dr. Tricia Lootens, English, Franklin College of Arts and Sciences

This interdisciplinary project explores early film adaptations of William Thackeray's 1848 novel *Vanity Fair* in attempt to determine the ways in which the enigmatic Becky Sharp was translated, successfully or not, into early Hollywood cinema. This particular novel and its leading lady inspired the production of various film adaptations from 1911 to 1935, including four silent films and the first film shot in full-spectrum Technicolor. Yet, the casting of Miss Sharp was no easy feat— the Becky of the novel wavers between charming coquette and femme fatale in a way that, at times, seems almost impossible for a camera lens to capture completely. This project investigates the 1932 adaptation of *Vanity Fair* starring Myrna Loy as Miss Sharp as a pre-code exploration of seduction and control that succeeds in fully realizing novel Becky's transformation from wily coquette to psychologically manipulative vamp. After comparing this film to its similarly pre-code precursors, I pit pre-code performances of Becky against the post-code exploration of Miss Sharp in the Technicolor world of the 1935 adaptation *Becky Sharp* in attempt to understand the combined influence of casting decisions and the censorship of the Hays Code on the performances and critical reception of this infamous female lead. Ultimately, a feminist theoretical lens will be applied to my study of the adaptations in order to reveal how the Hays Code and early twentieth-century audiences conceived the cultural ramifications of the temptress on-screen.

Carbon Monoxide Line Emission from Region of Molecular Cloud MBM 55

Amanda Stricklan, CURO Research Assistant
Dr. Loris Magnani, Physics and Astronomy, Franklin College of Arts and Sciences

We are analyzing the CO line emission from a region containing a translucent molecular cloud MBM 55. Over 1000 spectra were taken with the Arizona Radio Observatory 12 meter mm-wave radio telescope on Kitt Peak. The data were part of a project to compare sensitive CO observations

from 88 lines of sight through and around the cloud in an effort to determine how much low-level emission there was from the environs of the cloud core. To do this each of the 88 points was "mapped" using a 13-point pattern. For the original project, the 13 points were added together to produce one final spectrum for each of the 88 points. Our project is to look at each of the 13 paintings individually to see how the CO emission varies on small scales (the beam size is about one arc minute which corresponds to a linear size of about 0.03 parsecs at a distance of 100 parsecs). In addition to seeing how the CO line varies on small scales, we are also looking for individual points with isolated line emission. It is conceivable that some of the 88 lines of sight with non-detections, when all 13 points are added together, may have detections along a single or at most 2-3 lines of sight. By adding a few weak signals with about 10 lines of sight of non-detections, we will be able to determine the smallest connected regions with CO emission.

Bacteria-Phytoplankton Interactions in Understanding the Marine Carbon Cycle

Stephanie Stromp, CURO Research Assistant
Dr. Mary Ann Moran, Marine Sciences, Franklin College of Arts and Sciences

The marine carbon cycle is of major significance on a global scale. With the ever-increasing pressure of climate change, understanding factors that affect carbon flux in the ocean has become more important. The transfer of dissolved organic carbon from phytoplankton to marine bacteria is a major step in the marine carbon cycle, but many key compounds that link phytoplankton and bacteria through trophic interactions are unknown. A model microbial system using the marine diatom *Thalassiosira pseudonana* CCMP1335 and the marine bacterium *Ruegeria pomeroyi* DSS-3 is being used to investigate phytoplankton metabolites passed to bacteria. Genes encoding transporter proteins that were highly upregulated in the model system were identified previously. This project tests whether mutants with deletions in three of the highly upregulated transporter systems grew more poorly on phytoplankton-derived substrates than wildtype bacteria. Mutants for a sulfonate dihydroxypropanesulfonate (DHPS) transporter, a glycine betaine/proline transporter, and a possible allophanate transporter were used to compare growth differences of mutants compared to the wildtype strain. Growth was measured by optical density and flow cytometry. Decreases in observed growth rates for the mutant cultures compared to wildtype are being used to estimate the importance of each substrate as a source of carbon to bacteria growing on phytoplankton metabolites. Future studies will identify the importance of these compounds for natural bacterial communities inhabiting the surface ocean, and help in understanding importance of microbial interactions to carbon flux in our oceans.

In Vivo Assessment of Olfactory Receptor Neurons and Projection Neurons Using Appetitive Olfactory Inputs in *Drosophila* Larvae

Rajeev Subu, CURO Research Assistant
Dr. Ping Shen, Cellular Biology, Franklin College of Arts and Sciences

How smell or taste is translated into appetitive behavior remains poorly understood. *Drosophila melanogaster* has proven to be a powerful model to manipulate and to examine reception and perceptual processing of appetitive olfactory inputs in higher-order olfactory centers. In *Drosophila* larvae, olfactory information is encoded in the antennal lobe where the olfactory receptor neurons form a network with projection neurons in a one-to-one relationship in a complex sensory encoding system. It has been found that *Drosophila* larvae display impulsive feeding of sugar-rich food when presented with appetitive odors, such as pentyl acetate (PA) and 1-octanol (OCT). This finding has prompted us to investigate the potential functional differences in the brains of the third-instar larvae that are treated with distinctive appetitive odors through fluorescence-based imaging analysis. We will first screen for the ability of different appetitive odors to induce neuronal activity using CaMPARI. Following this, laser lesioning of neurons will be used on the screened projection neurons. We hope to determine which specific olfactory receptor neurons and their projection neuron counterparts are responsible for the appetitive odor-induced behavior through the use of behavioral assays using the odors. The successful outcomes from

this proposed study may help us better understand the olfactory circuits in higher-order organisms.

Open Versus Structured Rules: Examining the Policy Effects of Rule Choice in the House of Representatives, 2003-2016

Jessica Jin Suh, CURO Research Assistant
Dr. Anthony Madonna, Political Science, School of Public and International Affairs

This research examines the usage of special rules in the US House to restrict amending activities. Scholars have argued that the House majority party can bias policy output away from the floor median through the usage of restrictive rules, including both structured and closed rules. Scholars suggest that as a result, majority party centrists can incur a policy loss from restrictive rules. I argue that structured rules vary in their ability to restrict amending opportunities, distinguishing between that of closed rules. Accordingly, I argue that in order to secure the passage of restrictive rules, the majority party often makes concessions to majority centrist members through amending opportunities. To test my theory, I build off an earlier study that examined a new dataset of proposed amendments from the 109th to the 111th Congresses under structured rules. For each amendment, the amendment proposal, allowance, and adoption for each House were coded. This research extends that dataset to include amendments from the 108th, 112th, 113th, and 114th Congresses. Additionally, I include all amendments to bills considered under open rules. These amendments under open rules serve as a control group of sorts for my study.

Evolving Racial Perspectives in Haiti, 1785-1820

Christian Michael Sullivan
Kathryn Kostel
Dr. Jennifer Palmer, History, Franklin College of Arts and Sciences

This presentation analyzes contemporary perceptions of the relationship among race, politics, and socioeconomic classes during the Haitian Revolution. The goal of this project is to display that power struggles and economic inequalities served to prolong the conflict and overshadow the inherent racial disparities within Haitian society. The research was done by analyzing treatises and newspaper articles written by European observers. White observers highlighted the strenuous power struggles and economic inequalities alongside racial disparities. They recognized that the Haitian Revolution was not simply a conflict between French plantation owners and their slaves; rather it was a conflict with constantly dynamic opponents. As conflict unfolded, observers tended to shift towards viewing the war as a struggle for economic equality and control. Thus, a conflict that might initially appear on the surface to be only about race was actually a complex and dynamic power struggle that had economic and political inequalities at its core.

Nitrogen Use Efficiency across Soil Fertility Treatments in Cultivated Sunflower

Becca Sussman, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts and Sciences

Cultivated sunflower, or *Helianthus annuus L.*, is heavily dependent on access to nutrients for proper growth, with Nitrogen being one of the main limiting nutrients available for sunflowers. Sufficient N treatments have been found to increase crop productivity and yield. In our study, we examined how nutrient utilization efficiency (NUE) and nutrient acquisition efficiency (NAE) contribute to sunflower productivity. NUE refers to the amount of mass produced in relation to the amount of nutrients the plant obtained. NAE refers to the amount of nutrients the plant obtained in relation to the amount of nutrients available to the plant. Furthermore, we studied root systems and shoot systems separately to differentiate between the harvestable crop and the soil-bound portions of the plant. Plant tissue from 12 diverse lines of cultivated sunflower grown in a randomized complete block design under 4 nutrient treatments were ground and then analyzed for N content. We hypothesized that: roots will contain more nitrogen than shoots under high-fertility conditions; nitrogen allocation between above and below-ground matter will shift with low-nutrient stress, such that the proportion of root:shoot N will decrease; and genotypes with a higher NUE:NAE ratio to perform best under

low-nutrient conditions. From our results, we will be able to inform genetic breeding efforts of low-input sunflower cultivars.

Cognitive Control Differences in Bipolar Disorder in the Presence or Absence of Psychosis

Jane Sutcliff
Dr. Jennifer McDowell, Psychology, Franklin College of Arts and Sciences

Cognitive control is responsible for attention, inhibition, and working memory. Rapid eye movements called saccades have been used to index both the behavioral and neural processes underlying cognitive control. Prosaccade tasks index automatic-like orienting responses by requiring subjects to glance toward a suddenly appearing visual stimulus. Antisaccade tasks index the inhibition of automatic–like orienting responses by requiring subjects to look away from the sudden visual stimulus. Both tasks have been extensively used to study cognitive control deficits in people with psychosis, which are often manifested as higher antisaccade error rates, slower correct antisaccade latencies, and sometimes faster prosaccade latencies. Bipolar disorder can be manifested with or without psychosis symptoms, but it is unclear if deficits in saccade performance by people with bipolar disorder with psychosis also exist in the absence of the same disorder without psychosis symptoms. In this study, healthy comparisons (n=81), people with psychotic bipolar disorder (n=51), and people with non-psychotic bipolar disorder (n=62) completed pro- and anti-saccade tasks. We analyzed the three aforementioned saccade metrics used to index cognitive control in people with psychosis. Differences were assessed with one-way ANOVAs on all three metrics. Preliminary analyses show no significant differences between antisaccade reaction times. Antisaccade error rates in healthy controls were significantly different from both BD-P and BD-NP groups, although BD-P and BD-NP were not significantly different from each other. This indicates that although there are slight disparities in cognitive control between groups, the cognitive deficits between psychotic and non-psychotic bipolar disorder are not significantly different.

Clay Abyss: Underclays of the Şile Region Critical Zone

Sam Svoboda
Dr. Paul A Schroeder, Geology, Franklin College of Arts and Sciences

The Şile region of Turkey contains large amounts of economically significant clay deposits used mainly in the ceramics industry. These clays originate from the weathering of the Upper Cretaceous indurated and altered volcanic andesite in the paleo-lacustrine of the region. This research hypothesizes that composition of the plastic underclays will vary along a gradient that transitions from oxidized to reduced zones. Methods employed to measure the clay fraction include X-ray diffraction (XRD) using treatments of sodium (Na^+), magnesium (Mg^{2+}), and potassium (K^+) cation saturations. Saturations were examined using oriented slides in XRD in their air-dried, ethylene glycol, and heated (330 °C) states. Phases identified included quartz, kaolinite, discreet illite, mixed-layer illite-smectite (I-S), goethite, hematite, and bayerite. Simulations using NEWMOD® indicated the I-S is randomly ordered with a greater than 50% smectite. As depth increases in the critical zone below the oxidation front I-S decreases in abundance. There is a loss of smectite and goethite in the reduction zone. The crust layer is goethite-rich underclay, which marks the extent of the weathering front. This study suggests that significant weathering occurred deep under the surface leading to a low abundance of smectite and goethite with depth and the presence of bayerite. Greater concentrations of I-S were found to occur in the oxidized zone compared to the reduced zone. The suitability of the clays for industrial ceramic applications may therefore be influenced by the extent of modern post-depositional alteration in the critical zone.

Effects of Condense Tannins from *Lespedeza cuneata* on Oxidative Stress in Horses

Cody Alan Swint
Dr. Kylee Duberstein, Animal and Dairy Science, College of Agricultural and Environmental Sciences

Gaining popularity due to its anthelmintic effects in small ruminants, sericea lespedeza (*Lespedeza cuneata*) is becoming increasingly common and more readily available on the feed market. Sericea lespedeza is a legume that, when harvested correctly, has a high nutritive value. It is believed to have high levels of condensed tannins, which is what most researchers think causes the anthelmintic effects in small ruminants. Health benefits from lespedeza, such as reduced oxidative stress and treatment of inflammatory conditions, have been documented in humans. As well as the health benefits shown in humans, sericea lespedeza has a nutrient profile comparable to other high quality equine forages, and may prove to be advantageous as a feed source if it is able to reduce oxidative stress in performance horses. The objective of this study was to determine if incorporating sericea lespedeza hay into equine diets improved antioxidant capacity and reduced oxidative stress in response to a bout of moderately intense exercise. Twelve horses were used in a 6 week feeding trial, during which time half of the horses were fed 1% of their body weight daily in sericea lespedeza hay and the remaining six were fed 1% of their body weight daily in Russell bermudagrass. At the conclusion of the feed trial all twelve horses underwent an incremental standardized exercise test (SET). Blood was collected pre and post SET and tested for antioxidant capacity via assaying total, reduced, and oxidized glutathione, as well as markers of lipid and protein oxidation.

Hunting for Homology: The Role of Working Class Pride in Modern Skinhead Subcultures

Ryan Switzer, CURO Research Assistant
Dr. Cas Mudde, International Affairs, School of Public and International Affairs

The skinhead youth subculture has spent nearly fifty years divided. Beyond the classic Neo-Nazi skins popularized in film and news media, the skinhead community boasts an ideologically diverse corps ranging from SHARP (Skinheads Against Racial Prejudice), to apolitical skins, to gay skins, to Christian skins. This multiplicity of internal factions has led scholars to declare that the skinhead subculture has failed in achieving homology. The thinking goes: "beyond classic skinhead fashion and rowdy music, there is little that holds the community together." I argue that the Doc Martens and Oi! music hold the symbolic key to the subculture's homogeneity. Regardless of the skinhead's ideology, their aesthetic displays working class pride. It is the proletariat disposition that holds the skinhead community together. This study captures the multiplicity to the skinhead youth subculture, while identifying the factors that bind them in the contemporary world. In line with post-subcultural theory and Bauman (1998) globalization provokes multi-faceted transformations. The political, economic, and social alienation that led to the original emergence of skinhead subculture is amplified in its modern precarity (Butler 2013). Through an ethnographic, qualitative analysis of scholarship, skinhead biographies, fanzines, online forums and discography I trace the roots of skinhead proletariat pride from its roots in mid-century United Kingdom to its current fragmented state. I conclude by discussing my finding's implications for our understanding of post-subcultural value systems, cross-class alliances and the mission of white nationalist skins. This study adds to the neglected body of literature concerned with the relationship between aesthetics and politics.

Congressional Complexity: Modernizing Financial Legislation

Andrew Michael Teal
Dr. Anthony Madonna, Political Science, School of Public and International Affairs

The Financial Services Modernization Act of 1999 was acclaimed by both Republicans and Democrats as necessary legislation to push America's economy forward. The Act repealed key elements of the 1933 Banking Act (or "Glass-Steagall Act"). However, following the 2008 financial crisis, many politicians and political observers changed their tune and suggested the repeal played a causal role in the financial crisis of 2008 (see e.g. Stiglitz 2010). When considering the perceived failure of the Financial Services Modernization Act of 1999 (or "Gramm-Leach-Biley Act"), one must consider the complexity of the measure. Like most legislation related to banking, the Act required a great deal of specialized knowledge to comprehend. Accordingly, I argue that the high costs of specialized knowledge have increased over time as Congress has taken on more issues. Accordingly,

this increased difficulty for members of Congress to participate in the drafting and consideration of the act. This led to a great deal of deference being given to special interests and lobbyists who possess knowledge on this subject. Using a dataset compiled by the University of Georgia Congress Project, I examine all amendments to the Financial Services Modernization Act and other landmark financial reform bills. I argue that the average number of floor amendments offered to these measures has decreased over time. Further, I argue that the few amendments offered are significantly more likely to be offered by Banking Committee members who receive a great deal more in campaign contributions from the financial sector than other members.

Ferrohydrodynamic Separation of Prostate Circulating Tumor Cells

Chase Tenewitz
Dr. Leidong Mao, Electric and Computer Engineering, College of Engineering

Prostate cancer, the second leading cause of cancer death in men, is an uncontrollable propagation of cells in the prostate gland. As a disease that can be treated with the correct therapies, a search for a reliable, accurate biomarker that can predict responses to a treatment has begun. In addition, a need for an accurate biomarker that can provide a prognosis for the patient is needed. Circulating tumor cells (CTCs), cells that are shed from a primary tumor site that travel in the peripheral blood, can provide a marker of prognosis through their enumeration and molecular analysis. Our microfluidic device, which incorporates the principles of ferrohydrodynamics, can be used as a dependable resource to extract the CTCs from blood due to its low-cost, label-free, easy usage, high throughput and high efficiency.
Viability was tested with a control group and a group after cell separation. The separation experiment was conducted using a syringe pump with a flow rate of 100 μL/min with 100 CTCs spiked into 1 mL of blood. The cell separation efficiency was calculated by dividing the number of target cells found after separation by the number of cells spiked in the blood sample. This device successfully separated PC-3 cells at a separation efficiency of 82%. With the biocompatible ferrofluid, the cells remained viable after separation from the WBCs. Because this device is label-free and the cells remained alive, further analysis can be done on the CTCs.

The Contribution of Double Electron Capture Processes to Charge Exchange with Multielectron Targets

Jason Terry, Foundation Fellow
Dr. Phillip C Stancil, Physics and Astronomy, Franklin College of Arts and Sciences

Previous investigations into charge exchange and its applications to X-ray spectroscopy have tended to focus almost exclusively on single electron capture processes. Mounting evidence suggests that ignoring the contribution of double electron capture will yield inaccurate results. Accordingly, charge exchange cross sections for single and double electron capture are calculated using multichannel Landau-Zener theory for the system Ne^{10+} + He. (n,l,n',l')-resolved double electron cross sections are generated then used in conjunction with branching ratios to determine cross sections for double capture with and without autoionization. These cross sections are used to generate X-ray spectra for each of the processes. Results indicate that the inclusion of double electron capture events is important for some collision energies where they can redistribute the cross sections from the intermediate energy states towards both higher and lower energy states.

Studying Gene Flow in *Boechera stricta* to Understand the Impacts of Climate Change

Sunishka Thakur, CURO Research Assistant
Dr. Jill Anderson, Genetics, Franklin College of Arts and Sciences

Climate change is imposing novel patterns of selection on natural populations, influencing both the ecology and evolutionary dynamics of plants and animals. To investigate the effects of climate change on plants, we study *Boechera stricta* across elevational gradients, where conditions range from hot and dry in low sites to cool and moist in higher sites. This plant is an exceptional model species because it has adapted to variation in climate that it experiences across broad elevational and latitudinal gradients in nature. To investigate the extent to which climate change will alter trait

evolution, we have transplanted individuals from across the range into five common gardens. During the growing seasons, we measure fitness and other life history traits and collect samples to quantify morphology. During the academic year, we measure phenotypes on these collections, such as leaf morphology and seed physiology. We then use molecular tools to understand the rate of gene flow across these populations. We will use genome-wide association studies to map QTL (quantitative trait loci) for traits. The question we seek to answer is whether gene flow will promote adaptive responses to climate change by moving alleles from drought-adapted populations from the lower elevations into the higher elevation populations. This is how higher elevation plants could possibly adapt to changes in climate that they will experience in the near future, i.e. a climate similar to the lower elevations. The ultimate goal is to understand whether these plants can keep up with climate change.

Effect of Various Threat Categories on the Spatial Clustering of Threatened Mammals

Sunishka Thakur, CURO Research Assistant
Dr. Patrick Stephens, Ecology, Odum School of Ecology

Studies have found that biodiversity hotspots often include only a small percentage of threatened animals, but a large percentage of all species in the class, for most classes of vertebrates. Further, it has been shown the that there is high congruence among classes of terrestrial vertebrates in terms of spatial distribution of all the species belonging to them, but poor congruence in the spatial distribution of only the threatened species in each class. Based on this observation, it has been hypothesized that a greater congruence among threatened species could be seen if they were grouped according to the major threats affecting them rather than taxonomy. We tested this hypothesis on endangered and critically endangered mammals. The major threat(s) affecting each of these species were identified using the data on the IUCN red list. According to these, the mammals were grouped by categories of "major threats" and by taxonomic group (i.e., orders). We gathered a matrix of pairwise distance between all the species in each category based on the geographic range midpoints reported in the PanTHERIA database. The average of the distances between the range midpoints was taken as a measure of how spatially clustered all the mammals in that category were, in comparison to other categories. The goal was to determine whether mammals showed greater spatial clustering when grouped by source of threat than by taxonomy. We found that there was no significant difference the average spatial clustering of endangered species when grouped via source of threat compared to species grouped by taxonomy. Among sources of threat, species threatened by human showed the greatest spatial clustering (i.e., lowest average distance between the range midpoints of species) indicating that targeted action and awareness at the local and regional level for this issue may yield results that benefit multiple species. Species threatened by habitat loss showed the lowest spatial clustering, suggesting that this is a conservation issue to be tackled more globally.

Discovering the Antimicrobial Effect of the Lactoperoxidase/Hydrogen Peroxide/Thiocyanate System against *Streptococcus pneumoniae*

Rachel Thomason, CURO Research Assistant
Dr. Balazs Rada, Infectious Diseases, College of Veterinary Medicine

We encounter a variety of pathogens each day, and the vast majority, if not all, of people encounter the bacterium *Streptococcus pneumoniae.* While colonization of the nasopharynx in humans is usually harmless, if the bacterium is able to spread to other areas of the respiratory tract a rapid inflammatory response ensues that results in disease. *S. pneumoniae* can result in a large spectrum of diseases such as pneumonia, bacteremia, meningitis and otitis media which collectively makes it one of the leading causes of infectious disease in people of all ages, but is particularly threatening to young children, the elderly, and immunocompromised individuals. Among the many defense systems of the airways, our tracheobronchial epithelial cells express two NADPH oxidases, Duox 1 and Duox 2, proteins that are abundantly expressed and produce extracellular H_2O_2 . Duox1 is part of a three-component system that utilizes lactoperoxidase (LPO) to oxidize thiocyanate (SCN^-) using

Duox1-derived hydrogen peroxide (H_2O_2) in order to produce the antimicrobial anion hypothiocyanite ($OSCN^-$). This system has been shown to inactivate influenza virus and certain bacteria, but no studies have been performed testing this system on *S. pneumoniae*. Our results show that incubating bacteria with the full Duox/H_20_2/LPO/SCN- system compared with bacteria alone demonstrated a strong killing effect. Our objective is to explore the effectiveness of hypothiocyanite produced by the lactoperoxidase/hydrogen peroxide/thiocyanate system in killing *S. pneumoniae*.

Charlie Hebdo: Moral Injury and the Display of Religion in Satirical Press

Chelsea Thorpe, CURO Research Assistant
Dr. David Williams, Religion, Franklin College of Arts and Sciences

On January 7, 2015, terrorists attacked Parisian satirical magazine *Charlie Hebdo*, spurring worldwide panic and curiosity. The shooters were of Muslim background and were affiliated with the Boko Haram terrorist organization. The incident once again brought attention to the manner in which Western minority religions, specifically Islam, are depicted in the satirical press. As stipulated by France's secularism law, displays of any religious symbol, including, among other things, prayer, headscarves, and niqabs, are strictly prohibited in the public sphere. This law forms the backbone to the French constitutional principle of *laïcité*, which describes the absence of religious involvement in government affairs. The 1905 law was originally designed as an attempt at societal integration. But signs of reverse integration materialize as *laïcité* is now viewed as a form of suppression of religious freedom, specifically among religious minorities. With the recent terrorist attacks and modifications to *laïcité*, Muslim communities, in particular, are further marginalized. This research discusses the display of religious symbols in the infamous satirical newspaper *Charlie Hebdo*. If the weekly journal was obligated to the strict principles of *laïcité*, then *Charlie Hebdo* would be banned from publishing any depictions of religion. To investigate further, qualitative analyses of its weekly caricatures and timely releases from European media question the presence of moral injury. Considerable attention is designated to individuals who are marginalized by French society, specifically Muslims, due to increasing legal bans on faith-based practices in the public sphere.

How Does Resource Availability Affect Non-State Armed Group Recruitment?

Chelsea Thorpe, CURO Research Assistant
Dr. K. Chad Clay, International Affairs, School of Public and International Affairs

Ranging from the arid deserts of Sirte to miniscule Polynesian islands, many civilizations, whether or not they reside in conflict zones, have become prone to extremist attacks and violent resource extortion. In order for a terrorist group to successfully expand as an entity that imposes fear, both trustworthy financial and human capital are required to ensure organizational communication and global attention. Similar to a business or large corporation, non-state armed groups must have adequate resources to acquire and maintain covert supply chains through commerce and perhaps financial extortion. When recruiting and gathering resources, however, it is necessary to understand why, unlike a firm, non-state armed groups often use violence as a means of extraction. This answer requires an analysis of the decision-making behind various recruitment methods based on the structure, size, and objectives of each organization. This research uses qualitative and quantitative methods to analyze how geographical location, political regime structure, and technological availability affect the expansion of global terrorist organizations.

Plasticization of Nanocellulose Gel

Taylor Beth Timmons
Dr. Suraj Sharma, Textiles and Merchandising, College of Family and Consumer Sciences

Deriving from wood and cotton, cellulose is the most abundant organic polymer on Earth that is renewable, non-toxic, and biodegradable. Urges to use natural and biodegradable products aren't just coming from innovation, but out of necessity. Looking for alternatives and new research in a wide range of products eliminates ongoing issues and opens the field for future research. Using a high-pressure homogenization process with wood pulp slurry, cellulose is converted from a wood powder into nano-molecular gel. Thus, the

microfibrillated nanocellulose is modified to have plasticizing effects with the addition of the natural plasticizer, glycerin. Based on performance, optimal percentages of glycerin ranged from 10, 20, and 30%. For each of the glycerin plasticizer percentages, the hydrogel material was spin coated onto polyurethane and silicon films. The outcomes were characterized through water contact angle testing, a Scanning Electron Microscope (SEM), and biomedical tests. By adding a plasticizer, this allows for the cellulose based nano-composites to be used as coatings on catheter tubing to reduce biofilm formation. These biofilms cause infections through a buildup of bacteria in the tubing. Applying a thin coating of nanocellulose and glycerin plasticizer onto a catheter lead to reductions in biofilm formation. The adaption of cellulose turned a waste product into a non-toxic, biodegradable nanomaterial with biomedical applications.

Mapping Diverse Bicycling Experiences in Athens, GA

Sam Tingle, Foundation Fellow, CURO Research Assistant
Stephen Jordan
Dr. Jerry Shannon, Geography, Franklin College of Arts and Sciences

This study maps areas of Athens-Clarke County (ACC) that need bike infrastructure improvements while also providing a representative account of the diverse biking experiences of Athens, Georgia residents. 20-30 semi-structured interviews and cognitive mapping exercises will be conducted with bicyclists throughout the community. Narrative and GIS analysis will then be used to digitize and georeference these cycling experiences to produce geospatially accurate maps displaying pertinent data. ACC is lacking the comprehensive and representative data necessary to develop an equitable bike master plan. This study will assimilate quantitative and qualitative data representative of Athens' diverse biker subsets to better inform the ACC Bike Master Plan Committee.

The Effects of Type 1 Diabetes on Skeletal Muscle Endurance

Bethany Toney, CURO Research Assistant
Riley Jenkins
Dr. Kevin McCully, Kinesiology, College of Education

Type 1 diabetes (T1D) is an autoimmune disease affecting carbohydrate metabolism, which may alter muscle endurance. The effect of T1D on skeletal muscle endurance is currently unknown. The aim of this study was to measure muscle endurance in participants with a diagnosis of T1D and controls. The wrist-flexor muscles of participants with T1D (n=12) and controls (n=12) were electrically stimulated at frequencies of 2, 4, and 6 Hz for 3 minutes at each frequency. Muscle movement was measured with an accelerometer and analyzed with a custom MATLAB routine. Overall health of participants was assessed using an HbA1c test, casual glucose test, and adiposity measurements. T1D participants with an HbA1c of 7.3$\pm$0.8% were 20.8$\pm$2.2 years and had a BMI of 25.9$\pm$3.1. Controls with HbA1c of 5.2$\pm$0.4% were 20.8$\pm$0.4 years and had a BMI of 23.3$\pm$3.3. Adipose tissue measurements were 0.58$\pm$0.19 cm for T1D participants and 0.43$\pm$0.08 cm for controls. The endurance indexes were not different between T1D and controls ($P>0.05$ for all comparisons). Endurance indexes at 2, 4, and 6 Hz were 94.4$\pm$4%, 83$\pm$7.8%, and 69.5$\pm$14.8% for T1D and 95$\pm$3.9%, 87.6$\pm$6.2%, and 68.6$\pm$14.9% for controls. The hypothesis was not accepted that young people with well-controlled T1D had reduced muscle endurance compared to similar controls. Future studies could be performed on TID participants with moderate to poor control to determine the effect of blood glucose control on muscle endurance.

Emotional Modulation of the Late Positive Potential

Rebekah Trotti
Dr. Brett Clementz, Psychology, Franklin College of Arts and Sciences

The late positive potential (LPP) is an enhanced positive component of an event-related potential (ERP) elicited by emotional stimuli after 300ms. The LPP is sustained over the entire stimulus viewing window and continues after stimulus offset. This increased positivity reflects the allocation of neural resources to appetitive and defensive motivational stimuli. For this study, researchers used electroencephalography to record

ERPs while participants viewed unpleasant, pleasant, and neutral pictures from the International Affective Picture System. ERPs were elevated for unpleasant and pleasant stimuli from 500ms after stimulus onset to 250ms after stimulus offset at frontocentral and centroparietal scalp locations, indicating that the brain responds preferentially to emotional stimuli. Unpleasant and pleasant ERPs did not significantly differ, suggesting that the LPP is not valence-specific, but indicates processing of motivational picture content. Overall, these data demonstrate motivated attention in the brain.

Effects of Gender and Race on Speed and Accuracy of Facial Recognition

Skyler Tuholski, CURO Research Assistant
Samrina Jamal, Katie Lee, Nidhi Thiruppathi, Abby Thomas
Dr. Janet Frick, Psychology, Franklin College of Arts and Sciences

Gender and race of both viewer and target have been explored in the context of facial recognition accuracy, but factors predicting individual variability have not been as well investigated. Overall, women perform better than men in face recognition in terms of both accuracy and reaction time; women also display an own-sex advantage for recognition of female faces. In terms of race, it has been shown repeatedly that both males and females are better able to recognize faces of their own race when living in an area with a strong racial majority. In this study, we analyzed patterns of short term visual memory for both adult male and female Caucasian and Asian faces among male and female college-aged participants, using both accuracy and reaction time as measures of performance. We created a standardized experiment that contained a reaction time task and a short-term memory task, which consisted of blocks of white female, white male, Asian female, and Asian male faces presented in a random order. Preliminary data suggests that accuracy of both male and female participants is lessened, and reaction time is increased, when analyzing faces of another race. Additionally, our initial data supports our hypothesis that females show greater accuracy in recognizing female faces in either race condition, whereas males do not exhibit an own-sex advantage. These findings may have implications for understanding individual differences in factors underlying facial recognition and discrimination.

The Price We Pay: Analyzing the Over-Incarceration of Low-Level Juvenile Offenders in Georgia

Hannah Turner
Dr. Georgia B Calhoun, Counseling and Human Development Services, College of Education

This research explores the high rate of incarceration among low-level juvenile offenders in Georgia. Primarily, this work aims to answer what policy solution would effectively reduce incarceration rates while also befitting the juvenile offender and the public in general. Low-level offenders are youth who have committed minor crimes, yet face substantial damage to their future educational, employment, and mental health outcomes as a result of the time they are forced to spend in detention facilities. In addition, continuing to incarcerate children who arguably pose no threat to public safety costs taxpayers hundreds of thousands of dollars each year. A review of the literature revealed that many of these children are detained because there are few community-based sentencing options across the state that could mitigate the root causes of delinquency while keeping youth at home. To address this issue, I propose three different policy alternatives that each focus on increasing access to sentencing options within the community. The first would establish a state-wide grant program to fund mental health care for juvenile offenders, the second involves creating nonprofit networks to better serve youth doing community service, and the third requires each county in Georgia to adopt two community-based sentencing options. After considering the efficacy, feasibility, and cost-effectiveness of each alternative, the creation of nonprofit networks emerged as the best policy to reduce the number of low-level juvenile offenders currently incarcerated in Georgia.

Shedding Light: A Study of Light Pollution on the UGA Campus

Narissa Turner, CURO Research Assistant
Dr. Puneet Dwivedi, Forestry, Warnell School of Forestry and Natural Resources

Light pollution is the fastest growing pollution worldwide; however, many people are not aware of the adverse impacts of light pollution. Therefore, in this study I wish to identify the awareness level of UGA students about light pollution and attempt to determine the consequences of light pollution on the health of UGA students. I will also explore ways to reduce waste related to light pollution on the UGA campus. The data needed to successfully complete the first two objectives of the project will be collected using two different surveys. In the first survey, I will randomly survey 120 students in the Tate student plaza to determine their awareness level about light pollution. In the second survey, I will survey an additional 50 students living in UGA Housing to determine any adverse health impacts of light pollution. For the third objective, I will use the database maintained by UGA's Architect Office to define waste related to light pollution on the UGA campus. I hypothesize that the awareness level of students about light pollution will be low as the topic is very novel in nature. I also hypothesize that students living on campus may self-report several health-related issues which could be easily attributed to light pollution. Ultimately my goal for this project is to increase awareness about light pollution and to create opportunities for UGA to reduce waste related to light pollution.

Applicatives in Southern English

Nicholas Twiner, CURO Research Assistant
Dr. Vera Lee-Schoenfeld, Germanic and Slavic Studies, Franklin College of Arts and Sciences

This paper looks at three sentence types: Double Object Constructions (DOCs); Benefactive Constructions; and Subject Co-Referential (SCR) applicatives, demonstrated as follows: John gave Mary the book; John baked Mary the cake; and John caught him a fish. DOCs must have two objects following the verb. Benefactives and SCRs have optional objects (John baked a cake) which are introduced to sentences by silent components which compound with the verb. I seek to clarify the case assignments in these sentences. Every noun needs case; otherwise, the sentence will not satisfy the requirements for an acceptable sentence. There are two types of case: structural and nonstructural. Structural case is assigned to the subject, nominative, and to one object, accusative. Another silent verbal component called Active Voice assigns accusative. Accusative is not assigned in passive sentences because it lacks Active Voice. This diagnostic shows if cases are structural. Nonstructural cases are assigned via unique verbs or because of objects' roles in the sentence. The questions then remain: what assigns case to the direct object in the three sentences; and, for verbs like bake, which do not need an indirect object, what accounts for the alternation in case? Sometimes the direct object is structurally marked (The cake was baked), but sometimes the indirect object is structurally marked (Mary was baked a cake). I argue these constructions rely on nonstructural case. For DOCs, case is assigned by DOC verbs. For benefactives and SCRs, the functional component provides this case.

An Investigation of RIN4 Phosphorylation in Plant Immunity

Elizabeth Umanah
Dr. Marianne Shockley, Entomology, College of Agricultural and Environmental Sciences

RPM-Interacting Protein 4 (RIN4) is an essential regulator of plant defense in the model *Arabidopsis* - *Pseudomonas* pathosystem. This protein performs its role by activating both effector- and pathogen-associated molecular patterns (PAMP)-triggered immunity (ETI and PTI) by being phosphorylated. Current work in our lab has identified two kinases that interact with RIN4. The research being conducted seeks to understand the mechanisms behind the interaction of each kinase with RIN4 by examining if phosphorylation will occur at specific residues on the protein. It was hypothesized that elimination of RIN4 phosphorylation will inactivate its immune signaling function, rendering plants susceptible to pathogen infection. The research will be conducted by first performing an in-vitro kinase assay. Then, to elucidate the role of RIN4 phosphorylation, we will assess the presence of the hypersensitive response (HR) by co-infiltrating a bacterial effector and RIN4 phosphomimetic proteins into the plant *Nicotiana benthamiana*. The results of the experiment will allow us to understand how these two kinases interact with RIN4 to elicit the plant's defensive functions against an infection. With the knowledge from the results, the mechanism behind RIN4's plant

immune regulation and the protein's significance during the regulation will be determined.

The Ciliary Gliding Motility in Eukaryotes

Rachel Vaizer
Dr. Mark Farmer, Cellular Biology, Franklin College of Arts and Sciences

The ability of cells to move through their environment is one of the most ancient attributes of living cells. One way in which cells can move is through ciliary gliding, which is thought to be both ancient and highly conserved, even among human cells. Developing an understanding of the mechanism of ciliary gliding in Euglenid flagellates may help us understand this basic mechanism in other cells. This study is designed to determine the relative positions of two ciliary structures, the paraxial rod (PAR) and axoneme, relative to a substrate. The Euglenid cilium has an asymmetrical formation of the paraxial rod, a lattice-like fiber that extends the length of the cilium, and the axoneme, which has a 9+2 arrangement of microtubules. This unique formation allows us to study the potential orientation of the cilium relative to a substrate while an organism is gliding. To find which axonemal microtubular doublets are associated with the motive force responsible for pushing and pulling the cell, specimens will be prepared for and examined using transmission electron microscopy. This will enable us to determine the relative positions of ciliary structures relative to a substrate.

Understanding the Role of Social Determinants in Drug Overdose Deaths in Georgia

Christina Valentini
Dr. Jayani Jayawardhana, Clinical and Administrative Pharmacy, College of Pharmacy

Georgia has experienced an exponential increase in drug overdose deaths. Specifically, the number of deaths due to opioids and heroin has increased dramatically in Georgia within the last decade. However, the impact of social determinants on disparities in drug overdose deaths is not clear. Certain demographic groups could be adversely affected by this public health epidemic. While many studies have explored national trends of drug overdoses, few have specifically considered the epidemic in Georgia. This research examines the impact of social determinants on drug overdose deaths in Georgia. We use county-level drug overdose death data from the Georgia Department of Public Health's Online Analytical Statistical Information System (OASIS) for the analysis. Additional data on population demographics, poverty level, median household income, and geographical variation (rural/non-rural) are gathered from the US Census Bureau. Analysis data sample includes 2,703 observations from all 159 counties in Georgia from 1999-2015. Both descriptive analyses and regression analyses will be conducted to determine the role of social factors on drug overdose deaths in Georgia due to all drugs, opioids, and heroin. The results of this study will highlight the variations in drug overdose deaths across multiple social determinants in the state. The findings will help identify public health policy interventions that address the social determinants that are contributing to this public health priority in Georgia.

Investigating the Grindability of Woodchips at Varying Torrefaction Temperatures

Ian E Van Giesen, CURO Research Assistant
Dr. Sudhagar Mani, Chemical, Materials, and Biomedical Engineering, College of Engineering

Torrefied woody biomass, a promising alternative to coal, has great potential to be used in co-firing coal applications, however, a rigorous analysis of the energy required to grind the torrefied material is needed determine the economic feasibility of the alternative fuel. This study investigated the grindability of woodchips torrefied at four different torrefaction temperatures. Higher torrefaction temperatures increased heating values, but decreased the woodchips' durability. Lower durability woodchips require less energy to be ground, but are susceptible to deterioration and subsequent loss of material during transportation. The obtained results will be beneficial for producing a fuel whose characteristics are most similar to coal.

Adapting a CRISPR-Cas System into a Novel Gene Knockdown Platform

Nikita Vantsev, CURO Honors Scholar, CURO

Research Assistant, CURO Summer Fellow
Dr. Michael Terns, Biochemistry and Molecular Biology, Franklin College of Arts and Sciences

CRISPR-Cas adaptive immune systems of prokaryotes consist of a CRISPR locus containing an array of invader-derived sequences called spacers, separated by repeat sequences, and CRISPR-associated proteins. These systems function in three mechanistically distinct stages. First, there is an integration of spacers into the CRISPR array of the host genome to generate a heritable record of the invasion. Second, the CRISPR array is transcribed and processed into several guiding CRISPR RNAs (crRNAs) that each match a different invader sequence. Finally, the crRNAs are incorporated into a complex with Cas proteins and guide this crRNA-Cas protein complex in silencing invaders via cleavage and destruction of the foreign complementary nucleic acid. My research project focuses on utilizing the invader silencing complex of Type III-A CRISPR-Cas systems to design efficient gene expression suppression tools. In vivo expression experiments of the full and reduced complexes in *E. coli* bacteria coupled with Northern Blot analysis demonstrated that Type III-A CRISPR-Cas complex was capable of efficient RNA cleavage.

Association between Ankle Sprain History and Current Ankle Sprains in Collegiate Club Sports Players

Alyssa Varsalona
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Research suggests that ankle sprains are the most common sports-related injury, and players with a history of ankle sprains are likely to sustain recurrent ankle injuries. The purpose of this study was to determine if an association between previous ankle sprain history and current ankle sprains exists among a population of collegiate club rugby and ultimate Frisbee players. Participants self-reported previous injury history prior to the competitive season and submitted weekly surveys to document practice time and injuries that occurred during the previous week. University of Georgia's club rugby and ultimate frisbee players who had sustained any injury during the 2015-2016 school year were included in the analysis (n=30; 15 male, 15 female; age=20.6±1.7yrs, height=172.5±9.0cm, weight=75.0±17.4kg). Association between ankle sprain history and current season ankle sprain was computed using a Phi coefficient. Of the 30 participants, 12 (40%) reported having sustained an ankle sprain in the past, while 8 (26.7%) reported a current season ankle sprain. A statistically significant weak-to-moderate positive association was observed between ankle sprain history and current season ankle sprains (Φ=0.59, p=0.001). The strength of the association was likely a result of the small sample size. Confounding variables may exist, although they were not accounted for in this analysis. Based on the data obtained, we can conclude a weak-to-moderate positive association between the two variables is present, but cannot determine causality of the recurrent ankle sprains. Further research is necessary to conclude ankle sprain history is directly predicative of recurrent ankle sprains.

Structural Insights into the Role of [2Fe-2S] Clusters in Bacterial Ferrochelatases

Sheena Vasquez, CURO Research Assistant
Dr. Harry Dailey, Microbiology, Franklin College of Arts and Sciences

Heme is an essential cofactor of various enzymes in organisms. It is a key compound for several biological functions such as drug and hormone metabolism and oxygen transport throughout the cell. When the biosynthesis of heme is disrupted, the buildup of its precursors has been shown to cause genetic diseases known as porphyrias. Ferrochelatase is the terminal enzyme in the heme biosynthetic pathway that inserts ferrous iron into the porphyrin ring to make the complete protoheme compound. Human ferrochelatases are known to contain an [2Fe-2S] cluster; however recent studies have shown that bacterial ferrochelatases contain this cluster, as well. In addition, there are at least three different motifs hypothesized to coordinate the iron-sulfur cluster in these enzymes. The reason for mammalian and bacterial ferrochelatases containing this cluster is unknown. Therefore, the goal of this project is to provide structural evidence for how the [2Fe-2S] clusters are coordinated by the various motifs in these enzymes. Ferrochelatases from *Ruegeria pomeroyi*, *Myxococcus xanthus*, and *Caulobacter crescentus* were used for investigations.

Furthermore, techniques such as protein purification and crystallography were used. Initial crystal conditions were obtained for the ferrochelatases, and optimization experiments under these conditions are being actively conducted to produce high quality crystals for X-ray diffraction. These findings will provide insight into the coordination and purpose of the [2Fe-2S] clusters in bacterial ferrochelatases.

The Effect of Insulin Dysregulation and Breed on HPA Axis Function and Plasma Cortisol Binding Dynamics in Ponies and Horses

Sarah Vaughn
Dr. Kelsey Hart, Large Animal Medicine and Surgery, College of Veterinary Medicine

Mechanisms resulting in breed predispositions to insulin dysregulation (ID) and endocrinopathic laminitis are poorly characterized. The adrenal steroid cortisol antagonizes insulin, and free, biologically active cortisol can be increased in ID. Breed-related differences in serum free cortisol fraction (FCF) could contribute to ID in pre-disposed breeds such as ponies, but FCF has not been quantified in ID-predisposed-breeds. The objective of this study was to compare FCF between horses and ponies during health and ID. We hypothesized that: in health, FCF is higher in ponies than horses; and FCF is further increased in ponies with ID. Serum total cortisol (TC), ACTH, FCF and insulin were measured in 36 horses (age 1-24 years) and 31 mixed-breed ponies (age 4-27 years). Animals were sampled before morning feeding in their normal routine, and ID was defined as fasted insulin > 20 μIU/ml or non-fasted insulin > 60 μIU/ml when sampled on pasture. Data were compared with Mann-Whitney tests and Spearman correlation analysis ($P<0.05$). TC and FCF were comparable in healthy horses and ponies, but ACTH and insulin concentrations were 1.3-1.6-fold higher in ponies ($P=0.001$-0.041). In animals with ID, TC was similar but FCF and insulin were increased 1.6-fold and 3.2-fold respectively in ponies ($n=9$) compared to horses ($n=11$, $P=0.01$-0.049), and FCF and insulin were positively correlated ($P=0.04$, $r=0.45$, 95%C.I=0.014-0.746). These data demonstrate differences in hypothalamic-pituitary-adrenal axis function during health and ID between ponies and horses. Further study is needed to determine if and how such alterations impact insulin regulation and, ultimately, laminitis risk.

Computational Investigations of He-HD Collisions in the Interstellar Medium

Clark Goodman Veazey, CURO Research Assistant
Dr. Phillip C Stancil, Physics and Astronomy, Franklin College of Arts and Sciences

When conducting an examination of distant astronomical objects, scientists rely on measurements derived from astronomical observations of these objects, primarily using spectroscopy. The most obviously available data is in the form of radiation being transmitted to us from the source at the speed of light. Ideally we can interpret these incoming photons, which are emitted by charged molecules interacting throughout the interstellar medium, to generate accurate data detailing the way that these molecules are behaving, giving astronomers insight into the temperature and therein the energy of the source object. Seeing as most of the observable infrared radiation in the universe is emitted by molecules excited by collisional processes in the interstellar gas, generating accurate data on the rate of molecular collisions is of salient interest to astronomical endeavors. The collisional system we will be focusing on here is He-HD, an atom-diatom system in which He (Helium) collides with HD (Deuterium-Hydride). We are primarily interested in the cooling capabilities of this system, as these species are predicted to have played an important role in the formation of primordial stars, which emerged from a background composed solely of Hydrogen, Helium, and their compounds. Using an adaption of a public-domain scattering package known as molscat, cross-sectional areas of He-HD collisions are computed for a swathe of rotational and vibrational states across a range of relevant kinetic energies, then integrated to produce rate coefficients. In this research, the resources being utilized are the UGA GACRC z-cluster, and the Cray-XC/40a 30 peta-flop machine at NERSC.

Reducing and Preventing Sexual Assaults on Georgia College Campuses

Eashaa Velamuri

Dr. Chris Linder, Counseling and Human Development Services, College of Education

This policy research looks at the prevalence of sexual assault on college campuses within the University System of Georgia. It questions what is being done to combat sexual assault on these campuses and what could be done. This research goes on to develop policies to reduce and prevent the number of incidences of sexual assault at these Georgia schools. Through a literature review, some common themes were found as to why sexual assault occurs on college campuses and the effects of these sexual assaults on the victims of the attacks. Specifically, past research has shown that much of the problem stems from a lack of transparency within sexual misconduct policies and sexual health and violence prevention education. In addition, the short history of sexual assault policy and long history of "rape culture" on college campuses allows for more sexual violence perpetration. To address these issues, I created three policy alternatives, which include: amendments to the Sexual Misconduct Policy developed by the Board of Regents, introduction of a course on sexual violence prevention in 8th and/or 9th grade, and the creation of more consistency within the Clery Act. After comparing the different policy alternatives against the status quo and measuring the effectiveness, cost and benefits, and feasibility of each, I determined that the best policy alternative is to amend the current Sexual Misconduct Policy as it directly affects how sexual misconduct cases on college campuses are dealt with and thus would have the most immediate impact on victims of sexual assault.

Influence of Air Pollution and Socioeconomic Factors on Chronic Obstructive Pulmonary Disease (COPD)

Siva Venkatachalam, CURO Research Assistant
Dr. John L Gittleman, Ecology, Odum School of Ecology

The World Health Organization predicts COPD to be third leading cause of death worldwide by 2030. Therefore, it is important to find out the factors affecting the spread of COPD. This project focuses on how complex patterns of air pollution, disease mortality of COPD, and socioeconomic factors (GDP per capita/number of physicians) are related to one another. Using statistical analysis, I have depicted the correlation between each variable from the database and identified potential factors underlying their relationship. I used a statistical software (.JMP, regression, and PATH analysis), WorldBank data, and predictions from literature to identify if pollution levels correlate to a higher COPD mortality rate while socioeconomic factors make a negative impact on the spread of COPD. There was a significant, positive correlation between pollution levels (CO_2 emission) and COPD mortality rates. There was an even stronger positive correlation between GDP per capita and the rise in pollution. A potential explanation for this is that mainly urban cities with high GDP and population density often have higher pollutant levels (ex: Beijing, Mumbai, NYC) causing a positive relationship between pollution and per capita. Interestingly, there was even a stronger negative correlation between COPD mortality rates and GDP. Countries with higher GDP levels have a better quality of healthcare (higher number of physicians) which allow for less mortality rates in COPD. In conclusion, the medical community should target different types of air pollutants to prevent the spread of COPD and study COPD causes on a local level.

Visualization of Lung Inflammation

Mayank Verma, CURO Research Assistant
Dr. Ramana Pidaparti, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

The stochastic nature of cells makes it difficult to understand how certain pulmonary diseases such as asthma cause inflammation within the bronchial tubes. Since in vivo analysis is a challenging task, simulation-based modeling is fruitful in many cases in understanding the processes occurring at the cellular level. Cellular Automata (CA) based simulations offer a powerful solution to this problem by giving mathematical identities in the form of rules to these complex biological systems. These rules provide a medium to better understand how certain parameters such as; normalized thickness, normalized air pressure, Young's Modulus, and frequency of the breathing cycle affect the rate of inflammation on the lung tissue. In this study, we will develop rules and simulation frameworks in Java with a touch of

virtual reality to visualize the inflammation process and to acquire its corresponding metrics. Our preliminary sample tests suggest that varying the parameters plays a critical role on inflammation. We plan to extend this work toward a more robust CA simulation framework for various other diseases and inflammation simulations.

An Insight into Organizational Use of Business Process Management Tools and Technologies: An Exploratory Examination

Will Russell Vineyard, CURO Research Assistant
Dr. Dave Chatterjee, Management Information Systems, Terry College of Business

Business Process Management (BPM) is an interdisciplinary systematic approach to creating more effective and efficient workflows to support and empower operational and decision making activities. By employing various tools, techniques, and methodologies, BPM practitioners enable organizational decision makers to see past irrelevant complexities inherent to organizational clutter. This not only allows management to make decisions in a timely and well-reasoned manner, but provides them with a clear and direct way to communicate these decisions to their underlings. BPM practices are universally highly regarded and employed by large corporate firms, but they should not stop there. Through interviewing subject matter experts and reviewing a wide-variety of BPM literature and research, I have come across ways in which organizations in which BPM is not traditionally used stand to reap great benefits if they start engaging in BPM activities. My exploratory findings suggest that organizations of all sizes and purposes stand to benefit from integrating some degree of BPM to their operations, be they a Fortune 500 company or a ten-person non-profit. By doing so, not only will these organizations discover ways in which they can operate more efficiently and effectively, but they also might even provide new insights for BPM in the corporate world.

A Phylogenetic Analysis of *Pyractomena* Fireflies

Garrett Vollino
Dr. Kathrin F Stanger-Hall, Plant Biology, Franklin College of Arts and Sciences

Firefly species around the globe are known for emitting a wide variety of light colors; however the North American genus of *Pyractomena* displays the largest variation ranging from green to orange. In addition, very little is known about their evolutionary history or what factors determine the different distributions of the 16 *Pyractomena* species across North America. Using DNA extracted from 1-3 legs of individual firefly specimen this research study will generate the first *Pyractomena* phylogeny for 10 species with DNA grade specimen (based on three separate protein coding genes: mitochondrial COI and two nuclear genes WG and CAD). This phylogeny will be utilized with biogeographical data for a phylogeny-based analysis of biodiversity and for testing of evolutionary hypotheses on signal evolution in *Pyractomena* fireflies.

Exploiting CRISPR/Cas Genome Editing System in Ciliogenesis

Catherine Waldron, CURO Research Assistant
Dr. Jonathan Eggenschwiler, Genetics, Franklin College of Arts and Sciences

Dysfunction in ciliary processes can lead to a wide range of ciliopathies, which can be further studied and corrected for medical purposes. The overall goal is to study the regulation of ciliogenesis through investigation of proteins that are known to have a role that is not yet understood. The ciliary proteins we are investigating include intraflagellar transport (IFT) proteins, motors, and regulatory proteins that play a part in regulating the primary cilia. The specific genes of interest are Atat1, Kif7, CCRK, IFT122, and Bbs8. To investigate the roles of these genes, we used the CRISPR/Cas genome editing system and a Cre-LoxStopLox (LSL) transcriptional cassette to induce reversible mutations in the target genes. Generation and insertion of the LSL/Homology cassette into the mIMCD IFT88YFP cell line was successful. This will lead to further phenotypic analysis at the mechanistic level by observing the effects on the ability and rate of intraflagellar transport within the overall structure of the cilia.

Mapping and Modeling Hotspots of Schistosomiasis

Joseph Walker
Dr. John M Drake, Ecology, Odum School of Ecology

Schistosomiasis is a water-borne parasitic disease caused by flatworms of the genus *Schistosoma*. These parasites infect over 200 million people each year, mostly children living in rural Africa. Although Schistosomiasis is usually not lethal, chronic infection can stunt physical and cognitive development and hinder productivity at school and work. In 2010, the Schistosomiasis Consortium for Operational Research and Evaluation (SCORE) began conducting longitudinal studies in Tanzania, Niger, Kenya and Mozambique on the efficacy of Mass Drug Administration (MDA) for controlling the parasite. Investigators observed that some "responder" villages were able to significantly reduce the prevalence of Schistosomiasis by the end of the study period, while other "hotspot" villages experienced comparatively little change in prevalence. The goal of our work was to identify which factors influence the change in Schistosomiasis prevalence among Mozambique study villages. To accomplish this, we trained boosted regression trees on environmental and survey data associated with 120 of the 150 SCORE study villages in Mozambique. We then applied the resulting model to the remaining 30 villages in order to evaluate our prediction ability. Although our model was relatively successful at explaining the change in prevalence for the training villages (Pearson R^2 of 0.69), we were unable to make accurate predictions on the withheld test villages (Pearson R^2 of 0.03). In addition to our modeling work, we have created maps of all SCORE study villages in Tanzania, Kenya, Niger, Mozambique and Côte d'Ivoire.

Comparison of Female and Male Lone Star Tick Microbiomes in Watkinsville, Georgia

Lily Victoria Lee Wang
Dr. Travis Glenn, Environmental Health Science, College of Public Health

Ticks are vectors of many different diseases; however, we currently lack details of where, when, and how these diseases are distributed among ticks. By studying the population structure of tick microbial communities, we may be able to track the spread of pathogens by ticks and have a better idea of which pathogenic bacteria are able to co-infect ticks and at what proportions. I characterized the microbiomes of three sets of female and three sets of male lone star ticks collected on different dates from the same location near Athens, Georgia. I extracted DNA from 70 ticks, amplified 16S rDNA, which is specific to bacteria, and obtained an average of 12550 sequences per tick. I then searched for matching 16S sequences from a database of most known 16S sequences and putatively detected *Coxiella*, *Rickettsia*, and *Ehrlichia*. I tested for differences in the prevalence of these pathogens among each set of ticks. The results show that female lone star ticks had a significantly higher proportion of *Coxiella* in their microbial community than male lone star ticks ($p < 0.01$), leading us to conclude that female lone star tick microbiomes are significantly different from those of their male counterparts. Although additional studies characterizing more ticks are necessary to confirm my findings, this study provides a foundation for future studies relating to the population structure of pathogens in lone star ticks.

Identification of Vaccine Misinformation Online

Jonathan Waring, CURO Research Assistant
Prof. Shannon Quinn, Computer Science, Franklin College of Arts and Sciences

Vaccination provides the most effective method of preventing infectious diseases. While vaccine safety and efficacy has been widely studied and verified, there is still opposition from the anti-vaccine movement. It has led to vaccine hesitancy, which is defined as a delay in acceptance or a refusal of vaccine services. It is an ever-growing and constantly changing problem that needs constant surveillance. The internet plays a large role in disseminating vaccine misinformation to a large number of people, which contributes to the vaccine hesitancy problem. In order to combat the spread of misinformation online, it is important to first recognize true facts from false ones. We attempt to develop a machine learning strategy using natural language processing (NLP) that allows one to identify misinformation in vaccine-

related webpages. This will be accomplished through the use of the low-dimensional document embedding algorithm, Doc2Vec. Through the use of semi-supervised learning, we take a small sample of manually labeled vaccine webpages and a large amount of unlabeled vaccine webpages, and attempt to classify misinformed webpages from accurate ones. Doc2Vec also provides methods for determining how semantically similar two documents may be, which can be used to determine what makes a vaccine webpage misinformed. The results of this study could enable both public health practitioners and the general public to monitor vaccine misinformation online in order to reduce vaccine hesitancy and identify strategies to improve vaccine education.

The Expression of the Duffy Antigen Receptor for Chemokines in the Triple Negative Breast Cancer Cell Line, HHC1806

Lauren Taylor Wassel
Dr. Melissa B Davis, Genetics, Franklin College of Arts and Sciences

The Duffy Antigen Receptor for Chemokines (DARC), also known as Duffy or ACKR1, is a seven transmembrane atypical chemokine receptor present on a variety of cell types in the human body. DARC is considered an atypical receptor for two reasons. First, rather than being a signaling receptor, DARC acts as a chemokine sink to reduce the concentration of chemokines in circulation, indirectly influencing the migration of immune cells. Second, DARC is able to bind more than twenty different chemokines in two distinct structural classes, CC- and CXC-, which allows for its description as a promiscuous chemokine receptor. DARC has two distinct protein isoforms that are expressed differentially. This study follows isoform B, which differs from isoform A in the first 7 amino acids at the N-terminus of the protein, making up part of the extracellular binding region. Isoform B was overexpressed through transient transfection in the triple negative breast cancer (TNBC) cell line, HCC1806, to detect differential chemokine binding between the two structural classes. Overexpression was quantified using qPCR, and co-localization with chemokines from the two classes was completed with immunofluorescence imaging of DARC with CCL2 or CXCL8, two known ligands. Future studies will look at the binding affinities of these two chemokines to the different isoforms of DARC, in addition to investigating these interactions in cell lines representing other molecular subtypes of breast cancer.

Derivation of Aerosol Optical Depth and Total Column Ozone via DOBSUN Instrument

Nicholas D Weinand, CURO Research Assistant
Dr. Geoffrey D Smith, Chemistry, Franklin College of Arts and Sciences

Currently, most atmospheric components are measured using expensive, stationary or satellite-based instruments, limiting when and where valuable measurements, potentially elucidating changing climate conditions, can be made. Utilizing an Arduino microprocessor, an RGB color sensor, two UV analog sensors, and various pairs of UV-range band-pass filters, the DOBSUN instrument was designed to easily and inexpensively calculate aerosol optical depth (AOD) over three wavelengths of light, and derive total column ozone (TCO), both important measures of differing atmospheric components. Calculated AOD values were compared to NASA AERONET calculations, with previous measurements producing an average difference of 28% for the red wavelength (612nm), 34% for green (542nm), and 28% for blue (468nm). The DOBSUN calculated TCO values, derived from measuring the differing intensity of UV radiation at two different wavelengths, were compared to NOAA Brewer instruments, and differed on average by roughly 300%. Current efforts are being made to design an instrument case that would allow for a more standardized data retrieval method, theoretically increasing the accuracy of extrapolated factors used to calculate AOD and TCO. For additional comparison with theoretically accurate instruments, DOBSUN AOD measurements are being compared to those made by the Sun and Sky Monitoring Station, an established, inexpensive, sun photometer. Further development of the DOBSUN instrument could allow for its introduction into nearby middle or high school classrooms, as a means of introducing atmospheric science to younger students, while

producing accurate and valuable atmospheric data at a variety of locations.

Needs Assessment to Assess the Use of a Mobile Food Pantry in the Child Care Setting

Camaria Moné Welch, CURO Research Assistant
Dr. Caree Jackson Cotwright, Foods and Nutrition, College of Family and Consumer Sciences

Childhood obesity is a major public health concern. The objective of this study is to conduct a needs assessment to determine if a mobile food pantry and nutrition education intervention will increase fruit and vegetable (FV) consumption and self-efficacy to cook healthy meals. The target audience is early care and education (ECE) stakeholders, parents, and teachers serving low-income children in Northeast Georgia. The needs assessment methodology will include quantitative baseline data collection via surveys related to cooking self-efficacy and attitudes, FV consumption, and an inventory of FV served in the home. Barriers and facilitators to the use of mobile food pantry will be collected using qualitative methods including, key informant interviews, focus groups, and Photovoice. Surveys will be administered to participants in an existing mobile school food pantry with the Food Bank of Northeast Georgia and local ECE stakeholders. Focus groups and interviews will be conducted with ECE center directors, Food Bank managers, ECE teachers, and parents. Photovoice, an approach that combines photography and social action, will be implemented by families to assess their nutrition knowledge, food environment, and overall perception of the use of a mobile food pantry. It is expected that the target audience will have low baseline self-efficacy for consuming and preparing FV. We also expect to gain salient data on planning an intervention to increase knowledge and self-efficacy using a mobile food pantry. This study is significant because it adds to the dearth of knowledge about how to increase access to and preparation of healthy foods for low-income families.

The Sapelo Island Coloring Book

Abigail Elizabeth West, Foundation Fellow
Dr. Chris Joseph, Anthropology, Franklin College of Arts and Sciences

Sapelo Island is home to the only remaining intact Geechee community in Georgia. They are the direct descendants of slaves who bought and settled the land after the Civil War, and while they have managed to maintain much of their cultural heritage, the Hog Hammock community is threatened by loss of land, lack of employment, and an aging population. This research addresses the question: can art be used as a way to draw attention to their struggle to maintain a community on Sapelo? *The Sapelo Island Coloring Book* documents this unique island as it exists today, as seen through the eyes of the artist. While many artists have drawn and painted Sapelo's natural beauty, this book takes a more holistic perspective of what forms a place's identity, depicting places of cultural, historical, and environmental significance. Anyone who colors these pictures is encouraged to think about their narratives and to learn more about Sapelo and the Hog Hammock community. The artist used research methods including spending time exploring the island, observational drawing, renting a room and being immersed in Hog Hammock, chatting with locals, and reading. The coloring books have been well-received by both members of the Hog Hammock community and the public: as of February 2017, over 200 books had been sold. They are being sold in stores on and near Sapelo, in Athens, and online. All proceeds are being sent to the Sapelo Island Cultural and Revitalization Society, whose mission is to preserve and revitalize the Hog Hammock community.

Utilization of Organic Synthesis to Investigate Molecular Organic Frameworks

Aubrey Wheeler, CURO Research Assistant
Dr. Douglas M Jackson, Chemistry, Franklin College of Arts and Sciences

Metal Organic Frameworks, or MOFs, are hybrid 3-dimensional structures consisting of transition metal atoms linked via organic ligands. These compounds are porous and have applications in catalysis, molecular recognition, and separation. This work seeks to develop a metal-organic

framework in an array biocompatible zinc atoms that would connect a set of switchable organic linkers. Molecular switches are molecules which respond to an external stimulus by changing reactivity or configuration. The target molecular switch will be altered by changes in pH and/or ultraviolet light. Synthetic targets for this MOF will require a functional aromatic macrocycle that moves back and forth in a mechanical movement in response to an external stimulus thus altering the function of the structure. Potential applications include drug delivery, for example a drug may be encased in the overall structure, which could then be released only in certain target tissues without harming normal somatic cells. Current work for development of this molecular machine includes a novel synthesis of a mechanically interlocked macrocycle, rod-shaped backbone, and an endcap or stopper for containment along the backbone.

Effects of Pre-Transition Warnings and Contingency Statements on Compliance to Pre-Transition Demands and Problem Behavior

Allison N White, CURO Research Assistant
Dr. Kevin M Ayres, Communication Sciences and Special Education, College of Education

Research suggests that pre-transition verbal warnings alone are not a sufficient intervention in order to decrease latency to comply with transition demand and decrease problem behavior associated with transitions. The current study used an alternating treatment design embedded in a multiple baseline across types of transitions to evaluate effects of different verbal warnings and contingency statements on the latency to comply with demands and problem behavior during transitions. The researchers examined the effects of intervention on 4 elementary-aged students in their self-contained special education classrooms. Researchers collected data on students' latency to comply with transition demands and student-specific problem behavior. The anticipated effects of intervention are a decrease in latency to comply with transition demands and a decrease in problem behavior associated with transitions. The current study provides an evaluation of an easy to use but understudied pre-intervention study.

Hydroxyl Tracing in Diffuse Molecular Clouds

Josh S White
Dr. Loris Magnani, Physics and Astronomy, Franklin College of Arts and Sciences

In an attempt to determine the extent of "dark molecular gas" in the Galaxy, we have conducted a survey of hydroxyl (OH) in a region containing a low-density molecular cloud. Dark molecular gas is a term given to regions which contain H_2, but may not be detectable with radio spectroscopic tracers. We also seek to determine the overall efficacy of hydroxyl as an indicator of the presence of molecular hydrogen. We observed spectral lines of OH at multiple locations (491 individual pointings in 44 locations) on a grid in a region of the sky where molecular hydrogen had previously been detected. Our data were taken with the 305-m Arecibo radio telescope in Puerto Rico. The spectra were then each analyzed for the presence of OH emission lines. The results of this study should determine the extent of "dark molecular gas" in this region and perhaps be applicable to other regions with low-density molecular clouds. We also aim to determine conclusively whether OH is a better tracer of dark gas than the most common molecular tracer, carbon dioxide.

Two Dimensional Visualization of Higher-Order Relations in Biological Graphs

Matthew Wicker, CURO Research Assistant
Dr. Liming Cai, Computer Science, Franklin College of Arts and Sciences

Data visualization is a powerful tool in scientific investigations. It makes it possible to perceive significance and identify correlations or causalities across a complex system under investigation. While often such relations of data are modeled with graphs, it is quite challenging for a visualization tool to faithfully visualize the higher-order, crossing relations in a graph on a two dimensional medium. In particular, recent research at the UGA RNA Informatics lab has developed a graph model (k-tree) for RNA secondary and tertiary structure, enabling computational prediction of sophisticated nucleotide interactions. The work motivated our research to seek a visual abstraction method for the k-tree that captures

nucleotide interactions in order to evaluate and improve RNA nucleotide interaction prediction before rendering a 3D structure. The objective of our visualization research is to display the data such that we achieve: even distribution in the drawing space, minimal edge crossing, and preservation of any symmetry that exist in the data. After observing the effects of different graphing schemes on k-trees, we have found that force directed algorithms produce the most meaningful abstractions. Initial results in this direction have been encouraging. The use of a constrained Kamada-Kawai algorithm on known RNA tertiary structure allows an accurately represent biological structures. Further constraining this model and expanding into three dimensions should allow abstraction of significant information about RNA molecules based on the k-tree.

Online Activism: The Movement to Combat Honor-Based Violence

Ashley Willard, Foundation Fellow
Dr. Mark Cooney, Sociology, Franklin College of Arts and Sciences

Honor-based violence (HBV), a form of communal sanctioning used to restore familial honor following a perceived transgression, has existed in various male-dominated societies over the course of human history. In 2000, the United Nations estimated the prevalence of honor killings, the most extreme form of HBV, to be 5,000 deaths per year. This number is widely considered to underestimate the true prevalence, as the collective nature of the phenomenon facilitates the concealment of murders as suicides or natural deaths. The regions most affected by HBV are Southeastern Asia and the Middle East. Relatively recently, these practices have spread to the English-speaking world through immigration. A social movement has arisen in response. My research focuses on the development of this movement in the Western world. In a bid to assess the status of the Western anti-HBV movement, I conducted a search of organizations with an English language online presence (n=30, to date). I gathered and coded information on their missions, particularly the division into groups providing direct services to victims and those focusing on disseminating information, their social network involvement, their regional distribution, and the timeline and evolution of the social movement more generally. This research contributes to the sociology of social movements by consolidating fragmented resources and thereby providing an overview of concurrent cross-national activism in response to HBV.

Small Structures in the Magellanic Stream: Cloud-Cloud Interactions

Elliott Williams, CURO Research Assistant
Dr. Robin Shelton, Physics and Astronomy, Franklin College of Arts and Sciences

Our Solar System lies in one galaxy, the Milky Way (MW), surrounded by neighboring galaxies. Two of these neighboring galaxies, named the Large and Small Magellanic Clouds (LMC and SMC, respectively), have been caught in our gravitational field and are currently orbiting around the MW. As the LMC and SMC travel around the MW, gas is stripped from them and trails behind. The Magellanic Stream (MS) is a structure of mostly neutral and ionized hydrogen gas pulled from the LMC and SMC. It stretches ~100° along the southern polar axis relative to the MW. It is estimated to contribute ~0.4 solar masses of material to the MW per year via diffuse warm gas raining on the halo that has been decelerated enough to fall in. This study investigates the mechanics of small structures in the MS, specifically in dual cloud scenarios, through hydrodynamical simulations. Our simulations look at two clouds at varying distances, one directly downstream from the other, as well as a single cloud simulation, to understand how cloud-cloud interactions affect different processes such as gas infall rate and cloud survival. We will present the physical state of the gas from the clouds including its density and temperature in regions of cloud-cloud interactions. Using results from this study, we hope to aid observations by providing certain identifying characteristics of processes in the MS to better understand the evolution and future of the MS.

Investigating the Function of GABAergic Signaling during Neural Development of Zebrafish

Sydney Williams

Dr. James D Lauderdale, Cellular Biology, Franklin College of Arts and Sciences

Γ-Aminobutyric Acid (GABA) is known to be the primary inhibitory neurotransmitter in the adult vertebrate central nervous system. An imbalance of excitatory and inhibitory neurotransmitters can lead to seizure activity in the brain. Glutamate is converted to GABA via the Gad enzyme. The two isoforms of this enzyme are Gad67 and Gad65, encoded by the gad1 and gad2 genes respectively. Like mammals, zebrafish have both known gad genes; however, our lab has recently found evidence for a gad1 paralog in zebrafish. Using the zebrafish model to study these three gad isoforms and the role of GABA signaling is ideal because the animal is transparent and develops ex utero. To further investigate the function of the gad genes and to elucidate the role of GABA signaling during development, we are using CRISPR/Cas9 for targeted mutagenesis. A gad1b -/- mutant has been created in our lab already and we continue working towards making additional novel alleles for the gad genes in the zebrafish through this process. By performing gel electrophoresis and sequencing, we can assay for CRISPR/Cas9 success in inducing mutations in these alleles. Electrophysiological recordings have shown that our homozygous mutant has shown increased and abnormal brain activity as compared to wild-type animals. These experiments can be utilized to address the question of how genetic manipulations in GABAergic signaling affect neural development and neurological activity.

The Effectiveness of US Congressional Committees

Brad Louis Williamson
Dr. Charles Bullock, Political Science, School of Public and International Affairs

Committees are known as where bills go to die, but which committee kills the most bills and are there institutional differences between committees? More research in this specific area of study would lead to a better understanding of the most prominent institution in Congress. Through data collection going back to 1999, this study aimed to operationalize each committee by the percentage of bills it was responsible for killing. I gathered data on every bill that was submitted in each congress and tracked which committee it was assigned to. From there, I noted where the bill ended in the legislative process: in committee, in another area (on the floor, Presidential veto, conference committee), or was enacted into law. I compiled the data and broke it down by committee, congress, which party controlled which chamber, and whether or not there was a unified government. A byproduct of this research was the ability to contrast the internal atmosphere of the Senate and House through the comparison between committees with analogous jurisdictions. Thanks to texts such as Fenno's *Congressmen in Committee*, I was able to analyze the results in the larger context of the parent chamber as a whole. I found that the committees dealing with tax policy often killed the most bills while both Appropriations Committees had the best chance of dying in other areas or signed into law. This data can be used to better understand the inner workings of Congress as well as measure the probability of success for future legislation.

Habitat Provision Associated with Environmental Flows

Joshua R Willis, CURO Research Assistant
Dr. Bill Tollner, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

A comprehensive analysis of environmental flow schemes represents a key step in ensuring adequate water availability to meet increasing human needs while minimizing adverse impacts on aquatic ecosystems. This study investigates how several environmental flow methods affect habitat provision in the Middle Oconee River near Athens, Georgia. Historical discharge data are coupled with water withdrawal simulations for three common environmental flow types to examine trade-offs between ecological and social outcomes (i.e., habitat provision and water withdrawal, respectively). Hydraulic models are applied to translate hydrologic simulations into habitat suitability for three generic habitat types: shallow-fast, deep-fast, and shallow-slow. The availability and distribution of habitats are then analyzed with respect to increasing water withdrawal rates. Finally, we compare the utility of deterministic modeling approaches based on long-term average conditions relative to stochastic modeling approaches using frequency-weighted

outcomes. Our initial results for the Middle Oconee River show that percent-of-flow regimes are most conducive to providing deep-fast habitat while results are mixed for shallow-fast and shallow-slow habitat. Furthermore, our findings indicate that models based on average, annual discharge consistently overestimate total habitat. The analytical methodology and approach set forth in this paper is significant in that it may be easily adapted to inform environmental flow analyses at other study sites.

Environmental Conditions That Activate the *E. coli* RNA Repair Operon

Andrew Charles Wise, CURO Research Assistant
Dr. Anna Karls, Microbiology, Franklin College of Arts and Sciences

Escherichia coli contains within its genome a putative RNA repair operon consisting of two genes, *rtcBA*; RtcB is an RNA ligase, while RtcA is a nucleotide phosphate cyclase. The operon is tightly regulated under the control of a σ^{54}-dependent promoter that requires activation of RtcR, a bacterial enhancer binding protein, in order to initiate transcription; the specific signal that activates transcription is as of yet unknown. The purpose of this research is to determine environmental conditions under which the operon is expressed. This will be accomplished by creating a reporter strain using λ-Red recombination to replace *rtcB* with a *xylE*-Kan^R reporter fusion, which will allow us to distinguish when the operon is being transcribed. Using the reporter strain, we will test different conditions to determine which stressor(s) initiate expression of the operon, including those that are known to cause nucleotide damage or affect the ability of ribosomes to carry out translation. Determining which conditions activate the operon will provide vital information toward elucidating the specific molecular signal that activates RtcR. Additionally, the results in *E. coli* will be compared to those in *Salmonella* Typhimurium, which contains additional genes within the operon (*rsr-yrlBA-rtcBA*). Preliminary research suggests that, despite significant homology between the two species, the operon is activated under entirely different conditions. Overall, this project will further our understanding of the physiological roles for RNA repair in bacteria.

The Ugly Duckling Narrative: Identity Development in Multiracial Individuals

Taylor Withrow, CURO Honors Scholar, CURO Research Assistant
Dr. Valerie Babb, English, Franklin College of Arts and Sciences

Race has been a central factor in the development of society for hundreds of years, particularly in the creation of a social structure defined by a person's race or ethnicity. The power of race lies in its ability to segregate and isolate groups of differing races. However, racial mixing and the presence of multiracial individuals weaken this power because they prove racial barriers can be broken. As we rapidly move towards a more mixed world, it is becoming more important to understand these individuals who live on the border between races. The intriguing aspect of multiracial individuals is how the external environment, specifically society's objection towards racial mixing, can significantly impact the identity growth of multiracial peoples. Accordingly, this research focuses on how multiracial people develop identity in a society built upon racial segregation. To answer this question, past theories on multiracial identity growth and the depiction of multiracial characters in literature were examined to isolate patterns of identity development. Several different forms of identity development were isolated, indicating there is not one single process for identity growth but various processes all dependent on the individual's characteristics, experiences, and environments. Recently, there has been a shift toward the idea that race cannot be used as a legitimate tool for classification or categorization and at the forefront of this shift is the multiracial individual; therefore, understanding multiracial identity struggle and growth is key to understanding the evolving state of race perception and race relations in society today.

Effect of the Female Frequency on the Pollen Dispersal Distance in Natural Populations of the Wild Geranium, *Geranium maculatum*

Ariane Wong, CURO Research Assistant
Dr. Shu-Mei Chang, Plant Biology, Franklin College of Arts and Sciences

When a male-sterile mutation occurs in a hermaphroditic population, it can turn the population into one that is composed of both female (or male-sterile) and hermaphroditic genotypes, named a gynodioecious population. An increase of females in a gynodioecious population can subsequently select for an increase of male function in the hermaphroditic individuals, which can increase in the likelihood of a female-sterile (male) mutation occurring in a population, and eventually resulting in the evolution towards a dioecious system that contains separate male and female individuals. To test this theory, studies have been done that observe male function in hermaphrodites with increasing population female frequency. However, female frequency calculated at the entire population level may not be the best predictor for the pattern of selection in nature. This is because gynodioecious populations show spatially structuring of the sexes where females are often clustered in one portion of the population and pollen dispersal is often limited in distance in natural populations. In other words, female frequency in a population as a whole may not be a good representation of mating potentials since hermaphrodites that are surrounded by a cluster of females may experience different effects of mating behavior than those farther away from females. Instead, female frequency at the subpopulation-level, defined by the distance of pollen dispersal, could be a more accurate measure of mating potential for a given plant within the subpopulation. This study aims to test this hypothesis by estimating the distance of pollen dispersal by comparing the shared paternity between seeds of paired maternal individuals. I used DNA extraction, PCR amplification, and genotyping to obtain genetic data for seeds collected from maternal plants whose locations were mapped in 4 populations of *geranium maculatm*. Results from a preliminary study completed in the fall 2016 showed that populations with females have a lower average pollen dispersal distance than those that contain only hermaphroditic individuals. Continuing research will work to test male fitness as a result of female frequency in subpopulations defined by pollen travel distance.

Developing a Sub-Viral Particle Dengue Vaccine Using Computationally Optimized Broadly Reactive Antigen (COBRA) Technology

Dianna Wong, CURO Research Assistant
Dr. Ted M Ross, Infectious Diseases, College of Veterinary Medicine

Dengue is a mosquito-borne *Flavivirus* that causes dengue fever, which predominantly causes mild symptoms but can progress in severity and ultimately develop to lethal dengue hemorrhagic fever. The endemic is worldwide with less than half of the world's population susceptible to infection with limited treatment available. The virus has four serotypes and is sensitive to variability proving it difficult to develop a tetravalent vaccine. Computationally optimized broadly reactive antigen or "COBRA" technology addresses the antigenic diversity of each serotype by using global surveillance efforts to generate a consensus of sequence of the surface. Sequences to make chimeric E proteins can be generated by switching regions that elicit neutralizing antibodies representing different serotypes. The regions DIII and Hinge were chosen to make DENV1-DENV3 and DENV2-DENV4 sequenced chimeras. Recombinant sequences of the E protein are used to make subviral particles for the serological detection of antibodies in mice. This study describes how chimeric sequences using COBRA methodology are implemented through bacteria in a DNA purification system for subsequent use for harvesting subviral particles.

Indecent: The Show That Shut Down on Opening Night

Lukas Woodyard
Dr. Frances N Teague, Theatre and Film Studies, Franklin College of Arts and Sciences

This paper considers the reception of a lesbian kiss on stage, and what that reception tells us about American attitudes toward gender and sexuality in popular culture. In 1923, *God of Vengeance* by Sholem Asch was shut down due to indecency on their opening night when the American public first viewed the lesbian kiss. The second production was far more successful. The Jewish Repertory Theatre revived the show in 1992 and did better than the original production probably due to the loss of the shock value of the show. Most recently, Asch's play was revived by La Mama E.T.C. at the end of 2016. This

production precedes another work: the Pulitzer-Prize-winning Paula Vogel, a queer feminist playwright is premiering her new work *Indecent*, a play about the first production of Asch's *God of Vengeance*. Since the play will not open until April on Broadway and not be published until August, this study will focus on the reception of the three productions of Asch's play and the reception of earlier productions of Indecent (at Yale Repertory Theatre and at Vineyard Theatre).

Hydrophilic Top Coat on Nitric Oxide-Releasing Surfaces for Enhanced Antibacterial and Antifouling Properties

Christina Workman, CURO Research Assistant
Dr. Hitesh Handa, Chemical, Materials, and Biomedical Engineering, College of Engineering

Healthcare-associated infections have resulted in rising numbers of deaths and medical costs in the United States. A majority of these infections stemmed from opportunities provided by medical implants and surgical wounds. Implanted medical devices provide surfaces for proteins from body fluids to bind, leading to bacteria aggregation and platelet activation. Biomedical grade polymers that involve the incorporation of nitric oxide (NO), an antimicrobial agent, are being investigated to reduce the risk of infection. While the results have been widely successful in reducing the incidence of infection it has been discovered that NO-releasing surfaces consequently increase protein absorption to these surfaces. This research worked to prevent protein absorption on these surfaces by incorporating hydrophilic polymers as a topcoat to NO-releasing surfaces. Four different polymers, three thermoplastic polyurethanes and a silicone elastomer were evaluated for their surface characteristics, affinity towards protein and viable bacteria absorption. These traits were measured using methods such as spectroscopic ellipsometry, chemiluminescence NO analyzer and atomic force microscopy (AFM) to identify which polymer exhibited the most hydrophilic properties. Highly hydrophilic polymers, such as SP60D60, form hydration layers on their surface, protecting the surface from protein adhesion. The formation of a hydration layer can be attributed to low surface roughness, as identified with AFM scans. The antifouling property of SP60D60, top coated on a NO-releasing film provided a synergistic effect of reducing viable bacteria by 95.83% compared to the control and protein adhesion was minimal, as measured by change in thickness of the SP60D60 films (2.24±0.68 nm).

Studying the Effects of Valsartan on *Daphnia magna*

Alyson Ming Wright, CURO Research Assistant
Dr. Ford Ballantyne, Ecology, Odum School of Ecology

As pharmaceuticals constantly enter the environment, aquatic organisms are chronically exposed to these potentially harmful compounds. A small aquatic invertebrate, *Daphnia magna* play a key role in the freshwater ecosystem as important herbivores that help determine water quality and serve as crucial sources of food for many fish. Studying the effects of pharmaceuticals on *D. magna* is critical to gain an understanding of how they disrupt development and life history characteristics and to preserve the dynamics of freshwater ecosystems. Valsartan, a drug typically used to treat high blood pressure in humans, was found in the highest concentrations around United States water treatment facilities and its affects on daphnia are unknown. In this study, *Daphnia* were exposed to various concentrations of valsartan that reflect concentrations found in the environment. Development and life history traits of *Daphnia* were analyzed to see the effects. It is expected to find physical deformities, a reduced rate of fecundity, and a slower maturation rate across all treatment levels compared to the control.

Investigation of the Effectiveness of Geosynthetics in North Georgia Soils

Jason Christopher Wright, CURO Research Assistant
Dr. S. Sonny Kim, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

This study will a large specimen, 6' x 6' accelerated model, in conjunction with numerical modeling in order to determine the effectiveness of geosynthetics as a reinforcing material in the between the base course of pavement and the subgrade using different soil types of Georgia. There have been several studies investigating this but very few investigate the relationship of full

scale testing data with numerical finite element modeling. For this study, finite element analyses will be conducted using ansys. The model will include both the graded aggregate base (GAB) and subgrade soils to determine the vertical stress and horizontal strain numerically. There will be several different subgrade soils tested from varying parts of the state of Georgia in order to determine the effects of the base layer, subgrade layer and geosynthetic. In conjunction with the numeric modeling, a large scale test will be performed with each of the different subgrade soils with different geosynthetic reinforcements. From the accelerated lab testing the experimental vertical stress and horizontal strain will be extracted. This data will then be compared with the FEM data in order to produce a more accurate and reputable relationship between the two to provide recommendations to the Georgia Department of Transportation (GDOT) for the six different subgrade soils. The results of the numerical modeling and large scale test will be used to develop a Mechanistic-Empirical Pavement Design for the use of geosynthetics in North Georgia soils by GDOT. It is expected that the soil used in conjunction with the geosynthetic will perform better than the test specimen with no geosynthetic.

Educational Disparities between Rural and Urban Schools in the State of Georgia

Victoria Ayse Yonter, Foundation Fellow
Dr. Josh Kinsler, Economics, Terry College of Business

Disparities between K-12 education in metro and non-metro counties were found in the state of Georgia. Linear regression analysis was used to measure the differences in outcomes, with test scores as the measureable outcomes. Demographic controls including income, race, and education levels of the counties were used as controls and tested as explanatory variables. Determining the causes of the achievement gap among rural schools will help policies be crafted that can effectively alleviate these gaps. The effectiveness of the federal Rural Education Achievement Program was tested using difference-in-differences model. Testing the effectiveness of existing programs is important to improve these programs and encourage more successful future initiates. This paper hopes to address and describe the differences in rural and urban education, using Georgia as evidence, and test current efforts aimed at lessening these differences.

The Role of Chondrogenic Growth Factors in the Pathogenesis of Equine DSLD

Madeline Young, CURO Research Assistant
Dr. Jaroslava Halper, Pathology, College of Veterinary Medicine

Equine Degenerative Suspensory Ligament Desmitis (DSLD) is a disease afflicting a wide range of horse breeds that often results in mortality. Little is known about the pathogenesis of the disease making diagnosis and treatment of the affected horses difficult. Our lab has shown that the key histopathological sign of DSLD is an abnormal buildup of proteoglycans within connective tissue throughout the body with Safranin O staining which indicates the proteoglycan's sulfation. Additionally, at least one of the tendon proteoglycans, decorin, is abnormal in horses with DSLD, with chondroitin sulfate replacing the normal dermatan sulfate. The purpose of our current research has been to explain the abnormal levels of the proteoglycans by investigating the levels of the chondrogenic growth factors Bone Morphogenetic Protein 2 (BMP-2) and Transforming Growth Factor β1 (TGFβ). These growth factors regulate the production of proteoglycans by binding to the dermatan sulfate in decorin to suppress further production of the proteoglycans. When the dermatan sulfate is replaced with the chondroitin sulfate we believe the growth factors are unable to bind to the decorin which stimulates further production of proteoglycans by the tendon cells. Through immunohistochemistry staining, abnormally high levels of BMP-2 were found to be correlated with the overproduction of the proteoglycans and cellular activity. Interestingly, the levels of TGFβ were found to be low. Finding higher levels of the BMP-2 correlated with abnormally high levels of proteoglycans supports our hypothesis that growth factors are unable to bind to the altered decorin and could be leading to the progression of DSLD.

Pedagogical Methods for Developing Empathy in Engineering Students

Kathryn Marie Youngblood, CURO Research Assistant
Dr. Jo Walther, Environmental, Civil, Agricultural, and Mechanical Engineering, College of Engineering

Among the variety of design talents and technical expertise expected of engineers, recent critiques of engineering work have challenged problem-solvers to more closely examine the social contexts and consequences of their work. This challenge demands that engineers of the future be trained to empathetically interact with a diversity of stakeholders. The socially-situated and interdisciplinary nature of the grand challenges of the modern world necessitates a socially conscious engineer and one who integrates empathy into their professional way of being. There has, however, been little exploration of methods by which to cultivate empathy as part of the professional development of engineering students. Based on previous work establishing the utility and application of empathy, this research entails the development of a pedagogical intervention for fostering empathy in an engineering setting through skill building exercises and role play. Qualitative analysis of student reflections on these experiences reveals a wide range of understandings of empathy as it applies to professional practice and as a way of being, in addition to illuminating elements of engineering culture that may be detrimental to the empathetic development.

Long-Term Population Dynamics Pre-Die Off of the Vermetid Gastropod, *Ceraesignum maximum*, in Mo'orea, French Polynesia

Margaret Zacharias
Dr. Craig W Osenberg, Ecology, Odum School of Ecology

Coral reefs form some of the world's most productive ecosystems, but corals are currently threatened by physical and biological stressors. One of these stressors, *Ceraesignum maximum*, is a vermetid snail, which can densely populate coral reefs and are known to decrease coral survival, growth, and photosynthetic yield. Although these snails are a known stressor, not much is known about the ecology and biology of these snails. In 2015-2016, vermetid populations experienced an unforeseen, massive die-off throughout French Polynesia. To better understand vermetid population dynamics and recognize if there were warning signals for the die-off, we analyzed an 11-year time series (2006-2016) of photographs from Mo'orea, French Polynesia to quantify snail density and size structure as well as live coral cover. Photographs were taken annually at 6 different sites around the island, with 100 photographs per site. Results indicate that vermetid populations increased at an average rate of 0.29% $year^{-1}$ from 2006-2015, and areas with higher vermetid densities have lower coral cover. There appeared no warning of a population crash. While other factors may have led to the coral decline, we predict that the vermetid population crash will lead to increases in live coral cover. Future work will examine the correlation between different coral species and vermetid densities, as well as how size structure of the populations has changed over time. These data will help us to better understand dynamics of populations before massive die off events.

Exploring Grief: Accompanying End of Life Support with Palliative and Bereavement Care

Amy Zhan, CURO Research Assistant
Dr. Toni Miles, Epidemiology and Biostatistics, College of Public Health

With a cohort of nearly 50 million, Boomers quickly approaching their older years, aging is one of the most significant public health trends to monitor in coming years, along with the growing realization that our current models of end-of-life-care and bereavement management have major shortcomings. Death and dying will be experienced by millions of families across the United States, with few mechanisms in place to address the needs of those left behind. This research seeks to find effective means of supporting resilience and restructuring policies to renovate hospice care in order to restore good health for surviving family members and loved ones. Can we create policies to restore health following bereavement? A lack of clear evidence regarding the effects and nature of bereavement results in an inability to guide the development and allocation of bereavement programs, and the findings will have the potential to inform the

capacity and effectiveness of services and community organizations that are able to care for individuals who are bereaved, according to their needs. Palliative care is incomplete without bereavement training, and our work seeks to incorporate these aspects of care to create more efficient patient-centered care in nursing homes and hospice settings. We will be conducting interviews with health care providers and hospice residents, and compiling quantitative and qualitative data to support our findings. Such studies are essential for achieving equitable resource allocations within our health system and providing cost-effective measures with beneficial health outcomes for all.

Olympic Performance and Propensity for Interstate Conflict

Jonathan Zot Sr.
Dr. Andrew Owsiak, International Affairs, School of Public and International Affairs

Does a negative performance at the Olympic Games affect the aggressiveness of states that invest heavily in the international competition? Considering the sizable financial inputs of states, the widespread viewership of the events, and the opportunity for international leveraging, it is rational to assume that state governments are aware of the spectacle's political salience. With such high stakes, a significantly poor performance would be dissatisfying to both a government and its citizens. This paper explores aggressive foreign policy adoption in response to pervasive public discontent following Olympic underperformance, employing Diversionary War Theory as the state government's motivating factor. I observe the relationship between the two relevant aspects that encompass a state's overall experience: outcome and investment. Outcome was the difference between the final medal count and a count predicted by leading experts. To establish a baseline for Olympic potential, I developed a novel approach that uses each state's GDP per capita share to determine an unbiased medal count. This count was contrasted to the leading prediction to estimate investment. From these variables, I isolated a group of underperformers with high investments. In the period immediately following the Olympics, the states investing more in the games initiated a greater average number of Militarized Interstate Disputes than their low-investing counterparts when faced with Olympic underperformance. To further establish a link between Olympic performance and interstate aggressiveness, I plan to incorporate data from other Olympic years. This will offer empirical research supporting the political relevance of the event.
