6:15 p.m. Awards Ceremony

Classic Center, Parthenon Room

Presentation of CURO Summer Research Fellows, CURO Scholars, UGA Libraries Undergraduate Research Awards, and Best Paper Awards	Dr. Pamela B. Kleiber, Associate Director, Honors Program Ms. Caroline Barratt, Director, Miller Learning Center Library Commons Ms. Deborah Dietzler, Executive Director, UGA Alumni Association

*The Science as Art distinction denotes the interplay between science and art. Images were produced during the course of scientific research and chosen for their aesthetic excellence as well as scientific or technical interest.

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2001. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students. Awards will be presented at the CURO Symposium Awards Ceremony on Monday, March 29, 2010 at 4:00 p.m. in the Classic Center, Athena Ballroom E.

2010 Awards

Early Career Faculty Award
Dr. John C. Maerz, Assistant Professor, Warnell School of Forestry and Natural Resources

2009 Awards

Early Career Faculty Award
Dr. Brian S. Cummings, Assistant Professor of Pharmaceutical & Biomedical Sciences
Dr. Anna C. Karls, Associate Professor of Microbiology
Dr. Dawn T. Robinson, Associate Professor of Sociology

2008 Awards

Master Level Faculty Award
Dr. John J. Maurer, Professor of Population Health
Early Career Faculty Award
Dr. Walter K. Schmidt, Assistant Professor of Biochemistry & Molecular Biology
Program Award
Biomedical and Health Sciences Institute

2007 Awards

Master Level Faculty Award
Dr. Timothy Hoover, Associate Professor of Microbiology
Early Career Faculty Award
Dr. Steven Stice, Professor of Animal & Dairy Science

2006 Awards

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Associate Professor of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Associate Professor of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD student in Plant Biology

2005 Awards

Faculty Awards
Dr. Gary Barrett, Odum Professor of Ecology
Dr. Sidney Kushner, Professor of Genetics
Department Award
Department of Cellular Biology

2004 Awards

Faculty Award
Dr. William S. Kisaalita, Associate Professor of Biological & Agricultural Engineering

2003 Awards

Faculty Award
Dr. Jody Clay-Warner, Assistant Professor of Sociology
Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator
Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Professor
Dr. Marie-Michèle Cordonnier-Pratt, Senior Research Scientist

2002 Awards

Faculty Awards
Professor William D. Paul, Jr., Professor of Art
Dr. Katherine Kipp, Associate Professor of Psychology
Faculty Recognition
Dr. Susan Sanchez, Assistant Professor of Infectious Diseases
Department Award
Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head
Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Professor of Physics & Astronomy
Dr. Heinz-Bernd Schuttler, Professor and Department Head of Physics & Astronomy
Dr. Jonathan Arnold, Professor of Genetics
Dr. Susmita Datta, Professor, Georgia State University
Dr. David Logan, Professor, Clark Atlanta University
Dr. William Steffans, Professor, Clark Atlanta University

2001 Awards

Faculty Award
Dr. Marcus Fechheimer, Professor of Cellular Biology

Faculty Recognition
Dr. David MacIntosh, Associate Professor of Environmental Health Sciences
Dr. Dean Rojek, Associate Professor of Sociology

Department Award
Department of Genetics
Dr. John MacDonald, Department Head and Professor

Program Award
Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

Graduate Student Reviewers for CURO 2010 Symposium

Ibrahim Aljuffali	Pharmaceutical & Biomedical Sciences

Martin Rogers	Honors Program staff
Troy Smith	Honors Program staff

Demystifying the Conflict Culture: Understanding the Effects of Zero Tolerance on Students in a Georgia Disciplinary Alternative Education Program

Jeremy Akin
Dr. Larry Nackerud, School of Social Work, University of Georgia

The students impacted by exclusionary discipline policies—e.g., suspension, expulsion, and/or placement at alternative schools—comprise an ever-increasing population in Savannah-Chatham County Public Schools. Over the past several years, fighting remained the number-one cause for suspensions and expulsions, and the recent 78 percent increase in students at the local alternative program over just four months in 2008 raises questions as to the long-term effects of the school system's current application of "zero-tolerance." Problems surrounding overcrowding, recidivism, and juvenile prison rates highlight a great need to understand and include students in the development of programs that affect them and, indirectly, society at large. Through interviews and surveys of students, parents, faculty, and administrators in the public school system, this study conducted between January and March 2010 sheds light on the following questions: What are the root causes of the "conflict culture"—defined as the social code that says fighting is the only viable means for peace—and how can these be addressed? Furthermore, how does the zero-tolerance strategy impact the conflict culture within local public schools? Results from each interview and survey have been summarized, catalogued, and analyzed via basic descriptive and correlational statistics. For quantitative data, frequency distributions and correlations were developed. Research findings will be made available to system administrators and will inform the curriculum of a peer mediation program in which students at seven area high schools mediate real-life conflicts involving their classmates.

Effect of Cation Chelators on Biofilm Formation in a Prolific Versus Non Prolific Biofilm Forming Strain of *Listeria monocytogenes*

Christine Akoh – CURO Apprentice
Dr. Joseph Frank, Department of Food Science & Technology, University of Georgia

The mechanisms involved in *Listera monocytogenes* biofilm formation are largely unknown. Previous studies involving other bacterial pathogens suggest cations contribute to biofilm formation. The goal of this study was to provide insight into some of the external factors that enable efficient biofilm formation and persistence of *L. monocytogenes* on food processing surfaces. This study determined the effect of the cation chelators EDTA and EGTA, a calcium specific chelator, during biofilm formation on stainless steel surfaces by *L. monocytogenes* strain 311 (prolific biofilm former) and ATCC 19115 (poor biofilm former). Epifluorescent microscopy was used for visualization and quantification of the biofilms, and bacterial counts were obtained using the spread plate method. Microscopy results indicated that the presence of 30 mm of the cation chelators EDTA and EGTA completely inhibited bacterial growth and attachment when added initially and after 6hr of biofilm growth. Chelating cations in the growth medium appeared to enhance biofilm formation once biofilms had formed after 24 or 48 hours. Plate counts showed 2-3 log decreases in bacterial growth of both strains following the addition of EDTA initially and after 6hr and 3-4 log decreases following the addition of EGTA but no significant difference after 24 and 48 hours. Collectively, the data suggest that cations, especially calcium, play an important role in bacterial attachment and the subsequent biofilm formation. The information obtained from this study will provide insight into the external factors that enable effective and efficient biofilm formation in *L. monocytogenes*. This information can then be used as a tool to formulate effective intervention strategies against this pathogen of extreme importance.

Television News Coverage of the 2010 Tea Party: A Niche for Everyone?
Jessica Alcorn – CURO Apprentice
Dr. Audrey Haynes, Department of Political Science, University of Georgia

During its dominance, television news was viewed as a relatively homogenous product, catering and marketing to a rather large audience. However, as new forms of media challenged broadcast, primarily satellite and cable, and the major networks fought to retain their audience level, observers noted that "news" was changing. Simply the introduction of greater competition, competition that seemed to target a particular slice of the market, changed the nature of news. Many scholars began to discuss news as filtered through a prism, rather than a "fair and balanced" representation of "all you need to know." I will attempt to test this theory of niche news by analyzing the coverage of a politically charged event, the Tea Party Convention. If this hypothesis is true, the expectation is that coverage among the major news outlets (ABC, CBS, NBC, FOX News, MSNBC, and CNN) will differ significantly in their presentation. In the end, I expect variation in 1) how the Convention is framed, 2) how much attention is given to the event, and 3) the positive and negative connotations of the words used to describe the event. I will conduct a content analysis of news transcripts from the days immediately surrounding the convention according to particular variables, such as sources, ideological bias, and attention. Most of the data analysis will be descriptive, with quantitative support from correlation and cross-tabulation analysis. My expectation is a confirmation of the niche hypothesis. News no longer represents reality but rather reality through a particular market perspective.

Developing a Hybrid Molecule Aβ-a-factor to Study the Activity of IDE in Cleaving Aβ
Samar Aldrugh
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Alzheimer's disease (AD) is an irreversible, progressive neurodegenerative disease. One of the neuropathological hallmarks of AD is the accumulation of extracellular aggregates of Aβ peptides. Aβ peptides are generated via two-step proteolytic cleavage of a transmembrane protein (APP). Aβ (1-42) peptides are highly fibrillogenic, thus they are associated primarily with AD. Aβ is one of multiple substrates cleaved by insulin degrading enzyme (IDE). Expression of IDE in yeast promotes maturation and production of the a-factor mating pheromone, in the absence of the yeast enzymes, Ste23p and Axl1p. This observation indicates that the a-factor mating pheromone is a substrate of IDE. IDE cleaves Aβ between F19 and F20, thus we are interested in fusing Aβ (1-19) sequence to the mature a-factor. Our goal is to construct a yeast model as a tool to study the activity of IDE in cleaving Aβ. We hypothesize that a fusion between Aβ (1-19) sequence and the mature a-factor sequence should render a hybrid protein that is cleavable by IDE. This fusion is created via recombination cloning. We anticipate that if IDE is able to cleave Aβ-mature a-factor fusion, mating will take place, thus linking the production of Aβ to mating in yeast. The mating efficiency in yeast will be tested via mating assays. Using a yeast model to study the activity of IDE in cleaving Aβ is expected to be more cost effective than using a mouse model. These findings will advance our knowledge and understanding of Alzheimer's disease and guide potential therapeutic strategies.

Building a Baby College in Athens-Clarke County
Juliet Allan – Roosevelt at UGA
Dr. Diane Bales, Department of Child & Family Development, University of Georgia

Children in Athens-Clarke County (ACC) disproportionately live in households characterized by a low household income, a single parent, or parents with low levels of academic achievement. Nationally, these household demographics are correlated with high dropout rates and with grades and test scores below the national average. Relevant

Athens statistics illustrate that student performance falls below national standards. The academic struggles of many Athens children are partially attributable to the deficit of responsive parenting that is correlated with at-risk households. Scientific research demonstrates that during the early years of a child's life, responsive parenting supports children's language, cognitive, and social-emotional development. Delays in these cognitive development areas have long-lasting academic repercussions, such as low test scores, grade repetition, increased likelihood of dropping out of high school, lasting literacy struggles, and low wages. This paper proposes that Athens-Clarke County implement a "Baby College," which provides responsive parenting workshops for at-risk families in ACC. Studies at universities across the country indicate that early childhood intervention results in tangible improvements in at-risk children's academic performance. A systematic analysis of this research reveals that both center-based enrichment programs, such as Early Head Start, and improvements in the home environment are necessary for a maximum improvement in students' academics. ACC already provides strong center-based enrichment programs for at-risk children, and a "Baby College" would address the home environment component of intervention, complementing existing Athens programs. Finally, to ensure effectiveness, the program would coordinate with faculty at UGA and ACC community leaders for program evaluation and curriculum design.

Designing an Efficient and Effective Cap-and-Trade System

Juliet Allan – Roosevelt at UGA
Dr. Jeff Mullen, Department of Agricultural & Applied Economics, University of Georgia

Cap-and-trade represents a promising policy for reducing greenhouse gases and slowing the rate of climate change. The basic premise of cap-and-trade is a cap on carbon emissions that becomes increasingly strict over time. The cap is enforced by distributing allowances to emitters of carbon dioxide and punishing those who pollute without an allowance. An economic analysis of proposed cap-and-trade legislation, other cap-and-trade systems, and academic research on climate change policies reveals that a break from the traditional formula would improve the efficiency of the system and reduce its costs to the United States' economy. An upstream and economy-wide system would cap the amount of carbon-producing substances (such as oil, coal and gas) produced in or imported into the country as opposed to a cap on emissions. Upstream regulation allows for easier monitoring, reduced administrative costs, universal coverage of emissions in the country, and greater stability in the allowance market. Furthermore, an EPA-run auction of allowances, as opposed to free distribution, avoids windfall profits by carbon-intensive industries and would allow a redistribution of auction proceeds to American consumers. Methods for appropriate regulation of the auction, scientifically based reduction goals, and components such as offsets and banking of allowances are also discussed as ways to further increase the efficiency of the system. An efficient design of a cap-and-trade system is critical in minimizing short-term transition costs and ensures that the long-term benefits of improved air quality, technological innovation, and slowing climate change outweigh these costs in a cost-benefit analysis.

Creation of a Heme Biosensor

Amarachi Anukam – CURO Apprentice
Dr. Harry Dailey, Department of Biochemistry & Molecular Biology, University of Georgia

As a cofactor in gas-binding and electron transport proteins, heme is a vital molecule. Heme is also an important ligand for a number of regulatory proteins. Presently there is no way to determine heme concentrations in small samples, cells, or tissues. Using protein biosensors, it will be possible to detect and assess heme fluctuations. It would be beneficial to have a sensor that would permit us to detect cellular and tissue distribution of heme so that we can begin to understand heme transfer and heme fluxes in response to physiological stimuli. In addition, we would be able to follow heme distribution and flux during embryonic development. The protein Serratia marcesens

HasA was used to create the biosensor. The HasA DNA was replicated using PCR. The protein was then purified. Protein purification proved to be difficult. The best method found to purify the protein was to transform the protein into BL21 cells, grow the cells overnight, induce cells with IPTG, and allow cells to grow for another 3-4 hours. In the future, a better method will be found to purify the protein, after which, HasA will be expressed through protein expression.

Nanotechnology: Science Meets the Apparel and Fashion Industry

Hannah Avram
Dr. Ian Hardin, Department of Textiles, Merchandising & Interiors, University of Georgia

Nanotechnology is a relatively new and rapidly emerging science with tremendous potential. Nanotechnology aims to manipulate molecular matter—measured in billionths of a meter—to develop materials or devices. Applied properly, it may be able to improve quality of life in previously unimaginable ways, and create exciting commercial opportunities—opportunities that include the fashion industry. This research examines the potential uses of nanotechnology in the apparel and fashion worlds, and explores the risks that inevitably occur when dealing with molecules on this small scale (e.g., health issues). Part of the research will be to visit labs with nanotechnologists on the UGA campus to better understand the nature of nanotechnology treatments that can be applied to materials. Apparel and fashion companies that currently use nanotechnology will be contacted to discuss the products and processes they use, and the market potential they see. I am contacting retailers, presenting them with my findings, and determining their interest in selling products treated with or developed by the use of nanotechnology. In summary, my research assesses the current and future applications of this groundbreaking science, its fashion market potential, the risks that could pose barriers to its development, and ways to mitigate those risks. My conclusions will provide a more complete understanding of the nanotechnology opportunities in the apparel and fashion industries and evaluate the potential that nanotechnology has for our future.

Familial Predictors of Young Adult Romantic Relationship Functioning: A Closer Look at Boundary Dissolution

Emily Baggett – CURO Scholar
Dr. Anne Shaffer, Department of Psychology, University of Georgia

There is a large body of empirical evidence supporting the idea that early experiences within the family can impact one's romantic relationship functioning during young adulthood. Many studies have investigated the role of attachment in these associations. The current study proposes to look beyond attachment style to see how other familial factors might affect romantic relationship outcomes. Specifically, we will investigate the relationships between general parenting styles and experiences of parental boundary dissolution growing up and one's recent experiences within a romantic relationship. Drawing from findings of Shaffer and Sroufe (2006), we expect that childhood experiences of boundary dissolution—the disintegration of normal parent-child roles in which the child fulfills the parent's emotional needs to an inappropriate degree (e.g., parentification, role-reversal, enmeshment)—will predict romantic relationship outcomes over and above the variance explained by general parenting. Because the literature indicates that experiences with mothers and fathers can have distinct influences for sons and daughters, we will explore possible moderating effects of gender, both the parent's and the child's, on these associations. Participants include 800+ undergraduate students who will complete online questionnaires about their experiences growing up and their current feelings within a romantic relationship. We are currently collecting data through the web site Survey Monkey. Data will be imported into SPSS 15.0 and analyzed first with bivariate correlations and then hierarchical regressions. General parenting style is measured by the authoritative subscale of the Parental Authority Questionnaire. Parental boundary dissolution is ascertained by the

enmeshment subscale of the Parental Boundary Scale. Romantic relationships outcomes include measures of security, satisfaction, disclosure, and idealization.

Corpus-Based Analysis of Other-Directedness in Japanese

Thomas Bailey
Dr. William Kretzschmar, Department of Linguistics, University of Georgia

A characteristic traditionally attributed to Japanese discourse by qualitative research is "other-directedness." While this qualitative approach is not itself a problem, it is the responsibility of scholars to verify previous research. To this end, I sought to *quantitatively* evaluate this claim, as well as develop a concrete understanding of "other-directedness." I compiled two comparable corpora, both comprised of interviews freely available online. One corpus contained interviews with Japanese-speaking musicians, the other with English-speaking musicians (for comparative purposes). The interviews with Japanese musicians had been translated into English when published. I used three methods of comparison: investigation of normalized word frequencies, collocate analysis (examination of what words frequently occur near one another), and direct scrutiny of context through concordancing software, after which I assigned words into context categories and examined the numerical distributions thereof. Four language use patterns characteristic of "other-directedness" were found when comparing the Japanese musician interviews with the English-language corpus: formality, manifested in scarcity of contractions and increased use of polite language (especially fixed phrases); presence of private predicates, demonstrated by the verbs found most often near *I, we,* and *you*; humility, shown by the rarity of positive words near words relating to the musicians' in-groups; and finally, the importance of the group, exemplified in the presence of certain pronouns near *please*. This research is significant because it assesses accepted beliefs about Japanese speech, which impact wider attitudes toward the Japanese themselves. Furthermore, understanding of Japanese communication has significant implications for international business, where miscommunications are disastrous and costly.

I Do, but I Don't: The Politics of Dress in Gay and Lesbian Commitment Ceremonies in the United States

Caylee Bale
Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, University of Georgia

This paper explores the dress practices of gay and lesbian celebrants at commitment ceremonies. Dress includes all body modifications and body supplements that adorn a person. Homosexual celebrants' commitment dress not only carries deep personal meanings for the celebrants but also acts as a powerful means of nonverbal communication to the society. With the aid of numerous scholarly and popular resources, I conducted a systematic analysis of the dress practices of commitment ceremonies in the United States. While unable to use homosexual couples as a primary resource, I used secondary resources such as photographs and first-person stories to analyze the meanings of their ceremony dress. From my analysis, I have concluded that the commitment ceremony dress worn by the celebrants is a common form of expression for homosexual couples that represents three different social and sartorial scripts: conformity, rebellion, and social reformation. In conformity commitment ceremonies, the celebrants strive to dress in a way in which they will gain acknowledgement from the overall society as a legitimate couple. Therefore, they choose to conform to American social norms in their dress. In contrast, celebrants of rebellious commitment ceremonies deliberately defy the dress stereotypes of American society through the use of a drag costume or non-mainstream wedding dress elements. Finally, new and old dress traditions mesh when a social reformation commitment ceremony is held. Each commitment ceremony dress has its own unique, personal characteristics. However, by conveying one of these three themes, homosexual couples are dressing their bodies not only to celebrate their

commitment to each other but also to express a political stance. Each commitment dress style expresses a strong desire for equal marriage rights for gays and straights alike. The three different social/sartorial scripts—conformity, rebellion and social reformation—showcase three different ways of fighting for social acceptance and represent distinct paths for changing the definition of the institution of marriage in the United States.

Effects of Witnessing Maternal Psychological Abuse Perpetration on Undergraduate Women's Abuse Perpetration

Hannah Barfield & Brittany Baker
Dr. Joan Jackson, Department of Psychology, University of Georgia

Previous research indicates that children who witness domestic violence experience detrimental consequences. The present study examined how witnessing parental psychological abuse perpetration affects undergraduate women. Based on same sex modeling, we hypothesized that women who witnessed maternal psychological abuse perpetration during childhood would be more likely to perpetrate psychological abuse in their dating relationships. Women's perpetration of psychological abuse was measured using the Psychological Maltreatment of Women Inventory (PMWI). Exposure to parental perpetration of psychological abuse was measured by a composite of items used in prior research (Cronbach's α maternal perpetration = .91; α paternal perpetration = .94). In a sample of 167 undergraduate women, results of a multiple regression analysis indicated that exposure to paternal and maternal psychological abuse perpetration predicted women's emotional/verbal abuse perpetration in their dating relationships (accounting for 4% of variance), $F(2,166) = 3.57$, $p = .03$. As expected, maternal perpetration emerged as a unique predictor in the model ($\beta = .19$, $p < .05$), and paternal perpetration was not significantly associated ($\beta = .02$, $p = .81$). Witnessing parental psychological aggression did not predict women's psychological aggression as measured by the dominance/isolation subscale of the PMWI (model $p = .65$). In sum, witnessing maternal abuse perpetration was only associated with women's perpetration of verbal/emotional abuse. Although the effect was small, findings from this study provide qualified support for the modeling hypothesis and help explain the understudied phenomenon of women's violence and its consequences for children.

Optimization of Techniques for Identification and Analysis of N-linked Glycans Derived from Various Glycoprotein Mixtures

Sambita Basu – CURO Summer Research Fellow
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

The discovery that carbohydrates, in addition to gene sequences and proteins, serve as significant biomarkers presented important possibilities for the diagnosis and subsequent treatment of several diseases, such as mucolipidosis, muscular dystrophy, and cancer. Glycoproteomic analysis of serum has led to increased understanding of the development and detection of hepatocellular carcinoma. Efficient glycan identification can provide diagnostic tools and continue education of disease progression. The focus of my research was to optimize techniques for the identification and analysis of glycans from various glycoprotein mixtures. My experimentation involved 1) releasing and extracting N-linked glycan moieties from six mixtures with different proportions of ovalbumin and alpha 1-acid glycoprotein, 2) purifying the released glycans efficiently [purification techniques included solid phase extraction techniques with C-18 or graphite phases to separate glycans from detergents (or other interfering substances) from earlier cleavage stages], 3) permethylating the oligosaccharides for analysis by Maldi-Tof Mass Spectrometry, and 4) completing deuterium exchanges on the six samples for a better detection of anomeric signals by proton nuclear magnetic resonance (NMR) spectroscopy. Through analysis, I tried to determine whether my modifications to established glycoprotein identification techniques were successful. In addition to glycan purification, my research also

involved optimization of an existing peracetylation technique, which I used on egg yolk oligosaccharide samples, the ovalbumin/alpha 1-acid glycoprotein samples processed before, and human milk oligosaccharide samples to aid in the identification of different glycan moieties by NMR spectroscopy.

Open Textbooks and the Innovation of Education

Elisabeth Bentley
Dr. Richard Watson, Department of Management Information Systems, University of Georgia

This project focuses on discovering the academic, monetary, and social benefits of open textbooks, which are free digital textbooks provided digitally that can be remixed and edited by their adopters. The University of Georgia's Global Text Project serves as a model of an open textbook initiative for developing economies. The purpose of the research and its corresponding article is to determine the importance of open textbooks to university students, professors, and librarians and provide insights into effective practices for librarians in providing and disseminating information about such resources. Our research consisted of reviewing existing literature on the nascent field of open educational resources, conducting a focus group of university librarians, and interviewing the founder of the Global Text Project, Dr. Richard Watson, on how his initiative exemplifies the opportunities open textbooks provide to universities in developing countries. The resulting paper establishes the case for librarians in developing economies to take a leading role in deploying and managing open textbooks.

Preschoolers' Understanding of Arrows as Directional Indicators

Valerie Bidwell
Dr. Janet Frick, Department of Psychology, University of Georgia

Arrows are commonly used as directional indicators for both adults and children. Research has found that children are cued to look faster when cued by valid vs. invalid arrows. Yet, for such a common directional symbol, it is still largely unknown how children understand this directional indicator. They may be attending to the symbolic meaning of the arrow, or perhaps children are cued by more perceptual aspects like the visual weight of the arrow. This study presented 34 children with ten arrow stimuli that differed in direction and distribution of weight. We asked the children to use the arrow cue to find a hidden animal and recorded their eye movements as they were exposed to the various stimuli. Our results indicated that, on average, children three years and older were cued to look to the side indicated by the weight of the arrow but not to the side indicated by the direction. Children younger than three years of age were not cued by the weight or the direction of the arrow. These findings are consistent with past research on this topic and suggest that, though children at this age are cued by arrows, they may not necessarily be attending to the symbolic meaning arrows denote. These results demonstrate how perceptual processes can act as a foundation for the development of cognitive abilities like understanding written language and other abstract symbols.

Femininity, Freakishness, and Despair in the Novels of Harry Crews

Charles Blackburn – CURO Scholar, CURO Summer Research Fellow
Dr. Hugh Ruppersburg, Department of English, University of Georgia

This presentation will address several novels by the Georgia-born writer Harry Crews. *Karate Is a Thing of the Spirit*, *Feast of Snakes*, and *Body* each involve comparable female characters and potentially anti-feminist commentaries. Whether the author intends to convey anti-feminist messages or merely to depict faithfully the attitudes of the male, "grit" inhabitants of the Wiregrass Region of southern Georgia and northern Florida remains unsettled in critical accounts. Absent from criticism is explicit analysis of the contribution of female characters to a larger theme of the loss of the traditional, agrarian South and, by extension, to a theme of

existential despair. Previous criticism also fails to explore a connection between women and another class of characters, Crews's freaks. It is possible that women and freaks perform similar roles in the novels and make similar contributions to the author's vision of modernity and fiction writing. Crews has said, "freaks are human beings who happen to be 'enterable.'" How does Crews access character through physical appearance? What problems arise from this approach? This presentation will attempt to establish new connections between issues formerly explicated independently and, in turn, to shed new light on the debate over anti-feminism in Crews's fiction.

The Impact of Single-Parents and Their Disciplinary Strategies on Childhood Aggression

Andrea Borders, Blair Morton, Erin Gilstrap & Lauren Heard
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Current research on childhood aggression has shown significant relationships between the quality of maternal relationships and reporting external aggression in children during early childhood. Studies have shown that more aggressive and delinquent behavior is exhibited by children raised in single-parent homes than in two-parent homes. In studies of aggression in children, little evidence has been found to establish a relationship between the qualities of the parental relationship with the child to the likelihood of the child displaying excessive aggression. Furthermore, the few studies on relationships between children and their fathers are largely from middle-class samples, where the fathers are more likely to be married and committed to the child's mother. This study will examine the father-child relationship that exists in a different socioeconomic class since many of the children in this study do not reside within a two-parent home, or more frequently lack paternal guardianship. Therefore when investigating the results, the majority of children were raised by single mothers. This study examines whether externalized aggression was influenced by the absence of a second guardian. In addition, parental disciplinary strategies and their effects on children's aggression were assessed. The data were collected from the local Head Start program in the southeastern U.S. Data consist of parental surveys and teachers' social/emotional evaluations using the SCBE form developed by Peter LaFreniere. The presentation will include discussion of the differences that were found in the data between boys and girls in displaying emotions and aggressions.

Feeding the Energy Supply: The Market for Biodiesel in Costa Rica

Christy Boudreau
Dr. Rebecca Moore, Warnell School of Forestry and Natural Resources, University of Georgia

This study investigates the financial feasibility of producing biodiesel at the University of Georgia campus in Costa Rica. The study examines biodiesel, not ethanol, because the campus vehicle fleet is run on diesel fuel, not gasoline. Palm oil is the feedstock of interest because it is recognized as an efficient fuel source in government policy, produced on a national level, and traded on international exchanges. Life cycle analysis indicates that jatropha and algae may prove to be more efficient feedstocks, but energy yields are not known with certainty, and further investigation into these feedstocks is beyond the scope of this project. The qualitative aspects of the biodiesel market are emphasized, but attempts are made to quantify biodiesel costs and benefits. A *pro forma* income statement is constructed for a hypothetical refinery. The biodiesel project is evaluated using a flow-to-equity discounted cash flow analysis, and an internal rate of return is calculated. According to this model, the net present value (NPV) of a $640,000 equity investment in the hypothetical biodiesel refinery is $145,087. Hence, UGA stakeholders will be advised against investing (today) in the construction and operation of a biodiesel plant and, therefore, will not suffer the losses of an unprofitable investment. Breakeven analysis shows that a small per-gallon tax credit could shift the project's NPV into positive territory, however, so if society values the environmental

benefits of biodiesel consumption, the populace could subsidize the industry to make production economically feasible.

Variability of Motion in Individuals with Ankle Instability During Single Leg Jump Landings

Jason Bowman – CURO Apprentice
Dr. Cathy Brown, Department of Kinesiology, University of Georgia

Chronic ankle instability is a common condition prevalent in athletes and physically active individuals. Variability of motion may play a role in the development of ankle instability. The purpose of this study was to determine if there were significant differences in the coefficient of variation at the ankle, knee, and hip in three planes of motion during an anterior single leg jump landing. Eighty-eight participants were divided into four groups based on injury pathology criteria: mechanical ankle instability (MAI), functional ankle instability (FAI), copers, and controls. Participants wore reflective markers and performed 10 single leg landings while their joint motions and landing forces were measured. The coefficients of variation were calculated for each joint motion, a natural log transformation was performed on the data, and a one-way ANOVA tested for significant differences among groups with Tukey post-hoc testing at $\alpha = .05$. The control group demonstrated significantly greater variability (4.5 ± 1.2) than the FAI ($3.8 \pm .5$) and MAI ($3.8 \pm .6$) groups in hip frontal plane motion and than the FAI group in hip sagittal plane motion (4.3 ± 1.2 vs. $3.6 \pm .4$, respectively). The control group had significantly greater variability ($2.5 \pm .6$) than the coper group ($2.1 \pm .4$) in ankle frontal plane motion. Centrally mediated changes in lower extremity motion may cause individuals with chronic ankle instability to display limited joint motion variability during landing. A lack of flexible landing strategies may cause development of ankle instability and perpetuate the injury. Movement variability re-training at the hip, knee, and ankle may be an important component of rehabilitation following ankle injury.

Land Tenure Change in Africa

Kathryn Branscomb
Dr. Bram Tucker, Department of Anthropology, University of Georgia

Contemporary economic development in Africa has tremendous implications for the continent's myriad indigenous land tenure systems. These systems have been evolving in response to changes in culture and economy for as long as people have carved out places for themselves on Earth. This paper argues that the privatization of land in Africa as part of economic development policies is incongruous with indigenous African land tenure and has inadvertent consequences for the land and people. The paper draws its conclusions from a breadth of studies by anthropologists and social scientists. Their arguments were analyzed and synthesized to investigate common characteristics of indigenous land tenure that are being impacted by development. The characteristics that do not mesh with privatization include the role of social hierarchy in determining people's level of access to the land, the multiplicity of rights to the same land, and tolerated ambiguity in land titles. The paper reveals the challenges of introducing foreign economic concepts into well-established cultural systems and compares formal neoclassical economics with substantivist views that economy is embedded in culture. It is difficult to gauge local peoples' reactions to the changes; the complexity of the impact on stakeholders' adds another dimension to the issue. As new paradigms change the basic economic goals of Africans, land tenure systems must adapt to these new economic goals and encompass the way a particular people approach the land.

Not So Pretty: The Need for Cosmetics Regulation Reform

Jenny Brickman – Roosevelt at UGA
Dr. Jeffrey Fisher, Department Environmental Health Science, University of Georgia

Cosmetics represent a wide variety of products that are used by most, if not all, Americans. Even though 70 percent of chemicals placed on the skin can enter the bloodstream, the FDA

does not have the authority to ensure that the chemicals in cosmetics products on the market are safe for consumers. Due to this lack of government oversight, the U.S. relies on consumers to regulate the cosmetics industry. However, the lack of an adequate regulatory system has permitted the use of harmful toxins, such as carcinogens and neurotoxins, in cosmetics products that have the potential to cause negative health outcomes for Americans. This paper proposes that Congress create a new branch of the FDA, the Center for Cosmetics Evaluation and Research (CCER), to oversee cosmetics safety. The CCER will review and evaluate all existing cosmetics ingredients to ensure the safety of products on the market. The CCER will also create toxin-testing standards to test all new cosmetics ingredients. Finally, the CCER will review and evaluate all of these new ingredients for safety before use in products on the market. This will improve health outcomes for Americans by removing dangerous toxic ingredients from cosmetics. Based on the E.U. extended impact assessment of the Commission proposal for REACH (Registration, Evaluation, Authorization, and Restriction of Chemical Substances), a program to regulate the chemicals used by various industries, the health benefits of this proposed legislation can be estimated at 60 to 183 billion dollars over a 30-year generation from the reduction in cancer rates alone. Additionally, this legislation could make America's workforce more productive. A proper cosmetics regulation system is needed in the U.S. to improve health outcomes for Americans.

Time Resolved Photoelectron Spectroscopy and the Photoprotective Properties of Adenine

Amanda Brouillette
Dr. Susanne Ullrich, Department of Physics & Astronomy, University of Georgia

Pump-probe time-resolved photoelectron spectroscopy (TRPES) is used to study the electronic excited state lifetimes of the DNA base molecule adenine. Determination of these lifetimes leads to a greater understanding of the photostability of our genetic material under UV radiation. Photoion mass spectra and photoelectron kinetic energy spectra were recorded for an excitation wavelength of 251 nm and an ionization wavelength of 200 nm. Excited state lifetimes were found by varying the pump-probe delay and following any changes in the photoelectron spectrum. Our experimental setup includes a femtosecond (fs) laser system, gas-jet molecular beam source, and photoelectron photoion coincidence (PEPICO) spectrometer. Our initial results identify the states S2($\pi\pi^*$) and S1($n\pi^*$) as participants in the electronic relaxation and determine that the initially excited S2($\pi\pi^*$) state quickly ($\tau 1 = 71 \pm 16$ fs) decays to populate the S1($n\pi^*$) state, followed by a slow decay to S0($\tau 2 = 950 \pm 50$ fs). These results agree generally with previously reported experiments attempting to determine the excited state lifetimes of adenine.

On a Generalization of the Frobenious Problem

Alexander Brown
Dr. Dino Lorenzini, Department of Mathematics, University of Georgia

In this research group and presentation, we consider a generalization of the Frobenius problem, where we seek the computation of the greatest integer having exactly j representations by a collection of positive relatively prime integers. This is a multidimensional generalization of the "stamp problem" in which one finds all achievable postages given two stamps of relatively prime values. It is known that larger than a certain (easily computable) number, all postages are possible. We expected to find and did prove an analogue of a theorem of Brauer and Shockley using the methods of elementary number theory. This theorem that we proved makes it easier to compute examples in dimensions higher than 2, and we show how it can be used for such computation.

Derivation of Neural Progenitors from Induced Pluripotent Stem Cells

Michael Burel – CURO Apprentice
Science as Art
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Human embryonic stem cells (hESCs) are pluripotent cells capable of becoming all human cell types. More specifically, hESCs have been shown to differentiate into neural progenitors (NPs), multipotent cells able to differentiate into neurons and neuroglia. Due to their more focused potential and viability *in vitro*, NPs are prime candidates for neurodegenerative disease studies and treatment options. However, hESC-derived NPs pose an ethical issue due to initial embryonic destruction and preclude therapeutic and disease study benefits from being realized. Patients may face immune rejection upon hESC-derived NP transplantation, and creating disease-specific cell lines with the genetic and epigenetic characteristics of a neurological disease proves difficult. This study attempts to circumvent these obstacles by differentiating NPs from induced pluripotent stem cells (iPSCs), genetically reprogrammed somatic cells with hESC-like characteristics. To derive NPs from iPSCs, IMR-90 human lung fibroblasts were subjected to lentiviral vectors encoded for transcription factors promoting pluripotency. The reprogrammed fibroblast cells (now iPSCs) were cultured using a three-phase process utilizing different media and dish coatings to direct iPSC to the neural fate and ultimately the NP identity. Initial immunocytochemical results show successful differentiation of NPs from iPSC with the expression of markers previously observed in hESC-derived NPs (Nestin, Musashi-1, and SOX2). iPSC-derived NPs were further differentiated into terminal neurons, where staining suggests the positive expression of Tuj1, a more mature neuronal marker. The NPs will be differentiated into neuroglia, and positive/negative controls against cell lines will be quantified with real-time PCR and flow cytometry. iPSC-derived NPs could fully actualize the clinical potential NPs possess, opening avenues for the reverse-engineering of neurodegenerative diseases like Parkinson's and Alzheimer's while providing feasible treatment options to curtail the symptoms that dominate affected patients' lives.

C. elegans IDE: Gene Annotation and Ability of Protein to Cleave Aβ and a-factor

Mary Burriss
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Recently, the amyloid beta (Aβ) peptide has been the focus of research involving Alzheimer's disease (AD). Aβ accumulation causes neurodegeneration. The insulin-degrading enzyme (IDE) breaks down insulin, Aβ, and other biologically important peptides. If IDE activity, toward Aβ specifically, could be enhanced, the accumulation of Aβ would occur at a lower rate, delaying the progression of Alzheimer's. The Schmidt lab has identified eight compounds that activate rat IDE *in vitro*. For a cost efficient animal model to study IDE and its activators, we decided to utilize the *C. elegans* system. My aim was to create a *Ce*IDE expression vector and purify the enzyme to assess its ability to cleave relevant substrates and study the effects of the activators. After cloning the gene into the expression vector, the sequencing results showed a 48 basepair deletion in the gene. When comparing my sequence of *Ce*IDE with that predicted by the literature and with that of other species, the 48 basepair gap was present in the same location in all species examined except two orthologs of *Ce*IDE. I hypothesize that the published *Ce*IDE sequence is incorrectly annotated. To test this hypothesis, *Ce*IDE was purified using cobalt-sepharose column chromatography and assayed for activity using fluorescence-based *in vitro* assays. The enzyme cleaved Aβ and a-factor based substrates, so it is reasonable to believe the 48 missing basepairs do not affect the active site of the protein. If the compounds increase *Ce*IDE cleavage of Aβ, they could be used as therapeutic treatment of Alzheimer's disease.

The Abandonment of Truth: Imaging Brad Pitt as a Celebrity Hero
Corbin Busby – CURO Summer Research Fellow
Prof. Isabelle Wallace, Department of Art History, University of Georgia

Fashion photography is now being subjected to the kinds of analysis previously reserved for high art, with increasing but still limited numbers of books and articles published on the subjects of fashion photographers and their work. Emboldened by this trend, my research focuses on the photography of menswear in fashion editorials featuring celebrities. I will focus on editorials that were featured in fashion magazines such as *W* magazine, *GQ*, and *Vogue*. I also will also incorporate the films *Interview with a Vampire*, *Mr. and Mrs. Smith*, and *Fight Club.* The objective of the research is to do a close reading of several interrelated texts drawn from the fields of film, fashion photography, and entertainment news. What binds these texts together in my research is their reliance on Brad Pitt. The connections between these texts will be used for greater understanding of the separation and blending of Pitt's private and public life, and fictional and nonfiction characters and their development of his persona as a product available for consumption in a variety of mediums. Because Pitt is himself a product and because many photographers and filmmakers play with this idea while exploiting his capacity to sell, these texts are well suited to my goal of exploring the role of the celebrity in connection with mass culture and the consumer, as well as the gendering of capitalism and consumerism. Also at issue is the concept of intertextuality, which Vernon Hyde Minor defines as the inability of a work of art to be created in isolation because it has been influenced by earlier and contemporary works of art. When understood as a whole, these interrelated images exemplify and illuminate the phenomenon of *intertextuality,* which is in turn revolutionizing our relation to images and their meaning(s). This research has great implications for how the consumer interacts with the image and perception of self. The results of this research will benefit art historians' interpretations of contemporary art, especially portraiture, and marketers and advertisers who use images of celebrities to sell products.

Evaluation of Physical Activity, Spasms, and Diet After SCI
Elizabeth Callaway & Kirsten Battles
Dr. Kevin McCully, Department of Kinesiology, University of Georgia

People with spinal cord injuries (SCI) are more prone to metabolic and cardiovascular diseases. Contributing factors to these diseases include poor diet and reduced physical activity. The purpose of the study is to evaluate physical activity, diet, spasm activity, and blood glucose levels in a people with complete SCI. After human subjects' approval was obtained, 30 patients will be recruited from the Shepherd Center in Atlanta. Subjects with SCI will complete a food frequency questionnaire, the Physical Activity Recall Assessment for People with Spinal Cord Injury, and the Penn Spasm Frequency Questionnaire to sum up information regarding their diet, physical activity, and frequency of spasticity. Blood glucose levels will be obtained via finger prick to evaluate the risk of developing diabetes. We hypothesize that people with SCI will score lower on diet and physical activity scores than able-bodied people and that high glucose levels will be associated with poor diet, low physical activity, and low spasm activity. If successful, this study will provide a baseline assessment of physical activity, spasm frequency, and diet in people with SCI located in the state of Georgia and the surrounding region. This information will be used to guide future studies designed to improve health in people with spinal cord injuries.

A Georgia High School and Technical College Dual Degree Program
Kathryn Camp – Roosevelt at UGA
Dr. John Schell, Department of Workforce Education, Leadership & Social Foundations, University of Georgia

Georgia is ranked 47th in the nation for high school education due to low test scores and high dropout rates. Currently, Georgia "tracks"

students into either a college preparatory (CP) track or a technical preparatory track in their ninth grade year. The technical track provides courses to develop vocational skills but does not require students to take vital college-bound courses. This setup means that students must make a crucial decision for their future when they are only 14 years old that they cannot change later. In fall 2010, Georgia will eliminate the technical prep diploma to close the education gap. This paper evaluates the impact of this policy and analyzes the potential consequences, including the lack of vocational skill accumulation by students who do not plan to continue their education past high school. As proven through multiple studies by the department of education and independent researchers, this policy risks higher dropout rates and greater unemployment levels for Georgia. To maximize the potential for all students to obtain success, this paper proposes that Georgia create a dual degree program allowing high school students to take traditional high school classes as well as career-oriented courses from a local technical college for graduation. This will lead to lower dropout rates, higher college matriculation, and lower unemployment in the state.

One Heart Flaming More than All the Rest: Considering Biography When Reading the Poetry of Lady Mary Wroth

Julia Carpenter
Dr. Fran Teague, Department of English, University of Georgia

How are readers to take the sonneteer's life into account when analyzing poetry? This paper will consider the possible influence of Lady Mary Wroth's own life events on the sonnet sequence *Pamphilia to Amphilanthus*. Lady Mary Wroth, niece of the famous Sir Philip Sidney, was the first Englishwoman to author a sonnet sequence. The structure and style of *Pamphilia to Amphilanthus* reflect her deep connections to her uncle, Sir Philip Sidney, and to her aunt, Countess of Pembroke. Her scandalous relationship with her cousin, William Herbert, Lord of Pembroke, provides the subject matter. Wroth adheres to Petrarchan form, as seen in her uncle's poetry, and she follows a path blazed by her aunt, also a female poet writing in a time unreceptive to women authors. This paper will further examine why Wroth esteemed her familial ties so strongly. Lady Mary Wroth's poems have only recently been brought to modern light and thus have yet to be dissected ad nauseum. This paper will seek to elucidate further the circumstances that inspired Lady Wroth to write them as well as to investigate the possible bearing of her personal experiences on the meanings of *Pamphilia to Amphilanthus*. In analyzing the style of Wroth's and her uncle's poetry, inquiring into her relationships with the Countess of Pembroke, and immersively studying *Pamphilia to Amphilanthus*, this paper will explore how the unusual events of her life affected her poetic work.

Dispersion of Single-Walled Carbon Nanotubes in Aqueous Solution

Meagan Cauble
Dr. Marcus Lay, Department of Chemistry, University of Georgia

Single-walled carbon nanotubes (SWNTs) show great technological promise in a wide variety of electronic and structural applications. However, investigations and applications of individual SWNTs are severely limited by their insolubility in water caused by their strong inter-SWNT van der Waals attractions. Well-dispersed SWNT suspensions are imperative to the deposition of networks of SWNTs. In order to disperse individual SWNTs in an aqueous solution, surfactants must be used to form micelles around the tubes. In this study, a non-oxidizing purification method was used to remove any remaining bundles of SWNTs, carbonaceous impurities, and catalyst nanoparticles to form suspensions of undamaged, high-aspect ratio SWNTs. Transmission UV-Vis and near-IR spectroscopy were used to obtain extinction coefficients and to produce calibration curves for solutions produced under various conditions. Atomic force microscopy (AFM) was used to evaluate the effect of various suspensions on the average density of SWNTs deposited onto a substrate. This presentation will demonstrate that SWNT dispersion in solution is strongly

dependent upon the concentration of SDS and is not greatly affected by the initial concentration of SWNTs. As the SDS concentration increased, the amount of SWNTs in suspension increased. This was confirmed by AFM images because the density of SWNTs deposited onto substrates increased as the SDS concentration increased. Once the critical micelle concentration for SWNTs had been reached, however, increasing the SDS concentration had little effect on SWNT dispersion.

Characterization and Detection of Non-Covalent Binding of Single-Stranded Oligonucleotides to Single-Walled Carbon Nanotubes

Meagan Cauble
Dr. Marcus Lay, Department of Chemistry, University of Georgia

Studying the ways in which single-walled carbon nanotubes (SWNTs) interact with biological molecules is important as the mechanism of this interaction is poorly understood and is important for their utilization in biological systems. Furthermore, the effect of bound SWNTs on the stability of double stranded DNA has not been thoroughly investigated. In this study, single-stranded DNA (ssDNA) molecules were assembled to the SWNT surface after dialysis with a molecular weight cutoff of 20 kD to remove surfactant molecules used to disperse the nanotubes. Additional dialysis to remove non-bound ssDNA molecules resulted in a solution of ssDNA-SWNTs. The binding of ssDNA to SWNTs was visualized using UV-Vis, nIR, and Raman spectroscopy. nIR absorbance peaks shifted after ssDNA attached to the SWNTs. Furthermore, ssDNA was detected in the solution by UV-Vis spectroscopy, and SWNTs were detected in the solution using UV-Vis and Raman spectroscopy. Atomic Force Microscopy (AFM) was also used to characterize deposited solutions of ssDNA and solutions of SWNTs wrapped with ssDNA. Future experiments will detect the hybridization of complementary DNA strands to the ssDNA-SWNT complexes. Changes in concentration of unhybridized complementary DNA strands will be used to calculate the rate constant of the hybridization reaction. Experiments will be done with various DNA strands to determine if the DNA sequence affects the hybridization kinetics. These results are important because understanding SWNT and ssDNA interactions and hybridization events at the SWNT surface will aid further research for the development of technologies for gene delivery, molecular probes, nano-scale biosensors, and molecular labeling of cells.

Remote Sensing as a Generative Tool in the Creation of Fine Art

Daniel Cellucci
Prof. R. G. Brown, Lamar Dodd School of Art, University of Georgia

Assisting sculpture and studio foundations professor R. G. Brown with his artistic research, I have taken the data previously gathered from such instruments as Ground Penetrating Radar, Electromagnetic Conductivity, and SONAR, and seek now to use these samples to fabricate forms that can truthfully reflect the data from which they are derived. Building upon the results of a research project presented at the 2009 CURO Symposium involving applications of SONAR to underwater art, I will explore new opportunities presented by additional tools employed in the study of remote sensing to the area of sculpture. As defined by the National Aeronautics and Space Administration (NASA), "remote sensing," in the most generally accepted meaning, refers to instrument-based techniques employed in the acquisition and measurement of geographically distributed information. The aims of this research are twofold. The first aim is to create software tools that will convert the data into a format that can be read by machines which can precisely fabricate the necessary dimensions specified by the data. These tools hold value not only for the task at hand but also for future projects that require such translations. The second aim is to experiment with the machines that could be employed to create the sculpture and with the materials used for the sculpture itself. These tools will include, but are not limited to, metal fabrication, CNC router, and Rapid Prototyping devices.

Effect of GIPC-GAIP Coexpression on LPA Induced Signaling in CHO-K1 Cells Stably Expressing the LPA1 Receptor

Ariel Chan
Dr. Shelley Pence, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Ovarian cancer accounts for more deaths than any other cancer of the female reproductive system in the United States. Lysophosphatidic acid (LPA) serves as a signaling molecule that induces proliferation, metastasis, and migration of ovarian cancer cells through a set of G-protein-coupled receptors (GPCRs) and guanine nucleotide-binding proteins (G-proteins). Regulation of G-protein signaling (RGS) proteins plays a direct role in regulating signaling cascades initiated by GPCRs by accelerating the deactivation of the Gα-subunit of G-proteins. RGS proteins regulate LPA signaling in ovarian cancer cells. The exact process through which RGS proteins bind to Gα-subunits is unknown, however. Previous research suggests that the regulatory process is coordinated by G-proteins and GPCRs. The scaffold protein GIPC has been shown to interact with both RGS19/GAIP and the LPA1 receptor. Thus we hypothesized that GIPC regulates the interaction between LPA1 and RGS19/GAIP proteins. To investigate the relationship between LPA1, RGS19/GAIP, and GIPC, we tested the effect of expression of RGS19/GAIP and/or GIPC on LPA signaling in CHO-K1 cells stably expressing the LPA1 receptor. The ability of LPA to stimulate inhibition of adenylyl cyclase (cAMP) was measured in adenylyl cyclase activation assays. No consistent regulation of LPA stimulated Gαi activity was observed, suggesting that RGS19/GAIP and/or GIPC do not significantly alter activation of this pathway. Future experiments will investigate alternative pathways and additional RGS candidates. Establishing a novel mechanism for LPA signaling has the potential to advance prevention and treatment methods for ovarian cancer.

Factors Affecting Cardiovascular Disease in the Third World

Puja Chebrolu
Dr. Alex Anderson, Department of Foods & Nutrition, University of Georgia

Historically, cardiovascular diseases (CVD) have affected mainly the western world. Evidence suggests, however, that CVD is increasing in developing countries. Growing economies such as Ghana are particularly affected by CVD because of the disability it causes in their working population. Also, countries such as these have to deal with the double burden of infectious disease, which poses yet another challenge to growth. The existing body of published research suggests that hypertension and diabetes are increasing in all areas of Ghana, partly because of the nutrition transition effect. The purpose of this research is to increase scientific knowledge about CVD in rural Ghana. Blood pressure and blood glucose data will be used as indicators for CVD. Statistical analysis will be performed on pre-collected data to identify the factors influencing high blood pressure and high blood glucose among 308 women in rural Ghana. Hypertension will be defined as systolic blood pressure of >140 mmHg, prehypertension as 120-140 mmHg, and normal blood pressure as <120 mmHg. Diabetes will be defined as fasting blood glucose levels greater than 140 mg/dl, and prediabetes as 120-140 mg/dl. The results will be discussed in terms of potential factors such as maternal education, family history, weight, geography, prevention or control of rising prevalence of CVD, and development of methods of early detection of risk for CVD. This study will provide a better understanding of risk factors for CVD in developing countries and aid in implementation of programs and services to lower the burden of chronic diseases.

The Reinstatement of the USIA: Combating the Threat of Anti-Americanism in the Post 9/11 World

Katherine Cherry – Roosevelt at UGA
Dr. Howard Wiarda, Department of International Affairs, University of Georgia

Following the Cold War, the United States emerged as a hegemon lacking a clearly defined enemy. As such, the U.S. lost sight of the critical importance of maintaining a strong public diplomacy front. The abolishment of the United States Information Agency (USIA) symbolizes a shift in American foreign policy. The Clinton Administration created the new position in the State Department, the Undersecretary for Public Diplomacy and Public Affairs, replacing the former Director of the USIA. The new Undersecretary lacks the tie directly to the President formerly held by the Director of the USIA and therefore lacks relevancy and influence in the White House. This has resulted in disjointed, unsupported, and ineffectual public diplomacy efforts. It has also led to an unprecedented rise in anti-Americanism abroad, posing major danger to U.S. national interests, a trend highlighted by the tragic events of 9/11. Over the course of fall 2009, I gathered primary and secondary data on public diplomacy, the USIA, and anti-Americanism with the Center for the Study of the Presidency and Congress. The result of this research is the following conclusion: In order to combat the threat of anti-Americanism, the smart power of public diplomacy must be used. The most effective means to reinvigorate U.S. public diplomacy is to reinstate the USIA. This reinstatement will bring the necessary relevancy and influence back to this crucial part of American foreign policy. The benefits of this policy include increased international understanding and exchange, decreased anti-Americanism, and increased U.S. security.

Delayed Reproduction and Age/Class Structure in a Randomly Varying Environment

Rene Cieszewski
Dr. Daniel Promislow, Department of Genetics, University of Georgia

Various biological populations have been shown to tend towards reproductive behavior that counters common ideas of how such natural populations might act. This reproductive strategy foregoes optimizing short-term reproductive yield in order to maximize long-term reproductive fitness. In particular, these strategies have been extensively studied empirically and theoretically in plant populations. Here we intend to expand existing theoretical models in order to implement more detailed age and class structure in the population. Our model involves a population of seeds with the initial choice of reproducing or remaining as dormant seeds. The idea is that seeds do well when they germinate to become reproductive plants in a good environment but die if they germinate in a bad environment. A stochastic environmental variable determines a frequency of years that are either favorable or deleterious. A seed cannot predict whether it is germinating into a good or poor environment. Seeds that do not germinate have some constant probability of decay and death. Until now, most models have looked at populations where adults only live for one year, like dandelions. In our model, adult plants can delay reproduction and age further, or reproduce and die, though there is some risk that an adult will die without reproducing. We are attempting to derive an analytical solution for the optimal germination fraction using a set of algebraic equations. However, we may be unable to do so and may have to resolve the model with simulation or other numerical evaluations.

The Temporal Distribution of the Vesicular Stomatitis Virus in Experimentally Infected Cattle: An Immunohistochemical Study

Caroline Colden – CURO Scholar
Dr. Corrie Brown, Department of Pathology, University of Georgia

Vesicular stomatitis virus (VSV) is a single-stranded, negative-sense arbovirus in the Family Rhabdoviridae. Cattle, pigs, and horses can become infected. The virus settles in and causes damage to the surface tissues of the feet, tongue, snout, and teats, causing vesicular (blistering) lesions. Infection can have debilitating effects on the animals as they become reluctant to eat, nurse, or move around. They lose a great deal of weight, which diminishes their economic value. To devise effective control measures, it is important to understand how the virus spreads around the body and how it damages cells. In

this study, immunohistochemistry was used to detect the presence of the virus in tissues of cattle experimentally infected with VSV. Virus was inoculated into the skin at the top of the hoof (coronary band), and tissues were examined sequentially to envision presence of virus and associated damage. By immunohistochemistry, VSV was present in the coronary bands and draining lymph nodes 12, 24, 48, 72, 96, and 120 hours post-infection (hpi) with highest intensity in the coronary bands at 48 and 72hpi. Virus appeared predominantly in cells of the stratum spinosum layer, which exhibit unique intercellular bridges. Special staining for these intercellular bridges revealed a marked correlation between presence of this structure and replicating virus, indicating that the intercellular bridges may be functioning in viral entry or transport.

The Effects of Spinal Fusion on the Physical Function of Females with Adolescent Idiopathic Scoliosis

Jaharris Collier – CURO Apprentice
Dr. Kathy Simpson, Department of Kinesiology, University of Georgia

Adolescent Idiopathic Scoliosis (AIS) is a spinal deformity in which the spine curves left and right. The most widely used and accepted surgical procedure for scoliosis is spinal fusion. The exact limitations on physical functions that this procedure causes are currently unspecified. It is our goal to investigate what effect spinal fusion has on physical abilities. Females between the age of 16 and 25 with spinal fusion, with AIS, and with normal spines were compared to determine the effects of fusion on physical function. Radiographs to provide a visual of the spine were obtained from each participant. By using a Vicon machine to capture the movement of reflective markers strategically placed on the participants' body, the range of motion of the spine was determined for various physical tasks. A force platform was used to determine the balance and weight distribution of the participants as they executed certain basic tasks. The data from these test showed significant differences in the functioning of each test group. These differences indicate that performances of daily tasks are noticeably affected by the spinal fusion procedure to a quantifiable amount. By quantifying these differences, a prediction regarding the approximate effects that spinal fusion will have on physical capabilities can be provided to future surgical candidates.

Macular Pigment and Its Relation to Body Fat Distribution

Jessi Crabbe, Madison Asef & Daniel Tim
Dr. Billy Hammond, Department of Psychology, University of Georgia

Lutein and zeaxanthin are two carotenoids found readily in green, leafy vegetables and known to deposit heavily in adipose tissue and in the retina, where they are referred to as macular pigment. Macular pigment has protective benefits against age-related macular degeneration by reducing the amount of oxidative stress in the retina. The level of macular pigment appears to vary among individuals according to percentage body fat. The purpose of this experiment is to evaluate the relation between macular pigment and body fat percentage and to potentially explain sex differences through an analysis of adipose tissue distribution among different body regions. Eighty-six subjects between the ages of 18-40 completed measures of macular pigment optical density (MPOD) and body composition. Heterochromatic flicker photometry was used to determine MPOD, and dual-energy X-ray absorptiometry (DXA) scans assessed percentage body fat. Preliminary data indicate an inverse relationship between body fat percentage and macular pigment ($p < .05$). Evaluating the specific distribution of body fat in both sexes could lead to the discovery of a biomarker for groups at risk for macular degeneration.

Teaching Journalists to Cover Poverty: The Where, Why, and How

Carolyn Crist – CURO Scholar
Prof. John Greenman, Department of Journalism, University of Georgia

"Sense of place" is the way people relate to their environment. This paper aims to help journalists

learn to convey information using local identities to explain poverty in persistently poor locations. Sense of place, historical characteristics, narratives, and tradition should be used to cover poverty in a way that will draw in readers. Community members should be able to form accurate ideas about their locale and know how poverty affects it through crime, health, business, and education. National statistics, surveys, and legislation can be used at a local level to explain poverty trends. This paper provides specific ideas to incorporate poverty coverage in beats across the newsroom. Journalists can include several beats in the coverage, however, and should not hesitate to follow other journalists' examples of coverage. The 21 tip sheets were created for the poverty web site to instruct journalists on how to generate exemplary stories about poverty in relation to financial services, family, race, education, health, housing, and politics. The final section discusses how to market the web site and make it effective and accessible for journalists in the field.

Differentiation of Natural and Post-Vaccinal Canine Distemper Virus Encephalomyelitis

Kelly Cummings – CURO Summer Research Fellow
Dr. Scott Schatzberg, Department of Small Animal Medicine, University of Georgia

Canine distemper virus (CDV) is a highly contagious and infectious disease that affects the respiratory, alimentary, and central nervous systems (CNS) of dogs, with the latter characterized by encephalomyelitis (EM). Since their introduction in the 1960s, modified-live CDV vaccines have been effective in decreasing the incidence of the disease. Rarely, there have been outbreaks of dogs exhibiting CDV EM shortly after vaccination. Differing brain lesion and viral inclusion patterns in such cases served as pathological evidence for post-vaccinal CDV EM, but no definitive molecular proof existed. In this study, genetic differences between the wild-type and the three most common vaccinal strains of CDV were used to determine the origin of disease in previous cases of CDV CNS infection. RNA was extracted from formalin-fixed, paraffin-embedded brain tissue samples from nine dogs with suspected post-vaccinal CDV EM. Reverse transcription polymerase chain reaction (RT-PCR) performed with newly designed primers amplified regions of the phosphoprotein (P) gene identified as having the most genetic variability. DNA sequencing, sequence alignment, and phylogenetic analysis were used to confirm or disprove the presence of vaccinal nucleic acid in each clinical case. Research findings will allow for definitive discrimination between natural and post-vaccinal CDV encephalomyelitis and could aid in improving future vaccine development and disease treatment.

Diminution of Concentrative Nucleoside Transporter 1 (CNT1) Activity in Human Ovarian Cancer Cells: Subtype-Dependent Gemcitabine Response to Exogenously Expressed hCNT1

Shannon Cummins – CURO Scholar
Dr. Rajgopal Govindarajan, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Ovarian cancer is the fifth leading cause of cancer-related death in women worldwide and has the highest mortality rate of any cancer of the female reproductive system. hCNT1 (human concentrative nucleoside transporter 1) has been indicated as a high-affinity transporter of anticancer drugs (e.g., gemcitabine) in solid tumors, but its efficacy in ovarian cancer is unknown. In this study, we examined the functional expression of hCNT1 in normal and cancerous ovarian cells and compared its contributions toward gemcitabine efficacy in various histological subtypes of ovarian cancer. Immunostaining indicated that, unlike normal ovarian cells (IOSE80), cancerous ovarian cells lack hCNT1 expression at the cell surface. 3H-gemcitabine transport studies also indicate a reduction in transport (3-10 fold) by the ovarian cancer cells compared to IOSE80. Stable retroviral expression of hCNT1 in various ovarian cancer cell lines showed variations in hCNT1 localization, 3H-gemcitabine transport, and drug sensitivities. hCNT1-expressing endometroid cancer cells showed the greatest

change in drug sensitivity tests in which their IC50 values decreased from their wild type around 140 fold, and hCNT1-expressing serous cells also had a moderate decrease of around 25 fold. The teratocarcinoma cells and clear cell carcinoma cells showed no change. The exogenously expressed hCNT1 was not recruited to the cell surface in either of these cell lines. In the clear cell carcinoma cell, it was misdirected to the Golgi. These data indicate that hCNT1 transportability is highly diminished in human ovarian cancers and that reintroduction of hCNT1 to regain gemcitabine sensitivity is subtype specific.

Genetic Diversity of *Yucca filamentosa* and *Y. aloifolia* in Athens-Clarke County, Georgia

Nicholas Dallas, Michael McKain, James Leebens-Mack, & Jeremy Rentsch
Dr. Wendy Zomlefer, Department of Plant Biology, University of Georgia

Yucca is a genus of flowering plants in the agave family (Agavaceae) with approximately 40 species. Gene flow within and among *Yucca* species has been determined to be strongly affected by the particular breeding system. *Yucca filamentosa*, a native species, and *Y. aloifolia,* an exotic species, are both likely pollinated solely by the yucca moth, *Tegeticula yuccasella*. Since gene flow is restricted by the pollinator's limited range, we hypothesize more variation between populations than within populations. Five *Yucca* populations of these two species around Athens-Clarke County, Georgia were sampled to determine genetic variability between and within populations. Total DNA was extracted from frozen leaf tissue. Several plastid (e.g., ycf1) and three nuclear (e.g., ef1a) markers were chosen to capture the greatest amount of diversity among members of the population. These were amplified via PCR and Sanger-Sequencing methods. Sequences are being analyzed for variability, which will be quantified by several statistical methods such as the fixation index. Comparisons of plastid and nuclear DNA data will allow determination of the genetic diversity between populations versus within populations, clarifying conflicting data from previous studies. This study will further the understanding of gene flow between *Yucca* species attributed to yucca moths and provide insight into the possibility of population segmentation.

Calcium Imaging of Nodose Ganglion Cells in Response to Gastrointestinal Signals: CCK and CP 55,940

Kelly Darby
Dr. Gaylen Edwards, Department of Physiology & Pharmacology, University of Georgia

It has been demonstrated that fourth cerebroventricular application of cannabinoid agonist facilitates food intake at lower doses than effective doses injected in the lateral cerebroventricle. It has also been reported that direct injection of cannabinoid agonist into the lateral parabrachial nucleus facilitates food intake. These data indicate hindbrain endocannabinoid systems are important in the control of food intake. More recently, we have found that cannabinoid agonist injected into the fourth ventricle attenuates the elevation of cFos-immunoreactivity in the nucleus of the solitary tract after IP cholecystokinin injection. As an extension of those studies, we will focus on evaluating the activation of primary afferent neurons (nodose ganglion cells) by gastrointestinal hormones such as cholecystokinin (CCK) and the ability of cannabinoid agonists such as CP 55,940 to suppress this activation. Neuronal activation is evaluated by measuring calcium flux into the neuron with calcium-sensitive dyes. We expect to find that CCK will increase calcium flux into nodose ganglion cells and that CP 55,940 will decrease CCK-induced calcium flux. Our findings will be important in developing a better understanding of how neuromodulators like cannabinoids can influence afferent signaling from the gastrointestinal tract.

Constructed Wetlands and Southeast Waste Water Treatment Policy

Shanell Davis – Roosevelt at UGA
Dr. Ronald Carroll, Odum School of Ecology, University of Georgia

This paper reviews existing policies concerning waste water treatment in the southeastern region of the United States. Research has shown that constructed wetlands (CW) are better able, when compared to conventional waste water treatment plants (CWWTP), to degrade pharmaceuticals, hormone disrupting chemicals, and persistent organic chemicals/pollutants that are becoming increasingly harmful to the environment due to bioaccumulation in the ecosystem. This analysis reviews current literature on constructed wetlands and waste water treatment policies in the states of the southeastern region of the U.S. It also identifies the financial, political, and infrastructural challenges associated with implementing constructed wetlands in the Southeast. The paper identifies "best management practices" for CW, such as tolerant vegetation and sediment characteristics, and provides suggestions to augment or change waste water treatment policies to result in cleaner water flowing through the Southeast and how these changes will improve wildlife conservation.

Using the Public Value Mapping Model to Evaluate Groundwater Mining

Shanell Davis – Roosevelt at UGA
Malin Dartnell
Dr. Barry Bozeman, Department of Public Administration & Policy, University of Georgia

Plant Washington, a proposed coal-fired power plant in Sandersville, Georgia, recently received draft permits to withdraw surface and groundwater from the Oconee and Ogeechee River basins. If approved, the plant will withdraw an average of 16.12 million gallons per day (MGD) from fifteen wells in a river basin that has experienced considerable stress over the past decade due to drought. The free and, arguably, excessive use of groundwater by utility companies in the state of Georgia is a perfect context in which to analyze public values using the Public Value Mapping model (PVM) developed by Dr. Barry Bozeman. PVM is a framework used to analyze public values in a context orthogonal to the current economic model by identifying how the market and private sector fail to meet public values, i.e. public values failure. The economic rationale for groundwater usage by utilities will be identified and contrasted with the public values failure. This paper will use the PVM criteria to identify and analyze the public values failures and will recommend viable solutions.

Digital Proliferation: Discerning New Literary Genres Spawned by Digital Technology

Sara Day
Dr. Elizabeth Davis, Department of English, University of Georgia

With the proliferation of digital technology in the past few decades, we have been bombarded by a superabundance of information. As a product of this proliferation, part of a cultural transformation that operates on a paradigm of hypertextuality, literature has changed extensively in form and presentation. While poetic and dramatic modes have evolved with advances in digital technology, the development of narrative, and transformations in narrative theory as a result of hypertext fiction, more generally represent broad innovations in literary genres. Narrative predominantly performs the work of marrying old print traditions with new digital media by revealing the effects of print literature on new electronic forms of fiction, as well as electronic influences on the print novel. As seen in Mark Danielewski's *House of Leaves* and Jonathan Safran Foer's *Extremely Loud and Incredibly Close*, the print novel has become a cross-referential collage woven from an infinite variety of information. Prompted by the call of N. Katherine Hayles in her book *Electronic Literature*, this study responds to the need "to attend to the specificity of networked and programmable media while still drawing on the rich traditions of print literature and criticism." Following the approach of Walter J. Ong, who posited in the 1980s that the novel arose from the development of print technology and, to a greater extent, from the larger transformation of an entire worldview, this study answers the challenge of identifying new literary genres of narrative born from the intersection of print media and digital technology.

Karma in America: The Rebirth of the Male Adolescent Indian Immigrant into the American Hip-Hop Subculture
Katie Deray
Dr. Katalin Medvedev, Department of Family & Consumer Sciences, University of Georgia

When immigrants move to the United States, they often shed their native identity and appropriate a new American one to afford a place in society. The large increase in the Asian Indian-American population has brought about a greater visibility and prominence of the Indian Diaspora. Rather than adopt the mainstream, Anglo-Saxon identity their parents have tried to assume, some male adolescent Indian immigrants (MAIIs) choose the identity of a marginal subculture, specifically the African-American hip-hop subculture, and visually express it through hip-hop dress. In a still racially polarized society, where one is either "white" or "black," this MAII, who is "brown," identifies with African-American subculture. The construction of his new identity is based on his cultural-political-economic context, formed by popular media, and involves the appropriation of the stereotypical black male attitude associated with hip-hop archetypes. From this identification, he derives defiance, aggressive pride, masculinity, and status. His hip-hop dress becomes a proper reflection of his environment—the urban metropolitan scene—and communicates the hypermasculinity he wishes to possess to counteract the emasculation he has experienced as an immigrant and because of his social position as "Other." Based on personal observations, the insights of dress scholarship, and the findings of cultural studies on subcultures, this paper explores how hip-hop dress allows some MAIIs to be socialized into American society and fulfill an immediate social and affective need to belong in a new culture.

Somalia: Recommendations for Conflict Resolution Where Failure is the Norm
Ashley Doliber
Dr. Jaroslav Tir, Department of International Affairs, University of Georgia

Conflict has gripped Somalia for decades with little to no end in sight. While many have tried to resolve the conflict, a sustainable and successful strategy remains elusive. As a failed state with a bitter past and tenuous future, there is a tactical and moral imperative for the region and the global community to bring stability to Somalia. With a moderate government, international attention, and an as-yet imperfect insurgency, there may never be a better opportunity to act than now. Based on analysis of the Somali conflict history and context, as well as research on conflict resolution and management methods, and attention to the consequences of each prescription, this study outlines a comprehensive and multifaceted approach to achieving long-term peace in Somalia. The research indicates taking the conflict of Somalia and the semi-autonomous region of Somaliland on a separate—though mutually informing—basis. For Somaliland, partition is recommended to remove the region from the danger of continued attachment to Somalia proper as well as to encourage nascent state, civil and democratic institutions in Somaliland. In Somalia proper, however, a two-pronged strategy is best. This policy consists of peace- and state-building via coordinated international intervention (e.g., UN, AU, regional actors), followed by negotiations between the government, insurgents, and any other important players (e.g., warlords, clan leaders). Through a careful and considered application of these prescriptions, the country has a chance to usher in an era of stability, security, and opportunity that the people of Somalia have seldom seen.

The Youth of Roswell Voices
Joshua Dunn – CURO Scholar
Dr. William Kretzschmar, Department of Linguistics, University of Georgia

My research is a continuation of the Roswell Voices project, a linguistic and oral history project begun in 2002 by Dr. William Kretzschmar and the Roswell, GA Folk and Heritage Bureau in an attempt to capture the reality of linguistic change in a dynamic environment. While the project originally

focused on the past and the interviewing of older residents, I investigate how the speech—phonetics, syntax, and lexicon—of inhabitants of Roswell ages 18 to 30 groups them together as a distinct community. I also endeavor to characterize how their speech fits into the large picture of dialect research in the American South and whether new patterns and categorizations are pertinent. To accomplish this task, I interview nine informants for one hour each, discussing life in Roswell, and each interview is fully transcribed. For comparison, I also look at interviews of older informants from previous stages of Roswell Voices. I look for common speech phrases and lines of discussion to point to a sense of community. To establish where my younger speakers fall in the spectrum of Southern dialectology, I consult the relevant literature to compile a discrete list of features and then perform a statistical analysis to determine the significant recurrence of these features in the speech of my informants. I also run a computer-based acoustical phonetic analysis to aid in determining the extent to which my informants follow the proposed Southern Vowel Chain Shift.

The Medical Malpractice Crisis: A Proposed Radical Solution

Stephen Earnest – Roosevelt at UGA
Prof. Thomas Eaton, School of Law, University of Georgia

Medical malpractice cases are settled as torts through the civil court system. This method of compensating malpractice victims has been demonstrated to be ineffective, however, by the Harvard Medical Practice Study and two other similar supporting studies. These findings of these studies suggest that only about 1% of all patients injured by malpractice ever file a legal claim. Additionally, they revealed that older adults and low-income individuals were disproportionately less likely to file a claim. The court system is also undesirable from the perspective of most doctors. For both guilty and innocent physicians, trials are usually long, costly, and psychologically damaging, which may lead to lessened ability to provide care. To create a more effective system of compensating victims of malpractice, this paper proposes that the state of Georgia establish a no-fault system of compensation by forming a new government agency to deal exclusively with malpractice disputes. This new agency would standardize payments based on specific types of injuries in a way similar to worker's compensation. This agency would train, authorize, and commission agents to investigate and assess malpractice claims using predetermined criteria and price schedules. Because this process would be far less expensive and time consuming per individual, a far greater number of deserving individuals could be compensated using the same amount of resources. In this way, the no-fault system would provide a fairer means of allocating funds to malpractice victims.

Affordable Housing in Athens-Clarke County: A Two-Pronged Approach

Ellyn Echols – CURO Scholar, Roosevelt at UGA
Dr. Russell James, Department of Housing & Consumer Economics, University of Georgia

Across the United States, state and local governments are becoming increasingly aware of the need to provide affordable housing to their communities. The local government of Athens-Clarke County (ACC), Georgia has been one of many in the Southeast to add to these efforts. Affordable housing is widely defined as housing that costs a family no more than 30 to 35 percent of their annual income, including costs for taxes and utilities. In 2002, a Human and Economic Development study of Athens-Clarke County found that while there exists no real shortage of housing units in Athens, the affordability of these units continues to be a struggle for individuals earning 30 percent or less of the median family income in the area. Furthermore, the type of new development experienced in Athens has been mostly student driven by the large university presence, leading to households clustered together by economic class, and often race, limiting housing mobility and segregating communities. Providing affordable housing will require a comprehensive approach to bettering the lives of Athenians. This paper asserts that in order to provide

affordable housing to the community, zoning ordinances in ACC should be amended. Past zoning ordinances have served to segregate suburban neighborhoods and leave low- to median-income earners without access to affordable homes. By adopting inclusionary zoning (IZ) in Athens-Clarke County (ACC), the local government can promote the availability of housing for lower-income residents and integrate a socio-economically stratified community.

Inclusionary Zoning: Promoting Affordable Housing in the Southeastern United States

Ellyn Echols – CURO Scholar, Roosevelt at UGA
Dr. Andrew Carswell, Department of Housing & Consumer Economics, University of Georgia

Across the United States, state and local governments are becoming increasingly aware of the need to provide affordable housing to their communities. Affordable housing is widely defined as housing that costs a family no more than 30 to 35 percent of their annual income, including costs for taxes and utilities. Historically, the federal government has been the foremost enactor of policy to promote housing for low to mid-income individuals. Recently, however, local governments are utilizing inclusionary zoning (IZ) programs to provide a sustainable source of low-income housing. The local government of Athens-Clarke County (ACC), Georgia has been one of many in the southeast to add to these efforts. In 2002, an HED study of Athens-Clarke County found that while there exists no real shortage of housing units in Athens, the affordability of these units continues to be a struggle for those earning 30 percent or less of the median family income in the area. Furthermore, the type of new development experienced in Athens has been largely student driven, leading to households clustered together by economic class, and often race, limiting their housing mobility. This paper seeks to examine the use of IZ programs across the country and more specifically in the southeast. Combining an examination of the current literature on IZ practices and using ACC as a case study, implications of adopting IZ ordinances are examined. Subsequently, implications for policy makers are discussed.

Civilian-Oriented Preparedness for Radiological Terrorism

Nathaniel Edwards – Roosevelt at UGA
Dr. Dmitriy Nikonov, Center for International Trade & Security, University of Georgia

American security analysts in 2002-2003 predicted an incident involving a dirty bomb (a radiological weapon) within a decade, the most likely form of non-conventional terrorism to occur. The majority of the impact of such an event is psychological. This paper analyzes the harmful effects of trauma from such an event, including psychological and physiological harms, mass fleeing, and an overwhelmed local healthcare infrastructure. Despite predictions of the high level of anticipated psychological trauma after an event, the current policy surrounding radiological attacks focuses mostly on rebuilding and responding to the physical damage. Physical and professional preparedness do not prevent or mediate the psychological impact (the most significant source of disruption and harm) resultant in a radiological attack. This paper proposes that the Department of Homeland Security (DHS) adopt a two-pronged civilian-oriented preparedness program focusing on an education campaign and municipal meetings in high-risk cities. This approach is designed to communicate the risks of radiation and radiological terrorism as well as the best means to respond to an incident. By educating the public and involving them in local preparedness, DHS can develop a culture of resilience among Americans. A resilient community suffers less trauma and, thus, less psychological harm. In turn, a resilient community also suffers less disruption. Less disruption enables the government to provide better care to more victims by avoiding overwhelming local infrastructures and mass fleeing of the contaminated area.

An Examination of Motivation for Medication Adherence in Pediatric Patients with Inflammatory Bowel Disease and Parents

Shan Elahi & Caroline Cates
Dr. Ronald Blount, Department of Psychology, University of Georgia

Inflammatory bowel disease (IBD) is an autoimmune condition of the digestive system affecting approximately 100,000 American adolescents. Symptoms include abdominal pain, nausea, diarrhea, vomiting, and weight loss. These symptoms are treated with several classes of medications. Medication nonadherence places an adolescent with IBD at risk for increased morbidity and mortality. Examining reasons why adolescents and their families are motivated to adhere to IBD medication regimens are vital to improve adherence. The purpose of this study is to explore the relationship between adolescents' and parents' motivation for medication adherence and levels of adherence to prescription and non-prescription medication. Eighty-three adolescents with IBD between the ages of 11 and 18 and their parents completed an interview assessing medication adherence and the Treatment Self Regulation Questionnaire. The TSRQ measures motivation for adherence on three subscales: the autonomous regulatory style (self motivation or a feeling of choice), the controlled regulatory style (motivation due to pressure by others), and amotivation (lack of motivation). Results revealed that responses on the TSRQ for both adolescents and their parents were correlated with adherence to prescription and nonprescription medication. In both adolescents and parents, a positive correlation was found between reports of an autonomous regulatory style and adherence to prescription medications. In parents only, a positive correlation was seen for self-report of an autonomous regulatory style and adherence to non-prescription medication. Results show that higher levels of autonomous motivation are related to improved adherence.

Genomic Profiling of Ovarian Cancer Cells in Response to a Gonadotropin

Joanna Eldridge
Dr. David Puett, Department of Biochemistry & Molecular Biology, University of Georgia

Ovarian cancer is the most lethal gynecological cancer, due to the lack of methods for early diagnosis. High concentrations of the pituitary gonadotropin, luteinizing hormone (LH), and its receptor (LHR) have been found to precede and directly affect reproductive disorders that correlate to high incidences of ovarian cancer. Microarray analysis was used to test the hypothesis that LH may activate certain pathways favorable to tumor progression. This study determined acute effects of LH on the ovarian cancer genome by revealing differentially expressed genes that may result in a specific phenotype. A cell model was developed using human ovarian cancer cells (SKOV3) that do not express LHR (these LHR- cells serve as control), along with stable transformants expressing a known number of LH receptors (LHR+). LH was incubated with LHR+ SKOV3 cells, and following RNA isolation and reverse transcription of the cellular mRNAs, gene expression was measured at time intervals of 1, 2, 4, 8, and 20 hours and compared with ovarian cancer cells receiving no LH. Over 3,000 genes were differentially expressed at least 2-fold upon LH activation of LHR, and 16 pathways previously designated as essential to the survival of ovarian cancer were examined based on the temporal patterns of gene expression. Results indicated major variations in gene expression upon LHR activation, with some of the affected pathways being conducive to growth and others not. Additional studies are required to further delineate the biological meaning of these complex patterns of altered gene expression.

Energy Expenditure and Gain of Nut-Cracking in Wild Capuchin Monkeys (*Cebus libidinosus*) in Piauí, Brazil

Marianne English
Dr. Dorothy Fragaszy, Department of Psychology, University of Georgia

Wild bearded capuchin monkeys use large stones to crack palm nuts. The benefits of nut-cracking are unclear, especially since the activity appears energetically costly and exposes the monkeys to increased risk of predation. We determined whether the energy expended to crack a piaçava nut (*Orbignya*), the toughest nut the monkeys crack, exceeds the caloric value of the nut. From video, we coded nut-cracking behavior in five individuals (2.03 – 4.28 kg) during 50 nut-cracking episodes (striking the nut with the stone). We obtained maximum downward velocity of the 1.42 kg stone to calculate the maximum kinetic energy (work output) produced by the monkeys. Using published estimates of Mechanical Efficiency, ME (% of energy expended that is transferred from precursor to object) for humans, we estimated the monkeys' ME (range = 5% to 35%). Then we used the work output and the ME to estimate energy expended and compared it to the energetic value of an average nut (162 KJ). Our findings suggest that even with a 5% ME, the monkeys gained energetically from nut-cracking. To exceed the caloric value of the nut, the monkeys would have to perform more than 549 strikes on one nut (the maximum we observed in our sample to date was 36). We conclude that nut-cracking is worth the monkeys' efforts, energetically, even if they are intermittently successful at opening a nut. Energy expenditure devoted to search and transport of the nuts (1 – 2 kj/min) is not likely to change this conclusion.

Effects on Blood Flow Velocity and Arterial Diameter Produced by Compression Therapy

Melissa Erickson & Rebecca Parker
Dr. Kevin McCully, Department of Kinesiology, University of Georgia

Cardiovascular disease is the leading cause of death and disability in the United States, but exercise may decrease the risks of developing cardiovascular problems. Risk factors associated with cardiovascular problems are more prevalent in spinal cord injury and multiple sclerosis populations. This study will explore the acute vascular benefits of compression therapy as an exercise alternative. Six able-bodied control subjects completed two rounds of compression therapy—muscle pump (90mmHg @ 5s) and medium pressure (130 mmHg @ 10 s). Ultrasound velocity measurements of the femoral artery were taken during 3 minutes of baseline, 8 minutes of compression, and 2 minutes of recovery. Femoral artery diameter was recorded at baseline and immediately after compression ended. Resting velocities were calculated as average, positive, and negative velocities (10.7, +25.5, -12.3 cm/s, respectively). Velocities during "muscle pump" were 7.7, +30, -17.4 cm/s respectively. Velocities during "medium pressure" were 8.4, +32.3, -21.3 cm/s respectively. "Medium pressure" showed a greater change in positive and negative blood flow compared to baseline. Arterial diameter tended to increase after the "muscle pump" protocol, suggesting flow mediated dilation, a sign of a healthy vascular response. Preliminary evidence suggests that both compression therapy methods produce an augmentation in positive and negative flow but a decrease in net flow. Further testing is needed to determine if either protocol produces a healthy response in vascular dilation. Compression therapy holds promise for producing exercise-related vascular responses for individuals who cannot exercise.

Determination of Interferon Sensitivity of Wild-Type and Lab-Adapted Rabies Viruses

Joe Fang
Dr. Zhen Fu, Department of Pathology, University of Georgia

It has been reported that rabies virus (RABV) can evade the innate immune responses by interfering with interferon (IFN-α/β) responses, particularly the activation of IRFs and with STAT signaling. However, only lab-adapted RABV has been used in such studies. It is not known if wild-type RABV also interferes with IFN-α/β responses. We propose to determine the differences in IFN sensitivity between wild-type and lab-adapted RABV by employing two cell lines and four RABV strains in this study. Mouse neuroblastoma (NA) cells are capable of producing IFN-α/β, while baby hamster kidney cells (BSR) are not. The RABV for this study includes two lab-adapted (B2C and L16) and

two wild-type RABV (DRV and SHBRV). The cells are treated with the same concentration of IFN-α/β and then infected with different RABV. At 24, 48, and 72 hr after infection, the supernatant is harvested for virus titration and cells for assessing viral RNA replication using a spectrophotometer. If a particular virus is sensitive to interferon, a marked decrease should be observed for virus replication and production. The results from this study are important for understanding how RABV develops ways to counteract a host's innate immune responses and may have implications in developing therapy for clinical rabies.

The Perfect Man: Reconstructing the Self Through the Prose and Poetry of Muhammad Iqbal

Rebecca Faulkner
Dr. Max Reinhart, Department of Germanic & Slavic Languages

Muhammad Iqbal develops the ideal of the Perfect Man within the framework of Islamic theology through prose in *Reconstruction of Religious Thought in Islam* and through poetry in *Secrets of the Self*. Iqbal's writing is immensely significant: his thought forms a singular connection between Western philosophical methods and Islamic theology of the East. Iqbal explicates his account of the ideal Self by the philosophical and theological discussion of consciousness, tension, and immortality in *Reconstruction*, which sets the stage for a creative exploration of the same concepts in poetry. Each notion thematically corresponds to a character in *Secrets*; consciousness, tension, and immortality correlate to Saki, Khizr, and Moses, respectively. The concepts map out Iqbal's arguments in *Reconstruction*, and their coinciding personalities accompany his poetic narrative in *Secrets*. Each of the two methods, prose and poetry, illuminates the multiple levels of meaning in Iqbal's account—the different types of analysis necessary to glean meaning from both prose and poetry lend the reader the means to acquire a holistic understanding of Iqbal's work as philosophy, theology, and literature. *Reconstruction* supports the rich poetic palette of *Secrets*, allowing the interactive process of reading poetry to fill the spiritual gaps left by prose that must mesh with an established religious tradition. By examining Iqbal's conception of the Perfect Man, one opens an essential dialogue between East and West that provides opportunity for further scholarship in a largely under-researched field. This dialogue bridges cultures, religions, languages, and locations in an effort to spread understanding.

The Effects of Stress-Induced Analgesia and Peripherally Administered Cannabinoid Receptor Antagonists on Formalin-Induced Pain Behavior

Rebecca Feistritzer – CURO Scholar
Dr. Andrea Hohmann, Department of Psychology, University of Georgia

Stress-induced analgesia occurs when neural systems naturally inhibit pain following exposure to stress in the environment. These pathways release cannabis-like substances in the body called endocannabinoids. Endocannabinoids activate cannabinoid CB1 and CB2 receptors to suppress pain. The present studies evaluated the contribution of peripheral cannabinoid receptors, located outside the brain, in stress-induced analgesia. The formalin test was used to measure stress-induced analgesia in rats. Formalin injected into the rat paw produces pain behavior. It was measured in control rats as well as rats exposed to brief shock applied to the paws. Rats were exposed to footshock to create stress-induced analgesia before injection of varying concentrations of formalin. In both shocked and non-shocked rats, pain behavior increased with increasing formalin concentration. Pain behavior was lower overall in rats subjected to footshock. Thus, stress-induced analgesia suppressed formalin pain. The antagonists AM251 and SR144528 were administered locally in the paw before footshock and formalin administration to block cannabinoid CB1 and CB2 receptors, respectively. SR144528 increased formalin pain, implicating a role for peripheral CB2 receptors in stress-induced analgesia. AM251 produced a trend toward increased pain. Pain behavior of

rats pretreated with either antagonist resembled control rats without stress-induced analgesia. In summary, stress-induced analgesia reduces formalin pain, and blockade of peripheral cannabinoid receptors eliminates pain relief produced by exposure to footshock stress. Our studies suggest that endocannabinoids are released by exposure to footshock stress and activate peripherally located CB2 receptors to produce stress-induced analgesia. Stress-induced analgesia dampens formalin pain through activation of peripheral CB2 receptors.

Patriotism and Protest in Georgia's Civil Rights Movement: The 1971 Columbus Policemen's Strike

JoyEllen Freeman – CURO Apprentice
Dr. Barbara McCaskill, Department of English, University of Georgia

In the late 1960s and early 1970s, as many African Americans grew impatient with the tedious progression towards equality, the Civil Rights Movement became affected by an expression of black nationalism and the antiwar struggle. Influences such as Black Power and the Vietnam War affected the sentiments of many African Americans who still felt denied of equal rights. Using newspapers and court records, I investigated a representative example of the evolving Civil Rights Movement: the summer of racial tension in Columbus, Georgia during 1971. On May 31, 1971, seven African American policemen were arrested for ripping the American flags from their uniforms during a protest. The officers, all Vietnam veterans, claimed that racial discrimination prevailed throughout the police force, and they refused to wear the flag until they received racial justice. Their gesture triggered racial tension and violence, which reached its climax on July 31, 1971, when ninety-one African Americans protested outside of the police headquarters. My research reveals the influence of patriotic sentiments and Black Power ideology on Georgia's Civil Rights Movement. This event demonstrates how one Georgia city served as a microcosm of the heated feelings of impatience and racial power that brewed throughout the United States. Finally, the inclusion of my research in the pedagogical materials of the Civil Rights Digital Library makes knowledge of historical events during this time period accessible to the public through the web.

Charting the Legacy of Southern Womanhood in Southern Gothic Fiction

Charles Ginn – CURO Summer Research Fellow
Dr. Hugh Ruppersburg, Department of English, University of Georgia

The Southern Gothic movement in American literature is characterized by its heightened sense of reality and grotesque characters, who are subjected to the stifling atmosphere of life in the South. The crumbling landscape of the post Civil War era provides the setting for readers to experience many horrifying realities. However, instead of utilizing the Gothic tradition to evoke instances of sheer terror, authors of the Southern Gothic genre use it to explore social issues and the lives of marganialized figures. This research endeavors to analyze the legacy of southern womanhood through a variety of female characters within the genre. Southern antebellum society levied burdensome expectations upon Caucasian women, forcing them to embody the chaste, virtuous ideal of the culture while limiting them to the domestic sphere. Yet Southern Gothic fiction throughout the twentieth century still portrays females who come in conflict with these limitations that originated in the antebellum period. Therefore, this research will chart female representation in relation to the traditional southern ideal of southern womanhood. The implications of race, class, and sexual orientation, in addition to gender, will also be analyzed in order to suggest that oppresive limitations plague a majority of southern female characters within Southern Gothic fiction, regardless of other defining qualities. Futhermore, this research will consult both early twentieth century and contemporary Southern Gothic writers such as Erskine Caldwell, William Faulkner, Eudora Welty, Carson McCullers, Flannery O'Connor, Toni Morrison, Alice Walker, Dorthy Allison, and Harry Crews.

Deterministic Assumptions of Positive Freedom

Matthew Glass
Dr. Daniel Kapust, Department of Political Science, University of Georgia

Conceptions of positive freedom advanced by political philosophers such as Plato, Hegel, and Rousseau hold that free actions are those which conform to what Isaiah Berlin terms one's "true" self. That is, actions are only free when unconstrained by physical barriers and internal barriers such as ignorance and irrational thought. I will be continuing to examine the concept of positive freedom through a study of selected ancient, modern, and contemporary philosophical works, primarily including Plato's *Gorgias*, Rousseau's *On the Social Contract*, and Isaiah Berlin's *Two Concepts of Liberty*. I argue that the conception of positive freedom is self-contradictory and therefore impossible to hold logically. In order for an action to be free under the conception of positive freedom, the action must be perfectly rational. This implies that a perfectly rational action is possible. For this to be the case, the action must have knowable consequences. For actions to have knowable consequences, one must assume a kind of determinism. If any situation lacked causal determinism, then the consequences of the action would be unknowable and a person could not act freely. However, accepting determinism as true is self-defeating because determinism negates the possibility of choice and freedom as existent concepts. Positive freedom, then, assumes a concept which destroys it. It cannot be seen as a logical conception of freedom.

Health Care Around the World

Barrett Gold
Dr. Brenda Cude, Department of Housing & Consumer Economics, University of Georgia

There has been much political discussion in Washington about health care reform in the United States. The reform focuses on three main weaknesses of our current system: inequality in accessing health care, soaring administrative costs, and lack of uniformity. As policymakers try to solve these problems it is important to identify the causes of each problem and explore different solutions. The purpose of this study is to survey the different healthcare systems around the world and identify strengths and weaknesses in each. Ideally, the strengths of foreign systems could be optimally combined with an influx of American innovative ideas to create a sensible proposal for healthcare reform. Through secondary research, this study identifies countries (specifically Japan, Germany, France, Switzerland, and Taiwan) that excel in certain aspects of the administration of health care and identifies certain recurring patterns among the systems ranked most favorably by the World Health Organization. By evaluating the development of health care in the United States and American culture and politics, this study attempts to integrate the successful commonalities that improve efficiency, equality, and costs found in other systems with unique American proposals to create an optimal health care system that would be embraced by the majority of the American public and legislators.

Exploring the Mechanisms of Neuron Specific Glycosylation in Embryonic *Drosophila melanogaster*

Harrison Grace
Dr. Michael Tiemeyer, Department of Biochemistry & Molecular Biology, University of Georgia

Glycoproteins are immensely important molecules that cover the surfaces of cells and mediate many important cell-cell interactions and tissue specific processes. Especially important in neural development, specific glycoproteins direct synaptic plasticity and axonal pathfinding. The mechanisms that regulate tissue-specific glycosylation, however, are relatively unknown. A genetic screen for mutations that affect tissue-specific glycosylation in the embryonic *Drosophila* nervous system identified a novel mutation, designated sugar-free frosting (Sff). The homozygous Sff mutation altered glycan expression and created neural defects in NMJ formation. This led to behavioral defects in

locomotion. To study the connection between altered glycosylation and phenotypic defects and to explore the process of tissue specific glycosylation in neural development, other steps in the Sff-mediated control pathway need to be explored. Toward these ends, a genetic interaction screen was developed and implemented to identify mutations that interact with Sff. The mutagenesis screen was designed to test for non-complementation of the locomotion deficit and the glycosylation defect of Sff mutants. Going through multiple generations, novel behavioral tests and *in situ* antibody staining processed thousands of initial random mutants. Four candidate mutants have been recovered that show significant interaction with the Sff mutation. These mutants will be further characterized and analyzed for their place in the neuron-specific glycosylation pathway by assessing their neural development, glycan expression, and interactions with other genes. Characterizing how these mutations work together will help to elucidate the mechanisms that regulate glycosylation and neural development.

The Mystery of Telomere Recombination in Normal Yeast Cells

Zijing Guo
Dr. Michael McEachern, Department of Genetics, University of Georgia

Telomeres are protective caps at chromosome ends that are composed of direct repeats. These protective caps contribute to aging in humans. Most cells maintain telomeres by using the enzyme telomerase. If cells lack telomerase, however, they can sometimes elongate telomeres by utilizing homologous recombination. Previous research surprisingly has shown that telomeres in wild-type yeast cells can sometimes be recombined. This was shown by their ability to become extended by copying sequence from a transformed telomeric circle. However, it was not possible to tell if the recombined telomeres were normal length or abnormally shortened when they were recombined. Our goal is to construct and use mutationally tagged telomeric circles to distinguish whether telomeres in wild type cells have normal length or shortened length at the moment of recombination. First, DNA circles containing a mutated telomere and a *URA3* gene is constructed. This is done by ligation of a tract of mutationally tagged telomeric repeats into a *URA3* gene-containing plasmid and then excision of the telomeres-*URA3* fragment with restriction enzymes followed by self-ligation into a circle. Next, the circles are transported into *URA3*-deficient *Kluyveromyces lactis* mutant cells, and only the cells with *URA3* genes are able to grow. The telomere structures will then be analyzed to see if wild-type-length telomeres are recombined with the telomeric circles. This study is significant because it could help us see how telomeres elongate using recombination, a process that occurs in a subset of human cancers.

Effects of Daily Saccade Practice on Behavioral Plasticity in Schizophrenia

Erin Hansen – CURO Summer Research Fellow
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Patients with schizophrenia often have difficulty with behaviors that require executive functioning, such as inhibition. The purpose of this study is to determine if practicing a task that requires inhibition could result in improved performance on other measures of executive control. Over a two-week trial, patients with schizophrenia (n = 30) and healthy control subjects (n = 30) were assigned to daily practice of a saccade task; 15 participants from each group practiced either a prosaccade task (redirection of gaze toward a peripheral cue) or an antisaccade task (inhibition of a gaze toward a peripheral cue and generation of gaze towards the mirror image location of the cue). At the beginning and end of the trial, participants also completed two tests of executive functioning—the Ocular Delayed Response (ODR) task and the Wisconsin Card Sorting Task (WCST). In the preliminary results, every group showed improvement on the practice task. The schizophrenia antisaccade group showed improvement on ODR and WCST, while the schizophrenia prosaccade group showed poorer performance. Although both the schizophrenia and healthy antisaccade practice groups showed

improvement on ODR and WCST, the healthy group showed greater improvement. These results indicate that executive control in schizophrenia may be less malleable than in healthy controls. Also, since the schizophrenia antisaccade group did show improvement on ODR and WCST, the results also suggest that purposeful practicing of executive control tasks could be used as a means of improving generalized executive function in schizophrenia.

Conjugal Transfer of Virulence in the Opportunistic Intracellular Actinomycete *Rhodococcus equi*

Chris Harding
Dr. Mary Hondalus, Department of Infectious Diseases, University of Georgia

Rhodococcus equi is a soil-derived, facultative intracellular, Gram-positive actinomycete that can survive and replicate inside macrophages. It causes severe pyogranulomatous pneumonia in foals and immunocompromised humans. Strains isolated from foals and 30% of those from humans contain an 85-90kb virulence plasmid. Homology searches have shown the plasmid to contain genes with sequence similarly to those involved in conjugative DNA transfer in other organisms. Conjugative ability has been linked to bacterial biofilm formation, which can aid in the pathogenesis of an organism. The conjugative potential of the *R. equi* virulence plasmid has never been studied. This work addresses that deficiency and seeks to establish whether the virulence plasmid is conjugative as is hypothesized. A donor *R. equi* strain containing a marked virulence plasmid was mixed with a virulence plasmid-free recipient strain differentially marked on its chromosome. After incubation, bacteria were subjected to antibiotic selection plating specific for donor, recipient, and transconjugant strains. Putative transconjugants were recovered, and plasmid transfer frequencies were calculated using putative transconjugant/recipient values. Complete virulence plasmid transfer was verified by PCR analysis. Results show the virulence plasmid can be transferred from donor to recipient strains with a frequency ranging from 1 x 10-1 to 1 x 10-2. Plasmid transfer was minimally affected by the presence of DNase, required living cells, and prolonged cell to cell contact, factors consistent with conjugation as the means of transfer. If conjugation and biofilm formation are found to be linked, disruption of the former may prevent the latter and could alter disease transmission.

MicroRNA let-7f regulates STAT1 Activity in Human Lung Epithelial Cells

Craig Hayes – CURO Apprentice
Dr. Ralph Tripp, Department of Infectious Diseases, University of Georgia

MicroRNAs (miRNA) are short ~22nt RNA sequences that govern host gene expression in part by binding to complementary sequences in the 3' UTR of target mRNAs, resulting in their silencing. Hundreds of miRNAs have been discovered or predicted and are believed to target and repress hundreds of targets each. Virus infection of host cells affects miRNA expression, and one such miRNA, termed let-7f, has recently been implicated as important in the response to respiratory syncytial virus (RSV) infection. One function of let-7f appears to be in post-transcriptional regulation of the Signal Transducer and Activator of Transcription (STAT1) gene. In this study, to evaluate the role of let-7f on STAT1 gene regulation, let-7f mimics and inhibitors were co-transfected with Metridia luciferase reporter plasmids controlled by a CMV promoter and containing the STAT1-3′ UTR into human respiratory epithelial cells. The role for let-7f regulation of STAT-1 was determined via luciferase secreted in the cell supernatant, a technique that allows for evaluating the tempo of regulation via luciferase expression without lysing cells. The results showed that the let-7f mimic repressed luciferase expression while the let-7f inhibitor increased luciferase expression compared to mock transfected and non-targeting control transfected cells, confirming that let-7f is a regulator of STAT1 expression. Further studies are ongoing to determine other pathways affected by let-7f during RSV infection.

Gov. James McDowell and the Virginia Slavery Debate of 1831-1832
Mary Boyce Hicks – CURO Scholar
Dr. John Inscoe, Department of History, University of Georgia

James McDowell (1795-1851) was a planter and politician who resided primarily in Rockbridge County in the Blue Ridge Mountains of western Virginia. Because he was from the western part of the state, McDowell was not as involved in the elite social classes found in the state's Tidewater or Piedmont, where slavery was far more prevalent than in the mountains. He was elected to the state House of Delegates (1831-35) and then in 1841 was elected Governor, serving a single term. In 1831, Virginians underwent a major debate over the future of slavery in the state. Triggered by Nat Turner's insurrection, this series of hearings was meant to discuss this evil—slavery. McDowell was a major player in these debates that ultimately accomplished little. He was an excellent orator and delivered two major speeches. My thesis will focus primarily on this debate and McDowell's contribution. Why was so little accomplished? What did Virginians of all classes think of slavery at the time, including McDowell's constituents? How did McDowell's status as a slave-holding westerner affect his opinion on slavery and free blacks? Finally, how did this debate influence the perception of slavery and impact the course of slavery in Virginia up to the Civil War? I have researched in McDowell's correspondence in the Special Collections libraries at University of Virginia and University of North Carolina at Chapel Hill; these along with transcripts and newspaper account of the debates will be the means by which I answer these questions.

Analyzing the Function of O-GlcNAc in the *Drosophila* Nervous System
Marcus Hines – CURO Scholar
Dr. Michael Tiemeyer, Department of Biochemistry & Molecular Biology, University of Georgia

A dynamic cycle of addition and removal of *O*-linked *N*-acetylglucosamine (*O*-GlcNAc) at serine and threonine residues is emerging as a key regulator of intracellular protein activity. Like phosphorylation, the *O*-GlcNAc modification significantly changes the function of the proteins to which it is attached. In addition, the *O*-GlcNAc modification may compete with phosphorylation for certain Ser/Thr target sites. Although there has been considerable research on documenting the functional implications of phosphorylation, the functions for *O*-GlcNAc are just beginning to be understood. A significant amount of cancer and developmental biology research is focused on phosphorylation as a regulator of cell growth and differentiation, but relatively little attention has been paid to the involvement of *O*-GlcNAc in these processes. Like kinases and phosphatases, the enzymes of *O*-GlcNAc addition, *O*-GlcNActransferase (OGT), and removal, *O*-GlcNAcase (OGA), are compartmentalized and regulated. We have capabilities to analyze the presence of O-GlcNAc on the intracellular protein. This project focuses on dissecting cell autonomous and non-autonomous functions of *O*-GlcNAc by altering the expression of OGT and OGA within specific cells of the *Drosophila melanogaster* embryo in an effort to better understand the function of *O*-GlcNAc. Preliminary results have hinted that the addition of more *O*-GlcNAc in the engrailed cells of the *Drosophila* nervous system may hinder the engrailed cells' natural secretion of wingless cells. Further research on the function of *O*-GlcNAc, especially in the *Drosophila melanogaster* embryo, will continue to be conducted to obtain a deeper understanding of the glycan.

The Multimethod Analyses of the Three Separated Parts of a Roman Sarcophagus with the Myth of Marsyas' Musical Contest with Apollo
Shelby Hipol – CURO Apprentice
Dr. Frances Van Keuren, Department of Art History, University of Georgia

The identification of the quarry sources of marbles is important to art historians, geologists, and archaeologists. Two forms of analysis are commonly used: petrographic, the analysis of

the marbles' color and grain sizes, and isotopic, the measure of the marbles' Carbon 13 and Oxygen 18 isotope values. Although this dual method is more accurate than using a single form of analysis, it still often fails to limit the possible provenances to a single quarry. Therefore, Dr. Frances Van Keuren and I propose supplementing the usual two forms of analysis with Electron Paramagnetic Resonance (EPR). EPR is an analysis of the amount of magnesium in marbles' chemical compositions. When used in conjunction with the other two forms of analysis, it adds another element of distinction between the marble varieties. This project examines all the fragments from one of the sarcophagi in Dr. Van Keuren's larger project, Multi-Method Analyses of Twenty Sarcophagi in the Museo Nazionale Romano, Rome. The three fragments all show parts of the Marsyas myth and seem to join. Our EPR data show all the fragments as being of Proconnesian marble. Yet, our isotopic data indicate that the fragments are not of the same variety of Proconnesian marble. Using only isotopic and petrographic analyses would have yielded doubt as to our identification of the marble's quarry source. This study is significant because it shows that, occasionally, two varieties of marble can come together in a quarry and skew analysis results if a block is quarried in such an area.

Trends in Reporting Sustainability Actions
Kema Hodge – CURO Apprentice
Dr. Richard Watson, Department of Management Information Systems, University of Georgia

As consumers become more environmentally conscious, many businesses have begun acting sustainably. Government regulations have also been put in place to compel businesses to report on the decisions that could affect the health of our planet. As a result of societal demands and governmental regulations, the shift toward measuring the sustainability of a product or service, and thus a business, has become more pronounced in recent years. Consequently, many major global companies are willingly and proactively engaged in supporting this important trend of acting sustainably and reporting it. Some companies are reluctant to comply with environmental guidelines, however, and some companies do not report their compliance or non-compliance. This research reports on trends among different information technology sectors. It is based on data available in the annual or sustainability reports from companies in the Technology Hardware, Computers, and Telecommunications sectors. The analysis comes from queries executed in MySQL and will report on different companies' compliance level of environmental guidelines, which section of the global reporting initiative index has the most compliance across the various sectors, which sectors have the highest compliance, and which countries have the highest level of compliance. The release of the findings should encourage more reporting and compliance across the board by corporations, because it will reveal to stakeholders and consumers which businesses are complying with environmental guidelines set by the government. The findings may also shed light on current business efforts to promote sustainability.

A Study of Predictive Modes of Thought with a Focus on Religion, Astrology, and Probability Theory
Dillon Horne – CURO Apprentice, CURO Summer Research Fellow
Dr. Thomas Cerbu, Department of Comparative Literature, University of Georgia

How did predictive modes of thought become a viable tool with which to make predictions? The research begins with the idea of religion as a "first mover" in the explanation of the chain of events that made prediction a justifiable venture. It specifically deals with the concept of "belongingness" as a driving force in this progression of thought. From there, a focus on the 16th century figure of Gerolamo Cardano is placed. He holds special significance due to his early dealings with game theory, giving rise to precursors of modern concepts of probability. His work on astrology provides insight into the development of predictability and why it had such a stranglehold on humanity. Moreover, the esoteric nature of the topic at hand demands a critical analysis into what constitutes "secret"

information. From there follows a brief overview of the correspondence between Fermat and Pascal, but with a larger emphasis on probability as an emergent concept rather than an epochal shift. This leads into modern studies of economics, governmental policy, etc. In particular, what is the connection between predictability and persuasion, and did that relationship lead us into our current recession? This project will build upon other works of history of philosophy and mathematics by providing a more comprehensive focus on predictive modes of thought. In a world so caught up in numbers, the significance of an encompassing study on the development of probability will serve to provide a basis of credibility for acting on predictions.

Generation of a Mutant Core Streptavidin for Complexation with and Crystallization of Biotinylated Membrane Proteins

Steve Hsieh
Dr. Raquel Lieberman, Department of Biochemistry & Molecular Biology, Georgia Institute of Technology

There is a great need to facilitate the crystallization of membrane proteins because once the crystals are grown, the molecular structure can be determined by X-ray crystallography. Membrane proteins prove difficult to isolate and crystallize, however. Hydrophobic membrane proteins have limited hydrophilic interactions to stabilize the protein in its crystalline form, and the lipid membrane surrounding the protein must be replaced with a non-denaturing detergent. The overall goal of this project is to develop a new general procedure to facilitate the crystallization of membrane proteins. For our approach, we take advantage of the high affinity between biotin and streptavidin, a water soluble protein that crystallizes easily. We will crystallize the complex between streptavidin and a biotinylated membrane protein. To achieve this goal, we introduced four key mutations disrupting the streptavidin tetramer to generate a dimeric streptavidin construct with two biotin binding sites. Site directed mutagenesis, which encompassed primer design, PCR, DPN1 digest, transformation, cell culture, plasmid isolation, and sequencing, were used to introduce each mutation. The mutant streptavidin was then expressed and purified. Our next step was to form the streptavidin-biotinylated membrane protein complex. We are testing our method on a biotinylated form of signal peptide peptidase, a membrane protein. The complex was isolated by affinity chromatography. Crystallization trails are currently being conducted. If the approach we are developing is successful and we are able to solve the crystal structure of biotinylated SPP with streptavidin, it will be widely applicable to the structure determination of other membrane proteins.

Investigating a Novel Alternatively Edited Protein's Involvement in Mitochondrial DNA Maintenance

Tiffany Hu – CURO Summer Research Fellow
Dr. Stephen Hajduk, Department of Biochemistry & Molecular Biology, University of Georgia

Trypanosoma brucei is the causative agent of African trypanosomiasis (African sleeping sickness), a parasitic disease that affects humans and non-primate mammals. The parasite belongs to a unique class of protozoa called kinetoplastids, which contain a dense region of mitochondrial DNA named the kinetoplast. To form functional mRNAs, posttranscriptional modification is necessary for most of the kinetoplast-encoded genes found in *trypanosoma brucei*. Recently, alternative editing of the mitochondrial cytochrome oxidase III (COXIII) transcript was found to code for a novel membrane protein, alternatively edited protein 1 (AEP-1). AEP-1 stably associates with the tripartite attachment complex, a kinetoplast-flagellum linkage that is involved in mitochondrial DNA maintenance and segregation. Homology modeling of AEP-1 against the bovine COXIII crystal structure reveals that its N-terminus is positioned toward the mitochondrial matrix. We propose that AEP-1 interacts with the kinetoplast and is involved in its maintenance. In this study, dominant negative mutation was used to investigate the function of AEP-1 in the mitochondria. Cells

with truncated (mt-AEP-1(1-59)-GFP) and non-truncated AEP-1 (mt-GFP) expression were monitored for cell growth abnormalities, and the growth inhibition of mt-AEP-1(1-59)-GFP was stronger than that of mt-GFPs. Fluorescence microscopy revealed that the truncated protein localized to the kinetoplast region, and aberrant kinetoplast morphology or absence of the kinetoplast was observed. To further investigate AEP-1's involvement with the kinetoplast, we will recombinantly express the N-terminal region and perform electrophoretic mobility shift assays to determine its DNA-binding abilities. This study will help us understand the true function of RNA editing in the trypanosome mitochondria.

Effects of Steel and Aluminum Shoes on Forelimb Kinematics in Stock Horses

Elodie Huguet
Dr. Kylee Duberstein, Department of Animal & Dairy Science, University of Georgia

Horseshoes of various materials have been adopted to satisfy the need of performance horses. Steel shoes are common due to their durability, availability, and cost. Due to the importance of performance horses' gaits for competition and athletic purposes, however, lighter weight aluminum shoes have been implemented to accentuate foreleg action. Such shoes are seen to increase speed in horse racing by allowing for more reach and improve the quality of gaits in certain disciplines. By performing a repeated measures crossover study on nine healthy stock-type horses, the effects of these two horseshoe types on forelimb kinematics were analyzed at the trot. Horses were trotted in hand for three repetitions over a distance of 1969.13 meters at day 4, 18, and 32 of each cycle. Video footage was analyzed using gait analysis software (OnTrack EquineTM) for each repetition. Average stride length and velocity remained constant between treatments and times. However, breakover speed increased over time. Knee action showed a trend toward difference between treatment groups, with a larger knee angle observed for horses wearing aluminum shoes as compared to steel. This effect was significant at day thirty-two of each shoeing cycle, indicating that horses may show more treatment effect as they become acclimated to shoe type. This finding is of particular importance to performance horse disciplines for which ameliorated knee action is desirable. A follow-up study is being conducted to further examine the time effect and length of shoeing cycle as it pertains to knee action between shoe types.

Relationships Between Features of Infant Vocalizations and Later Language Development

Sarah Hutcheson – CURO Scholar
Dr. Suneeti Nathani Iyer, Department of Communication Sciences & Special Education, University of Georgia

The purpose of the present study was to examine the development of directedness of vocalizations and canonical babbling in infancy and their possible relationships with later expressive language measures in toddlerhood. The results of this study could potentially help establish a basis for the identification of children at risk for speech and language disorders. As part of an ongoing longitudinal study, 10 typically developing infants were recorded in a laboratory setting from 5 to 30 months at weekly to monthly intervals. The directedness of vocalizations, i.e., whether the vocalizations were undirected or directed toward a person or object, was ascertained at 6 and 9 months using muted video recordings. The age of onset of canonical babbling, or the production of well-formed consonant vowel sequences, was also determined. These results will be compared to scores obtained at 18 and 30 months of age on standardized expressive language and vocabulary size measures. It was expected that vocalizations directed toward a person or object would increase from 6 to 9 months of age as the infants' communication became more intentional. Based on results of previous research, a positive correlation between person-directed vocalizations and expressive language scores and vocabulary size was also expected. However, the prediction was neutral regarding the correlation between earlier canonical babbling onset and those same measures, as

previous research had obtained contradictory results.

The Scaling Relationship Between the Photocatalytic Decay Rate and Height of TiO2 Nanorods
Whitney Ingram – CURO Summer Research Fellow
Dr. Yiping Zhao, Department of Physics & Astronomy, University of Georgia

Titanium dioxide nanostructures (TiO2) are excellent candidates for purification of water and air using UV light energy. In order to optimize TiO2 photodegradation, numerous studies have been carried out to analyze the relationship between nanostructure and TiO2's ability to decay organic material. The quantitative relationship between the decay rate of one particular nanostructure, called nanorods, and their height has not been established. Through this study, we developed a systematic approach to relate the decay rate of TiO2 as a function of nanorod height. A theoretical model was also proposed to explain the experimental data. We systematically deposited nanorod arrays of different length and tested their photocatalytic decay rate of an aqueous solution of methylene blue (MB). The decay rate was measured by plotting the normalized absorbance peak of MB (λ = 664 nm) after regular UV-irradiation time intervals. It was found that the decay rate increased monotonically with nanorod height (h) and fit the power law $\kappa \propto Mh^{\xi}+N$, where M and N are constants, and $\xi = 1.0 \pm 0.5$. A theoretical model was derived that illustrates a direct relationship between the photocatalytic behavior and the morphological structure of TiO2. Both our experimental data and theoretical model fit very well. Our theoretical model also gives a detailed relationship between the photocatalytic decay rate and other experimental parameters such as UV light intensity and illumination area. We believe this quantitative model could be used for other photocatalyst systems with nanostructured morphologies.

Abandon Hope All Ye Who Enter: The Solution to the Cartel Crisis in Mexico
Archil Japaridze
Dr. Sergio Quesada, Department of Latin American & Caribbean Studies, University of Georgia

Amid the myriad conflicts in the world, few seem as hopeless as the drug wars in Mexico. Since President Calderon's declaration of war on the cartels, security in Mexico has rapidly disintegrated. My research attempts to answer the question of how to remove the cartels from power and re-establish the rule of law. The significance of my research lies in the potential to find a solution to this endemic problem. In order to find the keys to defeating the drug cartels, case studies and historical examples will be employed. For my case studies I will use secondary academic sources and primary journalistic sources to examine: the 1920s Bootleggers, the 1980s Colombian cartels, and the modern drug-backed FARC revolutionaries. I believe these cases to be particularly applicable since they showcase the pretenses under which governments have triumphed over extremely strong criminal organizations. Although these studies present valid points, however, Mexico is plagued by unique circumstances, making it imperative to understand the conditions on the ground and apply the relevant methods. Combining Mexico-specific methods and using examples from these case studies, I will formulate a comprehensive drug policy for Mexico to ensure a reasonably peaceful end to the cartel war. I anticipate that the most viable solution to the cartel war is to legalize and heavily regulate drugs, similar to prohibition era alcohol, but with thorough research I will find what offers hope for the fragile state.

How Broad Are Infants' Face Discrimination Abilities in the First Year of Life?
Ryan Jordan & Elizabeth Simpson
Dr Janet Frick, Department Psychology, University of Georgia

At birth, visual perception is broadly tuned, allowing infants to discriminate a wide array of stimuli. Infants who have not yet undergone

perceptual narrowing—whereby visual perception narrows as a function of experience—should have broad face recognition abilities and therefore should recognize faces of humans and non-humans equally well. Infants whose visual perception has already narrowed should easily recognize human faces and show more difficulty in non-human facial recognition. To test this model, facial identity discrimination was measured in 4-6-month-olds ($N = 89$), and 9-11-month-olds ($N = 70$) for the faces of three species: humans (*Homo sapiens*), capuchin monkeys (*Cebus apella*), and sheep (*Ovis aries*). In addition, we measured 4-6-month-olds' (N=10) discrimination of wasp (*Polistes fuscatus*) faces. These species are phylogenetically more distantly related to humans than species previously studied. A visual paired comparison task revealed that 4-6-month-olds discriminated all species' faces equally well ($p > .05$), while 9-11 month-olds were best at discriminating human faces ($p < .05$). These results reflect human infants' transition from being face generalists—broadly discriminating facial identity for numerous species—to being face specialists—becoming experts in discriminating human faces. This research contributes to a better understanding of the perceptual foundations of early social relationships.

Shaped Like Steiner: Biodynamic Farmers of Southern Germany Enacting a Century-Old Tradition of Sustainability

William Jordan – CURO Summer Research Fellow
Dr. Betty Jean Craige, Department of Comparative Literature, University of Georgia

In southern Germany, the concept of a sustainable or self-sufficient farm was introduced and methodized by Rudolf Steiner in a series of lectures he gave in the summer of 1924. This was the beginning of what is known today as biodynamic farming, a tradition still active in southern Germany. While most of Steiner's methods are centered on treating the farm as a self-contained organism, some of his more specific instructions for soil treatment are best described as mystical: they are based on knowledge that Steiner claims to have intuited. My project is an exposition of photography and journalistic writing about four biodynamic farms, all of which have different views on Steiner and implement his agricultural and philosophical guidelines in different ways. I give special attention to closed cycles of resources within these farms. In addition, I discuss how many ideas being presented today by Michael Pollan, an emerging leader in the U.S.'s sustainable agriculture movement, echo or complement those of Steiner.

The Impact of Reading One-on-One to Head Start Children

Meaghan Kelly, Kristina Housworth & Robert Gentry
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Children's reading abilities impact their academic learning and other aspects of life long after the initial stage of basic learning and development. The development of these reading abilities depends heavily on the literacy skills they acquire at an early age. For children to gain these crucial literacy skills, they have to first be exposed to, and gain interests in, books. Past research indicated that 47% of children had no books present in the homes receiving public aid. This sample of disadvantaged children made up a staggering, but not surprising, 35% of children who entered kindergarten unprepared to learn. Reading to children and other environmental conditions have been suggested to contribute to the development of literacy in preschool-aged children. The present study therefore examines the effects of reading on low-income children in terms of their interest in books. It is expected that one-on-one reading would increase the likelihood of children's selecting books as their favorite object. Forty-eight children ranging from 35 to 46 months old, from a larger study, were assessed before a one-on-one reading program began. Individual child's object selections from a toy box, including a small book, along with participating in a play session with12 toys and a book, were recorded as a baseline. Twelve lessons including reading were administered. Two follow-up assessments were

made, eight months and a year, after the program concluded. The results showed that more children selected books as their favorite objects. Detailed results and implications will be shared at the CURO symposium.

Examining the Substrate and Inhibitor Properties of Protease Inhibitors and Statins with OATP Transport Proteins

Fahad Khan – CURO Summer Research Fellow
Dr. Jason Zastre, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Protease inhibitors (PIs), which belong to Highly Active Antiretroviral Therapy, raise the likelihood of a heart attack by 26 %. The concomitant use of PIs and the cholesterol-lowering agents statins causes muscle toxicity and the disease rhabdomyolysis. The PI atazanavir is purported to be an inhibitor of the transporter OATP2B1, and pravastatin is its suggested substrate. We examined the substrate and inhibitor properties of atazanavir and pravastatin in OATP2B1 and their interaction with the transporter. Human embryonic kidney 293 (HEK293) and Chinese hamster ovary (CHO) cells were transfected to express OATP2B1. Model assessments and substrate/ inhibition studies were performed with transport assays. Estrone-3-Sulfate (E3S), estradiol-17-β-glucuronide (E17βG), and atazanavir solutions were tritium-labeled, and protein assays were performed to measure the final amount of radioactive solution. The OATP2B1 cells featured an average E3S uptake of 0.13 pmol/mg protein, and the control featured an uptake of 0.02 pmol/ mg protein. In the presence of atazanavir, uptake decreased ~ 2.5-fold. Atazanavir uptake was not affected by E3S. Increasing concentrations of pravastatin reduced uptake of E3S. Increasing concentrations of pravastatin did not decrease atazanavir uptake by OATP2B1. Atazanavir reduced E3S uptake, but E3S did not affect atazanavir, so atazanavir is an allosteric inhibitor of OATP2B1. Pravastatin reduced E3S uptake, so pravastatin is a substrate of OATP2B1. Pravastatin did not affect the uptake of atazanavir, so atazanavir is not a substrate of OATP2B1. Atazanavir inhibits OATP2B1 and diminishes the amount of pravastatin that can be taken up by hepatocytes, resulting in high bioavailability and muscle toxicity.

Ground Reaction Forces of Unicompartmental Knee Arthroplasty Patients During Stair Ascent

David Kim
Dr. Kathy Simpson, Department of Kinesiology, University of Georgia

Unicompartmental knee arthroplasty (UKA) is a surgical procedure during which only one side of the knee is replaced. Vertical ground reaction forces (VGRF) are applied to the foot from the ground in a vertical direction and affect knee joint loads and, thus, the length of time an UKA lasts. The purpose of this sub-study was to determine if VGRF were greater for the UKA compared to the non-UKA limb during stair ascent. Twenty-two unilateral UKA participants (age: 66 ± 13.6 yrs; height: 163 ± 7.8 cm; mass: 73 ± 12.3 kg) walked up four steps while stepping on two force-measuring platforms; one mounted in the ground and another in the first step. No significant differences were detected (paired t-tests: $p \geq .082$). Relative to body weight (BW), the maximum VGRF values for the UKA-limb and nonUKA-limb, respectively, were: 1.14 ± 0.09 BW and 1.17 ± 0.09 BW when the foot was on the ground and 1.19 ± 0.15 BW and 1.19 ± 0.13 BW during the first step. Surprisingly, however, more than 50% of the participants had higher VGRF values for their nonUKA-limb compared to their UKA-limb. Hence, many participants may have favored their nonoperated-limb, perhaps by shifting more of their weight to the nonUKA side of their body. Alternatively, these participants may have actively pushed against the ground with more force with their nonUKA limb. Physical therapists potentially should focus on reducing their UKA patients' uneven loading during rehabilitation.

Investigating the Early Developmental Expression of Lysosomal Enzymes in Zebrafish

Maximilian Klein – CURO Scholar, CURO Summer Research Fellow
Dr. Richard Steet, Department of Biochemistry & Molecular Biology, University of Georgia

Proper breakdown of molecules within the lysosomal compartment is necessary to maintain the normal function of cells and their surrounding environment. The importance of this process in human health is stressed by a growing number of genetic diseases that involve defects in the proteins and enzymes responsible for this task. These diseases (termed lysosomal storage disorders or LSDs) have a diverse etiology and are one of the most frequently occurring genetic diseases affecting children in the U.S., with an estimated incidence of 1 in every 5000-7000 live births. Using zebrafish as a model system for developmental studies has many advantages, which include but are not limited to large-scale experiment replication, early developmental genetic manipulation via the use of morpholinos, and microscopic phenotype analysis in the early stages of embryogenesis. Surprisingly, there is little known regarding the early expression of lysosomal enzymes in zebrafish as well as overall yolk biology. To better gauge which lysosomal enzymes are best suited for morpholino-based gene knockdown, developmental expression and regulation of zebrafish lysosomal enzymes were characterized for enzymes that are well understood in human disease. Several enzymes were then selectively targeted for morpholino-based knockdown, and the phenotypic and biochemical effects were analyzed. Additionally, the nature of several of these zebrafish lysosomal enzymes was better characterized by establishing pH activity profiles, yolk deposition, and percent mannose 6-phosphorylation, which yielded some novel findings in zebrafish lysosomal biology. Further developing the zebrafish LSD model will be a groundbreaking step in opening many doors for therapeutic possibilities.

Pediatric Seizures in Larval Zebrafish

Susan Klodnicki – CURO Scholar, CURO Summer Research Fellow
Dr. James Lauderdale, Department of Cellular Biology, University of Georgia

About 55,000 cases of pediatric epilepsy are diagnosed annually. Although there are seizure treatments for adults, there are no known effective treatments for childhood seizures. The reason is not well known and is the cause for our research. Study of neural mechanisms at a young age is necessary to provide knowledge that will allow other researchers to develop more effective drugs for childhood epilepsy. Epileptic episodes are characterized by recurrent unprovoked seizures that result from widespread abnormal brain activity with characteristic discharge patterns. The larval zebrafish is a useful organism that allows us to visualize seizures in a developing vertebrate using confocal imaging. These seizures have a similar pattern to that of children. Zebrafish transgenic for a calcium indicator can be used to monitor neural activity induced by chemoconvulsants. In imaging data, action potentials are sensed as calcium changes, and brain images are collected for further analysis. Using computational algebraic methods, individual seizures and neural pathways are detected, estimated and visualized. Prior to 5 days post fertilization (dpf) waves are characterized by short durations (33 sec/wave). After 5 dpf, cyclical wave patterns emerge, characterized by a series of short duration waves followed by a single long-duration wave (9 min/wave). These results show that the pattern and duration of seizure-induced neural activity change as a function of brain development. This work provides a better understanding of possible mechanisms involved in pediatric seizures that may lead to improved epilepsy treatment.

Effects of Social Institutions on Adolescent Alcohol Use

Rebecca Kopp
Dr. Thomas McNulty, Department of Sociology, University of Georgia

Underage alcohol use is considered a growing social issue. Social scientists often look at the social environment and the institutions of family, school, and religion to understand the onset of adolescent alcohol abuse. By looking at data obtained from Waves I, II, and III of the National Longitudinal Study of Adolescent Health, this research tests the extent to which family, school, and religion affect adolescent alcohol use. For a simplistic test, this research utilizes a multi-regression model focusing specifically on the independent variables: school attachment, time involved in afterschool activities, the amount of religious attendance, and family attachment of an adolescent, while controlling for age, gender, race, economic status, and access to alcohol in the home. To be consistent with other research on the subject, it is expected that adolescents with less time spent with family, at religious services, and participating in extracurricular activities will have higher frequencies of alcohol use and drunkenness in the past 12 months. The results, however, are mixed. Here, there is a significant effect only in family attachment and school activities for adolescent alcohol use. In the model, religion did not have a significant role in predictive adolescent alcohol use. This study aims to use the Add. Health survey to add to the current research on social predictors of adolescent alcohol use. By adding to the current literature, policy makers may be able to develop better programs to aid adolescents. Future research includes coupling this model with qualitative methods to help provide insights into adolescent choices regarding alcohol.

Coagulation Factors Involved in the Pathology of Placental Malaria

Lindel Krige – CURO Scholar
Dr. Julie Moore, Department of Infectious Diseases, University of Georgia

Pregnant women and children are most vulnerable to malarial infection. Malaria in pregnancy leads to intrauterine growth restriction and preterm deliveries, resulting in low-birthweight babies. The underlying mechanisms that lead to these poor birth outcomes are not well understood, but it is known that severe inflammation in the placenta, together with excessive fibrin deposition, are common features of placental malaria and correlate with low birthweight. This inflammation and coagulation process in the placenta occur as an immunological response to the malaria infection. This study addresses the hypothesis that local malaria-induced inflammatory responses induce placental coagulopathy, which is turn leads to significant compromise in placental function and, therefore, fetal distress. This study will focus on the role of coagulation and immunological factors in the disease response process of mice. Murine placental malaria has proven to be an effective model for *P. falciparum* infection in humans. Mouse RNA has been isolated, and primers for each coagulation factor have been developed. Using these primers and isolated RNA, the next step will be to conduct real-time PCR to determine possible upregulation of the coagulation factors. Further research possibilities include determining whether fetal or maternal cells initiate this immunological response leading to inflammation and coagulation in the placenta. Identifying the role of coagulation factors involved in the immunological response to placental malaria will provide further understanding on malarial pathogenesis and ways to prevent fetal growth restriction.

Public Views of Biculturalism

Josephine Kwon
Dr. Victoria Plaut, Department of Psychology, University of Georgia

As America becomes increasingly globalized, concepts such as multiculturalism and biculturalism are important to consider in public policy and social issues. Biculturalism in a psychological light refers to the process by which individuals consider two distinct ethnic cultures as integral to their ethnic identity and behave in a manner that expresses elements from both cultures. Bicultural individuals, generally from minority groups, will comprise an estimated 40% of the population by 2020. As such, considering biculturalism in a public light could illustrate existing attitudes in America.

Estimating the public opinion of biculturalism could indicate the type of social environment within which immigrants and their children live, as well as possible public issues in relation to globalization and biculturalism. To understand the public opinion of biculturalism today, we have composed a questionnaire to comprehensively determine if and what kind of public opinion exists regarding biculturalism. The questionnaire is meant to discern what kind of reaction the term biculturalism produces, how internalized the idea of biculturalism is, and how important biculturalism is perceived to be in America. The responses to this questionnaire could indicate any common attitude towards bicultural individuals in America.

The Old Made New: The Life and Work of Art Rosenbaum

Jared La Croix
Dr. Robert Pratt, Department of History, University of Georgia

I first saw Art Rosenbaum play banjo in the summer of 2009. His talent and enthusiasm impressed me to the point that I began to research who this man is. After conducting numerous personal interviews with Mr. Rosenbaum, I concluded that Art's ability to capture and preserve American folk life distinguishes him as an artist and individual. More than mere historical preservation, however, is Art's ability to transform a folk tradition deeply rooted in the past into a living art form pertinent to the present. While this paper is biographical in the sense that I recorded a chronology of Rosenbaum's life, this paper seeks to push beyond the life of Mr. Rosenbaum himself by examining how, in the words of the artist, "the old is made new." I investigated Rosenbaum's philosophical outlook on art in addition to specific paintings that manifest such viewpoints. What I discovered is a synthesis of a contemporary exposure to a preserved folk culture through mediums of song, painting, and musical recording creates an original experience in its own right. I believe the worth in this project is equally weighted between my own conclusions, such as the synthesis I mention above, and the life of Mr. Rosenbaum himself. In Shakespeare's *The Tempest*, Miranda says, "Your tale, sir, would cure deafness." Mr. Rosenbaum's life story exposes the relationship between who a man or woman *is* and what he or she *creates*, thus alerting his readers and listeners to their own inner passions while simultaneously inspiring external creations.

Renewable Biomass and Georgia: A Legislative Update

Jonathan Lee – Roosevelt at UGA
Dr. Robert Izlar, Center for Forest Business, University of Georgia

The Energy Independence and Security Act of 2007 (EISA) reduces Georgia's ability to economically manufacture renewable liquid fuel from forest biomass. Georgia ranks first in the nation in its endowment of recoverable forest biomass and third in total available biomass. While Georgia possesses 24.7 million acres of recoverable forest biomass, however, the EISA definition qualifies only 7.5 million acres as a source for "renewable biomass" feedstock. The purpose of this presentation is to explain new legislation passed or pending in Congress on this issue since 2007. The purpose of this research is to suggest and support a definition that would better enable Georgia to establish a viable renewable fuels industry. This definition should be a broader, more scientific definition that includes any organic material available on a renewable, recurring basis. This definition would likely incorporate appropriate federal lands and all private forestland in compliance with current Georgia Best Management Practices for timber harvest. Naturally regenerated hardwoods and plantation-grown pines would likely be included regardless of when they were last harvested. With this broad renewable biomass definition, nearly 24 million forested acres of Georgia's 34 million acre total land base would qualify for use in the production of transportation fuel under EISA. Research is based on literature, including congressional testimony, trade association position statements, personal interviews, and newspaper articles. Forest inventory reports and scientific journals are included when appropriate. The research intends to show that

current law will not have the long-term effect of stabilizing the size of Georgia's forest cover and may, in fact, decrease Georgia's forested estate due to the suppression of consumptive forest markets. Furthermore, the definition as passed jeopardizes the establishment of a renewable fuels industry in the state, and, finally, that its language is based on a precautionary, yet misguided, philosophy of environmental protection.

Complementation of Chromosomal Deletions in Mycobacteria

Natasha Lee – CURO Scholar
Dr. Russ Karls, Department of Infectious Diseases, University of Georgia

Tuberculosis (TB) is an infectious disease caused by *Mycobacterium tuberculosis* (*Mtb*). The World Health Organization estimates that one third of the human population is latently infected with *Mtb*. Those infected carry a 10% risk of developing TB. Understanding how this pathogen survives within a host will aid in efforts to prevent, diagnose, and treat TB. Defining the relationship between different *Mtb* genes and virulence is typically achieved by characterizing mutants with altered target genes. To ensure that the resulting phenotype is associated with the mutated gene, the wild type phenotype must be complemented (restored by reintroducing the wild type gene). This can be performed by PCR amplification of the gene and cloning the gene onto a plasmid that can replicate in *Mtb*. The focus of my research is to complement a 16-kb deleted region of the *Mtb* genome. This region is thought to attribute to virulence. Plasmids containing portions of the region have been created and will help define the functions of the encoded genes. Reconstruction of a plasmid with the entire 16-kb region has been problematic, however, leading us to pursue a strategy to recover this region by homologous recombination. Efforts are in progress to generate a system to screen for plasmids in which the targeted region has been recombined onto them. This work is anticipated to allow the generation of complementation plasmids that have a low risk of PCR-induced mutations. This system will aid TB vaccine research and facilitate studies identifying which *Mtb* genes encode virulence factors.

Rce1p Transmembrane Topology

Edward Lilla
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Uncontrolled proliferation and migration of transformed cells in the human body are two of the main characteristics of cancer. The Ras signaling pathway, which is essential for growth in normal human cells, is hyperactive in cancer. The oncoprotein Ras has been identified as a possible therapeutic target for treating cancer. Rce1p is a protease responsible for post-translation modification of Ras. By inactivating Rce1p, Ras will not be able to initiate cell propagation in cancerous cells. To manipulate the activity of Rce1p, a better understanding of the mode of cleavage and topology of the protease must be gained. Western blotting and PEG-mal (methoxypolyetheylene glycol 5000-maleimide) modification of cysteines found in Rce1p will help determine the topology of Rce1p. Several yeast mating test has been performed on yeast strains carrying various mutants of Rce1p. These mutants containing point mutations were in cysteines that were modified to alanines or serines. The mating tests have verified that the yeast strains successfully express the desired mutant strains of Rce1p. Next step of our project is to perform PEG-mal reactions on the mutant strains of yeast. Once the PEG-mal reactions are complete, Western blots can be performed on the samples. The results from the Westerns will help us determine if cysteine modification of Rce1p occurred. The combined results from these several mutants will help determine if our current topology map is correct or needs modifications.

Harboring an Ancient Killer: Restructuring Malaria Control in Nigeria

Ammarah Mahmud – Roosevelt at UGA
Dr. Christopher Whalen, Department of Epidemiology, University of Georgia

With 90 percent of malaria cases occurring in Africa, malaria continues to be a fatal concern in developing countries. Nigeria accounts for one-fourth of incidents in the World Health Organization's Africa Region with severe effects on the nation's socio-economic infrastructure. Nigeria receives a yearly allotment from global aid groups and spends over $85,000,000 on malaria control. Funding is poorly allocated, however, and the process lacks transparency. Only one-fourth of funding is directed toward the most necessary precautions against malaria. In similarly situated nations, cross-analysis reveals a correlation between a nation's financial assistance and effective control of malaria. This paper proposes that Nigeria restructure its funding system and allocate money to the most effective methods of disease control with consideration to Nigeria's particular economy and geography. Prevention methods should be simplified and taught to the population, with specific allotment to community clinics catering to rural populations. To assure transparency, this proposal envisions an oversight role for international organizations that contribute money to Nigeria's prevention campaign. Aid groups should stress that, in a mobile society, malaria in any part of the world is a threat to the international community. Thus, financial contributors have a right to oversee the maximum utility of supplies and distribution in areas still plagued with the disease. Health-focused groups should collaborate with other aid organizations currently engaged with Nigeria's government. Economic initiatives should incorporate requirements that Nigeria restructure its disease prevention program with greater transparency as part of an overarching development scheme.

The U.S. and the ICC: How the United States Has Behaved Toward the Court and How It Should Behave in the Future

Bridget Mailley – CURO Summer Research Fellow
Dr. Amy Ross, Department of Geography, University of Georgia

The International Criminal Court (ICC) is the first permanent, international court that prosecutes individuals for their actions during human rights atrocities. The U.S. and the ICC have claimed to have the same goals concerning justice. Throughout the U.S.'s ongoing relationship with the ICC, however, it has wavered from hostile, to acquiescent, to potentially an ally. According to my data, two of the main problems the U.S. has had with the ICC concern the breadth of the ICC's jurisdiction, and ICC's potential power to stall strategic American activities abroad. Although many steps were taken to impede the effects of the ICC on American power, including American Servicemembers' Protection Act, most of these steps have been rendered impotent since 2008. As of July 2009, statements from my interviews indicated that the Obama Administration was undergoing a policy review to understand what position the U.S. would take on the ICC in the future. Recent statements by Secretary of State Hillary Clinton and Ambassador to the UN Susan Rice have indicated friendly and more cooperative intentions from the U.S. One interviewee in particular, council to a Congressman dealing with the ICC issues, thought that even though the ICC is not currently a pressing issue for the government, the U.S. should become a collaborating party in order to protect American interests concerning the Court. My data suggest that the U.S. should adopt a more cooperative approach to the Court in order to rectify differences and ensure that the ICC can be a space for justice.

Separate but Not Equal: An Analysis of Segregation and Inequality in Georgia Public Schools

David Malison – CURO Scholar
Dr. David Mustard, Department of Economics, University of Georgia

It has been more than fifty years since the Supreme Court delivered the landmark *Brown v. Board of Education* opinion, banning compulsory segregation in schools across America. Although overt racial discrimination remains prohibited by law, schools today find themselves increasingly divided across racial lines. This trend has left many low-income, minority students concentrated in urban schools

while more affluent, white students receive their education in suburban neighborhoods. How have these trends influenced the black-white performance gap on standardized tests in Georgia? Using data collected by the Georgia Department of Education, our study aims to answer this important question. We have recently assembled a database that contains detailed information on every Georgia public middle school over the past five school years. We plan to analyze these data first with cross-sectional ordinary least squares regressions, and then by using a linear fixed effects model. Our primary measure of school performance will be the percentage of students meeting statewide standards on the Criterion-Referenced Competency Test (CRCT). We expect to find that increasing segregation has caused the black-white achievement gap to expand, consistent with other recent findings in this area. In today's economy, the impact that schooling has on future earnings cannot be overemphasized. A growing gap in educational achievement will ultimately lead to increased inequality across racial lines. By calling attention to these problems, we hope to encourage the Georgia public school system to explore and adopt policies that mitigate the negative consequences that segregation may have on students today.

Water Droplet Generation in Ferrofluid-Based Magnetorheological Fluid

Francisco Marrero – CURO Apprentice, CURO Summer Research Fellow
Dr. Leidong Mao, Department of Engineering, University of Georgia

Droplet generation is an important branch of microfluidics where micro- to femto-liter droplets are formed at the intersection of two immiscible liquids. Researchers have found various applications for these droplets in biology, chemistry, and pharmacy, where discrete and precise reaction chambers were generated at a high throughput. In a typical flow-focusing droplet generation device, the size of droplets is controlled by adjusting the flow rate ratio of continuous (usually oil) and discrete (usually water) phases. Droplet size is inversely proportional to flow rate ratio between continuous and discrete phases, while droplet velocity is proportional to the flow rate of the discrete phase. Independent control of the droplet size and its velocity is important for droplet-based microfluidic analytical applications. In this paper, we have developed a novel method that uses external magnetic fields to adjust the viscosity of the continuous phase and therefore control the size of the generated droplets. We use a magnetorheological fluid and ferrofluid mixture as the continuous phase. Both contain suspended micro- and nano-sized magnetic particles, which under an external magnetic field induce chain-like aggregates inside the mixture that effectively increase the fluid viscosity. Preliminary results show that the water droplet size can be controlled by changing the amplitude of the field. Moreover, this scheme enables us to manipulate and position individual droplets as desired. In summary, we have a developed a device that precisely controls droplet size and organization without affecting other variables. Applications include shortening prototyping phase, DNA amplification, study of crystal growth, and nanoparticle synthesis.

Increasing Personal Finance Education in Athens-Clarke County High Schools

Kathryn McCabe – Roosevelt at UGA
Prof. Michael Rupured, Department of Housing & Consumer Economics, University of Georgia

Despite growing support for personal finance education and its lasting benefits, American high school students continue to show a lack of financial literacy. On a 2008 survey distributed by the Jump Start Coalition polled the literacy of over 5,000 high school students in financial matters, students scored an average of 48.3 percent correct. Furthermore, the National Bureau of Economic Research estimated that as much as one-third of credit fees are related to a lack of financial knowledge. These statistics and other financial research surveys suggest that students are leaving high school without adequate knowledge of financial matters, making them susceptible to poor financial decision making in the future. This paper is a commentary that pieces together statistical information from different research-based

sources on environmental education and financial knowledge to make a policy recommendation for financial education reform in Athens-Clarke County. The policy proposes that the Athens-Clarke County School Board implement a standardized and mandatory personal finance program for its school system that would incorporate specific financial curriculum into a 6- to 8-week time frame, separate from economics subjects. A task force consisting of teachers and administrators would be responsible for assembling in-depth, practical curricula from existing comprehensive financial programs. They would also create a process for teacher certification to ensure teacher expertise in financial subjects. If undertaken, this policy would benefit Athens' students, both advantaged and disadvantaged, by providing them with knowledge that will help them become more informed financial decision makers.

The Elemental Problem in Grand Strategy: A Principle Model of Analysis

Bethany McCain & Christopher Looft
Dr. Brock Tessman, Department of International Affairs, University of Georgia

Grand strategy can be defined as a state's plan for the long-term connection of all available means toward the achievement of its fundamental goals. Past attempts at defining grand strategy rely too heavily upon the enunciation of hard power objectives as both a means for reaching goals and as the goals themselves. Our paper seeks to define grand strategy in a new, holistic, analytical model that recognizes the interrelated nature of the multitude of goals of any actor. This model is unique in its comprehensiveness and flexibility; it is not limited by perspective or time for analysis. This core model can therefore be applied to any actor at any time in history. Our tiered model rests upon the five principles of hard power, soft power, resource security, humanitarian leadership, and multilateralism, which together form the basic analytical lens for interpreting any event of grand strategic importance. From this analytical foundation stems the elemental layer, which consists of defense, diplomacy, resources and economics, and ideology. These layers form the organizational basis for our paper and is essentially universal as interpretational mechanisms: they are flexible enough to interpret grand strategy from any perspective, be it modern Chinese goals or those of ancient Athens and Sparta.

The Effect of Political and Economic Shifts on Private Charitable Giving

Connor McCarthy & Robert Thrasher
Dr. David Mustard, Department of Economics, University of Georgia

This paper will measure the effects of government economic policy on private charitable giving. We have three interrelated motivations for this study. First, we are personally convinced of the vast importance of private philanthropic giving to spur social progress in the United States. Second, we theorize that private philanthropic giving, much like private capitalist markets, tends to be more efficient than public funding. Third, given the current recession and the current administration's high level of spending, this study is relevant and timely. We use data from the Panel Study on Income Dynamics (PSID), a longitudinal survey begun in 1968 that tracks a representative sample of 7,400 U.S. households' economic, health, and social behavior, and from the Center on Philanthropy Panel Study, a component added to the PSID in 2001 to track philanthropic giving. Using the PSID, we control for household fixed effects, head of household and family demographics, and public and private financial status. We also include political, macroeconomic, and natural shocks as explanatory variables. In some cases, these are represented as dummy variables whereas others are numeric figures normalized to a base year. We complete the model using charitable giving and volunteering levels as the dependent variables regressed against these determinants. Our analysis includes discussion of the regression results as they differ between observed years and across sample groups. The purpose of this study is to determine the relationship between political and economic shifts and charitable giving. If a definitive

relationship is established, further research can assist in effective policymaking.

Serum Vitamin D and Bone Structural Development in Young Adult Females: A Three-Year Prospective Study
Leslie McConnell
Dr. Richard Lewis, Department of Foods & Nutrition, University of Georgia

Previous research has demonstrated the importance of vitamin D in bone health, but longitudinal studies in this area, especially in young adult populations, are lacking. The purpose of this study was to compare changes in vitamin D concentrations and bone strength of the tibia and radius in females (n = 69 at baseline age 18.2 ± 0.4; n = 66 at 3-year follow-up, age 21.3 ± 0.4). Lean mass, fat mass, and percent fat were measured using dual energy X-ray absorptiometry (DXA). Peripheral quantitative computed tomography (pQCT) assessed bone and muscle parameters at three different sites on the radius and tibia. Serum vitamin D [25(OH)D] levels in the blood were measured using a DiaSorin radioimmunoassay, and concentrations ranged from 45-150nmol/L at baseline and 48-168nmol/L at follow-up. Hypovitaminosis D ([25(OH)D] < 80nmol/L) was present in 35% and 30% of participants at baseline and follow-up, respectively. Paired samples *t*-tests demonstrated a significant increase ($p = 0.004$) in 25(OH)D concentrations over time. Pearson and partial correlations (controlling for baseline height) revealed significant positive associations ($p < 0.05$) between percent change 25(OH)D and percent change total cross-sectional area (CSA) at the tibia, but an inverse relationship ($p = 0.003$) between percent change 25(OH)D and percent change cortical thickness at the tibia. Increasing levels of circulating vitamin D may be beneficial with respect to tibial size in young adults, as demonstrated by changes in CSA, but future supplementation trials may elucidate the role of 25(OH)D in bone strength indices more definitively.

The Success of Recent U.S. Foreign Policy in Latin America
Sharon McCoy – CURO Scholar
Dr. Loch Johnson, Department of International Affairs, University of Georgia

In 1973, the United States engaged its intelligence and economic resources in the overthrow of the democratically elected, socialist government of Chile. A manifestation of U.S. foreign policy throughout the Cold War, these actions adhered to the prevention and eradication of communist and socialist governments worldwide. Since the close of the Cold War, a different U.S. strategy has emerged: advocating the spread of U.S. economic principles and interests over political ones. This paper examines past and present U.S. foreign policies toward Latin America to evaluate the viability of the policies and their implications for future U.S.-Latin American relations. Currently, data have been collected from government, academic, and journalistic sources regarding former U.S. actions in Chile with further information being compiled on recent U.S. policy decisions in Venezuela. A comparison of these two data sets will focus on the specific methods of U.S. action in each country; the factors influencing U.S. decisions at the time; and the subsequent societal, governmental, and international effects of the policies. The expectation is that both foreign strategies—that of the Cold War era and its successor—have failed to yield sustainable improvements in U.S.-Latin American relations and have neglected to thoroughly consider the ramifications for Latin American countries. The ultimate intention of this paper is to put forth suggestions for enhancing U.S. relationships with its southern neighbors based upon analysis of the successes and failures of the past and current U.S. foreign policies in the region.

A New Definition of Treason: The 1794 Treason Trials
Laura McDonald
Dr. Kirk Willis, Department of History, University of Georgia

This paper examines the 1794 Treason Trials as a turning point in the British definition of treason and how this turning point sheds light on the transfer of state power from the king to the people. Without a written constitution, British state power relied on a carefully balanced relationship between the king, Parliament, and the people. The definition of treason, however, identified state power as residing solely in the person of the king; threats to the people or to Parliament were not considered attacks on the state. When the spread of radical ideology from the French Revolution made such attacks seem imminent, Prime Minister William Pitt and his attorney-general John Scott brought the reform leaders to trial for treason. Ultimately, the defense, led by Thomas Erskine, was able to prove that the defendants' attempts to reform Parliament in no way represented an attack on the person of the king and therefore did not qualify as treason. The acquittal of the defendants led to new legislation that redefined treason to include attacks or threats to Parliament, acknowledging that state power had shifted beyond the king. The research for this paper relies on a close reading of the transcripts of the treason trials, personal accounts from the defendants and the lawyers, and secondary source material. The paper seeks to demonstrate that the trials marked not only a shift to a new definition of treason but also a recognition of a new definition of the power and rights of the state.

PAX6 Mutation Screen
Margaret McDougal – CURO Scholar
Dr. James Lauderdale, Department of Cellular Biology, University of Georgia

Aniridia is a rare congenital eye disorder characterized by partial or complete lack of iris. Additional defects include foveal hypoplasia, indicated by early infancy nystagmus, cataracts, corneal clouding, and glaucoma. The progressive nature of the disease leads to reduced visual acuity and blindness. Two-thirds of aniridic patients have heterozygous mutations in the *PAX6* gene. The PAX6 protein is a highly conserved transcription factor crucial for normal eye development and cornea homeostasis. The protein's exact molecular mechanism is still uncertain, however. Understanding the phenotypic variation caused by different *PAX6* mutations helps explain the molecular mechanism of the mutated protein and the complex role of PAX6 in the eye. In this project, we screened the *PAX6* gene of 153 individuals, representing 56 aniridic families, by direct gene sequencing and conducted detailed ophthalmologic evaluations for each aniridic patient. A total of 37 mutations were identified, including 19 novel mutations. I compiled our results with the Human *PAX6* Allelic Variant Database to create a total of 547 independently ascertained variants in *PAX6*. Of these variants, 534 are associated with ocular malformations, and 444 are specifically causal for isolated aniridia. Further analysis of mutation type frequencies, distributions, and hotspots indicate that nonsense (39%), frame-shift (29%), and splice junction (19%) mutations are predominately associated with aniridia, whereas the majority of non-aniridia phenotypes are caused by missense mutations (75%). This compiled mutation spectrum continues to yield important insight into the molecular mechanism of the mutated protein and the likely phenotypic defects.

The Skeleton Keyhole
Richard McKelvey
Prof. Andrew Zawacki, Department of English, University of Georgia

Problems arise in compromising the inherent and necessary difficulties of certain complex, opaque poetries in efforts to make such poetry more accessible to readers. The poetry, which I will term "contemporary American experimental poetry," hardly fits under a single umbrella of categorization but shares in common an unavoidable inaccessibility. Refusing populist compromises, I believe such poetry could, however, be more engaging to more readers through collaborations with other artistic media, including music. I intend to use experimental poetry represented primarily by the work of Susan Howe, Rosemary Waldrop, and Nathaniel Mackey, as a starting point. From there, I hope to marry the inevitable difficulty of this poetry

with my own populist ideals through musical collaboration. Similar collaborations in the past have sought to push the poetry itself outward. Such collaborators include Steve Swallow with Robert Creeley, Nathaniel Mackey in numerous instances, Philip Glass with Allen Ginsberg, and David Grubbs with Susan Howe. I diverge from this foundation primarily through the intent of my collaborations. I am not a jazz musician and have no qualms with setting my demanding style of poetry to pop music to expand readership. This does not mean the music cannot interact critically with the poetry, but simply that the primary purpose of the music is to increase accessibility. The final product will consist of roughly 20 pages of poetry, a critical introduction, and a full album of the entire collection set to music through collaborations with local musicians, myself included.

Children's Attachment Security and Mothers' Separation Anxiety

Amanda McKenley – CURO Apprentice
Dr. Hui-Chin Hsu, Department Child & Family Development, University of Georgia

The social environment in which a child is raised can greatly affect the quality of his or her attachment relationship, an enduring emotional bond with parents. The mother's emotional wellness, be it positive or negative, is an important aspect of a child's social environment. When mothers are unable to protect their children, they experience separation anxiety, which is an unpleasant state of guilt, worry, and sadness. The purpose of this study is to investigate whether a mother's separation anxiety is associated with a child's attachment security. It is expected that mothers' greater separation anxiety is correlated with lower quality in child attachment security. Using video data from a larger longitudinal research, 30 four-year-olds were observed interacting with their mothers and strangers and playing by themselves for more than two hours in a laboratory playroom. The quality of children's attachment security to their mothers was determined using the Q-sort method, which has 90-item descriptive statements of the style of child's behavior. An example of such a descriptor would be "Child cries when mother leaves him/her with a babysitter." The rater sorted items into nine categories according to their relevance to the behavior of the child being assessed. Attachment security scores were obtained by correlating raw scores from the Q-sort with the standardized criterion scores. Also, levels of separation anxiety in the mothers were obtained when mothers filled out the Separation Anxiety Scale twice, at the time of the observation session as well as at a lab visit four years prior.

Repression, Literature, and the Growth and Metamorphosis of Czech National Identity in the 20th Century

Ilana McQuinn
Dr. John Morrow, Department of History, University of Georgia

Czechoslovakia in the 20th century followed a tumultuous path that led it to freedom from the three-hundred-year yoke of the Habsburg Empire, an existence as a small democratic nation surrounded by dictatorship, Nazi occupation twenty short years later, and finally total and complete de-individualization under Soviet communism. The Czechs were pushed to independence by frustration with a protracted existence as the "other," or the marginalized minority nation not in power, in the German-dominated Habsburg Empire. A large component of the formation of Czech identity depended on linguistic differences and the contrast with the German, and as such struggled to develop an identity independent of the crutch of the "other." Some have argued that the muted method of resistance that the Czechs employed through the majority of the Nazi and Communist control of Czechoslovakia weakened the Czech claim to a unified identity as a people. The ironic comedies of Jaroslav Hašek and Bohumil Hrabal, however, exemplify how crucial intellectual and literary figures became for solidifying the Czech national identity. This paper examines the manner in which Czech culture and national identity developed in the 20th century with special attention to *The Good Soldier Švejk*, *Closely Watched Trains*, and *Too Loud a Solitude* from the repressive periods of

World War I, World War II, and Communist control.

A Tail's Tale: ErbB Structure, Evolution, and Function
Amar Mirza – CURO Scholar, CURO Summer Research Fellow
Science as Art
Dr. Natarajan Kannan, Department of Biochemistry & Molecular Biology, University of Georgia

Epidermal Growth Factor Receptor (EGFR), a multi-domain receptor tyrosine kinase, is the most frequently mutated tyrosine kinase in all human cancers. Activation of the cytoplasmic tyrosine kinase domain involves ligand-induced dimerization, conformational changes in the activation-loop, movement of the C-Helix, interlobe movement, and myriad other events. Coordination of all of the aforementioned events is critical for kinase activity, but existing methods (NMR and MD simulations) are not yet powerful enough to provide an explanation. To tease apart the details of this protein's regulation, we have constructed contrast-hierarchical alignments to identify specific amino acids which are most critical for EGFR and related kinase function. The biological relevance of these amino acid residues was uncovered by mapping them onto existing crystal structures of EGFR. It was found that segments of the N and C- terminal tail flanking the kinase core are distinguishing features of EGFR that have co-evolved with the kinase domain and are now an integral part of the kinase core. These flanking segments were found to be critical for controlling interlobe movement, ATP-binding, C-Helix positioning, symmetric and asymmetric dimerization, and activation-loop stabilization. These results elucidate previous experimental data that pointed toward a regulatory role for these regions. The results of this work have laid the ground-work for the development of novel allosteric inhibitors for the treatment of cancer, and this investigation has further characterized the effect of one of the most frequent mutations found in cancerous tissue.

Using miRIDIAN miRNA Mimics and Inhibitors for Evaluating the Contribution of Host miRNA Regulation of Respiratory Syncytial Virus (RSV) Replication
Patricia Mitchell – CURO Apprentice
Dr. Ralph Tripp, Department of Infectious Diseases, University of Georgia

Respiratory syncytial virus (RSV) infection causes substantial morbidity and some deaths in the young and elderly worldwide. There is currently no safe and effective vaccine available. RSV causes repeat infections throughout life, a feature in part attributed to virus gene regulation of the host immune response. Little is known about the host gene response to RSV infection, or the mechanism by which host genes are regulated. Recently, microRNAs (miRNA) have been shown to have a critical role in host gene regulation, cell differentiation, proliferation, and apoptosis. In this study, miRNA regulation of the host gene response to RSV infection was investigated using a panel of miRNA agonists and antagonists. Human respiratory epithelial cells (A549 cells) were transfected with specific miRNA mimics and inhibitors that were indicated by our experimentation using microarray analysis to be important in the response to RSV infection, specifically let-7f, miR 26b, miR 595, miR 24, miR 198, miR 224, and miR 337. The results confirm that some of these miRNAs are important in the host response to RSV infection and offer new insights into disease intervention strategies to control RSV-mediated disease pathogenesis. Recently it has been shown that miRNA could have a role in the treatment of pancreatic cancer and heart disease.

Racial and Skin Tone Differences in Facial Thermography and Self-Reported Emotion in Response to Visual Stimuli
Trenton Mize & Tré Myers
Dr. Dawn Robinson, Department of Sociology, University of Georgia

An emerging technique for studying emotions involves the measurement of facial temperature using infrared thermography. We focus on possible systematic differences in facial temperature as a function of participant's race.

This study used data from 82 women and 68 men who participated in a study of "Pictures and Feelings." Sixty-one participants self-reported as "white," and 21 self-reported as "black." Participants viewed images and completed self-report emotional measurements while their facial temperature was measured using infrared thermography. Images varied systematically in their capacity to elicit feelings of potency and activity in a 2 (potency: high, low) x 2 (activity: high, low) factorial design. The emotion manipulations were derived from the International Affective Picture System (IAPS). Based on previous literature, we predicted some differences in emotion as a function of self-reported race. These predictions were not supported. We analyzed differences in facial temperature throughout the experiment as a function of self-reported race. We found consistent differences in facial temperature by race across all images and all facial regions, with no interactions by facial region or image set. We also found a few differences in self-reported emotion by race but no differences that would explain the consistent temperatures differences. We believe that the facial temperature differences observed were due to different skin tone emissivities, which would cause lighter or darker skin tones to be read at different temperatures by the infrared camera. We present further analyses to test this possibility. These results could be important to consider when studying emotions across races and ethnicities.

The Local Weather: The Effects of Construal Level and Weather on Self-Control

Paul Moon
Dr. Michelle vanDellen, Department of Psychology, University of Georgia

Research on Construal Level Theory indicates that people process information on two levels: local and global. Locally, people are concerned with immediate consequences of behavior, whereas globally, people are concerned with future consequences. We were interested in whether construal level might affect how people process positive and negative information when they need to exert self-control and whether these decisions would be affected by situational factors. We recruited participants to complete a study regarding self-control decisions and recorded the weather each day of data collection. Through a Navon letters task, participants were randomly assigned to process information globally or locally. Afterward, they read a text that either highlighted the consequences or benefits of taking a zinc tablet. Trying zinc is an approach version of self-control because its benefits are at odds with its consequences. Next, participants rated their opinions of zinc and were asked if they would like to try the zinc. We had zinc available for those who wanted to try it. Results indicated that weather on the day of experimental session moderated the effect of construal level on participants' likelihood of trying the zinc. Participants were more likely to accept zinc if they had been locally primed and if it was raining that day. These results suggest that self-control could be based on environmental conditions and also construal level. This may be because when focused locally and when weather was bad, participants were more aware of the potential of getting a cold due to the rain.

Queens of Scream: The Making of Horror Film Heroines

Jill Moore
Dr. Katalin Medvedev, Institute for Women's Studies, University of Georgia

Since its inception, the film industry has greatly influenced fashion and society in America. Movies provide a recorded history of the culture that produces them. The way we view characters in film also speaks to our culture's preconceptions about gender roles. Out of all film genres, horror generates the most controversy. Horror pushes the boundaries of what is socially acceptable and forces the viewer to face the darkest facets of human nature. The visual portrayal of characters is much more important in horror films than in any other film genre because dialogue and character development are less important. How are women depicted in scary movies, and why? What does the portrayal of women in horror films say about expected gender roles in American society, and how does it challenge them? How have female

characters in horror films changed over time? These are the questions that I am exploring through the examination of "slasher" films. I chose this type of horror film because they depict real people more accurately than other horror subgenres. Many critics in the field of women's studies contend that horror films are misogynistic and exploitative towards women. In my paper, I hope to propose a different perspective and show how horror films may actually empower them. To write my paper, I have reviewed numerous sources on film theory, gender studies, and director perspectives and applied their theoretical frameworks to the most important films in the "slasher" genre.

The Epidemiology of *Staphylococcus aureus* in Kentucky and Georgia from 1995 to 2003

Tatum Mortimer
Dr. Susan Sanchez, Department of Infectious Diseases, University of Georgia

Methicillin-resistant *Staphylococcus aureus,* MRSA, is a growing problem in medical and veterinary fields as antibiotic resistant infections can be difficult to treat. The epidemiology of equine MRSA has been little studied to date. Our purpose was to study the epidemiology of equine *S. aureus* from Kentucky, where the racing industry predominates, and from Georgia's primarily recreational population. Clinical isolates of *S. aureus* were collected from horses in Kentucky and Georgia from 1995 to 2003. Pulsed field gel electrophoresis was used to create patterns of digested DNA from the isolates, which were compared to each other and twelve known human controls. We found that 65% of Kentucky isolates were MRSA compared to 18% in Georgia. The differences between the patterns were counted, and BioNumerics was used to create dendrograms of the samples. Analysis revealed that 60% of the MRSA isolates were closely related and 25% of the MRSA isolates were possibly related to the strain type USA500. Methicillin-sensitive *S. aureus* isolates showed a greater genetic variety, and only 10% of those isolates were possibly related to USA500. Urinary and reproductive isolates from Kentucky had the highest incidence of MRSA at 70%. The genetic resemblance of the MRSA isolates suggests that many of the isolates have a similar source, possibly the USA500 strain that presents itself in the human population. The markedly higher frequency of MRSA in the Kentucky isolates indicates that the husbandry and management of the racing horses aided in spreading MRSA more effectively than that of individually owned leisure horses.

Energy Efficiency Funding in Athens-Clarke County

Saptarsi Mukhopadhyay – Roosevelt at UGA
Dr. Tyra Byers, Odum School of Ecology, University of Georgia

Athens-Clarke County's (ACC) tax revenues have shrunk dramatically due to the weak economy. Consequently, ACC needs to reduce expenses to balance its budget as mandated by state laws. Energy costs are an ideal target for reducing overall costs. They are embedded in the costs of providing all services and can be cut with little adverse effect on the quality or extent of services provided. Through the implementation of various types of economically efficient energy upgrades, energy usage and costs can be reduced. To realize potential energy usage and cost savings fully, all upgrades need to be conducted simultaneously. The nature of energy efficiency projects is synergistic; different upgrades working in conjunction conserve more energy and money than would seem to be indicated simply by the sum of their individual effects. Hence, if all of these projects are not pursued in parallel, maximum potential savings simply cannot be realized. Unfortunately, ACC currently does not realize the maximum potential savings in energy costs due to its current piecemeal method of funding these projects. ACC should create a $500,000 "Energy Bank" based on a similar plan in place at Chapel Hill, NC through the issuing of municipal bonds and a process to use this fund for energy efficiency upgrades in public buildings to address these policy failures. This sustainable and stable source of long-term funding should allow all economically efficient energy efficiency upgrades to be implemented to achieve maximal cost savings, reducing the cost

of proving services and ultimately increasing social welfare.

Keeping PACE: Clean Energy Financing for Athens-Clarke County
Bryn Murphy – Roosevelt at UGA
Dr. Andrew Carswell, Department of Family & Consumer Sciences, University of Georgia

The Property Assessed Clean Energy ("PACE") financing program is a financial tool designed to make clean energy home improvements more accessible to homeowners. Through the PACE program, participating state and local governments offer funding through a municipal bond to eligible homeowners to cover the up-front costs of home energy retrofits. Homeowners then repay their loans through an additional periodic assessment on their property taxes. These energy retrofits not only lower a household's carbon emissions but also produce savings on homeowners' water and energy bills by ensuring that anticipated utility bill savings outweigh anticipated additional property tax assessments. This research seeks to determine the level of interest in the PACE program in Athens-Clarke County, and, if such interest is present, to adapt the program to better fit local concerns and conditions. Participants in a local class for new homebuyers were surveyed on their level of interest in the PACE program and level of attraction or aversion to specific components of the program (quantitative). Their specific comments and suggestions were also elicited (qualitative). The anticipated results of the survey include general interest in the PACE program but concern with specific components of the program, such as eligibility requirements, potential financial risk to homeowners, and perceived incompatibility of the PACE program with Athens-Clarke County's high percentage of renter-occupied property. An adaptation of the PACE program to meet local people's concerns has the potential to increase access to the benefits of clean energy in Athens-Clarke County and in demographically similar communities nationwide.

The Effect of U.S. Military Aid on Recipient State Cooperation in Pakistan: A Case Study
Emily Myers – CURO Summer Research Fellow
Dr. Patricia Sullivan, Department of International Affairs, University of Georgia

What is the effect of U.S. military aid on Pakistan's cooperation with United States foreign policy? If Pakistan does not always cooperate with the U.S. foreign policy objectives, why does the U.S. continue to fund them with massive amounts of military assistance? This study seeks to explain the phenomenon that as the United States gives Pakistan more military aid, Pakistan becomes less willing to cooperate with U.S. foreign policy goals. Key sources are U.S. legislation, transcripts of congressional hearings, Congressional Research Service (CRS) Reports, news articles from *The New York Times* and other major newspapers, and existing literature on U.S. military aid. These sources are used to analyze the relationship between the United States and Pakistan by explaining how U.S. military aid is generally allocated and how the U.S. government justifies giving aid, describing how U.S. military assistance to Pakistan has changed over time, tracking U.S. legislation, and discussing past problems the U.S. has encountered with countries to whom it has provided aid.

Epigenetic Effects of Bromate on p21 and Histone-2AX Expression in HEK293 Cells
Krelin Naidu
Dr. Brian Cummings, Department of Pharmacology & Toxicology, University of Georgia

The epigenetic effects of bromate (BrO3-) exposure in human embryonic kidney 293 (HEK293) cells were investigated. BrO3- is a byproduct of ground water disinfection procedures (oozonation). It has been designated a possible human carcinogen by the International Agency for Research on Cancer. BrO3- treatment (10 – 200 ppm) causes damage to HEK293 cells based on cell death assays and significant increases in specific regulatory proteins (e.g., p53, cdc2) in HEK 293 cells over

72 hours. Additionally, bromate-induced epigenetic changes were assessed by increased expression of phosphorylated histone-2AX (H2AX), a histone correlated with DNA damage that facilitates DNA repair. BrO3- exposure also led to a G2/M cell cycle arrest that correlated to increased expression of tumor suppressor gene, p-p53, and other regulatory genes p-p38, p21, cyclin B1, and p-cdc2. Treatment of cells for 48-hour low concentrations (1 – 100 ppm) showed similar trends in protein expression levels. This suggests that bromate's toxicity may lead to epigenetic alterations. To confirm the epigenetic changes, methylation specific PCR after bisulfite conversion will be conducted to assess the suspected methylation of specific cell cycle regulation proteins such as p21. Preliminary studies demonstrate that bromate treatment of human embryonic kidney 293 cells alters the methylation status of p21 and increases in the phosphorylation of H2AX. These modifications in DNA methylation and histone expression levels support the hypothesis that bromate, at low levels, induces epigenetic changes in both *in vivo* and *in vitro* models of toxicity.

Examination of Resuscitation-Promoting Factors in Potential Fish Pathogens in *Mycobacterium shottsii* and *M. pseudoshottsii*
Johnathon Nolen
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

Defining mechanisms of gene regulation is critical for understanding how pathogenic mycobacteria survive in diverse environments and to identify novel drug targets. For the human pathogen *Mycobacterium tuberculosis*, resuscitation factors are believed to play an important role in primary infections as well as for reactivation of latent infections. The main goal of the project is to identify the inter-species conservation and function of an important resuscitation-promoting factor (Rpf) from recently identified potential fish pathogens *Mycobacterium shottsii* and *Mycobacterium pseudoshottsii*. A significant impediment in mycobacterial research is the slow growth of these microbes *in vitro*, necessitating very long incubations that sometimes take months for appreciable growth. This research investigates whether RpfB proteins accelerate growth *in vitro* and whether Rpf proteins from one *Mycobacterium* species impact the growth of others. As proteins from this class are secreted into culture media, culture filtrates from aged bacterial cultures are tested for growth stimulation of low-density mycobacterial cultures. Recently, RpfB from *M. tuberculosis* H37Rv was over-expressed in *E. coli* strain CH3λDE3 and purified using Ni^{+2}- NTA chromatography. Further tests for growth stimulation are in progress. This research is beneficial in that Rpf proteins could potentially be used as a diagnostic marker for *M. tuberculosis* infection and may be helpful for diagnosing latent infections. Also, use of purified Rpf proteins may help accelerate culture of *M. tuberculosis* in sputum, thereby aiding in more-rapid diagnosis and treatment.

Reining in the Drone Wars: Creating Criteria for the C.I.A. Drone Program in Pakistan
Tony Pelli – Roosevelt at UGA
Dr. Fred Manget, Department of International Affairs, University of Georgia

In 2006, the United States Central Intelligence Agency (C.I.A.) began a covert action campaign, authorized by the President, to eliminate Al Qaeda and Taliban leadership in western Pakistan using armed unmanned aerial vehicles, commonly referred to as drone strikes. The C.I.A. chooses targets and executes the strikes with little oversight from other governmental bodies. This paper analyzes the efficacy and efficiency of the U.S. drone program and the corresponding number of unintended civilian deaths, as well as the change in those numbers since 2006. Examining arguments about the nature of conflict in Pakistan and clandestine action, as well as the aforementioned trends in casualty numbers from counterinsurgency and intelligence experts and legal scholars, this paper determines that the C.I.A. drone program needs greater oversight to be effective. The paper proposes that Congress separate the program's budget from the normal covert action budget, giving Congress greater oversight, and articulates specific criteria for the

targeting of drone strikes, most importantly ensuring that the target list for the strikes is restricted to leaders of Al Qaeda and the Taliban. Finally, this paper proposes a system—roughly following existing guidelines for other covert actions—by which certain, selected members of Congress will be informed of individual drone strikes. These changes will ensure that drone strikes are used sparingly to target only the most high-value targets, reducing Pakistani opposition to American goals in the region. Decreasing Pakistani resistance will enhance U.S. anti-terror strategies in one of the most crucial regions in America's struggle against transnational terrorism. Additionally, proposed changes will allow for greater democratic accountability and oversight of a previously clandestine program.

The Mixed Model of National Power and the Power Parity between the United States and China

Chadwick Peltier
Dr. Brock Tessman, Department of International Affairs, University of Georgia

Power Transition Theory suggests that the likelihood of conflict is greatest when the ratio of the challenging state's capabilities to those of the dominant state's is within 20 percent. Have the United States and China reached this critical range of power parity? In this study I will describe the relative powers of the United States and China as well as the relative power of the Group of Twenty (G20) member states in the year 2001. After assessing the strengths and weaknesses of each historical paradigm for understanding power, I propose a new model, called the Mixed Model of National Power, which is based upon two principles. First, each variable measures a distinct aspect of national power statistically and conceptually. Second, the formula seeks an appropriate tradeoff between accuracy in measurement and parsimony in the number of variables. Because univariate measures fail to capture all of a state's capabilities, six variables—GDP, healthy life expectancy, total population, urban population, total internet users, and environmental sustainability scores—are used that cover elements of hard and soft power, incorporate size and development variables, and balance between economic and military strengths but avoid the use of hundreds of variables. Based upon my results, I conclude that China and the United States have reached the critical point of relative power parity where conflict is most likely, and I explore the reasons and implications of this find to policy makers.

Identifying Human and Avian Influenza Binding Sites in Clam Tissue

Ariella Perry
Dr. Elizabeth Howerth, Department of Pathology, University of Georgia

Clams can remove large quantities of avian influenza virus from water within a small interval of time, leading to total water purification. However, how removal occurs is unknown, nor why clams themselves do not develop signs of infection. The goal of this project was to determine if clams have cell-surface receptors that will bind avian and/or human influenza viruses and could account for water purification. Via lectin immunofluorescence and immunohistochemistry techniques, we evaluated the presence of sialic acids in the alpha-2,6 linkage (human influenza virus receptor) with *Sambucus nigra* and sialic acids in the alpha-2,3 linkage (avian influenza virus receptor) with *Maackia amurensis* I and *Maackia amurensis* II in clam tissue. The results suggest that lectins attached to cillia covering the foot, mantle, and gills of individual Asiatic clams, indicating that removal of avian influenza from contaminated water is through attachment to ciliated surfaces. Verification that avian, but not human, influenza virus attach to these specific surfaces is pending. In the identification and attachment of the avian influenza virus, further understanding can be rendered as to the process of clams' purification of the water. These techniques could be implemented in the future for the purification of avian influenza virus from various media.

The Genetic Alteration of Soybean to Promote the Production of Astaxanthin
Emily Pierce – CURO Summer Research Fellow
Dr. Wayne Parrott, Department of Crop & Soil Sciences, University of Georgia

Carotenoids are pigments that range in color from yellow to red and that provide health benefits and coloration to a variety of organisms. Animals cannot synthesize carotenoids and must obtain them from their diet. Astaxanthin is one of the more important carotenoids and is added to the feed of salmon, shrimp, chickens and layer hens. However, astaxanthin supplements can account for 15 to 25% of the producers' feed costs. Since these animals are fed soy concentrate, the goal of this research is to genetically engineer soybean to produce astaxanthin and thus reduce producers' costs. The genes for astaxanthin production were obtained from two astaxanthin-producing bacteria and a yeast. The first gene (*crtB*) allows soybean to form β-carotene. Then, astaxanthin is produced from β-carotene via the action of genes *crtW* and *crtZ,* or alternatively, via another gene called *crtS*. Both of these alternatives are being tested in soybean. Analysis of the engineered soybean using thin-layer chromatography showed they produce β-carotene but not astaxanthin. Therefore, current work is trying to determine why there is a lack of astaxanthin formation. Results of this research should be economically valuable and may provide insight into metabolic engineering of soybean.

Estimating Detection Rates and Determining Site Occupancy of *Urspelerpes brucei* (the Patch-Nosed Salamander)
Todd Pierson
Dr. John Maerz, Warnell School of Forestry & Natural Resources, University of Georgia

In March 2007, University of Georgia researchers stumbled upon a new species of Plethodontid salamander, *Urspelerpes brucei* (the Patch-Nosed Salamander), in the Appalachian foothills of northern Georgia. While the discovery of the salamander is impressive in itself, very little additional knowledge has been gathered about its life history. So far, this species is known from only a handful of sites, all of which are within a several-mile radius of the type locale. To develop a plan of management for this new species, a better understanding of its life history and range must be gained. However, the presence of *U. brucei* at a given site can often be difficult to determine due to its secretive nature, and a system for determining site occupancy is in need of development. Because this small, cryptic species is often hard to detect, we will use a combination of leaf-litter traps and dip netting to estimate detection rates of *U. brucei* over time in streams that it is known to inhabit. Quantifying and understanding imperfect detection rates of *U. brucei* will allow us to effectively survey new sites for the species and determine occupancy across its potential range. Obtaining a more complete understanding of stream occupancy and range of *U. brucei* is critical in developing a plan of management for its conservation.

Measures of Working Memory: The Relationship Between Performance on the Operation Span Task and the Ocular Motor Delayed Response Task
Rachel Pocock
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Working memory (WM) is an important aspect of daily life and is associated with various measures of academic success, such as reading comprehension and reasoning ability. One standard measure of WM is the operation-span (OSPAN) task, which requires participants to complete a series of math operations while simultaneously remembering a particular sequence of letters. WM also can be evaluated by certain eye movement tasks, specifically an ocular motor delayed response (ODR) task. An ODR task requires that subjects remember the location of a target during a delay period and then move their eyes to the remembered location (i.e., "memory saccade"). Performance can be assessed by 1) evaluating the spatial accuracy of the memory saccade and 2) the frequency of saccades made before the delay period is over

("anticipatory saccades") using a video-based eye tracking system. Performance on the OSPAN task can predict performance on other eye movement tasks, but its relation to ODR is yet to be determined. Data from the OSPAN and ODR tasks will be collected from 40 undergraduate students at the University of Georgia. It is hypothesized that scores on the OSPAN task will be correlated with performance on the ODR task. Specifically, high OSPAN scores (indicating greater WM capacity) will be associated with better performance on the ODR task, as indicated by higher spatial accuracy and fewer anticipatory errors. These results may help researchers determine which tasks to use when assessing WM of participants with and without memory problems and may also explain the differences in results from studies utilizing different measures of WM.

Forbidden Fruit: Reforming the Penalties for the Importation and Distribution of Contaminated Produce

Shayna Pollock – Roosevelt at UGA
Dr. Lewell Gunter, Department of Agricultural & Applied Economics, University of Georgia

From 1993 to 2008, the U.S. saw an increase in the importation of fresh fruit from 10 percent to 32 percent of all domestically consumed produce. The Food and Drug Administration (FDA) and U.S. Customs monitor imports by randomly testing 5 percent of all produce, but they cannot control the pesticides used in other countries. Thus, the safety of imports is unreliable. According to the FDA, six percent of imports contain illegal pesticide residues, but the current system of bonds is ineffective in keeping this produce away from consumers. A 1992 Government Accountability Office report shows that 60 percent of all tainted imported produce reaches grocery stores despite knowledge of contamination. Based on an extrapolation using current import size, approximately 400-480 thousand metric tons of contaminated produce reached Americans in 2006. However, only 17 percent of the companies distributing tainted food paid damages. Thus, current regulations do not deter companies. After a literature review and analysis of current policy failures, this paper proposes that Congress should grant the FDA the ability to implement a system of civil fines. The fine schedule should consist of two sets of fines: one for the importation of a tainted good and a second for the distribution of contaminated produce. This civil fine system will promote self-regulation. While this new regulatory framework will result in potentially higher costs, this paper demonstrates methods for evaluating the significant social health benefits of reduced pesticide exposure. Further, a stricter system will lead to more sustainable international agriculture.

The Impact of Speech Impairment on Head Start Children's Social Emotional Competence

Leah Prestwood, Kiara Jones & Evin Winkelman
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Specific Language Impairment (SLI) is a language disorder that is not related to or caused by other developmental disorders such as hearing loss or acquired brain injury. Pragmatic difficulties that negatively influence effective social interactions have been found to be experienced by children with language impairments. Children with SLI experienced more difficulty in recognizing what emotion a social scenario might elicit in an inference task and pose greater risks for social problems. The current study is thus designed to examine the impact of SLI on young children's social emotional competence. Data from 21 Head Start children (7 girls) with ages ranging from 35 months to 47 months, collected by a larger study, were analyzed in the present study. Among these children nominated by their teachers in displaying a wide range of social emotional issues, nine children's language ability was below average. Teachers were asked to fill out Social Competence Behavioral Evaluations (SCBE) developed by LaFreniere. The results showed children who lack speech ability were more likely to be reported as timid sad/withdrawn ($r = .573$, $p = .016$) and to be rated by teachers using SCBE as isolated ($r = .553$, $p = .026$) and less social ($r = .504$, $p =$

.046). ANOVA results also revealed that speech significantly placed these children at risk of being isolated [$F(1, 18) = 6.83$, $p = .018$], dependent [$F(1, 18) = 7.432$, $p = .014$] and less social [$F(1, 18) = 8.297$, $p = .01$]. Implications and future steps will be addressed at the Symposium.

Humanities in Medicine

Ryan Prior
Dr. Katarzyna Jerzak, Department of Comparative Literature, University of Georgia

In his book, *Hot, Flat, and Crowded*, Thomas Friedman discusses how in traditional South African societies, those with chronic illness who sought treatment from healers were not instructed to take elixirs or remedies but were instead instructed to cook a meal for the entire village. The idea was that patients could help themselves by helping others. These societies realized that chronic illnesses were often the result of problems of the heart and successfully managed them in ways that might confuse the traditional Western medical establishment. Most people today think of medicine in terms of pills, surgery, and needles, but a survey of various civilizations' health traditions reveals highly sophisticated and surprisingly accurate ideas about how the human body works and how it can be treated that range from yogic meditation to herbal tea remedies. Like Western medicine, Chinese Traditional Medicine and Indian Ayurvedic medicine have developed over thousands of years. Practitioners of these systems glean their insights not so much with CAT scans and T-cell counts, however, as they do by examining the color and shape of a patient's tongue. This project began as an intended research paper but gradually evolved into a creative work that melded personal narrative and literary analysis to the initial philosophical questions. Because the quest for healing does not stop with scientific medicine but requires moral and spiritual satisfaction as well it is only through telling our own stories that we can ultimately find the healing we seek.

Castro as a Capitalist: The Role of Foreign Investment in Cuba

Lucas Puente
Dr. Maurits van der Veen, Department of International Affairs, University of Georgia

The collapse of the U.S.S.R. and the subsequent dissolving of its Council for Mutual Economic Assistance led to Cuba's "Special Period," in which investment in the domestic economy and access to foreign exchange disappeared. This forced the Castro regime to reevaluate its development policy and, for the first time, actively seek and promote foreign direct investment (FDI). Nevertheless, Cuba has refrained from providing a laissez-faire marketplace for foreign firms and investors; on the contrary, the Castro regime has been determined to regulate and control this investment as much as possible. As per the existing literature, this strategy is imprudent as FDI has been shown to have had a generally positive influence on several economic and political factors, such as growth, wages, civil liberties, and political empowerment. Given these self-imposed constraints, FDI's ability to engender change is expected to have produced much less impressive results in Cuba. Although I expect to find that this expansion of FDI has been a net positive in terms of promoting economic growth, its capacity to improve domestic human development and expand political freedoms appears to have been hindered. To determine the precise nature of this impact, I am examining sub-national data sets regarding the current nature of foreign investment in Cuba. Regression analysis will also be utilized to better understand the changes resulting from inflows of FDI.

Blood Velocity at Rest and After Ischemia

Rejina Pumachcharige
Dr. Kevin McCully, Department of Kinesiology, University of Georgia

Flow mediated dilation (FMD) is commonly used to measure vascular disease. FMD assumes that the blood velocity profile across the artery is constant. However, blood viscosity and wall "stickiness" can change with vascular disease.

This study will evaluate changes in the velocity profile of the femoral artery in healthy humans before and after a high-fat meal. The high-fat meal is hypothesized to alter the blood velocity profile. IRB approval will be obtained (under review), and healthy subjects (18-35 years old) will be recruited into the study. Eight subjects will rest for 10 minutes prior to resting measurements of the femoral artery velocity and diameter using an ultrasound unit. A cuff will then be placed below the subject's knee and be inflated for five minutes to occlude blood flow. The cuff will then be released and velocity and diameter will be measured during hyperemia. After the baseline measurement, the subjects will eat a high-fat meal consisting of "fast food" containing 1 gram of fat per 1 kilogram of body weight. The ultrasound measurements will be repeated two and three hours after the meal. The hypothesis is that fat in the blood will cause an increase in the standard deviation of instantaneous velocity measurements (the velocity profile).

Imagination and Institution: The Effects of Surrealism and Catholicism on the Work of Oscar Dominguez

Sarah Quinn
Dr. Janice Simon, Department of Art History, University of Georgia

The surrealist art movement emerged during the 1920s. Building on the previous Dada period, this style drew from numerous sources. Contemporary Freudian philosophy's investigation of the dynamic between the conscious and unconscious mind most notably figured in the development of the surrealist aesthetic. The work of the Spanish surrealist artist Oscar Dominguez exhibits these qualities while also proposing a unique intersection of cultural influences. Dominguez worked primarily in Paris, the center of Dadaism and home to the prominent surrealist theorist Andr Breton, but was born and raised in the traditionally Catholic country of Spain. This research aims to investigate the extent of Catholicism's influence on Dominguez's surrealist art through his implementation of symbols, motifs, theoretical references, and formal decisions. Previous research aligns surrealist philosophy and practice with the ancient concept of the sacred and the meditative capacity of mysticism. Catholicism's specific influence on the development of surrealist imagery, however, has yet to be examined in depth. Because of the paradoxical interconnectedness of the Freudian imagination, an idea perpetuated in France, and the institution of religion, supported by Spain, Dominguez's art could potentially serve as a unique visual union of progressive surrealist thought and traditional Catholic belief. A close examination of Breton's *Surrealist Manifesto*, Freud's *Interpretation of Dreams*, 20th century Catholic doctrine, and other relevant texts could provide greater insight into the enigmatic visual representations of surrealist thought.

Development of a Modified System to Create Mutations in *Mycobacterium tuberculosis*

Akanksha Rajeurs – CURO Apprentice, CURO Summer Research Fellow
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

One-third of the world population is infected with *Mycobacterium tuberculosis*. Annually, seven to nine million infected individuals suffer from active tuberculosis disease (TB), resulting in ~two million deaths. The current TB vaccine, *Mycobacterium bovis* BCG, is rarely used in the U.S. because of variable efficacy (0-80%) against pulmonary TB. Attenuating *M. tuberculosis* to produce a more-effective, safe, live vaccine will likely require deletion of multiple virulence factor genes from the chromosome. Current selection systems to delete genes from this bacterium replace the target gene with an antibiotic resistance gene. As a vaccine strain encoding multiple antibiotic resistances may lead to transfer of antibiotic resistance genes to other bacteria, our hypothesis is that we can develop a modified system to 1) replace a chromosomal gene with a gene cassette that will facilitate the study of the resulting mutants and 2) utilize a feature of the cassette to select for mutants that have deleted the cassette from the chromosome. This is a multi-step process to generate a pair of plasmids with

specific features. To develop these plasmids, multiple DNA cloning steps and PCR amplifications were performed. After each cloning step, plasmid DNAs were isolated and screened by restriction analysis. DNA sequencing was used for confirmation. Efforts are in progress to modify the plasmids to target a natural antibiotic resistance gene in *M. tuberculosis* and *M. bovis* BCG. Deletion of this gene will result in bacteria that can be killed by the antibiotic.

Epidemiology of *Salmonella enterica* Typhimurium in Songbirds in the Southeastern United States

Al W. Ray III – CURO Apprentice, CURO Summer Research Fellow
Dr. Susan Sanchez, Department of Infectious Diseases, University of Georgia

Salmonella enterica serovar Typhimurium outbreaks of unknown origin have plagued passerines, more commonly known as songbirds, for years, causing significant mortality in the wild. The illness is marked by enteritis with esophageal lesions, generally a clinical presentation not seen in other avian groups, including psittacines or gallinaceous birds—chickens and turkeys. These outbreaks have a devastating ecological impact on bird populations and might prove a significant threat to public health. These epizootic outbreaks are seasonal, occurring most frequently in winter and early spring. We do not know how *Salmonella* Typhimurium is transmitted in the wild bird population, the environmental reservoir, or factors responsible for these wild bird die-offs. During 2009, we observed a significant epizootic outbreak of *S.* Typhimurium in songbirds, especially in Pine Siskins. By Pulsed-Field Gel Electrophoresis (PFGE), we identified the same *S.* Typhimurium strain isolated from Pine Siskins and other passerines in multiple Southeastern states including Georgia, Tennessee, and North Carolina. In a retrospective comparison of this *S.* Typhimurium strain to an archival collection of *S.* Typhimurium from multiple animal sources, we found PFGE matches with songbird isolates from as far back as 1996. This strain appeared to be unrelated to *S.* Typhimurium strains isolated from other avian species, most notably psittacines and gallinaceous birds, and cattle.

Primary Transmission of *Salmonella* Contamination in Poultry Meat

Nick Regenold, E. N. Foxhall III, S. Frimpong, O. Grey, M. Kallaoun, J. Mansour & N. Wang
Dr. John Maurer, Department of Microbiology, University of Georgia

Salmonella is the leading cause of human food borne illnesses in the United States. Poultry has been implicated through multiple epidemiological studies as the major source of *Salmonella* outbreaks. In the United States, individual poultry companies control production from the parent flocks to their progeny to the slaughterhouse. *Salmonella* can be transmitted horizontally or vertically. Horizontal transmission occurs when the bird acquires *Salmonella* through direct interactions with its environment at any stage in poultry production. Vertical transmission occurs when *Salmonella* is passed from an infected parent to its progeny. We hypothesized that *Salmonella* contamination of chicken carcasses is due mainly to the vertical transmission of *Salmonella* from the primary parent flocks. *Salmonella* isolates were collected from poultry farms, contracted with two different companies, to identify the source of chicken carcass contamination within this poultry production system. Pulsed-Field Gel Electrophoreses (PFGE) are being performed to compare DNA fingerprints of specific *Salmonella* isolates from parent flocks and progeny to determine the type of transmission involved in carcass contamination. A total of 7630 samples were collected, from which 1642 were *Salmonella* positive. Statistical analyses indicate a strong role of vertical transmission in *Salmonella* dissemination within the companies. Quantification will be possible when PFGE profiles are available for all samples. After evaluation of our results, we can determine where to implement intervention strategies to limit *Salmonella* transmission. Further analyses can be done with the PFGE fingerprint databases at the Centers for Disease Control and Prevention (CDC) to determine the link between

poultry contamination with *Salmonella* and human disease.

Spiritual Life: Self-Transformation in the Ancient and Modern World
Joe Reynolds – CURO Scholar, CURO Summer Research Fellow
Dr. Frank Harrison, Department of Philosophy, University of Georgia

With the human population continuing to expand, a global society is on the horizon, if it is not already here. Global peace is a genuine concern, and religious fundamentalists and extremists threaten it in the name of their beliefs. The question then becomes—how can a global society exist and maintain peace when it contains religions with disruptive beliefs? This research intends to focus on one major religion, Christianity, and will explore writings of influential leaders in the Church to determine if the actions of fundamentalists are justified. First, it will discuss the rise of fundamentalism in modern Christianity. Then, it will discuss the position of Christianity in history, and especially how it was preceded and shaped by the Platonic tradition. Following this, it will look at the work of Pierre Hadot, a modern philosopher who claims the Platonic and Christian tradition are united in their spiritual exercises. Spirituality, from Hadot's point of view, is focused on the transformation of the entire human being, including her desire, intentions, and outlook on life. Finally, the research will determine if this viewpoint is justified by looking at the role of sin in separating us from God and how God transcends any symbol or conception. The research will emphasize the need for a re-evaluation of the role of spirituality in modern society, not as a set of beliefs but as a process of maintaining the human spirit. This is especially relevant given the mental health issues that currently plague our youth.

Respiratory Syncytial Virus G Protein Heparin-Binding Domain Interaction with Cell Surface Glycosaminoglycans Facilitate CX3C Chemokine Receptor Mimicry
Joseph Rimando
Dr. Ralph Tripp, Department of Infectious Diseases, University of Georgia

Respiratory syncytial virus (RSV) is a primary cause of severe lower respiratory illness in infants and children worldwide, also causing substantial disease in the elderly and immune-compromised populations. Previous research has shown that the RSV attachment (G) protein interacts with the CX3C chemokine receptor (CX3CR1) during the infection process to modify anti-viral immunity linked to the activities of fractalkine (CX3CL1), the natural ligand of CX3CR1. Evidence suggests that the G protein-CX3CR1 interaction is mediated in part by heparin-binding domains (HBD) on the G protein with glycosaminoglycans (GAG) on the host cell membrane. In this study, we investigate the role that several important members of the GAG family have in facilitating G protein binding to CX3CR1. The studies examine HBD-GAG interaction using flow cytometry to measure the level of G protein binding to CX3CR1 expressed on both wild type Chinese hamster ovary (CHO) cell lines and on multiple mutant CHO cell lines lacking certain GAGs. The preliminary results suggest that higher levels of RSV G protein bind to CX3CR1 expressed on wild type CHO cells than to CX3CR1 expressed on the mutant CHO cells. These preliminary results suggest that the G protein-CX3CR1 interaction is dependent on HBD-GAG association and that several GAG family members may be more important than others in facilitating the G protein-CX3CR1 interaction. Evidence from previous studies suggests that prevention of the RSV G protein-CX3CR1 interaction reduces RSV replication, and thus these GAG domains can be targeted as a novel disease intervention strategy to mitigate RSV disease pathogenesis.

Biogeography of *Triatoma sanguisuga* on two Barrier Islands off the Coast of Georgia, USA
Ashley Roden
Dr. Brian Forschler, Department of Entomology, University of Georgia

Triatoma sanguisuga is a known vector of *Trypanosoma cruzi*, the causal agent of Chagas' disease. Thirty-three *T. sanguisuga* adults and nymphs were collected at five sites on Cumberland Island and two sites on Sapelo Island in June and July 2009. The full length (699 base pairs) of the cytochrome oxidase II mitochondrial gene was sequenced for each specimen. Twelve unique haplotypes were identified, nine from Cumberland Island and three from Sapelo Island. Neighbor-joining and maximum parsimony analyses were used to establish phylogenetic relationships among the haplotypes. The analyses provided similar phylogenetic topologies with no distinct clades devoted to haplotypes from a single island. Nested clade analysis was also used to determine the haplotype network structure. Two haplotype networks were defined, and one contained only specimens found on Cumberland Island. The other network was a composite of specimens from both islands, with the ancestral haplotype from Sapelo Island. This pilot study is the first to illuminate relationships of *Triatoma* populations in the southeastern United States using the cytochrome oxidase II mitochondrial gene, while hinting at a cryptic species along the Georgia Coast.

The Importance of Peer Approval in the Sartorial Purchasing Patterns of University of Georgia Students
Mallory Roman
Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, University of Georgia

There is ample evidence that peer approval and group acceptance play a role in many social phenomena. This influence can manifest itself through the bystander effect, peer pressure, social facilitation, and in many other ways. However, dress as a means of social influence has been largely ignored. This study was designed to determine whether peer approval and group acceptance influence the sartorial purchases of college students and their participation in popular apparel trends on campus. The hypothesis, derived from Social Comparison theory and Social Impact theory, was that students' sartorial purchasing habits are considerably influenced by peers. To test this hypothesis, a survey was developed around 14 brand-name apparel items popular at UGA that solicited student response on the significance of peer approval in personal decision-making, perceptions of peers' purchasing motivations, personal feelings about peer approval, and personal involvement in popular trends. Results were analyzed using frequency statistics and categorization of responses. The majority of the respondents (85.96%) owned at least one item, and all respondents were aware of the popularity of the 14 items. In general, students were more likely to rate the behavior of others as more conforming than their own, which suggested that participation in the popular sartorial trends on campus is viewed as being driven by conformity. These results may hold significance for retailers in college towns making retail-buying decisions and serve as further evidence that peer approval can act as motivation for conforming behavior.

Writing in Conversation with the Traditional Narratives of Journey
Jane Rowden
Prof. Reginald McKnight, Department of English, University of Georgia

My research this semester focuses on the tradition of telling the story of one's travels and the significance that the journey holds for the traveler. My objective is to write my own creative work in a conversation with the existing literary canon. I am reading narratives of travel, from the *Epic of Gilgamesh* to Jack Kerouac's classic road novel, *On the Road*, with the research questions "What common themes and tropes are used in traditional narratives of journey, and how should I utilize them in my own work?" and "What are the common authorial voices in these traditional works, and how can I contribute to this literary

conversation?" I anticipate that each of these narratives will focus on the growth and change of the hero, and I intend to write a short story in which the hero's experiences impact his or her perspective toward the home. In my presentation, I will outline some of the common tropes (e.g., the road, the vehicle, obstacles) and explain their presentation in a few select pieces. I will address these questions in my presentation in addition to reading an excerpt from my piece.

Human Resistance to Infection by African Trypanosomes

Carla Rutherford
Dr. Stephen Hajduk, Department of Biochemistry & Molecular Biology, University of Georgia

Trypanosoma brucei brucei is a eukaryotic parasite that infects cattle and other mammals but is unable to infect humans due to the cytotoxic activity of a minor subclass of serum high-density lipoprotein called Trypanosome Lytic Factor (TLF). The mechanism of *T.b. brucei* killing by TLF is poorly understood. The cellular morphology of human serum or TLF-treated trypanosomes suggests two distinct phenotypes associated with cell death. To elucidate the mechanism of trypanosome killing by TLF, we undertook an analysis of the morphological changes associated with TLF treatment. Morphological changes associated with serum killing were examined using fixed cell imaging and time-lapse microscopy of live cells. Trypanosomes treated with freshly collected, high specific activity, human serum change rapidly in morphology, becoming "kite-shaped" prior to lysis. Treatment with serum having low killing activity, produced by prolonged storage or incubation at 62°C, resulted in the gradual formation of a large cytoplasmic vacuole and a delay in trypanosome killing (~16hrs). Immunofluorescence microscopy of cells treated with low activity serum suggests the vacuole is formed within endosomes and not lysosomes as previously reported. These studies support the hypothesis that TLF killing of trypanosomes involves the activity of multiple proteins and that one of these proteins may be selectively inactivated by heat treatment or storage, resulting in the distinct morphologies observed. Analysis of the morphological phenotypes of killing of the individual protein components of TLF may lead to a better understanding of the mechanisms underlying trypanosome killing by human serum.

The Biggest Loser: Restoring Self-Control After Rejection

Raha Sabet
Dr. Michelle vanDellen, Department of Psychology, University of Georgia

Previous research has indicated that social rejection leads to decreased self-control. Past research also suggests that after rejection, people become motivated to restore social connections. The hypothesis of this study was that motivation for social reconnection leads to increased performance on self-control tasks after rejection, if people think the tasks provide a chance to demonstrate social competence. We recruited participants from an undergraduate subject pool. When participants arrived, they were asked to complete a personality inventory. After completion, an experimenter supposedly scored the inventory. Participants then received accurate information about their level of extraversion. The experimenter also falsely informed participants that they would either live alone and have few social relationships or be unhappy in their future career. After receiving feedback, participants completed a self-control task that was either diagnostic or not diagnostic of social skills. The task they completed was the Stroop test, which is a color-reading test where individuals read the color ink in which words are written instead of the actual words. The printed words are color words whose semantic meaning distract from the ink color and make the test difficult. Finally, all participants were debriefed. Our findings supported our hypothesis. Among the rejected participants who believed the Stroop test diagnosed social skills, we found increased self-control and reduced negative affect. The findings have implications for understanding how we can help people cope with social rejection. Connecting social values to tasks that

may involve self-control may improve motivation and decrease self-control failure.

The Ties That Bind: How the Notion of Strategic Culture and Technological Advances Affect China and U.S. Perception
Aaron Sayama – Roosevelt at UGA
Dr. Seema Gahlaut, Center for International Trade & Security, University of Georgia

Strategy is the pervasive element within a nation's decisions; it is the motivating factor from domestic to foreign policy. One nation that takes the notion of strategy to the extreme is the People's Republic of China (PRC). For scholars and laymen, the PRC represents the ultimate enigma with regards to foreign policy and military doctrine—distilling some type of strategy remains elusive to policymakers. Yet, the world is beginning to notice the PRC's increase in investment in its military, and governments have started looking into possible reasons and outcomes for this seemingly sudden shift in Chinese military policy. Connecting political moves of other nations to broad strategic theory is one way scholars and policymakers address and identify problems in American foreign policy. My research attempts to connect defense acquisitions made by the PRC to strategic theory in an effort to improve American foreign policy regarding the PRC. Through a systematic exploration of the PRC's technology industry, paying special attention to their high-tech defense technology acquisitions, I attempt to present the explicit links between technology, security, and prestige in the PRC. I subsequently identify three major areas in which the PRC is competing with the U.S. Furthermore, I provide an analysis of their motivating factors and how current events fit under the PRC's strategic culture and discuss their political ramifications on global security.

Second Chances: Establishing an Administrative Expungement Procedure
John Seewoester – Roosevelt at UGA
Prof. Ed Risler, School of Social Work, University of Georgia

A Georgia Department of Corrections survey found that 36 percent of prisoners released from Georgia prisons in 2000 had reoffended within three years of their release. An analysis of relevant research suggests former criminals have difficulty obtaining gainful employment, accessing valuable state and federal welfare programs, and exercising their civil rights. In concert, these negative effects make it difficult for former criminals to reintegrate into society. Successful reintegration into society is critical to reducing former offenders' propensity to reoffend. This paper examines Georgia's current programs that encourage or facilitate reintegration and finds that the few programs that exist are insufficient because they lack clarity, simplicity, and ease of access. To address this insufficiency, this paper proposes that the Georgia State Legislature enacts an administrative expungement procedure that allows individuals convicted of certain crimes to clear their record if they complete a set of requirements designed to ensure rehabilitation. This paper examines the research supporting each of the proposed requirements and includes analysis of expected benefits and possible challenges associated with such a program.

The Significance of Spiritual Experience in Robert Penn Warren's Poetry
Matthew Sellers – CURO Summer Research Fellow, Roosevelt at UGA
Dr. Hugh Ruppersburg, Department of English, University of Georgia

Robert Penn Warren embarks on a spiritual journey beginning with his early poems and running through his later work, raising questions about the nature of transcendence, humanity's relationship with the natural world, and the impact personal, individual history (as opposed to a collective national identity) has on the individual. His journey culminates in *Altitudes and Extensions: Poems 1980-1984*, his crowning spiritual achievement. Though no critic has failed to note the spiritual side of Warren's work, few have treated the vacillation between the breathless anticipation of transcendental self-realization of poems like "Delusion—No!" and despondent crises of spiritual identity as in

"Covered Bridge," a defining characteristic of his last collection. This investigation probes the nuances of Warren's indecisive conclusions on the nature of spirituality and its relation to personal history and identity. Ultimately, the poet balances humanity's craving for spiritual fulfillment and surety against the weighty guilt of memory and conscience, the guilt "of forgetting the crime." An intense, incisive reading of his work illustrates that, in poetry, Warren recognizes his hopes and dreams alongside his failures and despairs; he grounds his outlook in human history, human intelligence, and human experience rather than divine beings or dogma. The iterative return to faith from its utter rejection marks the path by which Warren finds understanding. More importantly, doubt represents one of the ways Warren realizes identity. By considering the weight of past experiences and spiritual isolation, Warren suggests the necessity of spiritual transcendence to a meaningful quest for self-actualization.

Here and Queer: Creating Equal Protection for LGBTQ Students in Georgia Public High Schools

Matthew Sellers – CURO Summer Research Fellow, Roosevelt at UGA
Dr. Robert Hill, Department of Lifelong Education, Administration & Policy, University of Georgia

Lesbian, gay, bisexual, transgender, and queer (LGBTQ) students face harassment and bullying on a daily basis. A study by the Gay, Lesbian, and Straight Education Network (GLSEN) found that 86.2 percent of LGBTQ students reported harassment in the past year. Using a review of the literature and policy statements, the current project investigates the extent to which LGBTQ students are affected by harassment and assesses methods to mitigate its negative effects. According to survey data collected by the GLSEN, students who report harassment and violence based on sexuality or gender identity experience decreased educational and psychological outcomes, including lower GPAs, increased absenteeism and attrition, diminished post-secondary aspirations, and heightened risk of drug abuse and suicide. Moreover, these students later grapple with depression and insecurity in their adult lives. Faculty and staff play a significant role in the perpetuation of this harassment as they often ignore instances of harassment and bullying that merit intervention. The paper proposes the creation of a task force aimed at educating faculty and staff state-wide to increase efficacy in palliating the negative effects of harassment and bullying, including absenteeism; schools with supportive faculty who regularly intervene demonstrate half as much absenteeism as schools without supportive faculty. In addition to educating school employees, the policy suggests adapting anti-harassment and anti-discrimination policies to include sexuality and gender identity specifically since comprehensive policies successfully lower mean victimization scores by 12.5 percent. The paper finally explores the benefits of such a policy based on the correlation between lowered discrimination, harassment, bullying, and victimization and improved educational and psychological outcomes for LGBTQ students.

Dialectic in Late Plato

Michael Slade – CURO Scholar, CURO Summer Research Fellow
Dr. Frank Harrison, Department of Philosophy, University of Georgia

Questions of unity and plurality dominate Plato's late works. Nowhere is this more prevalent than his literary trilogy, *Theaetetus*, *Sophist*, and *Statesman*. Famous for its procedural asides, ethical digressions, and metaphysical flourishes, the trilogy engages an unrivaled spectrum of topics. But what is it that unifies the incredible variation in this particular group of writings? Upon a careful reading of certain key passages in *The Republic* and the beginning of *Theaetetus*, it becomes evident that Plato intended the trilogy to serve as an introduction to the dialectical science. When this idea is grasped, the once seemingly haphazard construction of the dialogues begins to neatly fall into a structured discourse on dialectical praxis and method. A demonstration is offered of both the "upward" and "downward" paths of philosophical process, complete with a running

commentary on the proper logical procedure for arriving at sound conclusions. The views propounded in the trilogy do not, as so many scholars believe, refute Plato's earlier philosophical orientation. Instead, we see in Plato's late technical works a consummation of his middle period metaphysics, offered with subtlety and sophistication.

The Philosopher's Progress: Eros, Dialectic, and Reality in Plato
Michael Slade – CURO Scholar, CURO Summer Research Fellow
Dr. Frank Harrison, Department of Philosophy, University of Georgia

The goal of my Honors thesis is to integrate previous Platonic research in CURO courses with a deeper understanding of the metaphysical reality in which Plato perceives the human being and, in particular, the philosopher operating. The dialectical and erotic approaches to the highest reality (be it the Good, the Beautiful, the One, etc.) seem, however, to often be at odds with one another. Given the association of these two concepts with the very nature of the philosopher and their proximity to some of the most important passages within the Platonic corpus, their seeming inconsistency is troubling indeed. The discovery of this incongruity has spurred me in two, opposite directions in regards to Plato's writing. On the one hand, I am driven back to the old, Socratic questions: What is virtue and, more specifically, what is human virtue? Further, how is individual practice of virtue connected to and influenced by the political practice of virtue? On the other hand, I find myself reaching upward toward the newer, Academic issues: What are the fundamental constituents of reality? What role do the Forms play (if any)? And, finally, how do these highest metaphysical realities affect the human being as such? While the two sets questions initially appear quite distant from each other, upon reflection it becomes evident that the answers to both sets together form the "playing field" within which human affairs are conducted and the twin processes of dialectic and Eros function. The characterization of this space of activity and the reconciliation of it with the philosopher's mode of existence is the primary goal of my thesis work.

Awareness of Borderline Personality Disorder in a University Population
Laura Smart
Dr. Rich Suplita, Department of Psychology, University of Georgia

Borderline personality disorder (BPD) is a psychiatric diagnosis that features instability of affect, identity, and relationships. It is estimated that 1-2% of the population has BPD. People with BPD often harm themselves and/or complete suicide. Despite the deleterious effects the disorder has on individuals, very few people are aware of its symptoms, and no empirical studies have examined public awareness of the disorder. The current study sought to test the hypothesis that undergraduates would not be able to identify the symptoms of BPD in vignettes describing persons with mental illnesses. Participants were recruited from the research pool and presented with several vignettes, each describing a person with a different psychiatric disorder, and asked to indicate what diagnosis (if any) they would give the person described. Results showed that none of the participants surveyed was able to identify symptoms of BPD, whereas a majority of the participants were able to identify schizophrenia, bipolar disorder, depression, an eating disorder, and substance abuse. These data indicate that BPD is a less known and therefore less understood disorder among the general population. Because previous research indicates that awareness and education decrease stigma of mental illness, interventions are needed to educate the public on BPD.

The Long Road to Zero: U.S. Declaratory Policy and Nonproliferation
Patrick Smith – Roosevelt at UGA
Dr. Dmitriy Nikonov, Center for International Trade & Security, University of Georgia

Early in his term, President Obama made the elimination of all nuclear weapons worldwide a goal of his administration in a major speech in Prague. Rogue state nuclearization, the constant

specter of accidental launch, and the declining legitimacy of the Nuclear Non-Proliferation Treaty (NPT) make this issue of capital importance. Moreover, the upcoming 2009 Nuclear Posture Review and 2010 NPT review conference afford the President and other leaders the opportunity to fundamentally address this issue. If the United States is serious about averting a "nuclear tipping point," Obama must follow through on his promise to reduce the role of nuclear weapons in our national security strategy. This paper proposes that the United States pursue a critical confidence-building measure that shifts our declaratory policy to one stating that the sole purpose of nuclear weapons is to deter a nuclear attack on the U.S., its forces, and its allies. While there is some support in the international community for this policy change, few realize the extent to which this move would aid nonproliferation goals. An in-depth review of the current literature reveals a strong need for a change in U.S. nuclear weapons policy and indicates that a "no first use" policy will be beneficial. Jump starting the process of delegitimizing nuclear weapons will help strengthen the NPT regime, reduce incentives for nuclear proliferation, and foster greater international cooperation on solving this transnational problem.

Promoting Sharing of OSINT Analysis Between Expert Institutions and the Intelligence Community

Irena Stevens – Roosevelt at UGA
Dr. Loch Johnson, Department of International Affairs, University of Georgia

As technology and general education continue to improve, open source intelligence (OSINT) is the fastest spreading, but most underutilized, form of information by intelligence operatives. The collection and processing of OSINT will become an insurmountable problem for the intelligence community (IC) without a venue for accessing the expertise of the academic, corporate, and research institutions on a need or demand basis. Since most of the information available to the analyst dealing with foreign events is open source, further development of an effective method of analysis can dramatically improve the framework of fragmented intelligence by filling in gaps and creating links. Effective analysis of OSINT can move the IC toward a greater understanding of other parties, especially in individual motivations and in cultural knowledge. This framework provides a more complete database to be supplemented by other forms of intelligence, such as those collected by clandestine or satellite methods. Since the internet is the main source of the expanding supply of information, it should also be used to organize and funnel ideas between outside parties and the intelligence community through a database of personnel and relevant research. The willingness to process and share information is rewarded with a system of incentives designed to benefit the analyst through recognition, monetary, professional, intellectual, and psychological rewards. By establishing a database of expert personnel and enabling them to share ideas, the intelligence community and research institutions can gain mutual benefit in processing open source information.

Effects of Weighing Protocol on Corticosterone Concentrations in Leghorn Chickens

Claire Stice
Dr. Kristen Navara, Department of Poultry Science, University of Georgia

In the poultry industry, weighing protocols often involve carrying and weighing the birds by the feet or the wings. There has been very little research studying how such handling techniques can affect their stress levels. The purpose of our study was to determine which weighing methods caused the most significant stress response. We hypothesized that coddling would provoke a smaller physiological stress response compared to birds that are handled in a less gentle manner such as by the wings or feet. We tested this hypothesis in two stages. For the first, we tested whether handling by the feet for 5min provoked a larger physiological stress response than coddling for the same period of time. For stage two, we weighed birds using one of three weighing protocols using similar durations to those in industry: handling by feet, handling by

wings, and weighing upright using a new weighing apparatus. Corticosterone levels, the primary stress hormone in birds, were measured 1h after handling using a radioimmunoassay. During stage one, birds inverted during handling produced significantly more corticosterone compared to coddled birds. During stage two, although we expected birds coddled and weighed without any physical restraint to have the lowest level of corticosterone, we saw no significant difference between any of the handling groups, perhaps due to the short handling duration used during the second stage. The findings from this experiment can be applied directly to industry as well as offer new questions for research and understanding the domestic chicken's response to stress.

Best Practices in Graduated Driver's Licensing

Theodore Story – CURO Apprentice
Dr. Don Bower, Department of Child & Family Development, University of Georgia

Automobile crashes are the leading cause of teen morbidity and mortality in the U.S. In recent years, increasing numbers of states have implemented legislation referred to as Graduated Driver's Licensing (GDL) as one approach to address this problem. Although GDL policies have been refined over time, remaining differences in the regulations among states (and even among countries) provide a rich research opportunity for recommending promising practice in this policy arena. This study attempts to answer this question of which current and proposed GDL practices seem to be most effective, with effectiveness being measured as effecting lower teen crash rates. The researchers will conduct a qualitative assessment of recent empirical research, trend analyses, government agency reports, and literature reviews for consistent and predominant themes. These themes will then be compared to current driver's licensing policies in Georgia to identify areas of potential improvement. Variables such as age at licensure, length of learning periods, cost of licensing, passenger and night-driving restrictions, testing procedures, and sanctions for violations are predicted to correlate with the effectiveness of practices. Existing literature that assesses the effectiveness of these practices is being reviewed and analyzed to create a compendium of research-based policy recommendations. Interstate as well as international GDL comparisons will be conducted and summarized. The product of this review will be a summary of best practice recommendations for consideration by Georgia legislators and agency administrators.

Novel Synergistic Inhibitors of Methicillin-Resistant *Staphylococcus aureus* (MRSA)

John Taliaferro
Dr. Timothy Long, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Haloenol Lactones (HEL) are a known family of 5- or 6-membered compounds that have proven to act as suicide inhibitors of serine proteases, much like human neutrophil elastase (HNE), chymotrypsin, and trypsin. Knowing HEL's targets for inhibition, it is thought that it could also cause inhibition of the serine protease β-lactamase. β-lactamases are enzymes produced by bacteria that cleave the β-lactam rings of β-lactam antibiotics. MRSA, a known strain of *Staphylococcus aureus* resistant to broad-spectrum antibiotics, produces high levels of β-lactamase, allowing it to resist antibiotics like β-lactams. For HEL to achieve inhibition of the β-lactamase, it allows the lactone to be hydrolyzed by the target protease enzyme. This hydrolysis reveals the reactivity of the molecule by exposing the electrophilic species of the HEL for the alkylation of the enzyme. The hydrolysis causes an acyl transfer to the active site hydroxyl group which releases an α-haloketone electrophilic moiety that alkylates the accessible nucleophilic residues at the active site. To test for inhibition of β-lactamase, multiple analogs of HEL were created using essential amino acids and alkylation of the free amine on each amino acid with propargyl bromide. From there, the lactone was formed by halolactonization. These analogs were placed at several different concentrations with a specific concentration of penicillin G and MRSA. One of the analogs showed zones of growth inhibition of the

MRSA, which grew larger as the concentration of the HEL increased. These increasing zones of inhibition showed that HEL has possible β-lactamase inhibition capabilities, and further analogs need to be created in order to test possible theories to why synergistic activity is observed.

DNA Methylation Related to Cancer
Yu Taniguchi – CURO Scholar
Dr. Shaying Zhao, Department of Biochemistry & Molecular Biology, University of Georgia

Xiao (~30kb) and Da (~280kb), meaning small and big, respectively, in Chinese, are regions found in the human genome. Since there has been no recombination between Xiao/Da sequences, we believed these regions are condensed, thereby preventing genomic rearrangement. Condensation of chromatin is usually directed by DNA methylation. Therefore, we believe that DNA methylation plays a key role in regulating these elements and preserving genome in these regions. To elucidate the key mechanism of heterochromatin formation in Xiao/Da and its effect, we have studied differences between methylated and unmethylated sequences by using Methylation-specific polymerase chain reaction (MSP). MSP allows us to differentiate methylated from unmethylated cytosine by using sodium bisulfite treatment of DNA that keeps the marks of methylated cytosines together with the specific amplification of this modified DNA utilizing primer sets that are only complimentary to the formerly methylated or unmethylated alleles. In order to perform MSP, I modified a wild type sequence of Xiao/Da into methylated and unmethylated sequences; designed wild-type, methylated, and unmethylated primers with UCSC genome browser and Primer 3 website; tested these primers with Bisulfite modified DNA in PCR; and ran agarose gel for a detection. We have expected to obtain results that show a strong methylation band and a weak unmethylated band. This may indicate that DNA methylation occurs in Xiao/Da regions and prove our hypothesis that DNA methylation causes condensation. DNA methylation would eventually contribute to preserving the human genome by avoiding any recombination between Xiao/Da sequences.

Breaking the Rules: A Qualitative Study of Academic Dishonesty at the University of Georgia
Michael Thomas – CURO Scholar
Dr. Mark Cooney, Department of Sociology, University of Georgia

Academic dishonesty is a frequently practiced behavior amongst students at the University of Georgia. Not to be confused with "cheating," a more vague term, academic dishonesty refers to any violation of a university honesty policy. Most academic dishonesty research predominately consists of extensive quantitative data gathered from a large number of universities. However, the literature lacks detailed accounts of the conditions preceding, during, and resulting from acts of academic dishonesty. By conducting extensive qualitative interviews with 17 University of Georgia Honors Program students and constructing a detailed database of their responses, my purpose was to discover what circumstances result in incidents of academic dishonesty, what sanctions are imposed on students found in violation of the University of Georgia academic honesty policy, and what preventive measures can be introduced to limit the frequency of academic dishonesty. Data revealed that despite the University's firm stance against violations of the academic honesty policy, students were exposed to numerous situations where acts of academic dishonesty could be easily commissioned. Interestingly, among the few students whom faculty detected for violations of the academic honesty policy, the vast majority were not reported to the University of Georgia administration but instead received informal sanctions. Though limited by a small sample size, these initial findings suggest that while still holding students accountable for academic honesty policy violations, faculty and administrators could introduce several simple strategies that would likely reduce the amount of academic dishonesty at the University of Georgia.

Application of Protein Interface Footprinting via Hydroxyl Radical Oxidation to Endopolygalacturonase II

Stephen Thompson
Dr. Robert Woods, Complex Carbohydrate Research Center, University of Georgia

Aspergillus niger is a fungus, commonly known as black mold, that secretes an enzyme, endopolygalacturonase II (PGII), that degrades the smooth regions of pectin in the cell walls of plants. PGII binds to the substrate polygalacturonic acid (PGA), a major substituent of pectin, and cleaves the internal bonds of homogalacturonan, which allows for the fragmentation and solubilization of pectin. To fully understand the function of PGII and the nature of its interaction with PGA, the location and function of the protein's active/binding site must be determined. Biomolecular surface mapping via hydroxyl radical footprinting offers an accurate method for the characterization of this interaction. Hydroxyl radicals, generated by nanosecond laser-induced photochemical dissociation of hydrogen peroxide, oxidize amino acid residues located on the protein surface to produce stable covalent modifications. When the ligand, PGA, is present on PGII, oxidation will occur on the amino acids not attached to the ligand. After protealitic digestion of the oxidized PGII via V8 protease, FT-LTQ mass spectrometry and ByOnic analysis software will be used to identify the non-oxidized fragments, which represent the active site of the protein. Comparison with solvent accessible surface area data will allow for the accurate development of a 3D structure for PGII, particularly the structure of its active site.

NCAMP-1: A Novel Host Danger Molecule in Catfish

Emilia Tuck
Dr. Liliana Jaso-Friendmann, Department of Infectious Diseases, University of Georgia

Host danger molecules are intracellular molecules that initiate inflammation when released into extracellular milieu upon tissue damage following trauma or infection. The innate immune response that ensues from the binding of these molecules to pattern recognition receptors (PRR) results in an increase in pro-inflammatory cytokine secretion and an increase in antigen presentation to adaptive immune cells. Danger molecules from microbial sources (e.g., LPS) and the mechanisms by which they induce inflammation are well understood, but less is known about their endogenous counterparts. Recent data from our laboratory have shown that a histone H1x-like protein, NCAMP-1, is released into serum of stressed animals and may induce activation of innate immunity in fish. Based on these findings, we hypothesize that NCAMP-1 may act as a host danger molecule. The objectives of this study are to assess changes in pro-inflammatory cytokine TNF alpha, IL-1 beta, and gamma interferon gene expression in catfish immune cells by quantitative polymerase chain reaction (qPCR). A time-dependent response in transcriptional activation of the genes of interest is measured following treatment of purified cells with recombinant NCAMP-1. The results demonstrate an increase in IL-1 beta message expression at 3 and 6 hours post-treatment. This information will provide knowledge about mechanisms by which the immune system may use self molecules to sense danger and produce inflammatory responses. Beyond the practical applications in the design of aquaculture vaccines, this work could also answer fundamental questions about chronic inflammation and autoimmune diseases in other species.

Glutamate Dehydrogenase and Its Role in *Helicobacter pylori*

Soumya Vaish
Dr. Robert Maier, Department of Microbiology, University of Georgia

The function of the enzyme glutamate dehydrogenase (GDH-ase), encoded by the gene gdhA, has not been studied in *Helicobacter pylori* bacteria. In *E. coli*, this enzyme catalyzes the formation of glutamate from α-ketoglutarate and thus assimilates nitrogen in the form of ammonia. Urease, another enzyme in *H. pylori*, forms ammonia from urea. We hypothesize that without the presence of GDH-ase, urease

activity may be decreased. As glutamate would not be produced, mutants may require a glutamate supplement to survive. Also, additional stress may cause lower growth rates and greater sensitivity to acidic pH. The wild-type strain, *H. pylori* 43504, and a constructed mutant strain lacking gdhA were both subjected to different growth conditions, including glutamate-supplemented blood agar media, Brain-Heart Infusion (BHI) media, and different levels of pH. Urease enzyme activity was also measured in both strains of bacteria. Our results did not support our hypothesis, as the growth rate, acid sensitivity, and urease activity of the mutant strain did not show any significant deviation from the wild-type strain. The construct was also able to grow on blood agar plates without supplemental glutamate. The survival of the mutant strain on blood agar suggests that there may be another pathway responsible for the synthesis of glutamate. This research broadens our knowledge of this common pathogen by drawing conclusions about the basic metabolic processes in *H. pylori*. Future experiments may involve comparing the two pathways of glutamate synthesis or conducting an assay measuring glutamate dehydrogenase specific activity.

Brain Activity Analysis of Good and Poor Performers During Inhibitory Eye Movements

Manouela Valtcheva – CURO Scholar
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Previous studies of eye movement performance in people with schizophrenia show that they make more errors than control subjects during tasks that require inhibition. One such task is the antisaccade task, which requires the subject to inhibit looking at a peripheral target and, instead, to generate a saccade (quick eye movement) to the mirror image location of the stimulus. Imaging studies in our lab and others have indicated that during the antisaccade task, people with schizophrenia exhibit decreased activity in prefrontal cortex and related circuitry. Such dysfunction in prefrontal cortex seems to be associated with poor performance on tasks requiring inhibition and working memory generally, not just among those with schizophrenia. The current study looks at differences in brain activity between undergraduate students selected for good and poor performance on the antisaccade task. It is hypothesized that there will be decreased prefrontal cortex signaling associated with poor antisaccade performance. The subjects were placed in a 1.5 T MR scanner while performing antisaccade tasks. Functional MRI data were obtained for 30 subjects (69% female, M = 19.6 (SD = 2.1) years, 100% right handed), representing the top and bottom third of an antisaccade proportion correct distribution (N = 114). The functional MRI data will be analyzed to evaluate activity differences in prefrontal cortex and other regions between groups of good and poor performing subjects.

Synthesis of a Robust Photoremovable Protecting Group for Photoactivation of Gene Expression

Alexandra Walker – CURO Summer Research Fellow
Dr. Timothy Dore, Department of Chemistry, University of Georgia

Photoactivation of gene expression is an invaluable technology that enables the study of intracellular physiology. Genes important to tissue development often have different functions at different stages of life. Utilizing two-photon excitation (2PE) allows for excellent spatiotemporal control of gene expression and is useful for the investigation of tissue-specific roles of developmental genes. A photoactivatable activator of gene expression based on the 8-bromo-7-hydroxyquinolinyl (BHQ) and the 6-bromo-7-hydroxycoumarin (Bhc) groups will be synthesized and tested for its photochemical properties. BHQ and Bhc are photoremovable protecting groups that are hydrolytically robust and sensitive to 2PE. They will be conjugated to a small molecule that induces expression of a developmental gene of interest. Release of this regulator through exposure to 2PE light will trigger the expression of a gene in a single cell at developmentally critical times. Significant progress toward

synthesis of the targets has been made, but the reactions have not been optimized to adequately produce the desired products. Bromide groups were effectively appended to BHQ and Bhc, but their subsequent replacement by dimethyldithiocarbamate groups was achieved for Bhc and not BHQ. Reduction of the dimethyldithiocarbamate groups to sulfides on Bhc was not accomplished without destruction of the coumarin ring, which is less robust than quinoline. Low-yielding steps early in the synthesis reduce the availability of materials for experimental reactions on the forefront. Theoretically, each step of the syntheses is possible to enact, but alterations should be made to the procedures and workups of each reaction to obtain the desired product.

Involvement of DNA Damage Response Factors in the Proliferation of Cancer Cells

Alice Weaver
Dr. Michael Terns, Department of Biochemistry & Molecular Biology, University of Georgia

Telomeres, protective segments of non-coding DNA at the ends of eukaryotic chromosomes, play important roles in aging and cancer. Telomerase is the enzyme that synthesizes telomeres, a process occurring early in human development. The absence of telomerase activity in adults results in gradual telomere shortening, which triggers cell senescence or apoptosis. In most cancers, telomerase reactivation renders cells immortal, allowing for continued proliferation. Thus, telomerase is a molecular target for halting cancer growth. To better understand how telomerase works, our lab has developed a fluorescence *in situ* hybridization (FISH) procedure to view the subcellular localization of telomerase in human cancer cells. Results indicate that telomerase is only recruited to a fraction of chromosomes during each round of telomere synthesis. Based on previous evidence, we hypothesize that the subset of chromosomes acted upon by telomerase may be the same subset where DNA damage response (DDR) factors are observed. We are performing two experiments in HeLa cancer cells to evaluate our hypothesis: a) FISH and immunofluorescence to test for the co-localization of DDR proteins and telomerase and b) protein knockdown and FISH to examine telomerase recruitment in cells where DDR is blocked. Our hypothesis predicts a positive correlation between telomerase recruitment and DDR proteins, which would suggest that DDR factors may be involved in telomere elongation and suggest directions for further cancer research.

Development of Consensus-Degenerate Hybrid Oligonucleotide Primers for Retroviral Discovery

Shuyan Wei – CURO Summer Research Fellow
Dr. Scott Schatzberg, Department of Small Animal Medicine, University of Georgia

Identification of infectious etiologies for diseases is necessary to allow appropriate diagnosis, treatment, and prevention of disease. Retroviruses are a common cause of disease, but currently available methodologies for identification of unknown retroviruses are time-consuming. The objective of this study was to develop a polymerase chain reaction (PCR) assay using consensus-degenerate hybrid oligonucleotide primers (CODEHOPs) for efficient identification of known and novel retroviruses. Using the CODEHOP strategy, two sets of PCR primers were manually developed based on published amino acid and nucleotide sequences of the polymerase gene from 57 retroviruses. The primers were designed to contain a 3' degenerate core, based on 3-4 highly conserved amino acids, and a 5' consensus clamp, based on the most common codon used for 6-8 amino acids upstream of the degenerate core. To evaluate one set of primers, reverse-transcriptase PCR was performed on nucleic acids extracted from reticuloendotheliosis virus, lymphoproliferative disease virus of turkeys, and feline leukemia virus. Amplicons of the expected size for all three viruses were visualized following electrophoresis and exposure to ultraviolet light. The results suggest the developed primers are able to recognize multiple retroviruses with one PCR assay as expected. In the future, both sets of primers will be tested on representative retroviruses from each retroviral family.

Specificity will be evaluated by sequencing of the PCR amplicons, and serial dilutions will be used to evaluate sensitivity. Ultimately, the primers will be applied to clinical cases of canine neurological disease where retroviruses are expected to play a role in pathogenesis.

Great Powers and Grand Strategy on the Korean Peninsula: The Gap Between Rhetoric and Action

Edward Wells – CURO Apprentice
Dr. Brock Tessman, Department of International Affairs, University of Georgia

The current diplomatic gridlock and nuclear standoff on the Korean peninsula is a product of the manner in which the six key actors in the region—China, Japan, Russia, the United States, South Korea, and North Korea—define their national interest. All of the states involved, except for North Korea, have publicly claimed to support non-proliferation and the reunification of the North and the South. Yet, their actions sometimes suggest other motivations. Though the public intent of key actors is to promote peace and principles, negotiating tactics and foreign policy behavior indicate an emphasis on power and prosperity. This difference between rhetoric and action has led to a lack of progress in achieving the set goals of non-proliferation and reunification. This paper acknowledges that states conceive their national interests based on the framework of the "4Ps"—power, peace, prosperity, and principles. Each actor claims peace and principles to be the top priority in promoting a unified and nuclear-free Korea, but power and prosperity tend to dominate the actual foreign policy agendas of these states. This argument is supported by the empirical record: after over a half-century of negotiations, conflicts, and compromises, the six parties have yet to resolve either the North Korean nuclear issue or the related challenge of reunification.

Heart Rate Plateau in Response to Exercise Follows Exponential Kinetics

Benjamin Wheeler & Destinee Ingrao
Dr. James Hargrove, Department of Foods & Nutrition, University of Georgia

The plateau principle postulates that health related transitions follow simple exponential kinetics. We tested the idea that change in heart rate during a timed step test could be modeled as an exponential function. The mathematical model is equation 1, where Mt is the value of a dependent variable such as pulse rate at time t, M0 is the initial value, Mss is the asymptote at the new steady state, and k is the first order rate parameter:

$$Mt = M0 + (Mss - M0)*(1- e\text{-}kt)$$

Subjects were 4 male and 27 female UGA students who were in good health. Data were collected with an Omron model HR-100C heart rate monitor. Each subject recorded heart rate at one-minute intervals while sitting, standing, and stepping up and down from an 18 cm step at a rate of 30 steps per minute. They sat down immediately after 3 min of stepping and recorded their pulse rates for another 3 min. Equation 1 was fit to individual and group average data using Solver in Microsoft Excel®. The rate parameter for approach to plateau in heart rate during the step test was 1.8 per min, and the plateau was 118 bpm. During recovery, the value of k was 1.5 per min, and the resting plateau was 75 bpm. We will present data showing that the equation can forecast changes in heart rate, namely, a reduction in mean heart rate and blood pressure, in response to short- and long-term training.

Habitats of West Nile Virus Competent Mosquitoes: The Effects of Urbanization in New York City

Abby Wong – CURO Scholar
Dr. John Drake, Odum School of Ecology, University of Georgia

West Nile virus (WNV), a flavivirus spread by mosquitoes, first appeared in the United States in 1999. Since then, more than 25,000 people have been infected, resulting in over 1,000 fatalities. Mosquito habitat modeling has become one of the primary methods for predicting WNV incidence in human populations. As part of an ongoing partnership between the University of Georgia's Odum School of Ecology and the New York State Department of Health and Mental Hygiene

(DOHMH) to examine the dynamics of vector-borne diseases in urban environments, a study was undertaken to understand distribution of WNV competent mosquito species. Results of a systematic review of the relevant literature showed that at the spatial scale of a city, competent mosquito species are rarely found in areas that have the highest percentage of impervious surfaces, but they are associated with moderate levels of development (e.g., areas with mild vegetation, medium population density, and artificial water sources, such as sewer treatment facilities or detention ponds). Therefore, machine learning algorithms were used to identify patterns in the relationship between mosquito species distribution and environmental variables associated with moderate levels of urbanization and postulated to influence local mosquito abundance. The results of these models will be mapped in New York City to identify hotspots of mosquito aggregation that may be targeted by DOHMH for mosquito control and thereby limit the transmission of WNV to human populations.

The Effect of Online Communication and Social Support on Positive Emotion and Health Outcomes in Individuals Treated with Ileoanal Reservoir Surgery

Sook Kyung Yoon – CURO Scholar
Dr. Kimberly Clay, School of Social Work, University of Georgia

This study will examine the use of the internet blog *jpouch.net* as a mechanism for the communication of positive emotional expression in survivors of chronic ulcerative colitis, colon cancer, and familial polyposis. The purpose of the study will be to measure the efficacy of this particular intervention method to promote positive mental health outcomes. Positive emotional expression is operationally defined using Fredrickson's Broaden and Build Theory of Positive Emotion in a mixed methods study based on survey data and messages from active participants in this online support group. The aim of this project is to establish the benefits of positive emotions and how these emotions are mediated and translated through the internet blog medium. The messages posted to the blog will be analyzed using content analysis. Statements will be coded via manifest and latent content, in which the explicit and implicit messages will be extracted and evaluated within the context of how they affect treatment outcomes. Data will be analyzed using qualitative analysis software NVivo and quantitative analysis software Linguistic Inquiry and Word Count. Survey data will also be assessed for statistical significance in SPSS. As results are compiled researchers will extract pertinent content and interpret its potential meaning and implications for the population being studied. The research will be conducted collaboratively with students and faculty from several different departments, including social work, communications, biochemistry, and textiles.

Creation of a Reporter Molecule That Will Identify the Pathway Used to Degrade Isoprenylated Molecules

Laura Zeidan
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Over the past decades, the function and existence of protein modification has been vague, but in recent decades the standard pathway of protein synthesis has been revised to include a final step, the posttranslational modification of proteins. Posttranslational modification can be followed by a reporter molecule, such as a plasmid. It has been observed that reporter molecules have altered steady states when not properly modified. The Schmidt lab has observed that cells recognize isoprenylated intermediates, proteins with additive hydrophobic molecules, and target them for protein turnover. We are concerned in this study with the fate of the intermediates of isoprenylated molecules when the Caax motif (prenylation, AAX tripeptide proteolysis, and carboxylmethylation) is improperly modified by proteolysis and/or carboxylmethylation. It was my aim to create a plasmid that allows me to identify the pathway used to degrade isoprenylated molecules. The knowledge of degradation mechanisms could lead to potential

discoveries of methods in which protein turnover can be regulated with therapeutic goals. The oncoprotein Ras is an isoprenylated and therapeutic target. Chemical agents that interfere with Ras Caax proteolysis and/or carboxylmethylation are in development and could be coupled with strategies to enhance turnover in order to deplete cancer cells of the Ras oncoprotein. Using PCR amplification, restriction digest, and ligations, a plasmid containing similar features to a-factor, the yeast mating pheromone, was created. The eventual goal is to use the plasmid that I created to reason the impact of inappropriate Caax modification on protein steady state levels.

CURO 2012 Symposium Call for Abstracts

The annual CURO Symposium provides a forum for undergraduates from all disciplines to present original research and creative works sponsored by faculty members. The Symposium highlights excellence in undergraduate researcher in the state of Georgia and promotes communication and cooperation between faculty and students.

Undergraduate researchers from all public and private higher education institutions in Georgia, and at various stages of the research process, are encouraged to submit abstracts for presentation.

Students may choose to present in one or more of the following formats: Oral, Poster or Thesis Roundtable.

Papers on work being presented at the CURO Symposium submitted by February 21, 2012* will be considered for **Best Paper Awards** in the categories of arts, biological sciences, civic responsibility focus, humanities, international focus, physical sciences and social sciences. Maximum length is 12 pages, double spaced, excluding references and appendices.

Abstract Criteria:

- **Abstract must be no more than 250 words and free of spelling and grammatical errors.**
- Abstracts must contain a thesis or problem statement, description of methods, statement of anticipated findings and a statement of the significance of the research. Abstract must represent ethical and responsible research.
- Abstracts must accurately reflect the extent of the undergraduate student's involvement in development of the research design and execution of the project. Research presented at the Symposium should go beyond work completed for a class paper or project.
- Abstract must be accompanied by a letter of support from the supervising faculty mentor **from the presenter's home institution.**

Submission Process:

- Undergraduates should submit an abstract on-line no later than midnight **January 27, 2012***. **Only abstracts limited to 250 words and free of spelling and grammatical errors will be accepted. Abstracts that do not adhere to stated criteria will not be considered.**
- The sponsoring faculty member must submit a brief supporting letter on-line by midnight **February 3, 2012***. The letter denotes the faculty member's support of the research abstract being published in the Book of Abstracts.
- Group research projects should be submitted with one application and one letter of faculty support.
- All abstracts will receive graduate student review and feedback.
- **Accepted participants will be notified by February 17, 2012***, and their abstracts will be published in the CURO 2012 Symposium Book of Abstracts.

* All dates are subject to change as dictated by the academic calendar.

The annual CURO Symposium is free and open to the public, and all interested faculty and students are encouraged to attend. For more information, contact Center for Undergraduate Research Opportunities at curo@uga.edu or (706) 542-5871

JURO@GA THE UNIVERSITY OF GEORGIA'S JOURNAL FOR UNDERGRADUATE RESEARCH OPPORTUNITIES

CALL FOR SUBMISSIONS

The Journal for Undergraduate Research Opportunities publishes original research papers in the areas of humanities, social sciences, and policy as well as art-related content. **You must present your work at the annual CURO Symposium to be eligible for publication**. Submissions are accepted throughout spring semester at http://www.uga.edu/juro/.

The following general format should be adhered to as closely as possible. The cover page should include the student researcher's name, major, year of anticipated graduation, faculty advisor's name, and institution attended. This information should be followed immediately by the abstract. The research article itself may be organized into the following sections: introduction, methods, findings, conclusion, and references.

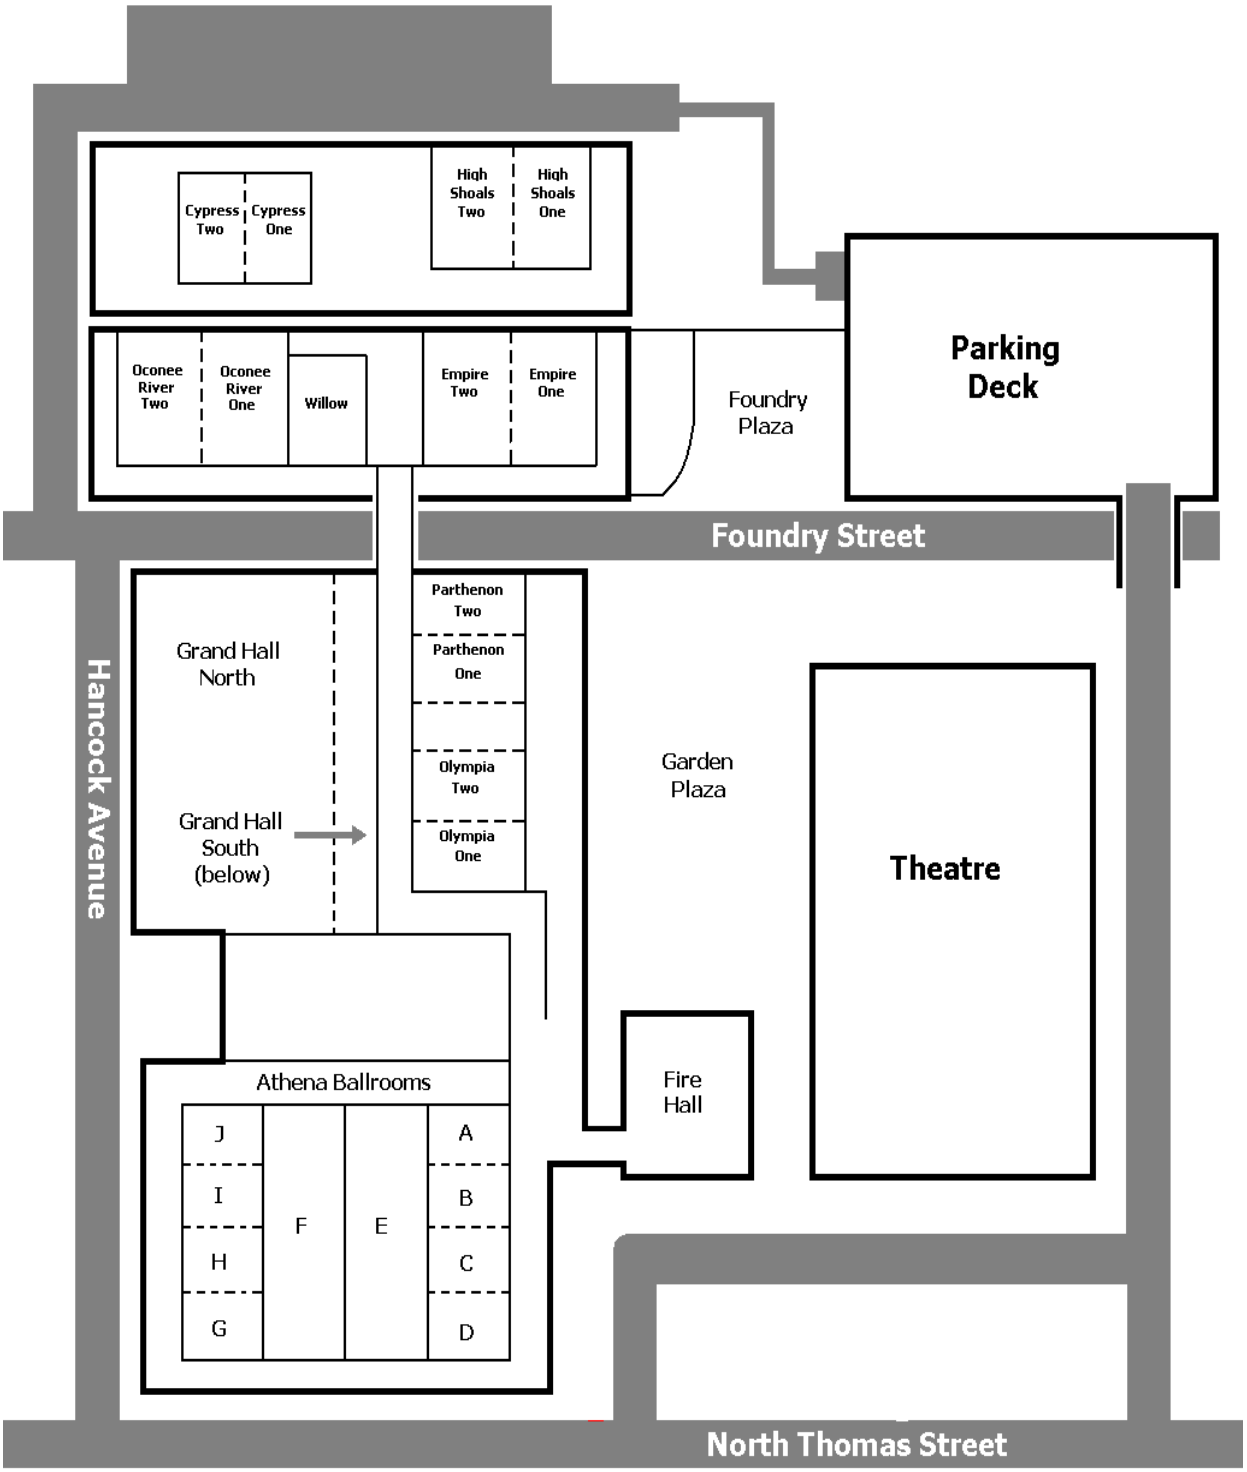
Additionally, work submitted to JURO@GA must adhere to the following guidelines:

1. Maximum length is 30 pages, double-spaced. Theses can be shortened to comprise the central idea of the research in order to be eligible for publication in the journal.
2. All submissions are submitted in English unless other arrangements are made.
3. All work must be submitted with an abstract no longer than 250 words. The abstract should provide a background sufficient to establish a context for understanding the research, summarize the research article itself, and highlight the major results.
4. References should be organized according to the standard format for the individual discipline the research topic falls under, e.g. Modern Language Association, Council of Biology Editors, American Psychological Association, or Chicago style format.
5. Work must be fully represented in digital form (preferably a Microsoft Word document for papers) and emailed to juro@uga.edu.
6. All submissions must be accompanied by a completed Submission and Faculty Advisor Approval Form found on the website at http://www.uga.edu/juro/.

Submissions will be evaluated according to criteria established by the editorial staff of the journal. Incoming research will be reviewed first by JURO@GA's content editors and other staff members. Prospective publications are subject to the approval of the journal's Editor-in-Chief. Upon completion of the review, the author may expect to receive either a notification of acceptance, acceptance with revisions, or a rejection of submission. Any questions about the submission process or the journal itself should be directed to juro@uga.edu. JURO@GA wishes you the best of luck with your CURO Symposium presentation and looks forward to reviewing the finished product of your hard work.

Contact JURO at JURO@uga.edu or visit our website at http://www.uga.edu/juro/

Classic Center Facility Layout



Monday, April 4, 2011

Begin registration of presenters; students hang up posters **8:30 a.m.**
Classic Center, Lobby

Concurrent Oral Sessions **10:10 a.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

Thesis Roundtable Session **10:10 a.m.**
Classic Center, Parthenon Room

Concurrent Oral Sessions **11:15 a.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

Thesis Roundtable Session **11:15 a.m.**
Classic Center, Parthenon Room

Concurrent Oral Sessions **12:20 p.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

Concurrent Oral Sessions **1:25 p.m.**
Classic Center, Athena Breakout Rooms A, B, D, G, H, J

Concurrent Oral Sessions **2:30 p.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

General Session **4:00 p.m.**
Classic Center, Athena Ballroom E **Dr. David S. Williams**
Associate Provost and Director, Honors Program

Remarks **Professor Jere W. Morehead**
Senior Vice President for Academic Affairs and Provost

Excellence in Undergraduate Research Mentoring Awards **Dr. David C. Lee**
Vice President for Research

Best Paper and UGA Libraries Research Awards **Dr. Laura Jolly**
Vice President for Instruction
Ms. Deborah Dietzler
Executive Director, Alumni Association
Ms. Caroline Barratt
Director, Miller Learning Center Library Commons

Introduction of Keynote Speaker **Ms. Sheena Zhang**
Foundation Fellow ’11, Ecology, Biology
and Sustainable Design in the Built Environment

Keynote Address: *Doing Science in the Face of a National Emergency* **Dr. Samantha Joye**
Professor, Department of Marine Sciences
Director, Center for Integrative Conservation Research

Poster Session, Science as Art & Reception **5:00 p.m.**
Classic Center, Grand Hall South (downstairs)

Monday, April 4, 2011

Concurrent Oral Sessions

Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

10:10 – 11:00 a.m. First Concurrent Session

Room A	**JoyEllen Freeman**	The Message Behind the Music: Blind Tom's Response to Nineteenth Century Views on Race
	Faculty Mentor	Dr. Barbara McCaskill, Department of English
	Isha Ghodke	Representations of Children and Childhood in Jurek Becker's Holocaust Novel *Jakob der Lügner*
	Faculty Mentor	Dr. Martin Kagel, Department of Germanic & Slavic Studies
	C.T. Bailey	Kanji and the A-curve
	Faculty Mentor	Dr. William Kretzschmar, Department of English
Room B	**Rachel Perez**	Oil Palm Proliferation in Latin America
	Faculty Mentor	Dr. J. Peter Brosius, Department of Anthropology
	Hank Schwartz	Reducing Water Usage by Repowering Plants in Georgia
	Faculty Mentor	Dr. Laurie Fowler, Odum School of Ecology
Room C	**Abby Wong**	Increasing Enrollment of Eligible Children in Georgia's Medicaid and CHIP Programs
	Faculty Mentor	Dr. Angela Fertig, Department of Public Administration & Policy
	Tiffany Hu	Mandating a Federal Excise Tax on Caloric Sweetened Beverages in the U.S.
	Faculty Mentor	Dr. Angela Fertig, Department of Public Administration & Policy
	Ammarah Mahmud	Revisiting U.S. Procurement of Non-Emergency Food Aid
	Faculty Mentor	Dr. Maria Navarro, Department of Agricultural Leadership, Education & Communication
Room D	**Pranav Kaushish**	Y-Linked Variation and Senescence in *Drosophila melanogaster*: Starvation Resistance
	Faculty Mentor	Dr. Daniel Promislow, Department of Genetics
	Michael Bray	Genetic Analysis of Pigmentation in *Drosophila tenebrosa*
	Faculty Mentor	Dr. Kelly Dyer, Department of Genetics
	Krelin Naidu	Epigenetic Effects of Bromate on p21 and Histone-2AX Expression in HEK293 Cells
	Faculty Mentor	Dr. Brian Cummings, Department of Pharmaceutical & Biomedical Sciences

Room G	**Ashley Bartlett**	The Elements of Chinese Grand Strategy: Applying a New Analytical Approach
	Faculty Mentor	Dr. Brock Tessman, Department of International Affairs
	Chad Peltier	Cognitive X's and O's: First Steps in the Resolution to the Offensive-Defensive Realist Debate
	Faculty Mentor	Dr. Jeff Berejikian, Department of International Affairs
	Edward Wells, Jr.	Grand Strategy as it Pertains to the Korean Peninsula
	Faculty Mentor	Dr. Brock Tessman, Department of International Affairs
Room H	**Tony Pelli, Katherine Arnold, Yuliya Bila, Rohan Mukhopadhyay, Shyam Shanker, Patrick Smith, Seth Taylor**	Battling With Bytes: A Cybersecurity Doctrine for the United States
	Faculty Mentor	Dr. Dan Everett, Department of Computer Science
	Lauren Howard	Thwarting Radiological Terrorism: Policies for Regulating the Security of High-Risk Radioactive Sources
	Faculty Mentor	Dr. Dmitriy Nikonov, Center for International Trade & Security
	Archil Japardize	Security Contractors: The Future of Peacekeeping?
	Faculty Mentor	Dr. Fred Manget, School of Law
Room J	**Daniel Cellucci**	First-Principles Investigations of Oxygen Vacancies on SnO2 Nanofilms
	Faculty Mentor	Dr. Steven Lewis, Department of Physics & Astronomy
	Whitney Ingram	Surface Plasmon Resonance Enhancement by an Electrostatic Sampling Device
	Faculty Mentor	Dr. Yiping Zhao, Department of Physics & Astronomy

10:10 – 11:00 a.m. First Thesis Roundtable Session

Classic Center, Parthenon Room

Table 1	**Tatum Mortimer**	Epidemiology of Equine *Staphylococcus aureus* in Georgia and Kentucky from 1995-2003
	Faculty Mentor	Dr. Susan Sanchez, College of Veterinary Medicine
	Muktha Natrajan	The Effects of Manganese on Human Neural Stem Cell Cultures
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
	Malavika Rajeev	The Effect of Parasite Infection on Monarch Butterfly Mating Behavior
	Faculty Mentor	Dr. Sonia Altizer, Odum School of Ecology

	Anna White	Clinico-pathological Characterization of Newly Isolated Newcastle Disease Viruses from Dominican Republic, Belize and Peru
	Faculty Mentor	Dr. Corrie Brown, College of Veterinary Medicine
Table 2	**Mary Burriss**	Characterization of *C. elegans* Insulin-degrading Enzyme
	Faculty Mentor	Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology
	Edward Lilla	Rce1 Membrane Topology
	Faculty Mentor	Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology
	Alexander Sevy	Ty1 Element Antisense RNA Activity from Natural Saccharomyces Isolates
	Faculty Mentors	Dr. David Garfinkel, Department of Biochemistry & Molecular Biology
Table 3	**Ryan Jordan**	Children's Directional Understanding of Arrows
	Faculty Mentor	Dr. Janet Frick, Department of Psychology
	Cody Nichol	Emotion Regulation in Children: Implications for Affect and Childhood Psychopathology
	Faculty Mentor	Dr. Cynthia Suveg, Department of Psychology
	Rebecca Parker	Evaluation on Blood Flow Velocity and Arterial Diameter Produced by Compression Therapy
	Faculty Mentor	Dr. Kevin McCully, Department of Kinesiology
	Sarah Thorne	The Effects of Lutein and Zeaxanthin Status and Macular Pigment Optical Density on Neural Efficiency
	Faculty Mentor	Dr. Lisa Renzi, Department of Psychology
Table 4	**Emily First**	Mineral Probes of Magmatic Processes at Valles Caldera, Northern New Mexico
	Faculty Mentor	Dr. Michael Roden, Department of Geology
	Anisha Hegde	The Boom That Saved the Day
	Faculty Mentor	Dr. Leara Rhodes, Grady College of Journalism &Mass Communications
	Sheena Zhang	An Analysis of Green Buildings: Comparing Tsinghua University's Sino-Italian Ecological and Energy-Efficient Building and UGA's Odum School of Ecology Building
	Faculty Mentor	Dr. Laurie Fowler, Odum School of Ecology

11:15 – 12:05 p.m. Second Concurrent Session

Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

Room A	**Malin Dartnell**	Where the Pavement Ends: An Evaluation of the Urban Heat Island Effect in Metropolitan Atlanta
	Faculty Mentor	Dr. Jenna Jambeck, Department of Biological & Agricultural Engineering
	Katherine Riccione, Ryan Boelter, Tina Carson, Chase Mooney	Design of a Computed Tomography Scanner with Components from an Existing DEXA Machine
	Faculty Mentor	Dr. Mark Haidekker, Department of Biological & Agricultural Engineering
	Pranay Udutha	Preserving Georgia's Waterways: Tackling Interbasin Transfer in Georgia
	Faculty Mentor	Dr. Laurie Fowler, Odum School of Ecology
Room B	**Katie Branscomb**	The Political Economy of the Textile Industry in Bangladesh
	Faculty Mentor	Dr. Santanu Chatterjee, Department of Economics
	Meredith Jones	Worse Before It Gets Better? Or Just Worse?
	Faculty Mentor	Dr. Santanu Chatterjee, Department of Economics
	Munir Winkel	Smart Moves: Avoiding Common Investing Mistakes
	Faculty Mentor	Dr. Swarn Chatterjee, Department of Housing & Consumer Economics
Room C	**Katherine Black**	Differences in Functional Movement Screen Scores Between Female Soccer Players That Were Injured vs. Uninjured
	Faculty Mentor	Dr. Cathleen Brown, Department of Kinesiology
	Jenny Brickman	Effects of Medial-Wedge Orthotics on Knee Frontal Plane Moments in Individuals with Valgus Knee Alignment and Lateral-Compartment Osteoarthritis
	Faculty Mentor	Dr. Cathleen Brown, Department of Kinesiology
Room D	**Ebony Caldwell**	Influences on the Outlook of the Post-college Educational Opportunities and Choices of Undergraduate Science Majors
	Faculty Mentors	Dr. Monica Gaughan, Department of Health Policy & Management
	Agni Chandora	U.S. Primary Care Physicians: A Dying Breed
	Faculty Mentor	Dr. Monica Gaughan, Department of Health Policy & Management
	Osama Hashmi	Creating the Physician of the Future: Addressing the Health Needs of Rural Georgia Communities
	Faculty Mentor	Dr. Monica Gaughan, Department of Health Policy & Management

Room G	**Anastasia Couvaras**	Perceived Barriers and Medication Adherence in Adolescents
	Faculty Mentor	Dr. Ronald Blount, Department of Psychology
	Hannah Machemehl	Developmental Changes in Human Infants' Strategies for Recognizing Human and Animal Faces
	Faculty Mentor	Dr. Janet Frick, Department of Psychology
	Cody Nichol	Emotion Regulation in Children: Implications for Affect and Childhood Psychopathology
	Faculty Mentor	Dr. Cynthia Suveg, Department of Psychology
Room H	**Vanessa Hanvey**	Spatial and Temporal Analysis of the Ceramics and Lithics at the Burnt Village, 9TP9
	Faculty Mentor	Dr. J. Mark Williams, Department of Anthropology
	Bryn Murphy	"Cuando uno toma el agua del Tambopata…": Migration and the Urban Environment in Madre de Diós, Peru
	Faculty Mentor	Dr. J. Peter Brosius, Department of Anthropology
	Rebecca Stein	How Leadership Makes a Difference: The Predictive Role of Managerial Leadership Competencies in a Multi-National Company
	Faculty Mentor	Dr. Karl Kuhnert, Department of Psychology
Room J	**Jessica Holmes**	Isolation and Characterization of Polyomavirus Middle T (PyVT) Mammary Cancer Stem/Progenitor Cells
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology
	Rachel Johnson	*Plasmodium falciparum*: Expression of the DBL3x region of VAR2CSA
	Faculty Mentor	Dr. David Peterson, Department of Infectious Diseases
	Emily Peng	A Flow Cytometry-Based Method of Glycosylation Profiling
	Faculty Mentor	Dr. Robert Woods, Department of Biochemistry & Molecular Biology

11:15 – 12:05 p.m. Second Thesis Roundtable Session

Classic Center, Parthenon Room

Table 1	**Dillon Horne**	Symbolization and Religious Thought
	Faculty Mentor	Dr. Thomas Cerbu, Department of Comparative Literature
	Caleb Moreno	Orpheus in Opera
	Faculty Mentor	Dr. Dorothea Link, Hugh Hodgson School of Music
Table 2	**Ashley Bartlett**	Democracy Blinded: a Study of the Afghanistan and Iraq Wars, 2001-2008
	Faculty Mentor	Dr. John Morrow, Department of History

	James Herman	John Lloyd Stephens and Mesoamerican Orientalism
	Faculty Mentor	Dr. John Short, Department of History
	Justin Leef	Salient Issues as Forces for Change in the Peach State: Bioscience and Research Meet Deep South Politics
	Faculty Mentor	Dr. Charles Bullock, Department of Political Science
Table 3	**Anna Legostaev**	An Analysis of Two Great Russian Poets and a Discussion of their Ties to Russia's History and its People
	Faculty Mentor	Dr. Elena Krasnostchekova, Department of Germanic & Slavic Studies
	Matthew Sellers	Every Man a King: Robert Penn Warren, Populism and Contemporary American Politics
	Faculty Mentor	Dr. Hugh Ruppersburg, Department of English
	Laura Wynn	Representations of the East German Secret Police in Contemporary German Literature
	Faculty Mentor	Dr. Martin Kagel, Department of Germanic & Slavic Languages
Table 4	**Melissa Brown**	Black Stereotypes in Reality Television and the Reinforcement of Prejudiced Attitudes
	Faculty Mentor	Dr. Leonard Martin, Department of Psychology
	Ah Hyun Jun	Characterization of Disease Causing Mutations of hENT3
	Faculty Mentor	Dr. Rajgopal Govindarajan, Department of Pharmaceutical & Biomedical Sciences
	Trenton Mize	Legitimacy and Status in Mixed-Gender Task Groups
	Faculty Mentor	Dr. Dawn Robinson, Department of Sociology
	Raha Sabet	Attuning to Positive Social Cues as an Effortful Process for Socially Anxious Individuals
	Faculty Mentor	Dr. Michelle vanDellen, Department of Psychology

12:20 – 1:10 p.m. Third Concurrent Session

Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

Room A	**Joshua Barnett**	Tri-state Water 'War': Media Frames and Weighing What is Best for the Apalachicola-Chattahoochee-Flint River Basin
	Faculty Mentor	Dr. David Radcliffe, Department of Crop & Soil Sciences
	Tatum Mortimer	Epidemiology of Equine *Staphylococcus aureus* in Georgia and Kentucky from 1995-2003
	Faculty Mentor	Dr. Susan Sanchez, College of Veterinary Medicine
Room B	**John Gaudet**	Studying Human Seizures Using Zebrafish as a Model
	Faculty Mentor	Dr. James Lauderdale, Department of Cellular Biology

	Camille Gregory	Investigation of the Protein Content of Hirano Bodies
	Faculty Mentor	Dr. Marcus Fechheimer, Department of Cellular Biology
	Jay Patel	Characterization of Striated Fiber Assemblins in *T. gondii*
	Faculty Mentor	Dr. Boris Striepen, Department of Cellular Biology
Room C	**Caitlin Cassidy**	The Art of Persuasion: How Small Business Owners Use Speech to Market Products in Roswell, GA
	Faculty Mentor	Dr. William Kretzschmar, Department of English
	Tyler Williamson	Business Model Generation and Energy Informatics
	Faculty Mentor	Dr. Rick Watson, Department of Management Information Systems
Room D	**Elodie Huguet**	Effects of Steel and Aluminum Shoes on Forelimb Action in Stock Horses
	Faculty Mentor	Dr. Kylee Duberstein, Department of Animal & Dairy Science
	Jonathan Jones	Renewable Energy-Powered Bulk Milk Cooling for Smallholder Dairy Farmers
	Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
	Waring Trible	Cuticular Pheromones and Fire Ant Queens: Smells Like Mom
	Faculty Mentor	Dr. Ken Ross, Department of Entomology
Room G	**Jessica Alcorn**	The Validity of the News Marketing Hypothesis
	Faculty Mentor	Dr. Audrey Haynes, Department of Political Science
	Dana Higgins	Risk-taking in Midterm Elections
	Faculty Mentor	Dr. Charles Bullock, Department of Political Science
	Justin Leef	Salient Issues as Forces for Change in the Peach State: Bioscience and Research Meet Deep South Politics
	Faculty Mentor	Dr. Charles Bullock, Department of Political Science
Room H	**Mary Golden**	An Analysis and Application of Foreign Language Education Methodology
	Faculty Mentor	Dr. Victoria Hasko, Department of Language & Literacy Education
	Matthew Seitz	A Cold Calculus: Spending in K-12 Education
	Faculty Mentor	Dr. Catherine Sielke, Department of Lifelong Education, Administration & Policy
	Taylor Whelchel	Academic Relevancy in the College Classroom
	Faculty Mentor	Dr. Christopher Pisarik, Division of Academic Enhancement
Room J	**Dina Abdulhadi**	Deep Horizon: the Politicization of Science
	Faculty Mentor	Dr. Leara Rhodes, Grady College of Journalism & Mass Communications

	Rebecca Arnall	The Influence of Soren Kierkegaard on the Work of Walker Percy
	Faculty Mentor	Dr. Hugh Ruppersburg, Department of English
	Anisha Hegde	The Boom That Saved the Day
	Faculty Mentor	Dr. Leara Rhodes, Grady College of Journalism & Mass Communications

1:25 – 2:15 p.m. Fourth Concurrent Session

Classic Center, Athena Breakout Rooms A, B, D, G, H, J

Room A	**Khalil Farah**	Delegates' Personal Interests and their Influence on Crafting Congressional Qualifications at the Constitutional Convention
	Faculty Mentor	Dr. Keith Dougherty, Department of Political Science
	Nathaniel Ament-Stone	Campaign Finance and Vote Outcomes in U.S. House Primary Elections
	Faculty Mentor	Dr. Jamie Carson, Department of Political Science
	David Mapp	The Effects of Negative Political Campaign Advertising
	Faculty Mentor	Dr. James Bason, Survey Research Center
Room B	**Kathryn Clifford, Sophie Winkler**	The EEOC and the Federal Court of Appeals
	Faculty Mentor	Dr. Scott Ainsworth, Department of Political Science
	Camille Gregory	Screening for Domestic Violence in Divorce Mediation
	Faculty Mentor	Prof. Raye Rawls, The Fanning Institute
	Christen Hammock	Without Anchors: Standardizing Child Placement After Deportation
	Faculty Mentor	Dr. Larry Nackerud, School of Social Work
Room D	**Jason Bowman**	Analysis of the Inter-Rater Reliability of the Functional Movement Screen
	Faculty Mentor	Dr. Cathleen Brown, Department of Kinesiology
	Melesse Nune	LysR-type Transcriptional Regulators
	Faculty Mentor	Dr. Cory Momany, Department of Pharmaceutical & Biomedical Sciences
Room G	**Alyson Dankner**	A Culture Identified by Canines: How Dogs Have Become an Integral Part of the American Public Self
	Faculty Mentor	Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors
	Christine Fekete	Traditional Textiles through a Modern Lens
	Faculty Mentor	Prof. Jennifer Crenshaw, Lamar Dodd School of Art

	Shelly Hagigi	Bedouin Dress: A Means of Cultural Continuity and Change
	Faculty Mentor	Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors
Room H	**Ryan Prior**	Witch-Doctoring Tolstoy: Applying Traditional Healing Philosophies to *The Death of Ivan Ilych*
	Faculty Mentor	Dr. Katarzyna Jerzak, Department of Comparative Literature
	Jennifer Skinner	Italian Futurists and Fascism
	Faculty Mentor	Dr. Nell Andrew, Lamar Dodd School of Art
Room J	**Tyler Bugg**	Geographies of Expression: the Arts within Space and Scale
	Faculty Mentor	Dr. Amy Trauger, Department of Geography
	Daniel Cellucci	Remote Sensing as a Generative Tool in the Creation of Fine Art
	Faculty Mentor	Dr. Ralph Brown, Lamar Dodd School of Art
	Brittany Norman	Dust and Breath - Works of Art and Technology
	Faculty Mentor	Dr. Martijn Van Wagtendonk, Lamar Dodd School of Art

2:30 – 3:45 p.m. Fifth Concurrent Session

Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

Room A	**Lisa Baer, Kacie Caudle, Robert Gentry**	The Relationship Between Personal Beliefs and Family Values in International College Students from a Hungarian University
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychological Science, Georgia College & State University
	Robert Daniel	Friends of Convenience
	Faculty Mentor	Dr. Michelle vanDellen, Department of Psychology
	Mona Malacane	The Influence of Popular Adolescent Television Programs
	Faculty Mentor	Dr. Leonard Martin, Department of Psychology
Room B	**Virginia Broyles**	Nice to Have: Expression and Movement through Film
	Faculty Mentor	Dr. Bala Sarasvati, Department of Dance
	Joanna Reising	*Victory Over the Sun*: The Russian Futurist Transcendence over Materiality
	Faculty Mentor	Dr. Nell Andrew, Lamar Dodd School of Art
Room C	**Debashis Ghose**	Stability Analysis of the Inhibitor Resistant Phenotype of AJP50 in Biomass Fermentations
	Faculty Mentor	Dr. Joy Doran Peterson, Department of Microbiology

	Courtney Ralston	Kinetic, Temperature Dependent and Structural Analyses Of YqhD, an Escherichia coli NADPH Dependent Oxidoreductase Enzyme
	Faculty Mentor	Dr. William Lanzilotta, Department of Biochemistry & Molecular Biology
Room D	**Christina Azahar**	Music Pedagogy in Latin America: A Case Study of El Sistema Venezuela and its International Expansion
	Faculty Mentor	Dr. Susan Thomas, Hugh Hodgson School of Music
	Smitha Ganeshan	Ready for Disaster
	Faculty Mentor	Dr. David Williams, Honors Program
	Matthew Passarello	Pronunciation of Word-Final [ə] by Older Male Speakers from the South of France
	Faculty Mentor	Dr. Diana Ranson, Department of Romance Languages
Room G	**Melissa Brown**	Black Stereotypes in Reality Television and the Reinforcement of Prejudiced Attitudes
	Faculty Mentor	Dr. Leonard Martin, Department of Psychology
	Daniel Smith	In the Image of the Artist
	Faculty Mentor	Dr. Asen Kirin, Lamar Dodd School of Art
	Jacob Young	Exploring the Life and Techique of Michael Chekhov
	Faculty Mentor	Prof. George Contini, Department of Theatre & Film Studies
Room H	**Sylvia Shin**	The Evolution of Aging in *Saccharomyces cerevisiae*
	Faculty Mentor	Dr. David Hall, Department of Genetics
	Stephen Thompson	Intramolecular Friedel-Crafts Cyclization with Arylsilanes
	Faculty Mentor	Dr. George Majetich, Department of Chemistry
Room J	**Tierney O'Sullivan**	Investigating Early Warning Signals and Critical Slowing Down in Changing Environments
	Faculty Mentor	Dr. John Drake, Odum School of Ecology
	John Rodriguez	Improving the Claims-Making Process in Context to the 2010 Deepwater Horizon Oil Spill
	Faculty Mentor	Dr. Leara Rhodes, Grady College of Journalism & Mass Communications
	Theresa Stratmann	Changing Environments: Effect on Extinction Time and Distribution
	Faculty Mentor	Dr. John Drake, Odum School of Ecology
	Sheena Zhang	An Analysis of Green Buildings: Comparing Tsinghua University's Sino-Italian Ecological and Energy-Efficient Building and UGA's Odum School of Ecology Building
	Faculty Mentor	Dr. Laurie Fowler, Odum School of Ecology

4:00 p.m. General Session

Classic Center, Athena Ballroom E

Introductions	Dr. David S. Williams, Associate Provost and Director, Honors Program
Remarks	Professor Jere W. Morehead, Senior Vice President for Academic Affairs and Provost
Excellence in Undergraduate Research Mentoring Awards	Dr. David C. Lee, Vice President for Research
Best Paper and UGA Libraries Research Award	Dr. Laura Jolly, Vice President for Instruction Ms. Deborah Dietzler, Executive Director, Alumni Association Ms. Caroline Barratt, Director, Miller Learning Center Library Commons
Introduction of Keynote Speaker	Ms. Shenna Zhang, Foundation Fellow '11, Ecology, Biology And Sustainable Design in the Built Environment
Keynote Address: *Doing Science in the Face of a National Emergency*	Dr. Samantha Joye, Department of Marine Sciences

5:00 p.m. *Science as Art**

Classic Center, Grand Hall South (downstairs)

Science as Art Poster #45	**Miles Keeney-Ritchie**	Extracting Power from Induced Airstreams on Expressways
	Faculty Mentor	Dr. John Schramski, Department of Biological & Agricultural Engineering

*****_Science as Art_ is the presentation of images or data gathered during the research process that demonstrate artistic principles such as balance, contrast, proportion, harmony and value. Mr. Keeney-Ritchie's submission was selected for the CURO 2011 Symposium *Science as Art* Award.

5:00 p.m. Poster Presentations

Classic Center, Grand Hall South (downstairs)

Poster #1	**Anuj Shukla**	Human Embryonic Stem Cell Derived Neurons as Biosensors for Neurotoxins
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
Poster #2	**Garrett Casale**	Role of the Telomere Binding Protein TPP1 in Recruitment of Telomerase to Telomeres in Human Cancer Cells
	Faculty Mentor	Dr. Michael Terns, Department of Biochemistry & Molecular Biology
Poster #3	**Rachel Appelbaum**	An RNA-Protein Complex of a Prokaryotic Immune System
	Faculty Mentor	Dr. Michael Terns, Department of Biochemistry & Molecular Biology

Poster #4	**Carla Rutherford**	Morphological Changes Accompanying Killing of *Trypanosoma brucei brucei* by Human Serum
	Faculty Mentor	Dr. Stephen Hajduk, Department of Biochemistry & Molecular Biology
Poster #5	**Alexander Sevy**	Ty1 Element Antisense RNA Activity from Natural Saccharomyces Isolates
	Faculty Mentor	Dr. David Garfinkel, Department of Biochemistry & Molecular Biology
Poster #6	**Samar Aldrugh**	Exploring the Effect of Cysteine Mutations on Rce1p Substrate Recognition and Enzyme Efficiency
	Faculty Mentor	Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology
Poster #7	**Daniel Hess**	Directed Differentiation of Human Embryonic Stem Cells to Mesoderm Lineages
	Faculty Mentor	Dr. Stephen Dalton and Dr. David Reynolds, Department of Biochemistry & Molecular Biology
Poster #8	**Byron Crowe**	Efficacy of Alternative and Combinatorial Drug Therapies in the Treatment of *Trypanosoma Cruzi* Infection
	Faculty Mentor	Dr. Rick Tarleton, Department of Cellular Biology
Poster #9	**Jeffrey Tran**	The Role of Indoleamine 2,3-Deoxygenase in CD8 T Responses to Influenza Infection
	Faculty Mentor	Dr. Kimberly Klonowski, Department of Cellular Biology
Poster #10	**David Liddle**	Polysialylation Changes During Human Stem Cell Development
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology
Poster #11	**Sarah-Bianca Dolisca**	Effects of N-Acetylglucosaminyltransferase Expression Levels on Colorectal Adenoma Progression
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology
Poster #12	**Shanterian Hester**	Exercising Glycoprotemics to Develop New Methodologies for the Detection of Early Breast Cancer
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology
Poster #13	**Melanie Fratto**	Do Black-Furred Animals Compensate for High Solar Absorption with Smaller Hairs? A Test with a Polymorphic Squirrel Species
	Faculty Mentor	Dr. Andrew Davis, Odum School of Ecology
Poster #14	**Malavika Rajeev**	The Effect of Parasite Infection on Monarch Butterfly Mating Behavior
	Faculty Mentor	Dr. Sonia Altizer, Odum School of Ecology

Poster #15	**Samuel Willis**	Diversity of Orchid Fungal Symbionts in Estonian Mine Tailings
	Faculty Mentor	Dr. Richard Shefferson, Odum School of Ecology
Poster #16	**Stenka Vulova**	Nutrient Enrichment Effects on Detrital Food Resources in Streams: Implications for Microbes and Consumers
	Faculty Mentor	Dr. Amy Rosemond, Odum School of Ecology
Poster #17	**Rebecca Risser**	Effects of *Ligustrum sinense* Presence and Removal on Nitrogen Mineralization Rates
	Faculty Mentor	Dr. Paul Hendrix, Odum School of Ecology
Poster #18	**Courtney Allen**	Salamander Trophic Position and Diet Diversity in Southern Appalachian Headwater Streams
	Faculty Mentor	Dr. Amy Rosemond, Odum School of Ecology
Poster #19	**Waring Trible**	Cuticular Pheromones and Fire Ant Queens: Smells Like Mom
	Faculty Mentor	Dr. Ken Ross, Department of Entomology
Poster #20	**Georgianna Mann**	*Bufo marinus* Pathogen and Parasite Analysis as a Model for Ecosystem Change
	Faculty Mentor	Dr. Sonia Hernandez, Warnell School of Forestry & Natural Resources
Poster #21	**Erin Giglio**	Sensory Systems in *Drosophila* Courtship
	Faculty Mentor	Dr. Kelly Dyer, Department of Genetics
Poster #22	**Zijing Guo**	Telomere Recombination in Wild Type Yeast Cells
	Faculty Mentor	Dr. Michael McEachern, Department of Genetics
Poster #23	**Rakia Nasir**	Analysis of rRNA Maturation in *Escherichia coli*
	Faculty Mentor	Dr. Sidney Kushner, Department of Genetics
Poster #24	**Anisha Hegde**	Medical Therapies and Clinical Characteristics among Patients with Duchenne and Becker Muscular Dystrophy
	Faculty Mentor	Dr. Michael Terns, Department of Biochemistry & Molecular Biology
Poster #25	**Erica Gibson**	How Effective Are "Fuzzies" as a Tool for Developing a Holistic Understanding of Basic Genetic Principles?
	Faculty Mentor	Dr. Eve Wurtele, Department of Genetics, Development & Cell Biology, Iowa State University
Poster #26	**Akanksha Rajeurs**	Development of a System for Targeted Mutagenesis in *Mycobacterium Tuberculosis*
	Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases
Poster #27	**Elena James**	Development of a Plasmid to Detect Cobalamin Transport Mutants in *Mycobacteria Tuberculosis*
	Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases

Poster #28	**Oluremi Ojo**	Expression of the DBL3x Domain of VAR2CSA in *E. coli*
	Faculty Mentor	Dr. David Peterson, Department of Infectious Diseases
Poster #29	**Jenna Adair**	Virulence Associated Protein A is the Only Vap-Family Member Required for Virulence in the Intracellular Actinomycete Pathogen *Rhodococcus equi*
	Faculty Mentor	Dr. Mary Hondalus, Department of Infectious Diseases
Poster #30	**Elizabeth May**	Assessment of 5-Aminolevulinate Acid Synthase Expression & Purification Methods
	Faculty Mentor	Dr. Harry Dailey, Department of Biochemistry & Molecular Biology
Poster #31	**Lauren McLeod**	*Zot* as a Potential Virulence Factor for *Neisseria meningitidis*
	Faculty Mentor	Dr. Anna Karls, Department of Microbiology

Excellence in Undergraduate Research Mentoring Awards

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2001. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students.

Awards will be presented at the General Session of the CURO 2011 Symposium on Monday, April 4, 2011 at 4:00 p.m. in the Classic Center, Athena Ballroom E.

2011 Awards

Master Level Faculty Award
Dr. Eric Stabb, Department of Microbiology
Early Career Faculty Award
Dr. John Drake, Odum School of Ecology
Program Award
Savannah River Ecology Laboratory
Dr. Kenneth McLeod, Interim Director

2010 Awards

Early Career Faculty Award
Dr. John C. Maerz, Warnell School of Forestry & Natural Resources

2009 Awards

Early Career Faculty Award
Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences
Dr. Anna C. Karls, Department of Microbiology
Dr. Dawn T. Robinson, Department of Sociology

2008 Awards

Master Level Faculty Award
Dr. John J. Maurer, College of Veterinary Medicine
Early Career Faculty Award
Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology
Program Award
Biomedical and Health Sciences Institute
Dr. Harry S. Dailey, Director

2007 Awards

Master Level Faculty Award
Dr. Timothy Hoover, Department of Microbiology
Early Career Faculty Award
Dr. Steven Stice, Department of Animal & Dairy Science

Excellence in Undergraduate Research Mentoring Awards

2006 Awards

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Department of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Department of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD candidate in Plant Biology

2005 Awards

Faculty Awards
Dr. Gary Barrett, Odum School of Ecology
Dr. Sidney Kushner, Department of Genetics
Department Award
Department of Cellular Biology

2004 Awards

Faculty Award
Dr. William S. Kisaalita, Department of Biological & Agricultural Engineering

2003 Awards

Faculty Award
Dr. Jody Clay-Warner, Department of Sociology
Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator
Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Department of Plant Biology
Dr. Marie-Michèle Cordonnier-Pratt, Department of Plat Biology

2002 Awards

Faculty Awards
Professor William D. Paul, Jr., Lamar Dodd School of Art
Dr. Katherine Kipp, Department of Psychology
Faculty Recognition
Dr. Susan Sanchez, College of Veterinary Medicine
Department Award
Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head

Program Award

"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Department of Physics & Astronomy
Dr. Heinz-Bernd Schuttler, Department Head, Department of Physics & Astronomy
Dr. Jonathan Arnold, Department of Genetics
Dr. Susmita Datta, Georgia State University
Dr. David Logan, Clark Atlanta University
Dr. William Steffans, Clark Atlanta University

2001 Awards

Faculty Award

Dr. Marcus Fechheimer, Department of Cellular Biology

Faculty Recognition

Dr. David MacIntosh, Department of Environmental Health Sciences
Dr. Dean Rojek, Department of Sociology

Department Award

Department of Genetics
Dr. John MacDonald, Department Head

Program Award

Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

Thanks and Acknowledgements

Deep Horizon: the Politicization of Science

Dina Abdulhadi, Roosevelt @ UGA
Dr. Leara Rhodes, Grady College of Journalism & Mass Communications, University of Georgia

Up to this point, response to the Deepwater Horizon Oil Spill has mostly addressed economic impacts for Gulf residents. The Gulf Ecosystem Restoration Task Force aims to address issues of long-term environmental resiliency in the Gulf Region, including environmental issues, such as hypoxia, that existing before the spill. Which concerns are deemed important enough to address, however, depend on initial assessments of how the spill has changed Gulf ecosystems. The different hands involved in research--BP, Federal environmental agencies, and university researchers--have little coordination or collaboration. Estimates of oil persistence conflict; as of August 2010, FEMA stated that only 25 percent of the oil remained in the Gulf Ocean, while the Georgia Sea Grant estimated between 70 and 79 percent [1]. Disagreement over this foundational understanding and the effect of dispersant use will make future environmental policies insufficient in addressing human and ecosystem health; while Exxon ended cleanup after oil was no longer easily visible, NOAA discovered that "very little" of the original oil from Exxon Valdez had "disappeared" by 2007, almost 18 years after the spill [2]. By researching the role of science in creating policy with retrospect to Exxon Valdez, this study aims to outline potential strategies for standardizing research in order to prevent ideological or economic biases from preventing implementation of needed environmental protection measures.

Virulence Associated Protein A Is the Only Vap-family Member Required for Virulence in *Rhodococcus equi*

Jenna Adair
Dr. Mary Hondalus, Department of Infectious Diseases, University of Georgia

Rhodococcus equi (*R. equi*) is a facultative intracellular pathogen of macrophages. It causes severe pneumonia in young foals, and has also emerged as an opportunistic pathogen in immunocompromised people. *R. equi* contains a virulence plasmid housing a pathogenicity island (PAI) upon which resides the novel *vap* gene family encoding the virulence-associated-proteins (Vaps ACDEFGHIX). The functions of the individual Vap proteins are unknown but studies have shown that the *vapA* gene is essential for virulence. Deletion of this gene abolishes the ability of *R. equi* to replicate within macrophages and to cause disease in a mouse infection model system. However, expression of *vapA* alone is not sufficient; additional PAI-encoded genes are required for manifestation of the full virulence phenotype. The focus of this study was to determine whether any of the related Vap protein family members are necessary for *R. equi* virulence. To address this question, a series of mutants with deletions of one or combinations of various *vap* genes were constructed via allelic exchange and their growth capacity in macrophages was analyzed by dilution plating of infected macrophage lysates. Results from intramacrophage growth assays showed that deletion of all the *vap* genes, with the exception of *vapA*, had no significant impact on the bacterium's ability to replicate in macrophages. These data suggest that *vapA* is the only *vap* protein absolutely essential for virulence.

The Validity of the News Marketing Hypothesis

Jessica Alcorn, CURO Summer Fellow
Dr. Audrey Haynes, Department of Political Science, University of Georgia

Network news, introduced during the mid 20th century, was originally regarded as a prompt and parsimonious manner of learning about the most important events of the day—plain and simple-facts. However, as network news viewership increased, reaching high points in the 1980s and 1990s, so did the number of possible news sources-the traditional newspaper, cable news, the internet, and talk radio, to name a few. As a result, news networks were forced into a more competitive market. In order to retain viewers, network news stations began marketing their news to particular loyal subsets of the population. Using a coding system, we systematically examined the transcripts from Presidential debate commentary for three major television networks-FOX, CNN, and NBC. We exclusively analyzed the period from 1980 to 2009, as technology allowed for an increase in overall TV and news viewership during this time period. This study seeks to determine whether the materialization of various competing news sources has permitted each station to target a specific demographic and ideological viewpoint, thereby yielding the audience of each news source largely homogenous. We are still currently working on measuring the significance of the quantitative results gathered in this study. If the news marketing hypothesis were validated, a news viewer's perception of critical events could be considerably skewed according to the news outlet chosen.

Exploring the Effect of Cysteine Mutations on Rce1p Substrate Recognition and Enzyme Efficiency

Samar Aldrugh, CURO Scholar
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Uncontrolled cell proliferation and migration are common characteristics of malignancies. One causative factor is the aberrant constitutive activation of Ras GTPase proteins, which can result in tumorigenesis. In fact, Ras point mutations are generally found in 20% to 30% of all human cancers, and higher incidences in specific tumors (e.g. pancreatic). Ras undergoes several post-translational modifications, including proteolysis by Rce1p, which cleaves within a C-terminal-CaaX motif found on precursors of Ras and other substrates, such as the a-factor yeast mating pheromone. Initially, it was proposed that Rce1p is a cysteine protease. A cysteine-less form of Rce1p, however, is functional *in vivo,* indicating that cysteines are not critical to the enzymatic activity of Rce1p. On the other hand, we have observed that cysteine-less Rce1p does not efficiently cleave short synthetic peptides based on Ras and a-factor *in vitro*, indicating a possible role for cysteines in substrate recognition. We hypothesize that Rce1p binds substrates in a dual mode via a CaaX proximal cysteine-dependent recognition element (PRE), and a CaaX distal cysteine-independent recognition element (DRE). We predict that WT Rce1p relies on both PRE and DRE for recognizing and cleaving its substrates, whereas cysteine-less Rce1p relies on DRE. This prediction is being evaluated with a series of *in vivo* reporters having modified recognition elements in combination with WT and cysteine-less Rce1p. We anticipate that our findings will better our understanding of Rce1p mechanism of action to effectively design inhibitors that can be used as anticancer drugs.

Salamander Trophic Position and Diet Diversity in Southern Appalachian Headwater Streams

Courtney Allen
Dr. Amy Rosemond, Odum School of Ecology, University of Georgia

Diet and life history data are important to understanding how organisms will respond to global environmental changes. Mobilization of nitrogen (N) and reductions in availability of phosphorous (P) globally are influencing organic matter processing in aquatic ecosystems. These changes in key food resources will influence production and distribution of top predators, such as stream salamanders. We investigated how salamander elemental body composition and diet varied with body size in non-impacted

streams. Through investigation of carbon (C), N and P content as well as isotopic signatures, we gathered baseline data on trophic position of black-bellied salamanders, Desmognathus quadramaculatus, (n = 10) in five southern Appalachian headwater streams at the Coweeta Long-term Ecological Research (LTER) site. Additionally, through gut content analysis, we investigated the diet composition of the salamanders. Using linear regression, we measured declines in body C:N and C:P, and C and N isotopes of D. quadramaculatus with increasing body size. Although changes in N and P concentrations are expected with increasing body size in vertebrates due to potential diet shifts and bone growth, size-dependent isotope patterns were not explained by differences in diversity or composition of invertebrate prey items. Further examination of the composition of prey items in D. quadramaculatus guts may explain size-dependent declines in body C and N isotopes. Understanding baseline trophic dynamics in freshwater systems will allow us to quantify and predict the relative impacts of various ratios of N and P inputs, as well as other types of global change on headwater stream food webs.

Campaign Finance and Vote Outcomes in U.S. House Primary Elections

Nathaniel Ament-Stone, Roosevelt @ UGA
Dr. Jamie Carson, Department of Political Science, University of Georgia

Even as public confidence in Congress sits near all-time recorded lows— a recent CBS poll pegs congressional approval at 24 percent—retention rates for House incumbents remain historically high, with 94 percent (on average) of incumbents reelected, and all but 11 renominated in party primaries, in the past four election cycles. High retention rates, despite public disapproval, represent a loss to the public interests of competitive elections and responsive representation, and prompt the question of how to promote greater levels of effective electoral competition—that is, competition which, on average, lowers incumbent renomination rates and victory margins. Based on an examination of how campaign spending levels affect renomination rates in the House of Representatives, this paper compares alternative campaign finance regulations to incentivize primary competition. Applying data from previous studies correlating campaign spending to election outcomes, this presentation compiles relevant political science research and incorporates recent election data and legislative history. Several possible alterations to campaign finance law are then compared based on their projected cost-effectiveness, political and administrative feasibility, and effects on free speech. The alternatives examined are a repeal of individual campaign contribution limits, a matching public subsidy scheme for primary challengers who raise a starting sum of $25,000, and a lower ($2,400 per primary election) limit on contributions from party or political action committees. The research concludes that the most effective policy, repealing individual contribution limits, is also the likeliest to withstand Supreme Court First Amendment review, though it faces challenges regarding political feasibility.

Healthy Teens: a Longitudinal Study of 'At Risk' Secondary Students

Amarachi Anukam, CURO Summer Fellow
Dr. Pamela Orpinas, Department of Health Promotion & Behavior, University of Georgia

Healthy Teens is a longitudinal study of a cohort of students from Northeast Georgia who were surveyed yearly from grades six through twelve. The goal of Healthy Teens is to examine the developmental pathways that students follow during middle and high school—crucial stages in the journey to adulthood. In this study, we explored the relation between neighborhood environment and delinquent behavior. The sample consisted of 581 students (52.5% male, 45.4% Caucasian, 38.2% African American, 11.2% Latino, 1.2% Asian, and 4% Multiracial/Other). In sixth grade, students attended one of nine middle schools in NE Georgia, representing a diverse group of schools (urban/rural location, SES of students, racial diversity). Using an adapted version of the Neighborhood Observational Checklist, we collected data on physical characteristics of the neighborhoods of the last known address of Healthy Teens participants. Based on participant

self-reported data, we have identified three delinquency trajectories. We compared neighborhood characteristics, for example, condition of homes, police presence, type of housing, and graffiti, by delinquency categories. None of the neighborhood characteristics differed significantly by delinquency trajectory. The presentation will discuss the qualitative aspects of the students' resident communities and dropout rates for each trajectory. Through further analysis of data from the Healthy Teens study, we hope to understand how adolescent behaviors interact, so that strong prevention programs may be developed for youth, families, and schools. Such prevention programs will aim to help youth make healthy and non-violent choices.

An RNA-Protein Complex of a Prokaryotic Immune System

Rachel Appelbaum, CURO Scholar
Dr. Michael Terns, Department of Biochemistry & Molecular Biology, University of Georgia

Recently, a small RNA-guided prokaryotic immune system was discovered that protects organisms from viruses, plasmids and other invaders. This immune system is called the CRISPR (Clustered, Regularly Interspaced Short Palindromic Repeat)-Cas (CRISPR-Associated) system and is composed of small RNAs from the CRISPR gene locus called prokaryotic silencing, or (psi)RNAs, and proteins from the Cas genes. The focus of this research is a specific psiRNA-Cas protein complex that was isolated in the Terns' lab and shown to function in psiRNA-guided destruction of invader RNA. The specific goals of this research include: (1) to reconstitute the RNA-protein complex and show that it binds psiRNA and cleaves target RNA; (2) to understand RNA-protein interactions within the complex; (3) to determine protein-protein interactions within the complex; and (4) to determine which proteins are required for function of the complex. The reconstitution of this RNA-protein complex from incubation of synthetic psiRNA with recombinant Cas proteins shows cleavage of a target RNA sequence, like it is in vivo activity. The results of protein co-expression assays (via simultaneous transformation of two plasmids with different selection markers) indicate at least three instances of protein-protein interactions between two of the Cas proteins. RNA binding studies suggest that four of the six Cas proteins are critical for association with the psiRNA. All six of the Cas proteins are required for the RNA-protein complex to function efficiently. Understanding the molecular organization of this RNA-protein complex is vital in understanding the mechanism of prokaryotic defense against viruses and other potentially harmful mobile genetic elements.

The Influence of Soren Kierkegaard on the Work of Walker Percy

Rebecca Arnall
Dr. Hugh Ruppersburg, Department of English, University of Georgia

The existential movement, especially the writings of Christian existentialist Soren Kierkegaard, influenced the writings of Walker Percy, a philosophical novelist of the American South. In his works, Kierkegaard describes three stages through which he believes people move in their search to find their reason for existence, or the worth, significance, or authenticity they find in their lives. He calls these the aesthetic, ethical, and religious stages. According to Kierkegaard, not all people progress through all three stages. Some even regress, yet at any time they will reside in one of the three stages. After comparing the protagonists of Percy's fiction to Kierkegaard's stages as outlined in his books *Either/Or* (1843) and *Fear and Trembling* (1843), I have found that, following a sudden realization regarding the futility of their pursuits, each of Percy's protagonists follows a different path through Kierkegaard's stages in his search for meaning. This search is often colored by the loose brand of Catholicism practiced by Percy's protagonists, which often hinders them from reaching the religious stage. This research explores the influence of Kierkegaard's three stages on Percy's fiction, as he explores each protagonist's individual struggles and search for meaning. Understanding Kierkegaard's influence on Percy—especially on the struggles of his protagonists—enables an understanding of Kierkegaard's thought and of existentialism in general.

Lutein and Zeaxanthin Availability in Bodily Tissue

Madison Asef
Dr. Billy Hammond, Department of Psychology, University of Georgia

Lutein and zeaxanthin are two carotenoids, found readily in green, leafy vegetables, known to deposit heavily in adipose tissue and in the retina, where they are referred to as macular pigment. Macular pigment has protective benefits against age-related macular degeneration by reducing the amount of oxidative stress in the retina. The level of macular pigment appears to vary among individuals according to percentage body fat. The purpose of this experiment is to evaluate the relation between macular pigment and body fat percentage and to potentially explain covariates of lutein absorption in the tissue after a dietary intervention. 86 subjects, between the ages of 18-40, completed measures of macular pigment optical density (MPOD) and body composition. Heterochromatic flicker photometry was used to determine MPOD and dual-energy X-ray absorptometry (DXA) scans assessed percentage body fat. Baseline data indicated an inverse relationship between body fat percentage and macular pigment ($p<0.05$). 63 subjects remain in the ongoing study, 10 of which have completed all measurements through the 12-month study. Visual analysis of the completed data suggests that the inverse relationship no longer exists, possibly due to other variables including sex, blood lipid values, body fat distribution, and serum response to lutein. Identifying the role of these covariates may contribute to an understanding of the competition hypothesis which states that adipose tissue and retinal tissue compete for absorption of lutein.

Non-Formal Music Education in Latin America: A Case Study of El Sistema Venezuela and Its International Expansion

Christina Azahar, CURO Apprentice
Dr. Susan Thomas, Hugh Hodgson School of Music, University of Georgia

The Venezuelan music education program, El Sistema, is a groundbreaking youth orchestra system that demonstrates a praxis of Paolo Freire's theory, the Pedagogy of the Oppressed. By utilizing music as a force of social change, El Sistema seeks to improve children's lives not simply through providing material resources, but also by changing students' perspectives on their identity and their responsibilities and rights as a citizen. This "re-humanizing" educational method is central to Freire's theory, and El Sistema has had immense success in developing not only knowledgeable citizens, but also great artists through a philosophical and spiritual approach to learning music. Because of this, it has grown from a small program in Venezuela into an international movement, and has served as a model for socially conscious music education programs in Latin America and across the world. El Sistema's expansion raises the following questions: How is El Sistema's pedagogy adapted to other societies? Why is it so effective in creating social change? Does the openly political ideology of El Sistema transfer along with its music pedagogy? To answer these questions, I will examine case studies of El Sistema-derived programs in both the United States and Colombia to determine how this pedagogy has been used for both structural and humanist reform. This will include reading interviews of students, teachers, and policy-makers, as well as reviewing scholarly literature on El Sistema and non-formal education in Latin America. Through this study I hope to demonstrate how music can both materially and humanistically improve society's well-being.

The Relationship between Personal Beliefs and Family Values in International College Students from a Hungarian University

Lisa Baer, Kacie Caudle & Robert Gentry
Dr. Tsu-Ming Chiang, Department of Psychological Science, Georgia College & State University

An individual's personal beliefs often reflect their family and cultural values. These beliefs may vary with socio-historical changes. However, limited research has been conducted to examine whether personal beliefs and ideologies change across generations in the Hungarian society because of the language barrier. Hungarian students are now taught basic understanding of the English language, which

makes it possible for data collection. This research aims to contrast the family core values of international students collected from a Hungarian University. Sixty-seven international students (Male = 13), with average ages of 23.6 for male and 21.61 for female participated in the study. This cross-cultural study in family values and parental beliefs is beneficial to increase awareness of culture's core beliefs and values. A survey was used to explore ethnic norms, parenting techniques, and future parenting techniques through quantitative and qualitative measures. Particular interests include comparisons between students' past experiences and future plans as prospective parents in permitted age to date, differences in bedtime and curfews, and parental involvement in daily life, etc. It is expected that participants' future plans are consistent with their parental beliefs in items that either they accepted or perceived as reasonable. Preliminary results, utilizing SPSS, revealed significant relationships between parental values and individual beliefs in group dating ($r = .87$, $p = .01$), individual dating ($r = .64$, $p = .01$), make up age ($r = .53$, $p = .01$), sleepover ($r = .69$, $p = .01$). More data and results will be shared at the CURO 2011 Symposium.

Frequency Distributions of Japanese Characters

C. T. Bailey, CURO Summer Fellow
Dr. William Kretzschmar, Department of English, University of Georgia

The linguistics of speech is a new model of language study which gives pride of place to language in use (Kretzschmar 2009). Instead of relying on rules to describe language, it uses frequency information. One of its central findings, the A-curve, reveals that in a text there are a few very common linguistic items and many uncommon ones. Research has shown that variant vowel realizations and words both follow this distribution, but researchers have not addressed meaning-carrying items smaller than the word. To remedy this, my study examined kanji, Japanese characters that carry meaning and can be smaller than a word. First, I collected 70 interviews with Japanese musicians from the Internet. The data was subdivided into male and female subsamples, and Wordsmith Tools was used to create a list of kanji frequencies for both. The subsample and total frequencies were then plotted using Open Office Calc. I found that kanji did form an A-curve, and that, furthermore, this A-curve exhibited the scaling property predicted by the linguistics of speech. This meant that though the A-curve was present at multiple levels of scale, the subsample frequencies did not reflect the frequencies in the data as a whole. These findings are significant because they support the linguistics of speech as a robust model of language and suggest that similar forces may operate across multiple levels of linguistic analysis. This challenges the common practice of separating areas like syntax, morphology (which studies word formation), and phonology (which studies speech sounds).

Kretzschmar, Jr., William. *The Linguistics of Speech*. Cambridge: Cambridge University Press, 2009. Print.

Tri-state Water 'War': Media Frames and Weighing What Is Best for the Apalachicola-Chattahoochee-Flint River Basin

Joshua Barnett
Dr. David Radcliffe, Department of Crop & Soil Sciences, University of Georgia

In the southern United States a modern-day environmental dispute is taking place. At the center of this controversy is the Apalachicola-Chattahoochee-Flint (ACF) river basin. The large river basin encompassing Alabama, Georgia, and Florida has spurred much economic and ecological strife as each state has lobbied for its own interests in this incredible water resource. Much attention has been focused on the "Tri-State Water War" by television and print media, and it is those media that have named the dispute in this way. Commentary on the dispute has likened it to "battles," "struggles," and "fights to the death." Indeed, it is a battle being waged in the courtrooms, on the editorial pages of local newspapers, and, recently, on the cinematic screen. Drawing from news stories in the *Atlanta Journal-Constitution* and case studies presented

in the recent documentary entitled "Chattahoochee: From Water War to Water Vision," I answer the question, How has the war frame been, and continued to be, employed in news media to relate a particular understanding of the dispute? Moreover, based on this close textual analysis, I suggest that framing the dispute as a "war," in fact, undermines the efforts of stakeholders to reach a resolution on the management of the ACF river basin. This study adds to our collective understanding of the Tri-State Water War, and concludes with suggestions for a more productive discourse surrounding the dispute.

Democracy Blinded: a Study of the Afghanistan and Iraq Wars, 2001-2008
Ashley Bartlett, CURO Scholar
Dr. John Morrow, Department of History, University of Georgia

The terrorist attacks on September 11, 2001 led to the United States' invasions of Afghanistan and Iraq. While many observers are concerned with the justness and conduct of the resulting conflicts, they often ignore a far more important question—how has the "war on the terror" affected the democratic principles of the United States? What can nearly ten years of war teach the U.S. about terrorism, warfare, and its own democracy? These conflicts in Afghanistan and Iraq began a new era for the United States. Iraq has cost the United States $11 billion a month. Afghanistan has cost a total of $190 billion. In the words of John Quincy Adams, America's paranoia over the September 11 attacks made her "go abroad in search of monsters to destroy." Preemptive war, the use of mercenaries and torture such as water boarding—these previously questionable ideas and methods became household words between 2001 and 2008. Have these wars had any effect on the democracy of the United States? This thesis suggests that a sense of urgency and fear of the unknown blinded American democracy. This fear and paranoia led to the compromise of America's democratic ideals and institutions, as exemplified by the government infringing on civil liberties, Congress yielding legislative power to the President, and the United States reneging on various international treaties. By launching wars to destroy the terrorist threat and democratize an entire region of the globe, the United States may in fact be undermining democracy at home.

The Elements of Chinese Grand Strategy: Applying a New Analytical Approach
Ashley Bartlett, CURO Scholar
Dr. Brock Tessman, Department of International Affairs, University of Georgia

Uncertainty about China's long term intentions has generated anxiety among many western leaders, and has led to a deadlock among international relations scholars. Will China try to assert regional dominance in East Asia? How feasible (and advisable) is it for the United States to seek to stop or stall China's meteoric rise and maintain unquestioned hegemony? In order to adequately answer these questions, one must better understand the origins and many facets of Chinese grand strategy. Through deeper appreciation of the basic way in which a country like China develops foreign policy goals and seeks to mobilize its resources in order to achieve them, one can better analyze past decisions and be better positioned to predict future behavior. This presentation will discuss China's grand strategy from the beginning of Hu Jintao's presidency in 2002 to the present. In order to do this, I will use a new analytical approach: a model for researching grand strategy. This model uses "elements" and "principles." The elements consist of four separate categories: defense, diplomacy, resources/economics, and ideology. All four elements combined form a "principle," a specific pillar to an actor's grand strategy. Using this analysis, I determined China's grand strategic principles: international institutions, modernization, resource security, and reunification. Together, these principles form China's grand strategy: "partnership." It is through the lens of "partnership" that the United States should interpret, and react to, the wide range of foreign policy behavior that is of increasing global importance.

Differences in Functional Movement Screen Scores Between Female Soccer Players That Were Injured vs. Uninjured.

Katherine Black
Dr. Cathleen Brown, Department of Kinesiology, University of Georgia

Due to the contact nature of soccer, athletes are prone to numerous lower extremity injuries. Pre-season screenings may identify movement deficits exhibited by athletes that could be addressed with rehabilitation programs, thus reducing injury risk. Our objective was to determine if there was a significant difference between the number of lower extremity sprains sustained in female soccer players with higher functional movement screen (FMS) scores (>12) when compared with female soccer players with lower FMS scores (≤12). A score of 12 was previously established a clinically meaningful difference in performance. Members of a collegiate women's soccer team (n=31) performed and were scored on the 7 components of the FMS in the spring or summer prior to their competitive fall season by trained FMS professionals. After the season, an injury report was obtained, and 8 joint injuries were catalogued regardless of contact of non-contact nature. An injury was defined by an athlete's complaint or injury that resulted in evaluation and treatment by an athletic trainer. Using a Pearson chi square-analysis, a significant difference in observed vs. expected joint injury counts ($\chi 2 = 7.4$, $p = .0075$) was found, with players scoring ≤ 12 experiencing more sprains than expected. These results indicate that soccer players with low FMS scores were most likely to suffer a joint injury during the season. Pre-season training should focus on improving muscular strength and neuromuscular control in order to increase FMS scores, which may lead to a reduced risk of injury during the season.

Analysis of the Inter-Rater Reliability of the Functional Movement Screen

Jason Bowman, CURO Apprentice
Dr. Cathleen Brown, Department of Kinesiology, University of Georgia

The Functional Movement Screen (FMS) was recently developed to identify athletes at risk of incurring injury. It consists of 7 movements assessing strength and range of motion deficits and asymmetries on a 1-3 scale. Current research on the sensitivity, validity, and inter-rater reliability of the FMS is limited, as is the difference in reliability between "expert" and "novice" raters. The purpose of this preliminary study was to assess novice inter-rater reliability on the 7 movement tests. Six undergraduates with limited background in the FMS were taught the scoring criteria for test. Videos of 5 participants completing the FMS movements were created. The 6 student raters then scored the videos following the guidelines on 3 separate occasions, and the inter-rater reliability was assessed using the generalized kappa statistic. The deep squat, shoulder mobility, and straight leg raise tests were all found to have generalized kappa statistics indicating moderate to strong inter-rater reliability that was better than chance (Kappa = .37-.60; Standard Error (SE) = .11-.16; $p < .05$). However, the kappa statistic indicated poor reliability when scoring the hurdle step, in-line lunge, push-up and rotary stability tests where agreement was no better than chance (Kappa = .02-.46; SE = .12-.51; $p > .05$). These low agreements may be due to scoring errors made by novice raters. Additionally, the kappa statistic is reduced if 1 class category dominates the rating, as happened with these data. Future studies should increase rater training, utilize more varied performance in class categories, and possibly apply different statistical procedures.

The Political Economy of the Textile Industry in Bangladesh

Katie Branscomb
Dr. Santanu Chatterjee, Department of Economics, University of Georgia

Textiles have been Bangladesh's primary economic industry since before Bangladesh's independence in 1971. Beginning with jute production for the colonial shipping industry and transitioning to readymade garment production in recent years, fifteen million Bengalis currently depend on the textile industry for their livelihoods. In 1974, the Multi-Fibre Agreement exempted Bangladesh from the import quotas it placed on other countries. Based on the principles of the "infant-industry argument" the

special treatment was meant to give Bangladesh time to strengthen its textile industry before exposing it to the free market on January 1, 2005, when the quotas expired. The literature unambiguously finds that the import quotas were beneficial to the Bengali textile industry. The question now is whether the protections that Bangladesh enjoyed for thirty years created enough benefits to outweigh the costs that Bangladesh faces in an import quota-free world. This paper presents the consequences of removing the Multi-Fibre Agreement's import quotas for the textile industry in Bangladesh. Data analysis comes from information on economic indicators (like the trade balance and GDP), discussion of trade liberalization policies, and government's role in structural adjustment in order to determine how evolving economic actions and trade policies have impacted the Bengali textile industry and the households that depend on it for their livelihoods. As one of the world's poorest countries, Bangladesh's economy is an international concern. We must understand the economics of developing countries like Bangladesh in order to determine the best course of action that will most effectively challenge the status quo.

Genetic Analysis of Pigmentation in *Drosophila tenebrosa*

Michael Bray, CURO Summer Fellow
Dr. Kelly Dyer, Department of Genetics, University of Georgia

Pigmentation is a trait that evolves rapidly in many species of animals. An example includes the quinaria group of *Drosophila*, in which most species are yellow in body color with distinct dark spots spaced around the abdomen. The sole exception is *Drosophila tenebrosa*, which has a completely diffuse, dark melanic abdomen. In this experiment, I interbred *Drosophila tenebrosa* with a closely related yellow species, *Drosophila suboccidentalis*, looking for the genetic basis of inheritance of the melanic abdomen. I then performed backcrosses, using the F1 female hybrids crossed to each male *D. suboccidentalis* and *D. tenebrosa*, respectively. I scored and ranked the offspring based on pigmentation intensity of the dorsal abdomen. By analyzing the progeny of the F1 hybrids and F2 backcrosses, it appears that the unique pigmentation phenotype in *D. tenebrosa* is caused by two main loci, a locus on the X chromosome and a locus on an autosome. I then used a candidate gene approach to ask which genes in the pigmentation pathway are associated with dark pigmentation in *D. tenebrosa*. I found two genes, *yellow* and *ebony*, that contribute to the dark pigmentation phenotype of *D. tenebrosa*. The *yellow* marker is located on the X chromosome, and the *ebony* marker is on an autosome. These or closely linked genes appear to have an additive effect to pigmentation and together can explain the majority of the dark pigmentation phenotype. This work will ultimately help us understand how changes on the gene level affect changes on the phenotypic level.

Effects of Medial-Wedge Orthotics on Knee Frontal Plane Moments in Individuals with Valgus Knee Alignment and Lateral-Compartment Osteoarthritis

Jenny Brickman
Dr. Cathleen Brown, Department of Kinesiology, University of Georgia

Individuals with valgus knee alignment have an increased risk of developing lateral compartment knee osteoarthritis (OA), a common disease. Orthotics used to realign the foot and leg may offer a relatively inexpensive, noninvasive treatment option. Large knee joint valgus moments have been linked to lateral compartment knee osteoarthritis. The purpose of this study was to determine if valgus moments decreased in valgus-knee aligned participants with or without medial-wedge orthotics during tasks of daily living. Three participants with an average age of 61 with valgus knee alignment and self-reported lateral compartment osteoarthritis were tested using biomechanical motion analysis equipment. Knee moments in the frontal plane (maximum and minimum during the loading phase) were measured during three tasks: gait, sit to stand, and stepping down from a box. Qualitative descriptions were used to assess changes in moments. During the gait task, orthotics did not significantly change the valgus moment. In the sit to stand task, orthotics shifted the moment toward the valgus direction

by 14.9%. However, after omitting one subject's data, the results showed that orthotics were beneficial and the moment shifted toward varus by 11.4%. During the step task, orthotics decreased the valgus moment by 10.2%. These preliminary results indicate most participants experienced decreased valgus moment in each task when wearing orthotics, potentially decreasing the load on their affected knee condyle. However, the impact of orthotics on valgus moment may change on an individual basis. Further research should be done gain more accuracy and insight into individual differences.

Sex Differences in the Mechanisms Underlying Facial Expression Recognition: Effects of Cognitive Load and Facial Mimicry on Facial Expression Recognition

Lindsay Briggs
Dr. Janet Frick, Department of Psychology, University of Georgia

Humans use at least two routes for recognizing emotion: an empathetic route that involves facial expression mimicry (matching), and a cognitive route that does not involve mimicry (Stel & Knippenberg, 2008). Facial mimicry is a process in which people automatically imitate others' facial expressions. The cognitive route is a slower process which involves matching visual input with one's knowledge about emotions. Males and females may differ in which route they use (Simpson & Fragaszy, 2010). Facial mimicry may play an important role in facial expression recognition, particularly for females. The extent to which males and females differ in the cognitive route remains untested. We explored two mechanisms which may underlie sex differences in facial expression recognition: the extent to which mimicry facilitates recognition, and the amount of cognitive resources necessary for recognition. We predicted that while females use the empathetic route and mimic more than males, males more often use the cognitive route. If this is the case, females' performance (i.e., speed, accuracy) should decrease when mimicry is prevented, while males' performance should decrease when cognitive load is increased. Participants were asked to rate facial expressions. We manipulated cognitive load with a word memory task. We also manipulated the extent to which participants could mimic facial expressions by having them hold a popsicle stick between their teeth. We are currently collecting data and will present preliminary findings. This work has implications for communication between the sexes, as well as implications for those who suffer from impairments in facial expression recognition.

Black Stereotypes in Reality Television and the Reinforcement of Prejudiced Attitudes

Melissa Brown
Dr. Leonard Martin, Department of Psychology, University of Georgia

The proposed studies explore the relationship between stereotypes of Black Americans presented in reality television shows and the racial attitudes of White Americans. They also explore the possibility that this relationship is affected by White Americans' real-world and mediated exposure to diversity. The experiment begins with a content analysis of reality television shows, focusing on the presence of minority contestants in a majority cast as well as how minority contestants interact with non-minority contestants and main characters. Content analysis will highlight instances such as how duration of a minority on camera, the nature of the behavior while on camera, whether or not the behavior may be perceived as positive or negative, and how frequently these instances occur. Study 1 will survey White Americans regarding their reality television viewership and their racial attitudes. Study 2 will content analyze reality television shows to determine which specific aspects of the shows may drive overall depictions of Black Americans. It is hypothesized that the more negative stereotypes of Black Americans a show contains, the more likely it is that White Americans who possess negative racial attitudes will consider these stereotypes to be accurate portrayals. It is also hypothesized that more intergroup contact will lead to more positive racial attitudes, regardless of stereotype knowledge. Such findings will elucidate the real world effect the unreal stereotypes displayed in this type of television media has on minorities.

Nice to Have: Expression and Movement Through Film

Virginia Broyles
Ms. Bala Sarasvati, Department of Dance, University of Georgia

Nice to Have is a work I created to explore the integration of dance and film. How can film techniques and editing contribute to the expression of a choreographic idea? Traditionally, concert dance is performed onstage, and while many elements with lighting and set design are utilized, the choreographer is still somewhat limited in angles and distance from the viewer. With film this can be manipulated throughout the piece. Historically speaking, dance for camera is still a new medium, and I wanted to not only effectively present the choreography, but also use film to better fulfill the emotional content and story. The piece explores a relationship that is physically represented by fabric that ties two people together. I explored movement ideas and motifs through improvisation. Then I developed movement phrases and integrated them with the fabric, exploring the limitations and inspirations that came with using a prop. Working with film offered many options for viewing the dance choreography, but having so many options was also a challenge. Location was an important element to consider in the piece, as well as the lighting possibilities available. I planned filming to acquire a variety of shots, especially from various points of view and distances to express an intimacy that is not usually experienced when viewing a dance onstage. The next creative step was exploring how through editing of the film I could enhance the expression of the choreography and create a cohesive and interesting dance piece.

Geographies of Expression: the Arts within Space and Scale

Tyler Bugg
Dr. Amy Trauger, Department of Geography, University of Georgia

To date, inquiry into a geographical understanding of the fine arts, and of theatre arts in particular, has been largely absent. It is this silence that this research attempts to fill with staple concepts of the geography discipline. As geographical discourse is largely occupied with elements of *space* and *scale*, it becomes an applicable tool for describing the experiences to be had through the theatre arts. *Spatiality*, as geographers understand it, is fundamental to the experience of the theater. It is central to explaining the relationships between performers in productions, audiences that attend them, venues that host them, and state institutions that fund them; each player has unique spatial interactions with each of the others. Moreover, geography asserts that these interactions are situated in levels of *scale*. The full process of the theatre arts involves actors as small as the individual body of the performer and as large as the regulatory functions of state arts institutions. Interview and observational analysis of the theatre arts as both an academic discipline and a business of entertainment is at the center of this research, deriving data from the experiences of actors and directors, theater patrons and ushers, and state arts policy agencies. Geography, then, is a mediator of the interactions that make theatre the artistic outlet as we know it. As such, the experiences of the theatre arts can be viewed as *geographies of expression*, where the artistry of creative expression grows out of the geographies that give them root.

Characterization of *C. elegans* Insulin-degrading Enzyme

Mary Burriss, CURO Scholar
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Recent research on Alzheimer's disease (AD) has focused on the amyloid hypothesis, which states that accumulation of the beta amyloid (Aβ) peptide causes neurodegeneration. The insulin-degrading enzyme (IDE) degrades insulin, Aβ, and several other biologically important peptides. If IDE activity, towards Aβ specifically, could be enhanced, the accumulation of Aβ would predictably occur at a lower rate and perhaps delay the progression of AD. The Schmidt lab has identified compounds that activate *Rn*IDE *in vitro*. For a cost efficient animal model to study IDE and its activators, I have investigated the utility of the *C. elegans*

system. In the first part of my study, I created a bacterial vector for recombinant expression of *Ce*IDE, which was purified via cobalt-sepharose column chromatography. A series of *in vitro* studies demonstrated the ability of recombinant *Ce*IDE to cleave Aβ and other substrates that are cleaved by IDE family members. Additional studies determined that *Ce*IDE is not a good target for investigations of *Rn*IDE activators due to lack of cross-specificity. In the second part of my study, *Ce*IDE was investigated using a yeast system that allows for studies of the *in vivo* specificity of IDE family members through production of the **a**-factor pheromone. I created a yeast vector that was used to express *Ce*IDE in yeast and demonstrated via genetic methods that *Ce*IDE promotes pheromone production with the same efficiency as other IDE family members. These studies reveal that *Ce*IDE has biochemical and enzymatic properties similar to mammalian IDE and other IDE family members and suggests that the *C. elegans* system can be used to study the physiological role of IDE enzymes more thoroughly, although there are limitations with respect to investigations of IDE activators.

Influences on the Outlook of the Post-College Educational Opportunities and Choices of Undergraduate Science Majors

Ebony Caldwell, CURO Summer Fellow
Dr. Monica Gaughan, Department of Health Policy & Management, University of Georgia

Women and members of some racial and ethnic groups are under-represented in the fields of science, medicine, and public health. In the field of medicine, minorities represent less than 15% of the physicians entering the workforce. This disparity is even more present in academic institutions at the faculty level, where minority representation is 5% despite the US population of minority groups being over 30%. Additionally, there are shortages of professionals from all backgrounds performing research in the sciences and practicing medicine in the United States, and these shortages are only expected to increase in the future. However, before these faculty members and professionals enter the workforce, they experience myriad influences as undergraduate students that shape their future employment and educational decisions. The study focuses on the factors that influence the intentions for post-baccalaureate studies of undergraduate students. The participants of this study are University of Georgia undergraduate science majors recruited through either a snowball sampling or a convenience sample. All data collected were gathered through semi-structured interviews with a protocol of questions that asked participants how they perceived their academic and professional futures and what factors influenced their pursuits of these plans, including themes such as race and early education. The collected data served as the basis for qualitative analytic work exploring how different social constructs, such as family, gender and ethnicity, have affected the perceptions of the opportunities and likelihood of success for the participants in the study.

Role of the Telomere Binding Protein TPP1 in Recruitment of Telomerase to Telomeres in Human Cancer Cells

Garrett Casale
Dr. Michael Terns, Department of Biochemistry & Molecular Biology, University of Georgia

Telomerase is the ribonucleoprotein responsible for lengthening telomeres at the ends of eukaryotic chromosomes. Telomeres are RNA-protein complexes that protect chromosomes from gradual degradation caused by the end replication problem. While most normal human somatic cells do not express telomerase, cancer cells have been found to possess reactivated telomerase activity. As an enzyme paramount to the survival of cancer cells yet dispensable in most adult tissues, telomerase is a promising target for future chemotherapeutic treatments. We are investigating the mechanism of recruitment of telomerase to telomeres in human cancer cells. We show here that TPP1, one of six core telomere binding proteins, is critical in telomerase recruitment to telomeres. Depletion of TPP1 expression via RNA interference inhibited telomerase recruitment to telomeres. Loss of telomerase recruitment was restored with the expression of an RNA interference-resistant form of TPP1. Furthermore, we found that the oligonucleotide-binding fold (OB-fold) domain of TPP1 is required for TPP1 to function

as a telomerase recruitment factor. These results identify and support a direct role of TPP1 in telomerase recruitment to telomeres and suggest that the OB-fold domain of TPP1 mediates the direct interaction of telomerase with telomeres.

The Art of Persuasion: How Small Business Owners Use Speech to Market Products in Roswell, GA

Caitlin Cassidy, CURO Summer Fellow
Dr. William Kretzschmar, Department of English, University of Georgia

Linguistics is a field that is not often explored within the context of marketing and business management. Rather, its study is often confined to analysis of historical languages and language acquisition, leaving little room for discoveries in the art of modern communication. My research intends to open doors to discoveries in the field of sociolinguistics, with regards to how speech can be used as a business strategy. The primary objective of this research is the identification of patterns in communication that characterize new members of the business community and allow for their success in the free market. I am looking for characteristics that help to establish credibility as an entrepreneur. I have conducted recorded interviews with three volunteers from the Roswell community who have come to Roswell from abroad and started businesses. Included in the recordings are conversations related to personal background, the decision to immigrate to Roswell, and the challenges one can expect from opening a small business. I have transcribed each of the interviews and have reviewed them in the hope of discovering specific themes. In particular, I am comparing these themes with what is already known about the speech of Roswell residents. I believe that a new understanding of the integration of international residents and their businesses will emerge and give the community of Roswell a means of improving communication between buyers and sellers, ultimately helping the local economy to continue grow and prosper.

First-Principles Investigations of Oxygen Vacancies on SnO2 Nanofilms

Daniel Cellucci, CURO Summer Fellow
Dr. Steven Lewis, Department of Physics & Astronomy, University of Georgia

The *n*-type semiconductor tin dioxide (SnO_2) has long been used as the working material for robust, inexpensive oxidizable-gas sensors. In recent years, advances in nanofabrication have made possible the well-controlled formation of SnO_2 nanocrystals. Since gas sensing in SnO_2 involves changes in surface resistivity as a function of gas concentration, nanocrystalline SnO_2 holds great promise for high-sensitivity gas sensors, due to the high surface-to-volume ratio. A key feature of the sensing mechanism is the facile formation and destruction of oxygen vacancies at (or near) the surface. In this talk I will discuss our ongoing first-principles investigations of surface oxygen vacancies in SnO_2 nanofilms. We have focused on vacancy formation among the so-called bridging oxygen atoms on the (110) surface of rutile SnO_2, as a function of vacancy concentration and film thickness, studying the effect on local atomic and electronic structure. This work is the first phase of a longer-term investigation of surface vacancy phases on SnO_2 (110) as a function of temperature and oxygen vapor pressure.

Remote Sensing as a Generative Tool in the Creation of Fine Art

Daniel Cellucci,
Dr. Ralph Brown, Lamar Dodd School of Art, University of Georgia

As defined by the National Aeronautics and Space Administration (NASA), remote sensing refers to instrument-based techniques employed in the acquisition and measurement of geographically distributed information. The author has taken the data previously gathered from such remote sensing instruments as ground penetrating radar, electromagnetic conductivity, and SONAR and now seeks to use these samples to fabricate forms that can truthfully reflect the data from which they were derived. Building upon the results of research projects presented at previous CURO symposia that involved applications of SONAR to underwater art, the

author seeks to explore new possibilities in the area of sculpture that are offered by other tools that are employed in the study of remote sensing. The aim of this research is to take the data generated from these processes and to create a series of software tools that can effectively present this information in a virtual space. The virtual works created from these tools will be made visible via a technique known as augmented reality, whereby the use of specifically equipped mobile technologies can access the work in real time. In particular, two attempts to convey this space will be presented. The first will be in an indoor piece, involving fiduciary markers that will map the work into a gallery setting and the second will involve applications of GPS and accelerometer data to geographically positioning the user in an outdoor environment. The frameworks used to accomplish this feat will be capable of expanding to additional works and allow the placement of these works in otherwise inaccessible locations.

Assessing Baseline Characteristics of Mother-Child Dyads Participating in the AFFECT (A Family Focused Emotion Communication Training) Pilot Study

Kristen Cerny & Julia Taylor
Dr. Anne Shaffer, Department of Psychology, University of Georgia

The relationships between parents and children set the groundwork for the child's future relationships as well as general wellbeing and the development of psychopathology. Parenting interventions are used when parents need assistance communicating with, disciplining and strengthening their relationships with their children. Many interventions exist that use operant learning methods to improve child behavior (Eyberg, et al., 2008). While these interventions are effective, they do not directly address children's emotional functioning. The current study is a pilot test of AFFECT (Shipman & Fitzgerald, 2005) a community-based intervention designed to bolster parents' skills in active listening, emotion coaching, and emotional support. Participants currently include 13 families; data collection is ongoing. Families participate in a pre-intervention assessment where they complete self-report measures and a structured interview. This study describes the characteristics of families who choose to enroll in AFFECT. Descriptive analysis of baseline presenting characteristics will allow us to understand the scope of the intervention and inform directions for future expansion of AFFECT. The Difficulties in Emotion Regulation Scale (DERS) and the Parenting Stress Index, Short Form (PSI-SF) will be used as measures of parental functioning. Child emotional and behavioral problems will be measured using parent report (Child Behavior Checklist) and child report (Child Depression Inventory, Multidimensional Anxiety Scale for Children). Although the current sample is too small to compare pre- and post-intervention data, it is important that an understanding of the participants' presenting characteristics is obtained to identify families who are likely to enroll in and benefit from this intervention.

U.S. Primary Care Physicians: A Dying Breed

Agni Chandora, Roosevelt @ UGA
Dr. Monica Gaughan, Department of Health Policy & Management, University of Georgia

Primary Care Physicians (PCPs) are at the forefront of medical care since they are among the first health professionals an ill individual encounters. A sizeable primary care workforce usually coincides with better health results. Currently, the U.S. has one of the lowest ratios of primary care physicians to total population in the developed world, and it has recently started to experience a decline in the percentage of medical students entering primary care. The growing and aging U.S. population needs a far larger number of primary care physicians than are projected to be produced, creating a shortage of at least 50,000 by 2020. Additionally, a PCP shortage already exists in rural areas due to an imbalanced distribution. This paper explores the future shortage and present maldistribution of primary care physicians in the U.S. and evaluates possible policy solutions to increase the provision of primary care services. Through literature and legislative reviews, background information was gathered to understand the problem, and four policy alternatives (status

quo, counseling for medical school students, increasing the use of International Medical Graduates, and expanding nurses' scope of practice) were created. Each alternative's outcome was then evaluated using the criteria of political feasibility, efficiency, and equity. The analysis suggested that expanding the scope of practice for nurse practitioners was the most favorable alternative for increasing primary care services. Finally, the challenges and implementation efforts associated with the recommendation are explained. This analysis offers the optimal solution based on the selected criteria to alleviate the PCP shortage.

The EEOC and the Federal Court of Appeals
Kathryn Clifford & Sophie Winkler
Dr. Scott Ainsworth, Department of Political Science, University of Georgia

Since the creation of the Equal Employment Opportunity Commission (EEOC) by the Civil Rights Act of 1964, the agency has been the federal government's primary means for addressing employment discrimination. Related to its mission, the EEOC has been involved in hundreds of federal Appeals Court cases from 1965 to 2000. Our purpose is to determine whether political influence affected the decision of these cases. For each case in which the EEOC was involved, data were collected on the court's decision, the nature of the three-judge panel resolving the dispute, and the state of the economy when the decision was rendered. The initial results are straightforward: the Appeals Court decide cases differently depending on the partisan and economic circumstances surrounding the cases. Under better economic conditions, panels tend to favor the EEOC, particularly when the partisan composition of the panel coincides with the party in control of the executive branch. The results show that even though the EEOC was designed to be an independent agency, it is still subject to partisan judicial review.

Perceived Barriers and Medication Adherence in Adolescents
Anastasia Couvaras
Dr. Ronald Blount, Department of Psychology, University of Georgia

The purpose of this study is to examine the relationship between perceived barriers and medication adherence for adolescents who are diagnosed with Inflammatory Bowel Disease (IBD). Barriers to adherence include unpleasant side-effects, forgetfulness, faulty organization methods, and oppositionality. It is important that these barriers be acknowledged and addressed because nonadherence to medication may lead to increased risk of mortality and morbidity. The participants in this study will be both the adolescents ranging from 11-18 years of age who have been diagnosed with IBD and their parents/caregivers. In order to determine individual barriers that need to be overcome, each parent/caregiver will complete the Parent Medication Barriers Scale (PMBS) and each adolescent will complete the Adolescent Medication Barriers Scale (AMBS) (Simons & Blount, 2007). Medication adherence will be assessed using the Medication Adherence Measure (Zelikovsky & Schast, 2008), a structured interview conducted separately with parents and adolescents to determine the extent to which adolescents adhered to their prescribed medication intake during the past week. A greater number of both parent and adolescent reported barriers will be associated with lower adolescent medication adherence. Therefore, there is a negative correlation between both parent and adolescent reported barriers and medication adherence. We will attempt to identify adolescent and parent perception of barriers that interfere with their medication adherence. By identifying barriers we can work to individualize solutions to improve medication adherence and health outcomes of adolescents with IBD.

Efficacy of Alternative and Combinatorial Drug Therapies in the Treatment of *Trypanosoma Cruzi* Infection

Byron Crowe
Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia

Chagas disease, the largest infectious disease burden in Latin America, is caused by the protozoan *Trypanosoma cruzi* and affects 16 to 18 million people. An estimated 50,000 people die every year due to infection, which chronically persists undetected for many years in the host. Benznidazole (BZ), the principle drug available for the treatment of *T. cruzi* infection, has largely unknown efficacy and substantial side effects. Importantly, the side effects are believed to increase with cumulative dosage. Benznidazole is usually administered for 30 to 60 days in humans, and we have recently developed several model systems, including a forty day consecutive treatment protocol, that allow for the detection of parasitological cure in mice. Posaconazole (POS), an experimental anti-fungal compound, has also demonstrated activity against *T. cruzi* with markedly lower toxicity compared to BZ. In this work, we asked if less frequent treatment with BZ and POS might be equally effective at curing *T. cruzi* infection in mice as compared to the standard 40 day BZ treatments. While 40 day treatments of POS or BZ show similar efficacy, shorter regimens using just POS were much less effective than identical treatments with BZ. Surprisingly, results suggest that treatment with POS for five consecutive days followed by seven doses of BZ at 5 day intervals was more effective at curing the infection than the same regimen with only BZ. These results suggest that treatments involving less frequent and thus less potentially toxic treatments may be effective in humans.

Friends of Convenience

Robert Daniel
Dr. Michelle vanDellen, Department of Psychology, University of Georgia

Research indicates actual rejection and fear of possible rejection decreases a person's ability to exert self-control. This decrease coupled with a desire to be in social groups creates an environment where people may join groups without commonalities. The purpose of this study is to measure the innate desire people possess for groups and how rejection affects that desire. We recruited participants from the research pool at the University of Georgia to participate in a study designed to measure people's desire to be in groups and the effect social rejection has on people seeking group membership. Four people were placed in a room with each other and completed a measure of personality purportedly so that we could test a software program that forms people into groups based on similarities. While the software was running, people completed an online ball toss game where they were rejected or included by others. The results were then shared on an individual basis and participants told the software didn't place them in a group. The participants were then asked if they would like to join the group regardless of having few commonalities with the group or work alone. Results show that people desire to be in groups. The inclusive nature along with the rejection manipulation showed a decrease in self-control. These factors work in conjunction to produce groups with identities distant from our actual values, which has implications for people's satisfaction with relationships and for how peoples' identities are formed within the context of group membership.

A Culture Identified by Canines: How Dogs Have Become an Integral Part of the American Public Self

Alyson Dankner
Dr. Kaitlin Medvedev, Department of Textiles, Merchandise & Interiors, University of Georgia

In contemporary society, people surround themselves with material objects to fit in or stand out and have begun to use pets, especially dogs, as a means of self-identification. Today, dogs are often dressed like people, treated like children, and have better nutrition and healthcare than some humans. People are using dogs to improve their physical and mental health, enlarge their social circle and even attract members of the opposite sex. In this process dogs have become the new "accessory" of humans; they are dressed to complement their

owners' personal style and project their most important character traits. This paper will discuss this phenomenon and will show that an entire industry was created to pamper and decorate dogs, possibly making them the most versatile and expensive accessory ever. To arrive at my conclusions I have explored the history of the relationship between human and canines, studied the presence of dogs in literature, and read accounts about America's "First Dogs" in the White House. My study will first discuss the commercialization of the historical bond between humans and their canine companions by investigating the emergence of the dog fashion industry. Next, I will demonstrate that the items with which people choose to adorn their canine pets reflects the owners' personal interests and desires and conveys their social status and aspirations. I will show that in a society compelled to judge a book by its cover, we routinely make assumptions about a person's lifestyle, persona, and social status based on their dogs.

Where the Pavement Ends: An Evaluation of the Urban Heat Island Effect in Metropolitan Atlanta

Malin Dartnell, Roosevelt @ UGA
Dr. Jenna Jambeck, Department of Biological & Agricultural Engineering, University of Georgia

High concentrations of dark, impervious surfaces in urban areas can cause environmental problems (e.g., stormwater run-off and heat transfer) and generate high costs (e.g., through management of stormwater and excessive heat) for cities and their residents. One problem related to urban infrastructure is the Urban Heat Island Effect, a phenomenon of increased average temperatures in cities compared to surrounding rural areas. The Urban Heat Island Effect augments energy demand during the summer, reduces the air quality of the city, and can cause heat-related health problems and changes in local climate patterns. Many individuals and businesses lack the incentive or means to combat the Urban Heat Island Effect alone; therefore, an overall strategy is needed for an urban center. This study evaluates three broad strategies from the literature for combating the Urban Heat Island Effect for the city of Atlanta, Georgia (where the Urban Heat Island Effect has been documented to be a problem). It begins with an introduction to some of the most effective mitigation strategies, before evaluating three options: 1) maintaining the status quo, 2) increasing the albedo of surfaces in the city, and 3) utilizing a combination of vegetation and high-albedo surfaces. Using a decision matrix, each strategy is examined for its effectiveness, feasibility (including relative costs), and efficiency, then ranked to recommend a strategy for Atlanta. Results of the study found that requiring high-albedo pavement is a reasonable strategy for Atlanta in order to increase the albedo of the city to reduce the Urban Heat Island Effect.

Intron Loss and Gain in the Br2/Dw3 Gene Across Grass Subfamilies

Victoria DeLeo
Dr. Katrien Devos, Department of Crop & Soil Sciences, University of Georgia

Documentation of intron loss and gain in conserved genes provides insight into the mechanism of genome evolution across organisms. This is a relatively unexplored area in plants. Studies in *Arabidopsis* and rice, two species that diverged around 150-200 million years ago, have shown differential presence for about 5% of introns, mostly due to intron loss. This study will look in particular at the orthologs of a highly conserved gene that codes for a p-glycoprotein involved in auxin transport. This gene, known as Br2 in maize and Dw3 in sorghum, has mutated forms that reduce the height of a plant by reducing the length of its internodes. Comparison of the sequence of the recently isolated gene in pearl millet with the orthologous gene sequences from maize and rice has shown evidence of at least two independent intron gain or loss events in the evolution of this gene in the three species. We have designed primers in conserved exons of the gene and are using those to amplify the introns in selected members of four grass subfamilies. Sequencing of the introns and intron-exon boundaries may provide insight into the mechanism of intron gain and loss. We aim to explore the evolutionary history of this gene in the grass

family and identify which grass has the most ancestral form of the gene.

Effects of N-Acetylglucosaminyltransferase Expression Levels on Colorectal Adenoma Progression

Sarah-Bianca Dolisca
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

Colorectal cancer is currently the third most prevalent form of cancer. Adenomatous polyposis coli (APC) gene mutations are attributed to multiple intestinal neoplasia (Min) within $APC^{Min/+}$ mouse models. The expression of this genotype results in progression of colorectal adenoma ,a precursor to colorectal cancer. N-Acetylglucosaminotransferase V (GnT-V) is a glycoprotein whose functional role is the biosynthesis of N-linked glycans. GnT-V is associated with metastatic potential. $APC^{Min/+}$ mouse models with varying levels of GnT-V expression were used to investigate regulation of colorectal cancer formation and progression. Antibody and lectin blotting experiments were conducted on the colorectal tumors of the $APC^{Min/+}$ mice to identify glycan and signaling pathway changes. Results supported findings that downregulation of GnT-V in $APC^{Min/+}$ mice significantly inhibited progression of colorectal adenomas. The molecular mechanism that allows the knockdown of GnT-V to significantly decrease the progression of colorectal adenoma provides a potential preventative method of treatment of colorectal cancer.

A Sensitive Approach in Evaluating the PBP (Penicillin Binding Protein) Binding Specificity of Penicillins Using Activity Based Protein Profiling

Vinh Dong, CURO Apprentice
Dr. Timothy Long, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

This study synthesized and evaluated a novel beta-lactam probe that tests for the inhibition of certain penicillin binding proteins (PBPs) in different bacteria. Previously, beta-lactams with radioactive or fluorescent tags were used to label and visualize active PBPs in membrane preparations. However, these methods were time consuming, hazardous, or inefficient because either the tags they use are radioactive, or that they attach a large fluorescent dye to the core scaffold, reducing both target affinity and cell permeability important for *in vivo* studies. Contrary to prior methods, the probe used in this study is nonradioactive, and utilizes a simple fluorescent dye, such as rhodamine and dansyl, attached to azidocillin core scaffold that bypasses these complications. Additionally, once the azidocillin is attached to the interested PBP, the dye reacts only with the PBP that has that scaffold. Thus, the assay development using this new probe is important because it provides the sensitivity and target specificity necessary to discover new, unknown targets of beta lactams for the development of new antibiotics.

The Use of Twitter by University of Georgia Student Organizations and Their Members

Eric Ekwueme, CURO Apprentice
Dr. Brenda Cude, Department of Family & Consumer Sciences, University of Georgia

The internet is constantly changing; websites are quick fads that go in and out of style within a few years. A new social network site called Twitter is based on the premise of micro-blogging short messages about anything a person can think of. Twitter is slowly becoming a very powerful tool in the business world because of its advertising potential, but it seems to be lacking the same power on college campuses. This research studied usage of Twitter by the University of Georgia's student organizations and the undergraduate population. This study's central focus was the effectiveness of Twitter for student organizations and their members. To conduct this research, I selected 10 student organizations and contacted their presidents/ public relations chairs for interviews. During the interview, we discussed the reasons their organizations did or did not use Twitter and if they did, how Twitter was used. I then sent an online survey to a convenience sample of UGA's undergraduate population recruited via Facebook, Twitter, listservs, and word of mouth. The questions focused on students' Twitter use, why some decided to get an account while others did not, if the students were following

student organizations, and overall opinions on Twitter and student organizations using the site. Through this study, I hope to get an idea about how prevalent Twitter is on UGA's campus in regard to student organizations. I also want to identify ways student organizations could use Twitter to reach their desired audience.

Delegates' Personal Interests and Their Influence on the Crafting of Congressional Qualifications at the Constitutional Convention

Khalil Farah
Dr. Keith Dougherty, Department of Political Science, University of Georgia

The paper seeks to determine what level of self-interest the founders exhibited during their framing of the U.S. Constitution. My hypothesis holds that the founders voted with respect to their future political ambitions when deciding who was eligible to run for national office. To evaluate this claim I look at the coded votes of delegates at the Constitutional Convention and compare individual votes to a delegate's economic standing. My research confirmed that no delegate distinctly voted to bar himself from being eligible to run for public office. This exhibits a degree of self-interest on the part of the framers of the Constitution. These finding are relevant to the current debate that has arisen over the place of the Founding Fathers in modern judicial interpretations of the Constitution. The theories of "original intent" and "original interpretation" exhibit deference to the founders as more noble than the people of the present. Showing that, to some degree, self-interest motivated the founders brings into question the views of some justices, like Anthony Scalia, who use the founders as justification for their rulings. No previous study has taken the founders' political aspirations as an explanation for their votes.

Luche Reduction

Jessica Fazio, CURO Summer Fellow
Dr. Richard Hubbard, Department of Chemistry, University of Georgia

The organic chemistry laboratory manual has become outdated and, thus, should have a makeover. It is important to move away from a "cookbook" approach of the procedure to a more investigative approach by the students through the addition of several unknowns. Moreover, reduction of the times spent for the reactions to take place should be reduced in order to implement more time for hands-on instrumental analyses. The addition of the Luche reduction experiment does both of these. By using different terpines such as carvone, menthone, and pulegone with different solvents like methanol and different ratios of methanol with water, varying percentages of diasteriomer products are yielded. The experiment is carried, out by mixing and using the distillation method with the microscale glassware. The end product is then used in the polarimeter to get the optical rotation reading. Depending on the initial products used, the students will receive different readings for their optical rotation and then be able to calculate the absolute optical rotation of their product. This is an introduction to a new instrumental technique that will be used in the labs. The menthone has so far shown positive results. It has yielded a 18:82 neomenthol to isomenthol product which was solved after having a +34 degree rotation of the polarimeter. The expected ratio was to be 21:79, so the experimental results were very close to this. This shows good signs of advancing toward adding this experiment into the organic lab manual.

Traditional Textiles Through a Modern Lens

Christine Fekete
Prof. Jennifer Crenshaw, Lamar Dodd School of Art, University of Georgia

The tradition of textile making is rooted in repetitive processes. Some traditional fabric methods that employ a repetitive process are loom weaving, knitting, wool felting, embroidery, and screen printing. The intention of my art is to manipulate fabric through the use of technology to create a new textile surface. My recent projects explore the use of the repeating module stitched together to create a single surface. An important part of my process is transforming the material I start with, transparent cotton fabric, into something new. My method involves painting yards of this fabric with glue and allowing it to dry. This treatment

stiffens the fabric, making it suitable to be cut cleanly into any shape. I then use a laser cutter to cut multiples of the same shape out of the treated fabric, which I then arrange and stitch into a large panel. Each of these steps is repeated until the finished panel is the right size. The process I have invented is far from traditional but keeps intact the repetitive nature of traditional textile making. Even though the finished textile is intended to be displayed in a gallery setting, it could also be used for the construction of high fashion garments or in interior design as a room divider or window covering.

Mineral Probes of Magmatic Processes at Valles Caldera, Northern New Mexico

Emily First
Dr. Michael Roden, Department of Geology, University of Georgia

The Ma Valles caldera and its volcanic products have played a central role in our understanding of catastrophic, caldera-forming eruptions. We are using mineral compositions determined on the UGA JEOL microprobe in an attempt to understand processes in the magma chamber(s) responsible for the caldera-forming eruptions and ensuing post-caldera eruptions. Specifically, we are using compositions (S, F, Cl and by calculation OH) of the phosphate mineral apatite to infer evolution of magmatic volatiles from before until after the caldera-forming eruptions. We expect to see evidence of significant degassing in post-caldera units, indicated by apatite with low Cl, S and OH. This would imply eruption from the same magma chamber as the caldera-forming units. However, if more recent units show an increase in volatile content, this could indicate the intrusion of new magma and the potential for dangerous eruptions in the future. Preliminary findings show that apatite in one post-caldera unit, the South Mountain rhyolite, is fluorapatite (~3.5 wt% F, ~0.1 wt% Cl), consistent with eruption from a previously degassed magma chamber. An initial microprobe survey of the groundmass of the Bandelier tuff, the caldera-forming unit, indicates that apatite, if present, is rare and small. These findings are not unexpected, given the very low reported phosphorus concentrations for this tuff, which are likely due to apatite fractionation prior to eruption. The abundant apatite we find in the groundmass of more recent eruptions (e.g., Banco Bonito) suggests that these later units came from a new or recharged magma chamber.

Do Black-furred Animals Compensate for High Solar Absorption with Smaller Hairs? A Test with a Polymorphic Squirrel Species

Melanie Fratto
Dr. Andrew Davis, Odum School of Ecology, University of Georgia

In polymorphic mammalian species with multiple color forms, those with dark pelage are more prone to overheating, especially in warm climates, because their fur absorbs solar energy at a higher rate. However, studies indicate that physical properties of their fur prevent or minimize heat stress, although it is unclear which properties. We tested the possibility that black-furred individuals simply have shorter or thinner hairs, creating a lighter (in weight) coat or one that allows greater airflow for evaporative cooling. We examined museum specimens of eastern fox squirrels (*Sciurus niger*), a species that displays brown, grey or all-black pelage color, and used image analysis to quantify hairs from the dorsal surface and tail. From examination of 43 specimens (19 brown, 9 black and 15 grey), and 1,720 hairs, we found no significant difference in hair lengths across color morph, but significant differences in hair widths. Black squirrels had thinner body hairs than other forms (7% thinner), but thicker tail hairs (9% thicker). Given that the dorsal surface would be directly exposed to solar radiation, we interpret this as an adaptation to prevent heat stress during the day. Thicker tail hairs may be an adaptation for nighttime thermoregulation, since squirrels sleep with their tails wrapped around their bodies. These results add to a growing literature body of the functional significance of mammalian pelage.

The Message Behind the Music: Blind Tom's Response to Nineteenth-Century Views on Race

JoyEllen Freeman, CURO Apprentice, CURO Summer Fellow
Dr. Barbara McCaskill, Department of English, University of Georgia

Today, the name "Blind Tom" possesses little or no meaning for most Americans. Just one hundred years ago, however, its mere mention would have excited people across the country. Thomas Wiggins (1849-1908), popularly known as Blind Tom, was a black musical prodigy born blind, autistic, and enslaved near Columbus, Georgia. Most scholars have shied away from exploring Tom's perspectives on race and race relations because they do not believe that he had an extensive understanding of social life. As to be expected, many of Tom's original compositions do seemingly avoid or acquiesce to nineteenth-century American attitudes towards race. However, drawing from archival newspapers, sheet music, eugenics literature, books on slave resistance, and conversations with experts, I found that he demonstrates an awareness of and protest against racial limitations because many of his later pieces resemble the work of Frederic Chopin (1810-1849). Chopin was known to use his works to evoke emotion and assert the independence of his homeland, Poland, from Russian tyranny. My findings reveal that Tom and Chopin had similar musical and biographical experiences. I argue that Tom may have drawn from the works of this composer to advocate freedom from the racial boundaries that attempted to confine him as an African American musician. Looking at Tom's life through his music is important because it reveals the hardships and expectations that African American artists faced during the nineteenth century due to racism, and it provides insight into the racial struggles that contemporary artists still encounter today.

The Biogeochemistry of Hammock Groundwater

Ashleigh Gainer
Dr. Samantha Joye, Department of Marine Sciences, University of Georgia

Hammock groundwater research, a component of the Georgia Coastal Ecosystems Long Term Ecological Research on Sapelo Island, is investigating the possible effects human development has on hammocks off the coast of Georgia. A hammock is an upland area between the mainland and a larger barrier island. Hammocks are popular locations for homes or vacation spots and therefore, can be greatly affected by development. Two undeveloped hammocks (HN_i_1 and PC_i_29) of similar size and vegetation zones were used to investigate hammock groundwater biogeochemistry in a natural environment. At both sites, groundwater wells are located at different land areas including the marsh, upland, and hammock. Samples were also collected from a local creek. Groundwater samples were analyzed and compiled with relevant data from previous years. The salinity, chloride, and sulfate concentrations at both sites were higher in the creek and marsh well locations in comparison to the upland and hammock locations. This is due to the inflow of seawater. The phosphate and ammonium concentrations were much higher in the marsh and upland wells at site HN_i_1 in comparison to site PC_i_29. The higher concentration of phosphate at site HN_i_1 may be related to the Holocene era from which the hammock originated. Understanding the biogeochemistry of the groundwater at these natural hammocks will give a means of comparison for developed hammocks in future research.

Ready for Disaster

Smitha Ganeshan, Roosevelt @ UGA
Dr. David Williams, Honors Program, University of Georgia

In the past decade, the oil industry and regulatory body, the Bureau of Ocean Energy Management, Regulation and Enforcement, has conducted three surprise inspections and eight emergency drills. These emergency drills are the

only chance for oil companies to practice and rehearse emergency preparedness plans. Without follow-up inspections or guidelines to mandate the BOEMRE's recommendations, the incentive to maintain an evolving, ready-to-mobilize emergency preparedness plan is low and the risk of disaster remains high. Further, relationships between industry regulators and oil companies compromise the standards of evaluations. An extensive literature review coupled with a cost/benefit, timeline, and impact analysis led to the selection of a particular policy alternative from a list of five other viable options, which would allow oil companies to augment the perceived importance of emergency preparedness and risk mitigation. Through this policy alternative, each company will achieve a culture of risk mitigation and emergency preparedness by overseeing standardized quarterly emergency drills and regular self-inspection. The portfolio of each company's reports will be evaluated during rigorous, unannounced inspections and follow-up evaluations by the BOEMRE. This is the most effective way to affect the oil industry's underlying culture that shapes risk mitigation behaviors and emergency preparedness initiatives. This policy alternative will ensure that a disaster like the Deepwater Horizon oil spill will not occur again and, in the event of a crisis, that the oil industry will be well prepared to respond to the crisis.

Studying Human Seizures Using Zebrafish as a Model

John Gaudet
Dr. James Lauderdale, Department of Cellular Biology, University of Georgia

In humans, an epileptic seizure is marked by a sudden, stereotyped increase of brain activity. The increase in activity is due to the uncontrollable discharge of many neurons and results in involuntary contractions of random muscle groups, and sometimes a loss of consciousness. The underlying basis for seizure disorders is largely unknown, and is difficult to study in humans. We hypothesize that zebrafish (*Danio rerio*) exhibit human-like seizures and can therefore be used as a comparatively simple vertebrate model to study these neurological events. To compare seizures in zebrafish to those in humans, adult zebrafish were treated with a common chemiconvulsant (pentylenetetrazole, PTZ) and observed for both behavioral and electrophysiological symptoms of seizures. It was found that zebrafish swimming in a PTZ solution experienced violent, uncontrolled muscle spasms, and in a 10 mM solution or greater, all fish (n = 79) went catatonic. Also, preliminary electrophysiological recordings reveal that the neuroelectrical patterns in seizing zebrafish are comparable to the stereotyped patterns in humans. This data provides evidence that perhaps the adult zebrafish central nervous system is sophisticated enough to produce human-like seizures and is therefore of merit to study. Future goals of this research include studying the molecular and cellular basis for epileptic seizures and using zebrafish as a screen for anti-epileptic medication.

Representations of Children and Childhood in Jurek Becker's Holocaust Novel *Jakob der Lügner*

Isha Ghodke
Dr. Martin Kagel, Department of Germanic & Slavic Studies, University of Georgia

Jurek Becker is an East German novelist who survived a childhood divided between a Polish ghetto and German concentration camps. His 1969 novel *Jakob der Lügner* features an 8-year-old named Lina who secretly lives with the main character, Jakob. Children are seldom examined in the context of the Holocaust or its literary representation because those younger than 16 were not allowed to work in Auschwitz and those who could not work were killed. Young children often dictated the fate of their mothers because children represented a future that the Nazis aimed to eliminate. Focusing on the depiction of children such as Lina is significant, because it provides insight into the development of a generation that was responsible for raising itself during the Holocaust and that was so often caught between the blurred lines of childhood and adulthood. Specifically, the focus sheds light on the early years of today's survivors, as most were children during the Holocaust. I anticipate that Lina's role as a child will be

ambiguous, and characteristics representing a childlike state, such as gullibility, will instead be apparent within the adults of the ghetto. The purpose of this study is to examine Becker's use of storytelling as a theme in the novel through the interchange of childlike characteristics by analyzing the conflicting depictions of childhood and adulthood between Lina and the adults surrounding her.

Stability Analysis of the Inhibitor Resistant Phenotype of AJP50 in Biomass Fermentations

Debashis Ghose, CURO Summer Fellow
Dr. Joy Doran Peterson, Department of Microbiology, University of Georgia

The United States' dependence on foreign oil has increased demand for alternative fuels. Switching to biofuels would also lessen human contribution to greenhouse gases since emissions produced when the fuel is burned would be offset by the carbon sequestered in growing new feedstock. Lignocellulosic biomass, such as pine wood, can be fermented into fuel ethanol by a biocatalytic organism, such as *Saccharomyces cerevisiae*. Therefore, adapting *S. cerevisiae* to the harsh conditions found in biomass fermentations is vital to biofuel production. Strain XR122N was adapted by continuous fermentation of pretreated pine wood to yield strain AJP50. It has been previously shown that AJP50 will produce more ethanol and grow more rapidly than XR122N in pine wood fermentations. The present study used a Bioscreen C machine to create growth curves for both strains in various media. AJP50 was able to grow more rapidly and produce more ethanol than XR122N in all media examined. To determine if AJP50 retained its inhibitor resistant phenotype, the strain was cultured on solid and liquid YPD media for 48 hours. Growth curves were created to compare the growth of the newly cultured cells to the freezer-stock AJP50. Approximately 62% of the fresh culture maintained the same level of resistance as freezer-stock while other times they reverted to the parent phenotype, indicating the resistant phenotype is not completely stable. Developing culture techniques that will allow AJP50 to retain its phenotype would aid in study of the strain's genetics, allowing for the creation of strains with advanced fermentation capabilities.

How Effective Are "Fuzzies" as a Tool for Developing a Holistic Understanding of Basic Genetic Principles?

Erica Gibson
Dr. Eve Wurtele, Department of Genetics, Development & Cell Biology, Iowa State University of Science and Technology

When learning genetics, high-school students often develop misconceptions about concepts being taught. For example, students often develop a shallow understanding of inheritance and its underlying factors. As a solution, we chose to create an enjoyable way for students to develop a holistic understanding of basic genetics concepts. This study measured the effectiveness of using an educational game to teach these concepts. Effectiveness was measured by player satisfaction based on survey results and inter-rater reliability on player's recorded facial expressions during play. We also measured effectiveness by how much the player learned, which was based on pre- and post-test scores. The game was developed through an iterative design process in which the educational objectives remained the same but level of player interaction differed. Two game prototypes were developed in the process. One group of students played the first game prototype, while another group played the second. In both games, the objective is to breed and grow simple organisms called "Fuzzies" so that their color and pattern match that of a goal pattern. The main difference between the two versions was the level of interaction allowed. Players were able to interact with the process of meiosis in one prototype whereas the process was automatically carried out in the other prototype. We expected that a higher level of player interaction would increase the difference between pre- and post-test scores. Due to a small sample size the results were not significant. More extensive studies will reveal whether a holistic understanding was developed.

Sensory Systems in *Drosophila* Courtship
Erin Giglio
Dr. Kelly Dyer, Department of Genetics, University of Georgia

All species use distinctive courtship patterns to identify mates of the same species. These patterns may involve stereotyped motions, pheromonal excretions, visual displays, or combinations of all three. The purpose of this project is to examine the sensory systems used in courtship behavior by two closely-related *Drosophila* species. *D. recens* and *D. subquinaria* are two species which do not mate with one another in the wild. It is possible that they avoid intercrossing by using different sensory systems during courtship, such as wing-based song, pheromonal smells, or visual displays. Alternatively, the two species may avoid crossbreeding with one another by using the same sensory system, particularly in populations where both species are present but using different forms of display within each system. To test which of these hypotheses was correct, I performed a series of individual crosses to identify the emphasis on each sensory system within each species. Flies from *D. recens* and two populations of *D. subquinaria* will be studied—one population living alongside *D. recens* and one population which does not share territory with *D. recens*. Within each population, the mating successes of flies for three sensory system losses will be assessed: those without wings, those without antennae, and those without vision. Finally, I will look at the gender-based differentiation of these categories by surveying the differences between courtship success with different combinations of intact or altered males with intact or altered females. Thus, I will measure the importance of these systems on courtship success.

An Analysis and Application of Foreign Language Education Methodology
Mary Golden
Dr. Victoria Hasko, Department of Language & Literacy Education, University of Georgia

This paper practically examines methodology used in past and present foreign language classrooms. This paper first includes a critical review of several major methodologies used in foreign language classrooms, including the Grammar Translation Method and the Communicative Approach in attempt to understand why each method continues to be or is not longer popularly used today. These methods, especially the Communicative Method, are compared with the ACTFL Standards. The writer also examines various Spanish textbooks to see which methods are manifested by the manner in which the textbooks are written. Furthermore, the writer discusses an observation of the "communicative" classroom of a high school Spanish teacher. The paper then shows an application of the most effective methods, especially the Communicative Approach, by giving examples of two lesson plans. The thesis includes a discussion of the results of the lesson plans after they were implemented in a high school Spanish classroom. Through this application, the paper seeks to analyze and practically apply foreign language education methodology to aid in creating more effective lessons for foreign language students.

Investigation of the Protein Content of Hirano Bodies
Camille Gregory, CURO Summer Fellow
Dr. Marcus Fechheimer, Department of Cell Biology, University of Georgia

Hirano bodies are actin-rich, highly structured protein aggregates found in the hippocampus of patients with many neurodegenerative diseases, including Alzheimer's disease. The role of Hirano bodies in disease progression is largely unknown due to the lack of *in vivo* models. Previous studies of autopsied brain samples have shown that some proteins tend to appear in the same location as Hirano bodies. Mislocation of these proteins within Hirano bodies could be beneficial or harmful to the cells during neurodegeneration depending on the protein, the protein's normal function, and the protein's alternate function in disease. In cultured cells, Hirano bodies have been shown to reduce AICD-dependent apoptosis. Further investigation of Hirano bodies could provide clues to their physiological function. Previous experiments have purified Hirano bodies and used mass spectrometry to determine which

proteins co-localize to the formations in *dictyostelium*, a slime mold model organism. These data provide evidence as to which proteins could be associated with Hirano bodies and potentially explains how these structures are interacting in the cell and affecting neurodegeneration. Using immunofluorescent staining, I prove conclusively that certain proteins co-localize with Hirano bodies in dicyostelium. These experiments clarify the previous purification work by corroborating the mass spectroscopy data. The association of these proteins with Hirano bodies provides an indication of their role in disease and leads to further inquiries into their functional impact.

Screening for Domestic Violence in Divorce Mediation

Camille Gregory, Roosevelt @ UGA
Prof. Raye Rawls, The Fanning Institute, University of Georgia

Domestic violence affects the divorce process in significant ways depending on the type of controlling behavior exhibited between the couple. The most important consideration in divorce cases affected by domestic violence is the protection of victims from further harm; therefore, it is critical for the arbiters of divorce disputes to understand the power dynamics involved in the relationship. Mediators in the state of Georgia do not uniformly receive specialized training to recognize domestic violence, nor do they all learn how to assess the degree of coercive control exhibited by a divorcee over his or her partner. Policy does not align with significant changes in the study of intimate partner violence in the last decade. Analysis of the state's current system in conjunction with a review of new intimate violence assessment techniques reveals promising areas for improvement. Several alternatives to the current system, including maintaining the status quo, the elimination of mediation, the use of the DOVE screening process, the use of the Controlling Behaviors Scale, or the creation of a new coercive control measure, were evaluated based on three criteria: effectiveness, feasibility, and cost. The results of this analysis in conjunction with detailed literature review reveal that the reform of the mediation process must include changes in mediator training procedures. Assessments of the degree of coercive control between divorcing couples using the Controlling Behaviors Scale ought to become standard procedure for mediators. With the results of such assessments, mediators will be able to make informed decisions about how to handle each case.

Telomere Recombination in Wild Type Yeast Cells

Zijing Guo
Dr. Michael McEachern, Department of Genetics, University of Georgia

Telomeres are protective caps at chromosome ends that are composed of short tandem repeats. Their function has been tied to carcinogenesis and aging in humans. Most cancer cells maintain telomeres by using telomerase, while somatic cells have little or no telomerase activity. However, cells lacking telomerase, including a subset of human cancers, can sometimes elongate telomeres by utilizing homologous recombination. Previous research has shown that telomeres in wild type yeast cells can sometimes be recombined. This was shown by their ability to become extended by copying sequence from a transformed telomeric circle; however, it was not possible to tell if the recombined telomeres were normal length or abnormally shortened when they were recombined. Our goal was to construct and use mutationally tagged telomeric circles to distinguish whether telomeres in wild type cells have normal length or shortened length at the moment of recombination. First, telomeric circles containing phenotypically silent Bcl mutant telomeric repeats (that each contains a *Bcl*I restriction site) and a *URA3* gene were constructed. Next, these circles were transfected into *URA3*-deficient *Kluyveromyces lactis* mutant cells and only the cells with *URA3* are able to grow. The telomere structures in these transformants will be analyzed using the southern blot technique in order to see if wild type length telomeres are recombined with the telomeric circles. This study is significant in the way that it could help us understand the situations in which normally functioning telomeres can recombine.

Bedouin Dress: A Means of Cultural Continuity and Change

Shelly Hagigi
Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, University of Georgia

Dress plays a crucial role in people's lives; therefore, in today's globalized world it is important to understand the multiple uses and meanings of people's dress practices in cultures other than ours. The way people dress depends on their personality, lifestyle, political beliefs, and the physical environment that surrounds them, among other factors. This paper investigates the changing aesthetics and the complex cultural and gendered meanings of contemporary Bedouin dress in Israel's Negev Desert. With the aid of academic and visual sources, as well as field research that included participant observation, a visit to Joe Alon Center's Museum for Bedouin Culture, and communication with Bedouin women, I have concluded that dress is a key element of the Bedouin culture. The Bedouins live in a patriarchal and collectivist society. Bedouin women's highly decorated yet non-revealing garments indicate a strong tribal identity and emphasis on the Islamic virtues of honor and modesty. In addition, their dress projects their marital and social status, conveys their personal aesthetics and sophistication of manual skills. The Bedouins' layered dress styles also aid their physical survival as their garments are specifically designed to withstand the extreme climate changes of the desert. Just like other cultural and ethnic groups, today the Bedouins are also affected by modernization, which is changing their traditional lifestyle and appearance. This study contributes to the existing studies on Bedouin dress the documentation of the recent changes in the dress practices of this intriguing nomadic culture and provides reasons for this change.

Without Anchors: Standardizing Child Placement after Deportation

Christen Hammock, Roosevelt @ UGA
Dr. Larry Nackerud, School of Social Work, University of Georgia

United States immigration policy essentially consists of two comprehensive bills passed in 1996—the Illegal Immigration and Immigrant Responsibility Act and the Anti-terrorism and Effective Death Penalty Act. These bills do not effectively address the issues of "mixed-status families," those in which two members of the same family hold different immigration statuses. This demographic is particularly problematic in Georgia, whose immigrant population increased 372% between 1990 and 2006. When immigrants living in Georgia establish families, their children are citizens by birthright. Their welfare is therefore Georgia's responsibility. Additionally, they are not eligible for removal, while their parents still remain deportable according to federal law. When removal of a parent occurs, the opposing goals of federal immigration court and state family policy cause de facto deportation of citizen children or an increase in foster care placement. Both result in a burden on Georgia's agencies and taxpayers. This paper's research consists of examining the failures of and gaps in current legislative and judicial code, as well as a review of other states' approaches to this problem. This paper intends to provide solutions for filling this gap in policy, evaluate the solutions according to relevant criteria, and ultimately argue for the creation of a liaison department within Georgia's Department of Family and Child Services to ensure that the best interests of the child are met in every case of removal.

Spatial and Temporal Analysis of the Ceramics at the Burnt Village, 9TP9

Vanessa Hanvey, CURO Scholar
Dr. J. Mark Williams, Department of Anthropology, University of Georgia

The Burnt Village, also known as Okfuskenena, is located three miles west of present day LaGrange, Georgia. On September 21, 1793, white colonists burnt this Creek town and either killed or kidnapped the inhabitants.

Harold Huscher of The University of Georgia excavated the site during the field seasons of 1966-69. No final report was published and much of the collection has not been analyzed. Over the past year and a half, I have analyzed the ceramics and lithics from the Burnt Village. The pottery analysis allowed for the identification of several occupational periods at the site. These periods include the Middle Woodland, Middle Mississippian, Late Mississippian, and Historic periods. Using the mapping program Surfer, I will attempt to identify the geographical distribution of these differing occupational time periods. I will present the latest findings concerning spatial and temporal analysis of this data.

Creating the Physician of the Future: Addressing the Health Needs of Rural Georgia Communities

Osama Hashmi, Roosevelt @ UGA
Dr. Monica Gaughan, Department of Health Policy & Management, University of Georgia

The Georgia State Office of Rural Health states that rural Georgians are less healthy than those living in urban areas, are more likely to be uninsured, and have a higher probability of developing heart disease, obesity, diabetes, and cancer. Studies show that health care workers in these communities must be prepared to treat these patients holistically by overcoming physical, cultural, and social barriers. In response to this need for holistic medical education, medical schools must be better equipped to prepare their students to handle community health problems. In addition, rural Georgians are faced with an extreme shortage of Georgia medical students who choose to become primary care physicians. These physicians are essential for the detection and prevention of illnesses and are necessary to the well-being of high risk, rural communities. This paper proposes that Georgia implement a community health rotation program, available to Georgia medical students and health professionals. A cost benefit analysis of cost, feasibility, and effectiveness of Georgia's present resources indicates that a community health rotation program has the greatest potential for improving the quality of rural health care. Current rotation programs in other states offer health care students first-hand experience in caring for patients in disadvantaged communities. By exposing medical students to the rewarding field of community health, a community health rotation program in Georgia has the potential to increase the number of students entering primary care as well as improve the overall quality of rural health care.

The Boom That Saved the Day

Anisha Hegde, Roosevelt @ UGA
Dr. Leara Rhodes, Grady College of Journalism & Mass Communications, University of Georgia

Emergency preparedness—including efficient oil clean up—was lacking in the aftermath of the Deepwater Horizon oil spill. To fix this shortfall, oil companies should be required to formulate efficient emergency plans, and the Bureau of Ocean Energy Management, Regulation, and Enforcement (BOEMRE) should be required to inspect each rig's capability to carry out its plan. Currently, the BOEMRE does not inspect emergency plans and each rig is expected to monitor its own response capabilities. However, literature reviews confirm that the Deepwater Horizon did not possess the fire boom it claimed to have on-site. Experts predict that immediate usage of booms would have restricted the spill to 100 miles offshore, preventing 211,680,000 gallons of oil leaked from reaching the coast. Despite a 10-day delay in boom usage, 125 burns conducted using booms had destroyed 2.8 million gallons of oil by June. A shortage of boats and clean-up crews was also evident. The Coast Guard needed 14 boats equipped to burn oil, but officials were only able to contract 8 boats. 20 skimmers were needed to collect oil on days with waves higher than 3 feet, but only 2 were on fully on-duty. The National Oceanic and Atmospheric Administration (NOAA) also reported a shortage of crews, which should have numbered 40 by June. If each oil company detailed a plan with an economical response toolkit—complete with manpower, booms, and boats—and the BOEMRE inspected each rig's capability to carry out its plan, future oil-related disasters could be contained more expediently.

Medical Therapies and Clinical Characteristics among Patients with Duchenne Muscular Dystrophy

Anisha Hegde
Dr. Michael Terns, Department of Biochemistry & Molecular Biology, University of Georgia

Duchenne Muscular Dystropy is the most common fatal genetic disease diagnosed during childhood. Over the last four years, the DuchenneConnect Registry, a resource connecting the DMD community, has collected data from 1,273 participants to better characterize patients and educate others. In this study, analysis of the data regarding steroid and therapy usage as well as behavior and learning concerns was performed by comparing usage and diagnosis frequencies to the clinical histories of respondents. This study found that a significantly higher percentage of patients who need walking aids use corticosteroids than those who can walk without assistance and that deflazacort, a drug not yet available in the U.S.A, is used almost twice as frequently as prednisone in boys who require walking aids. Heightened levels of autism, ADHD, and OCD were found in the DMD population when compared to the general population, and the incidence of behavioral concern diagnoses was found to increase in the later stages of the disorder. Therapy usage also increases as the disorder progresses. Analysis of therapy usage amongst DMD patients, however, exhibits no correlation indicating the effectiveness (measured in prevention of heart, bone, muscle, and tendon problems) of various therapies. 12.42% of those who have never tried any therapy have experienced broken bones related to the muscular dystrophy, versus 12.46% of those who have tried therapy. The findings ciphered from DuchenneConnect will help bridge the gap in knowledge between laboratory research and public health concerns of the DMD population.

John Lloyd Stephens and Mesoamerican Orientalism

James Herman
Dr. John Short, Department of History, University of Georgia

Published in 1841, John Lloyd Stephens's *Incidents of Travel in Central America, Chiapas, and Yucatán* introduced American readers to the previously "undiscovered" Mayan civilization. In addition to his writings on Mesoamerica, he also documented his travels in Eastern Europe, Egypt, and the Levant. Stephens, however, has remained largely forgotten by historians and literary critics alike. The portrait that emerges from the little scholarship that does exist suggests that his travel writings, particularly those on Mesoamerica, were the product of the American Romantic Imagination and, in the spirit of Manifest Destiny, treated Mesoamerica as a blank canvas on which to express American colonial ambitions. The aim of my research, however, is to contest this claim. Long before he had set foot in the Yucatán, Stephens traveled extensively throughout the Orient, and in engaging the unexplored world of Mesoamerica, Stephens borrowed language definitive of European travel literature about the Orient. It was not the Romantic Imagination, renowned for its celebration of originality, which informed Stephens's discovery. It was, instead, the European tradition of presenting the Orient, through the use of both Oriental imagery and language, as a timeless and unchanging entity. A close analysis of his writings suggests a subtle transposition of these images over the Yucatán. Aside from the fact that virtually no scholarship exists on this important work, the significance of my research is that it sheds light on the historical evolution of American language of the exotic as well as the long-term structuring of American perceptions of the foreign.

Directed Differentiation of Human Embryonic Stem Cells to Mesoderm Lineages

Daniel Hess, CURO-BHSI Participant
Dr. Stephen Dalton and Dr. David Reynolds, Department of Biochemistry & Molecular Biology, University of Georgia

During early development, complex signaling from surrounding embryonic structures patterns cells as they pass through the primitive streak into the various mesoderm lineages including paraxial, intermediate and lateral plate mesoderm. Lateral plate mesoderm further divides into splanchnic and somatic mesoderm. The various mesoderm progenitors give rise to specific tissues of the human body. We sought to mimic the natural environment and elucidate the differentiation pathways of these mesoderm progenitors using an *in vitro* human pluripotent stem cell model. These mesoderm progenitors give rise to skeletal muscle, somites, kidneys, gonads, heart, and bone. Successful differentiation of human embryonic stem cells (hESCs) to any of these cell types has therapeutic potential for treating a wide variety of current diseases, such as muscular dystrophy, renal failure, heart disease and osteoporosis. hESCs were grown in chemically defined media containing an assortment of factors known to play a role in differentiation such as Activins, Wnts, BMPs and retinoic acid. Differentiated cells were analyzed by qPCR and immunofluorescence for markers of the various mesoderm progenitors. Initial data indicates differentiation of hESCs to paraxial mesoderm, evidenced by upregulation of Pax3 and Pax7. Preliminary data also demonstrates differentiation from lateral plate mesoderm (Brachyury+) to both splanchnic mesoderm (Foxf1+) and somatic mesoderm (Irx3+). Further experiments are necessary to show differentiation of hESCs to intermediate mesoderm and to more fully characterize the different mesoderm progenitors and their potential.

Exercising Glycoprotemics to Develop New Methodologies for the Detection of Early Breast Cancer

Shanterian Hester, CURO Summer Fellow
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

Breast cancer is the second leading cause of cancer deaths among women, discovery of new biomarkers would enhance current methods used for diagnostics, monitoring and better prediction disease reoccurrence. Identifying Glycosylphosphatidylinositol (GPI) anchored proteins through new methodologies and technologies on breast tissue could lead to the discovery of new biomarkers for the early detection of breast cancer. GPI anchored proteins is a posttranslational modification that anchors the modified protein to the outer cell membrane. The synthesis of GPI anchored proteins requires approximately 20 enzymes, one of them being GPI transamidase (GPIT), which adds the GPI anchor to the C-terminus of the protein. Preliminary studies have shown GPIT is over-expressed significantly in breast cancer. In addition, GPI-PLD, another enzyme with the responsibility of cleaving GPI anchored proteins, was found at high levels in human serums and shown to be expressed at elevated levels in several cancer cell lines. This suggests that GPI anchored proteins may be increased in breast cancer patients due to elevations of the enzymes within the GPI biosynthetic pathway. In our study, we are utilizing glycoproteomics analyses and various methodologies to identify potential GPI anchored proteins specifically to breast cancer patients.

Risk-taking in Midterm Elections

Dana Higgins
Dr. Charles Bullock, Department of Political Science, University of Georgia

Since 1934, the president's party has lost seats in the House of Representatives in every midterm election with only two exceptions. With such a strong empirical trend in favor of the challenging party, more challengers to the party in control should strategically choose to run for the House in midterm election years. Thus far, research has focused solely on why the midterm

loss occurs and ignored the effect such a trend has on candidate emergence. This research seeks to establish a trend of challengers in midterm elections using previously established theories explaining the behavior of candidates. Candidate's behavior will be evaluated in context of the midterm election when empirically the president's party loses House seats. Data collected from both midterm and presidential year elections for the United States House of Representatives will be analyzed in a district-level test of the following hypotheses: 1) more districts held by the president's party are less safe in midterm elections than presidential year elections, 2) the average number of risk-takers, from a party other than that of the incumbent president, running for election is higher in midterm years compared to presidential election years, and 3) the average number of experienced risk-takers, from a party other than that of the incumbent president, running for election is higher in midterm election years than presidential election years.

Isolation and Characterization of Polyomavirus Middle T (PyVT) Mammary Cancer Stem/Progenitor Cells

Jessica Holmes, CURO Scholar
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

Transgenic mice carrying Polyomavirus middle T (PyVT) antigen are commonly used models to study mammary tumorigenesis and metastasis, and are valuable tools to analyze the molecular and cellular mechanisms of breast cancer induction and progression. The biomarkers expressed in PyVT-induced tumors exhibit similar morphologic and histologic properties to that of human breast cancers, and are associated with a poor prognosis. Recent studies also indicate that mammary tumorigenesis may arise from the mammary stem-like cells which are found in higher concentrations in PyVT-induced mammary tumors. Effective identification and characterization of such mammary stem cells in PyVT-induced tumors can provide valuable diagnostic tools and subsequent treatment methods for human breast cancer. The focus of my research is to obtain, culture, and characterize key biomarkers present on mammary cancer stem cells using tumors obtained from PyVT transgenic mice. My experiments involved setting up appropriate mating and genotyping of the mice using DNA extraction, Polymerase Chain Reaction (PCR), and gel electrophoresis to identify mice carrying the PyVT antigen. After obtaining PyVT mice, I isolated tumor cells and collected mammary cancer stem cells from tumor tissues by flow cytometry using stem cell marker antigen. By understanding more about mammary cancer stem cells, researchers can begin to characterize important molecular biomarkers, proteins, and signaling pathways which can lead to aggressive diagnostic and treatment strategies for human breast cancer.

Symbolization and Religious Thought

Dillon Horne, CURO Scholar
Thomas Cerbu, Department of Comparative Literature, University of Georgia

Competing interpretations on the reason for the origins of religious thought attempt to reduce this analysis to one variable. However, this field is irreducibly complex. For that reason, an interdisciplinary perspective can link different inqueries into a cohesive structure. These connections will emphasis evolutionary biology, theology, and epistemology. This paper draws upon a range of journal articles and books in an effort to provide a more holistic picture of current ideas. Specifically, it will focus upon the evolution of symbolization in religious thought framed within an adaptationist perspective. Religion not only improved social structures, but personal belief systems too. Current research supports that in our prehistory the human mind attributed ethereal influence to ambiguous events. This demand for explanatory causation, where x always points to and clarifies y, reveals an infatuation with coherence that implies the human mind finds necessity in space free of chance. Evolutionary biology indicates that as our ancestors physically developed so too did their capacity for abstract thought. Communal relationality, and its preference towards inclusiveness, evolved beyond human to human contact. The human mind, at some point along the evolutionary timeline, began to struggle with questions of meaning and belonging. Relations

transcended localized and immediate concerns by moving into the realm of the non-corporal. The symbol was born. The implications of this thesis impact important questions on issues of human uniqueness and meaning, as well as provide a more complete idea on the origins of religious thought.

Thwarting Radiological Terrorism: Policies for Regulating the Security of High-Risk Radioactive Sources

Lauren Howard, Roosevelt @ UGA
Dr. Dmitriy Nikonov, Center for International Trade & Security, University of Georgia

The September 11th terrorist attacks heightened international concerns regarding the security of specialized sources containing radioactive material, as extremist groups such as al Qaeda have made known their desire to use dirty bombs designed to disperse radioactive material in an act of radiological terrorism. The Nuclear Regulatory Commission's (NRC) current licensing mechanism fails to prevent wide variation in the physical protection systems which safeguard these sources because responsibility for maintaining security is broadly dispersed. Implementation of an adequate physical protection system is entirely the responsibility of the licensee in the majority of cases, and requirements for implementation are only general. As a result, the status quo is unsustainable in that the current requirements for accountability of radioactive materials do not reflect the threat level associated with radiological terrorism. This paper evaluates policy alternatives for regulating the security of high-risk radioactive sources in the United States. Three alternatives are compared to the status quo in terms of enhanced safety and security, cost-effectiveness, equity, and political feasibility. Projected outcomes for each alternative are based on a review of the existing literature, and when recommending a policy, the criteria most influential in mitigating the threat of a terrorist attack involving a dirty bomb and enhancing national security are weighted. This selection methodology advises Congress to amend current legislation and incorporate the alternative under which the NRC mandates all persons or companies to have installed an adequate physical protection system prior to being granted a license for housing radioactive materials.

The American Obesity Epidemic: Creating Incentives for Nutritional Choices at the Point of Purchase

Tiffany Hu, Roosevelt @ UGA
Dr. Angela Fertig, Department of Public Administration & Policy, University of Georgia

Obesity rates among adults and children in the United States have doubled to 30% and 17% respectively over the past 25 years. A major contributor to this trend is increased snacking, particularly of foods and drinks with a high sugar content, rather than larger meal sizes. This paper examines policy alternatives to reduce the consumption of high calorie, unhealthy drinks. The following criteria were used to evaluate the alternatives: positive impact on American diets, minimization of social costs, efficiency, political feasibility, and ease of implementation. Based on these criteria, a federal excise penny per ounce tax on caloric sweetened beverages was found to most effectively reduce sugar intake and reverse current obesity rates. Thirty-three states already have soda sales taxes in effect. Their ineffectiveness to lower consumers' BMIs, however, appears to lie in the current magnitude, ranging between 1.5% and 7%, and the application of the tax. In particular, the current state taxes are applied after the point-of-purchase and thus only weakly affect consumers' beverage purchases. A heftier penny per ounce tax applied at the point-of-purchase would raise the price of beverages such as soda by 15% to 20%. Reports by the Economic Research Service of the United States Department of Agriculture (USDA) suggest that this price change would reduce soda consumption and lower rates of obesity in the U.S. substantially. The tax would also generate revenue for potential use in public health initiatives.

Effects of Steel and Aluminum Shoes on Forelimb Action in Stock Horses

Elodie Huguet
Dr. Kylee Duberstein, Department of Animal & Dairy Science, University of Georgia

Horseshoes of various materials have been adopted to satisfy the need of performance horses. Steel shoes are commonly used for their affordability and longevity; however, the use of aluminum horseshoes is being appropriated to the various requirements of equestrian activities, such as accentuating foreleg action for ameliorated movements. Consequently, the purpose of this study is to assess the effect of steel and aluminum shoes on forelimb kinematics of trotted horses. The objective is to determine which shoeing type allows for improved quality of gaits in order to increase performance in its various aspects. By performing two repeated measures crossover study on nine healthy stock-type horses, the effects of these two horseshoe types on forelimb kinematics were analyzed at the trot. Horses were trotted in hand for three repetitions over a distance of 50 meters every other week for two shoeing cycles. Video footage was then analyzed using gait analysis software (OnTrack Equine^{TM}) for each repetition. A preliminary six week study showed a trend towards increasing knee angle in horses wearing aluminum shoes versus steel shoes. A secondary study was conducted with more controlled marker placement and extended shoeing cycles by two weeks to allow for additional recording and data. The results obtained were analogous to the preliminary study in that there was a significant treatment effect with horses wearing aluminum shoes having a larger knee angle than horses in steel shoes ($p<0.5$). This finding is of particular importance to performance horse disciplines for which ameliorated knee action is desirable.

Microplasma Ion Ablation by Electrostatic Sampling Device for SERS Sensing

Whitney Ingram
Dr. Yiping Zhao, Department of Physics & Astronomy, University of Georgia

Raman spectroscopy involves the change in the frequency of a photon to determine the molecular identity of a particle. However, Raman spectroscopy is inefficient for commercial use due to its limited detection ability. Surface enhanced Raman spectroscopy (SERS) based on metallic nanostructures, enhances the signal of a normal Raman spectrum by order of $10^8 – 10^{10}$ magnitude. Our lab uses silver coated nanostructures fabricated by oblique angle deposition. For SERS enhanced substrates, they have demonstrated excellent sensitivity for virus detection. It is our purpose to further increase the effectiveness of the SERS substrates by using an electrostatic device (ESD). An ESD is a small light-weight device, which uses a sharp pointed probe and high voltage to produce corona discharge. The discharge from the probe will produce ions that will ablate the surface of the SERS substrate. Our hypothesis is that this method will increase the signal to noise ratio of the SERS signal by removing the contaminants from the SERS surface. To observe enhancement of SERS signal, the sample will be contained in a glovebox purged with Argon, with the ESD device discharging directly onto the substrate. 2mL of BPE (trans- (bis) pyridyl-ethene) will be observed before and after exposure to the ESD on a glass substrate. Finally, a Raman spectrometer will be placed directly over the location of discharge. If the ESD shows enhancement of the signal of BPE, then the device will prove to be an effective tool for identification and detection of particulates such as viruses and TNT.

Development of a Plasmid to Detect Cobalamin Transport Mutants in *Mycobacterium tuberculosis*

Elena James, CURO Apprentice
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

Tuberculosis, a disease resulting from infection by the bacterium *Mycobacterium tuberculosis*, kills approximately 2 million people annually. Vitamin B12 is a cofactor in various *M. tuberculosis* enzymatic reactions. Although the mechanism is not known, recent research has shown that this pathogen utilizes vitamin B12 when added to culture medium. As a result, vitamin B12 transport proteins may serve as

useful targets for the development of drugs that block uptake of the vitamin. In bacteria, riboswitches are RNA structures that block translation upon binding of a specific molecule. In *M. tuberculosis*, two vitamin B12 riboswitches have been identified. My project is to develop a genetic screen for vitamin B12 transport mutants in mycobacteria. Thus far, I have been working to create a plasmid that places a drug-resistance gene under the control of a B12 riboswitch. This plasmid, which can replicate in mycobacteria and in *E. coli*, is being modified by addition of DNA elements in the following order: a transcription terminator, the promoter and B12 riboswitch for the *M. tuberculosis metE* gene, a promoter-less resistance gene for the antibiotic apromycin, and a promoter-less counter-selectable gene, *sacB*. We hypothesize that this plasmid will confer to mycobacteria resistance to apromycin only when vitamin B12 is added to culture medium. If this system functions as anticipated, the next step will be to perform transposon mutagenesis to mutate the bacteria and select for vitamin B12 transport mutants.

Security Contractors: The Future of Peacekeeping?
Archil Japaridze
Dr. Fred Manget, School of Law, University of Georgia

The objectives of this research are to assess the current and potential impact of Private Security Contractors (PSCs) on combat and peacekeeping operations. The research question addresses if PSCs would be able to effectively replace international peacekeeping forces (UN, NATO, AU). The private security industry is an increasingly growing field, one which serves a critical role in the War Against Terror. Although many contractors fulfill support and administrative tasks, a large amount serve in combat operations. These combat operations will be the topic of the research. The research will cover two aspects. The primary aspect will examine PSC combat operations throughout the course of modern warfare. This history-oriented portion will focus on operations in post-colonial Africa. This section will evaluate the efficacy of PSCs as peacekeeping forces. In addition to analyzing PSC efficacy, the research will scrutinize international peacekeeping operations. By studying these two entities (UN peacekeepers and PSCs) the researcher will examine the feasibility, advantages and disadvantages to fielding PSCs in peacekeeping operations. The second portion will focus on the future of PSCs, especially on their potential role as peacekeeping forces. Traditional peacekeeping forces have historically come up short in many conflicts. The research will address the reasons for this shortfall, and in turn advocate for replacement. Due to the increased professionalism and training of PSC forces, the researcher anticipates that PSCs would be able to readily replace traditional forces.

***Plasmodium falciparum*: Expression of the DBL3x region of VAR2CSA**
Rachel Johnson, CURO Apprentice
Dr. David Peterson, Department of Infectious Diseases, University of Georgia

Infection by the parasite *Plasmodium falciparum* causes nearly 200 million cases of malaria annually. Pregnancy Associated Malaria (PAM), often resulting in fetal and/or maternal complications, is caused by the binding of parasite infected erythrocytes to chondroitin sulfate A found in the placenta of pregnant women. We are particularly concerned with VAR2CSA, a member of the Duffy-binding like (DBL) protein superfamily, which has previously been shown to mediate the binding of parasite to host. In this project, the DBL3x domain of the VAR2CSA protein was cloned into E.coli cells and expressed for protein binding studies. The DBL3x portion of the var2csa gene was amplified from blood samples from Kenya using PCR methods. The amplified inserts were then purified, cut, and ligated into a PET-28 expression vector. The ligation product was transferred into chemically competent cells using heat shock protocol. The presence of the insert-carrying PET-28 vector was confirmed using PCR colony analysis and again by restriction digests. The VAR2CSA protein was expressed and purified in these cells. We are now using this protein to study the binding of *Plasmodium falciparum* to chondroitin sulfate A in the placenta. Understanding the binding

properties of VAR2CSA to the placenta may lead to a vaccine and the prevention of PAM.

Renewable Energy-Powered Bulk Milk Cooling for Smallholder Dairy Farmers
Jonathan Jones
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

Uganda's population is approximately 30.7 million, 85.2 percent in rural agricultural areas. Agriculture makes up 15.1 percent of the country's total GDP and 90 percent of its exports, with dairy production commanding a large portion of the country's livelihood. Due to poor road networks, insufficient labor, and lack of electricity, many smallholder dairy farmers lack the means to preserve or refrigerate night milk, which results in large economic losses. Previous studies by the Uganda Industrial Research Institute and the Kisaalita Lab at the University of Georgia have shown success in developing a 15.5-liter renewable energy-powered zeolite absorption evaporative cooler that lowers the temperature of milk 18° C, allowing farmers to preserve night milk. In previous field trials, the 15.5-liter capacity was found limiting. The purpose of the current project is to scale-up the cooler to approximately 100-liter capacity. With a larger capacity, the system can be easily diffused among the more educated dairy farmers with more milk, which will increase the adoption of both the technology. The use of the these innovations will permit more milk from smallholder dairy farmers to enter cold chain, facilitating increased incomes and overall increase of GDP of Uganda. The device will also potentially allow farmers to use excess biogas for cooking and lighting, decreasing the demand for woody biomass, which will reduce the deforestation rate, and reduce the release of methane gas from fermenting cow dung, which is a 21 times more potent as a greenhouse gas in comparison to carbon dioxide.

Worse Before it Gets Better? Or Just Worse?
Meredith Jones, Roosevelt @ UGA
Dr. Santanu Chatterjee, Department of Economics, University of Georgia

In 1993, the Treaty of Rome established the European Economic Community. In order to protect against encroachments on national sovereignty, article 296 detailed that the customs union would not be extended to the defense industry. However, in 2009, EU Member States introduced a directive that would drastically reduce barriers to military and defense trade in an effort to allow European military supply companies to become competitive with other world suppliers. This decision was obviously made due to economic reasons. Legally, it conflicts with the Treaty of Rome. More broadly, it contradicts the supposed wish of Member States to keep their defense departments national. This decision speaks to Member States' priorities: economics, then politics. Thus two questions are raised: Firstly, will this progressive step towards economic integration outweigh such woes as debt crises and a euro that is rapidly losing value or will it just make a mild improvement in a system that is doomed to fail? Secondly, what impact on political integration and loss of national sovereignty will the introduction of this directive have? A simple cost-benefit analysis of the directive will show that it does indeed have economic benefits. Most of these benefits, of course, occur in the defense industry, though other industries are positively affected as well. It is unclear whether these benefits will "outweigh" the European Union's other problems, though further integration seems inevitable and unaffected by predictions of success or failure. This paper will also analyze look at the political ramifications of defense industry integration.

Children's Directional Understanding of Arrows
Ryan Jordan
Dr. Janet Frick, Department of Psychology, University of Georgia

Endogenous orienting is the phenomena through which attention is cued by a "meaningful"

stimulus toward a peripheral target. Previous studies have examined endogenous orienting through arrow cues in adults and in children. Children as young as five years of age are capable of using the directional meaning of the arrow to cue their attention to the target. However, children younger than five years of age seem to rely more on the perceptual properties of the arrow, such as size or weight, to orient their attention. The manner in which 3- to 4-year-olds' abilities (to recognize arrows as symbols indicating direction) were tested may not reflect their true understanding. Therefore, the current study will extend previous findings by using 3-to 4-year-old children to test the hypothesis that children as young as three years of age are capable of understanding arrows as a directional symbol. In order to determine that children are cued by the direction of the arrow and not other perceptual properties of the arrow (such as weight) only arrow heads and arrows with arrow heads on both sides will be presented. Children are presented with a computerized reaction time task. Participants are first cued by a central arrow, followed by a peripheral target that is either congruent or incongruent with the direction of the arrow. The child's task is to press a spacebar key as soon as the target appears. Speed and accuracy will be analyzed as a function of age. This work has important implications for understanding the development of cognitive processes, and more specifically, language development.

Characterization of Disease Causing Mutations of hENT3

Ah Hyun Jun
Dr. Dr. Rajgopal Govindarajan, Department of Pharmaceutical & Biomedical Science, University of Georgia

Human equilibrative nucleoside transporter (ENT)-3 is one of the three members of the ENT family, also known as the Solute Carrier 29 family, that facilitative movement of nucleosides across cellular membranes for salvage synthesis of nucleic acids. Unlike the other members of the family (hENT1 and hENT2), hENT3 alone exhibits pH-dependent transport characteristics, with its maximal activity observed at an acidic pH level between 5.5 and 6.5. hENT3 is also unique in that it is localized intracellularly in the mitochondria and lysosomes and is thought to facilitate physiological roles of these organelles, although direct evidence supporting this conclusion is not available. In our previous studies, we have identified mutations in hENT3 that cause human disorders such as H and Pigmented Hypertrichosis Insulin-dependent Diabetes Mellitus (PHID) syndromes and shown that these mutations can affect transport properties, cellular localization, and stability of the protein. Emerging studies suggest that there are several additional genetic disorders (e.g. Familial histiocytosis, Rosai-Dorfman Disease) that are caused by mutations in other regions of hENT3. In my proposed honors thesis project, I will functionally and biochemically characterize all known clinically-relevant mutations of hENT3 linked to genetic disorders in humans utilizing cellular and molecular techniques. Specifically, I will use site-directed mutagenesis and Xenopus-based uptake studies to create mutants and study their effect on transport and cellular localization. These studies will enhance our understanding of hENT3's structure-function relationship as well as its role in health and disease states.

Y-Linked Variation and Senescence in *Drosophila melanogaster*: Starvation Resistance

Pranav Kaushish
Dr. Daniel Promislow, Department of Genetics, University of Georgia

The Y chromosome is generally regarded as possessing primarily male sex-determining genes in most organisms. In 2008, however, researchers found that the Y chromosome in the fruit fly, *Drosophila melanogaster*, actually houses polymorphic regions that affect expression of both X-linked and autosomal genes. Among these influenced genes were ones that affect many important cellular processes that could be linked to aging. Previous studies on the genetics of aging have not considered Y-linked genes. Given that Y-linked variation exists, it is therefore possible that genes on the Y chromosome may contribute to longevity in natural populations. Research has shown that stress resistance can be used as a proxy for

lifespan. Here, we assayed starvation resistance in two groups of flies that varied in the Y chromosome but were otherwise genetically identical. The flies were derived from two distinct populations, including Raleigh, North Carolina, and a region in Africa. Females possess two X chromosomes and do not have a Y, so they served as the control group. Survival analyses using the logrank and Cox proportional hazards models were performed along with analyses of variance to determine if the lines had significantly different mortality rates from one another. Ultimately, only one set of male lines showed significantly different longevity, but one group of female lines also displayed variability, suggesting that the experiment must be replicated before accurate conclusions can be drawn.

Extracting Power from Vehicle Induced Airstreams on Expressways

Miles Keeney-Ritchie
Dr. John Schramski, Department of Biological & Agricultural Engineering, University of Georgia

Diversifying our energy production infrastructure is now a priority with global energy demand rapidly increasing, and fossil fuel price volatility. This process entails researching every known source of extractable energy. To this end, this research identifies the sources and characteristics as well as determines the viability of capturing the airstreams generated by vehicles on expressways from the strategic placement of wind turbines. First, we conducted case studies of common vehicles with known drag coefficients to develop the theoretical maximum extractable power transferred to the air from moving vehicles. These analyses indicate consumer vehicles should dissipate 14 kW to 29 kW per vehicle indicating sizeable available energy on major highways with high traffic flow rates. In the second stage of this research we constructed a computer model of the fluid flows around a vehicle to refine our estimate of the energy transferred to the air and the characteristics of the ensuing airstream vortices. This allowed us to typify the directions, velocities, turbulence, and duration of vehicle induced wind at possible locations for wind turbines.

Comparing the Effects of the Ras Inhibitor Manumycin A with Novel Ras Converting Enzyme 1 Inhibitors

Song Kue
Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Science, University of Georgia

Ras is a small GTPase protein involved in receptor mediated signal transduction pathways such as the Mitogen Activated Protein Kinase (MAPK) pathway that can elicit cell growth, differentiation, and survival. The proper subcellular localization and biological activity of Ras is dependent on post translational lipid modification which occurs in four steps: isoprenylation, proteolysis, methylation, and palmitoylation. Upregulation of Ras can lead to uncontrollable growth and cancer; therefore enzymes involved in lipid modification of Ras, such as farnesyltransferase (FT) and Ras converting enzyme 1 (Rce1), are potential targets for chemotherapeutic agents. In this study, novel compounds (C1, C4, C9) previously screened for anti-Rce1 activity in yeast were compared to a validated FT inhibitor, Manumycin A, in human cancer cells for their ability to inhibit Ras dependent MAPK phosphorylation. SKOV3 ovarian cancer cells were treated with Manumycin A and the novel Rce1 inhibitors in the presence of serum. We used Western blot analysis to determine the inhibition of MAPK phosphorylation using the known pharmaceutical inhibitor Manumycin A and the novel compounds. Compounds C1 and C4 had no apparent inhibitory activity, suggesting that Ras is fully functional. However, the compound C9 was able to inhibit MAPK phosphorylation. Ongoing experiments will be done if the effects are specific, and to determine the effect of this compound on overall cell viability and toxicity. In conclusion, these novel Rce1 inhibitors pave the way for developing novel chemotherapeutic agents targeting Ras.

A Salient Issue of Today and Tomorrow: Biotechnology and Research Face Peach State Politics

Justin Leef
Dr. Charles Bullock, Department of Political Science, University of Georgia

Researchers and businesses associated with Georgia's biotechnology field represent considerable economic and educational forces today. Experiencing more than 40% growth in the past decade, this industry is poised to build upon its 21,000 jobs and roughly $961 million in wages for Georgians. Record partisanship within the General Assembly and statewide offices combined with extreme ideological oppositions from small portions of the electorate stand to possibly stunt future biotech and research growth. Legislative indifference stands to weaken the industry in Georgia as much as outright opposition. Interviews conducted with politicians, researchers and administrators from universities, private companies, business entrepreneurs, and individuals in the popular press believe that Georgia must embrace ideological moderation concurrent with political support and positive legislation. Objective analysis of the biotech industry's current status within the state is needed in order to determine how to enhance its strengths and correct areas of weakness. A synthesis of this knowledge with a detailed evaluation of how other states have successfully grown their own biotech industries and research facilities will prove vital. The Peach State has overcome resistance to the installation of industry, facilitation of higher education, and racial desegregation within the last century. Just as political leaders of the state's past worked together to galvanize an embrace of progress, so too must they in the future by facilitating the growth of Georgia's biotech industries and research organizations.

An Analysis of Two Great Russian Poets and a Discussion of Their Ties to Russia's History and its People

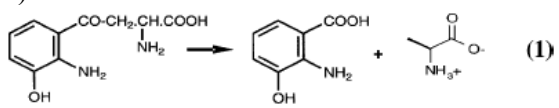
Anna Legostaev, CURO Scholar
Dr. Elena Krasnostchekova, Department of Germanic & Slavic Languages, University of Georgia

A Russian czar, Nicholas I, once called Alexander Pushkin the most intelligent man in all of Russia. Alexander Pushkin lived in the nineteenth century, and during his short thirty-eight years of life, wrote the most beloved poetry in Russian history. However, it was not simply love for Pushkin's poetry that drove the Czar of Russia to personally censor his work. Alexander Pushkin had his own political agenda, and was quick to pass an unfavorable judgment about the state of the political system. Pushkin was very closely associated with the Decembrist Revolt, a famous uprising plot of the noblemen to abolish serfdom. By examining his more radical poems such as "Ode to Liberty", I hope to show Pushkin's connection to the political and social turmoil of his time period. The somewhat ambiguous relationship between the Czar and the poet also sheds light on the degree of power Pushkin wielded with his pen. Ultimately, it was Pushkin's involvement with the intrigues of the high society of Russia, which led to his untimely death in a duel.

Kynureninase and Its Affect on Late Onset Diseases

Asaph Levy
Dr. Robert Phillips, Department of Chemistry, University of Georgia

Kynureninase is a part of the aspartate aminotransferase superfamily, which is dependent on pyridoxal 5'-phosphate (PLP). Mammalian kynureninase catalyzes the hydrolytic cleavage of 3-hydroxy-$_L$-kynurenine to 3-hydroxyanthranilic acid and $_L$-alanine (eq 1).



(1)

We have worked closely with the enzyme after isolating it from a human cell by first testing for enzyme activity in our buffered solution, as well

as after purifying our enzyme after running it through a Ni-CAM (Sigma) resin column. Purified kynureninase showed acceptable enzyme kinetics which indicated a successful yield of enzyme. Plasmids have been isolated for use as a vector to replicate our desired sequence by PCR. We are currently studying the effects of the N-Terminus on the Kynureninase enzyme. Bacteria have an N-Terminus whereas humans, and other upper level eukaryotes, do not. This is important because Kynureninase is a key enzyme in the Kynurenine pathway, which degrades most of our dietary tryptophan. This pathway's genes are expressed in immune system cells; with the main metabolite produced being Quinolinic Acid (QA). Excessive QA in CNS tissues, due to overstimulation of the Kynurenine pathway, is thought to contribute to many neurodegenerative diseases such as: Alzheimer's, Stroke, Epilepsy, and Huntington's disease. If we can test the affects of the N-terminus on the bacterial Kynureninase, we should be able to clone human Kynureninase with N-Termini and develop a cure/preventative agent for these diseases.

Polysialylation Changes During Human Stem Cell Development

David Liddle
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

Embryonic stem cells (ESCs) possess pluripotency, the ability to develop into any type of cell, and this renders them ideal tools for prevention and treatment of diseases. Previous research has shown that polysialic acid (PSA), a polymerized glycan, may be involved with the mechanism of stem cell differentiation. PSA shows high expression in developed cells, but is absent in ESCs. This trend is analogous to the expression of PSA in neural precursor cells which are also undergoing differentiation. PSA contains a polyanionic charge that may regulate stem cell migration and subsequent differentiation through electrostatic repulsion forces. The first goal of our research was to elucidate the protein to which PSA attaches in developing stem cells. This was accomplished by comparing ESCs and developed stem cells using immunoblotting after SDS-PAGE. The results showed that the neural cell adhesion molecule (NCAM) is the PSA acceptor in developed stem cells. The second goal of our research was to investigate the function of PSA. Small interfering RNA was used to knockout the gene for the polysialyltransferase PST (ST8SiaIV), the enzyme that binds PSA to NCAM. Through recombinant technology, a plasmid with the siRNA gene was transfected into human ESC samples. Then the growth factors BMP and WNT were added to induce differentiation. Future results will reveal whether knocking out PSA blocks stem cell differentiation, thus indicating whether PSA plays an integral role in the process. Ultimately, a better understanding of the differentiation mechanism will provide important advances in stem cell biology and medicine.

Rce1 Membrane Topology

Edward Lilla
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Uncontrolled proliferation and migration of transformed cells in the human body is one of the main characteristics of cancer. The Ras signaling pathway, which is essential for growth in normal human cells, is hyperactive in cancer. The oncoprotein Ras has been identified as a possible therapeutic target for treating cancer. Rce1p is a protease responsible for post-translation modification of Ras. By inactivating Rce1p, Ras will not be able to initiate cell propagation in cancerous cells. In order to manipulate the activity of Rce1p, a better understanding of the mode of cleavage and topology of the protease must be gained. Western blotting and PEG-mal (methoxypolyetheylene glycol 5000-maleimide) modification of cysteines found in Rce1p will help determine the topology of Rce1p. Several yeast mating tests have been performed on yeast strains carrying various mutants of Rce1p. These mutants contain point mutations were in cysteines were modified to alanines or serines. The mating tests have verified that the yeast strains successfully express the desired mutant strains of Rce1p. The next step of our project is to perform PEG-mal reactions on the mutant

strains of yeast. Once the PEG-mal reactions are complete, Western blots can be performed on the samples. The results from the Westerns will help us determine if cysteine modifications of Rce1p occurred or not. The combined results from these several mutants will help determine if our current topology map is correct or needs modifications.

Developmental Changes in Human Infants' Strategies for Recognizing Human and Animal Faces

Hannah Machemehl
Dr. Janet Frick, Department of Psychology, University of Georgia

Infant face recognition is a popular topic of study within developmental psychology due to its dynamic development in the first year of life. In the present study we examined human infants' and adults' strategies for recognizing faces, as well as differences in the discrimination of human and animal faces. Participants included 4- to 6-month-old infants (n = 61), 9- to 11-month infants (n = 44), and adults (n = 67). Participants passively viewed faces of humans, capuchin monkeys, or sheep. These faces were manipulated in three ways: feature spacing (e.g., distance between the eyes), feature identity (e.g., eyes and mouth taken from one face and placed on another face), and facial contour (i.e., inner contents of the face on different heads). Participants were first familiarized with a face for 20 seconds. They were then shown 30 trials in which the same face was paired with a novel face for 4 seconds. We measured the proportion of time looking to the novel faces as a measure of discrimination. We found that with age, humans use additional strategies for recognizing faces. Specifically, 4- to 6-month-old infants only discriminated faces with different head contours. Older (9- to 11-month-old) infants also were sensitive to changes in facial features. Adults were additionally sensitive to feature spacing. We are currently examining differences across species. This work gives us insight into the development of face recognition, which is a fundamental ability for species-typical social relationships.

Membrane Topologies of E. coli HemH and HemG Biosynthetic Protein Studies Using Alkaline Phosphatase Fusions

Aisha Mahmood
Dr. Harry Dailey, Department of Biochemistry & Molecular Biology, University of Georgia

Heme biosynthesis in both eukaryotes and prokaryotes occurs via a highly regulated metabolic pathway of seven enzymatic steps, starting with the precursor compound 5-aminolevulinic acid. In the final two steps, a protoporphyrinogen IX oxidase (PPO) yields protoporphyrin IX, which reacts with ferrochelatase to yield protoheme. Research has focused on characterizing these enzymes at the molecular level. Presently this is achieved through cloning, over-expression and characterization of the enzymes of a multitude of organisms. PPO activity in eukaryotes occurs on the cytosolic side of the inner mitochondrial membrane and requires molecular oxygen as an electron acceptor. The membrane topology, however, is unclear in E. coli. There are various ways to determine sites where a membrane protein interacts with other proteins. A genetic method offers the advantage of independence from exposure or reactivity of amino acid side chains. Proteins that span the cytoplasmic membranes of E. coli have different domains exposed to the cytoplasm and periplasm. Fusion of a membrane protein to alkaline phosphatase can help characterize these domains and protein position. This experiment uses fusions of alkaline phosphate to both HemH and HemG to determine their membrane topologies. Ultimately determining the locations of these proteins will allow us to identify more effective drug targets in E. coli and lead to a deeper understanding of heme biosynthesis in eukaryotes.

Revisiting U.S. Procurement of Non-Emergency Food Aid

Ammarah Mahmud, Roosevelt @ UGA
Dr. Maria Navarro, Department of Agricultural Leadership, Education & Communication, University of Georgia

Non-emergency food aid assists 925 million chronically hungry people worldwide. The

United States is the largest contributor of foreign food aid, donating 55% of all food assistance in the past decade. Legislation requires the U.S. to purchase domestic goods and ship food on U.S.-flagged vessels. These requisites increase the costs of procurement and shipment, and reduce the quantity of food supplied per dollar spent. From 2001-2007, the costs of international transportation led to a 52% decrease in average tons delivered. The United Nations emphasizes the link between local production of agriculture and development, but procurement from target countries is not considered. The current policy's emphasis upon U.S.-domestic procurement and its misuse of expenses decrease the efficiency of non-emergency food aid. This paper discusses three potential policies to improve procurement efficiency. The first alternative suggests procuring food regionally and locally from target countries. The second delineates a public-private partnership between the U.S. federal government and a private organization. The final alternative advises the U.S. to buy the least expensive goods, and lacks domestic preferential treatment. Potential solutions are evaluated according to their effect upon target countries, political feasibility, and cost-effectiveness. This paper proposes the U.S. to partner with administrative organizations to research target areas and determine their local food production. This provides a direct relationship between the U.S. and target area, while maintaining a U.S. role when local goods are inadequate. This paper analyzes three competing alternatives and determines which is most efficient in combating hunger and developing long-term stability.

The Influence of Popular Adolescent Television Programs

Mona Malacane
Dr. Leonard Martin, Department of Psychology, University of Georgia

Sexual imagery in shows targeted toward adolescents may increase adolescent sexual behavior and body dissatisfaction. The present studies examine whether this imagery has increased in the past two decades and if it predicts attitudes toward women. In Study 1, we content analyzed a three episode sample of six adolescent show's Sexual Appearance and Sexual Behavior. We found that recent shows contained more Sexual Appearance and Sexual Behavior variables compared to older shows included in this content analysis. In Study 2, we will survey participant's viewership of these shows as well as their attitudes on ambivalent sexism, beliefs about women, their body shape and self esteem, and beliefs about female leaders. Based on participant's viewership, we anticipate finding that those who endorse ambivalent sexism, have more negative attitudes towards women, have lower body shape self esteem, and who view women as less effective leaders also watched more hours of recent television shows. Our research suggests that watching adolescent shows with more sexual variables influences attitudes towards women. Implications for more positive messages being used in the media are discussed.

***Bufo marinus* Pathogen and Parasite Analysis as a Model for Ecosystem Change**

Georgianna Mann, CURO Summer Fellow
Dr. Sonia Hernandez, Department of Wildlife Disease, University of Georgia

As human populations continue to increase, effects on the natural environment are inevitable. Quantifying these changes and their implications on species are imperative for ecological research. The Rio Tempisque Project in the Guanacaste region of Costa Rica attempts to address this through ecosystem experiments to measure the effects of human activity on the surrounding environment. This research strives to reveal if the cane toad, *Bufo marinus*, would be an effective sentinel species. Pathogens and parasites lead to detrimental effects on the health of amphibians. By studying the pathogen and parasite burden of cane toads in two different types of land management practices (high and low pesticide use), I aimed to determine: 1) if high pesticide agricultural areas can be long term surrogate habitats for cane toads, and, 2) if cane toads are an appropriate sentinel species for land use changes in the Rio Tempisque Basin. In June 2010, 18 *Bufo marinus* were collected in four field sites with various pesticide regimes in Costa Rica. Each were measured, sexed, necropsied and had fecal, intestinal and organ samples collected. The samples were examined

for lung and intestine endoparasites. The prediction of a positive correlation between the pesticide use and parasite prevalence was disproven. However, a positive correlation between location and parasite load in the toads was discovered, indicating that human land use may lead to an increase in parasite abundance. As a sentinel species, *Bufo marinus* would allow the Rio Tempisque project to scrutinize environmental changes as a result of human influence.

The Effects of Negative Political Campaign Advertising

David Mapp, CURO Apprentice
Dr. James Bason, Survey Research Center, University of Georgia

Between 60-65% of political campaign expenses are used for television advertising (Hale, Fox, and Farmer 330), making it the dominant modern campaign tool; however, in the recent gubernatorial election in Georgia, a large deal of political ads via television and other communication mediums were negative in nature meaning a portion of campaign expenses were used to simply discredit fellow competitors. Candidates for elective office today spend millions of dollars on negative political ads. Although some research has been conducted that examines negative political advertising, results of the effects they have on Georgia constituents have been mixed. My research will examine the opinions of Georgians regarding the prevalence of negative political advertising in the recent gubernatorial election between former Governor Roy Barnes and the eventual winner, Governor Nathan Deal. Using data from the Fall 2010 Georgia Poll conducted by the Survey Research Center at The University of Georgia, descriptive statistics on whether or not Georgians thought negative ads were present during the campaign will be computed, and the nature of how Georgians felt about the ads will be coded through responses to open ended questions. Finally, analyses will be conducted to see if demographic differences among Georgians regarding negative campaign ads existed.

Study of the Genetic Diversity of Isolated *Veratrum woodii* Populations in Georgia Using AFLPs

Alexandre Matte Santos
Dr. Wendy Zomlefer, Department of Plant Biology, University of Georgia

Veratrum woodii is a rare and protected plant species in Georgia. The species occurs in the southwestern and northern part of the state. These clusters of populations are separated by a distance of several hundred miles that would seem to prohibit outcrossing. Given the species' rarity in Georgia, managers at the Georgia Department of Natural Resources would like to know whether the southwestern and northern Georgia populations are genetically distinct. A management plan for the species should also include information on the overall genetic variation within and among of *Veratrum woodii* populations in Georgia. Over the course of the semester we identified primer combinations for Amplified Fragment Length Polymorphisms (AFLPs) for 13 populations *Veratrum woodii* and used these to characterize variation within and among populations that have been sampled from all known Georgia populations. These primer pairs are used to selectively amplify fragments of varying sizes of DNA; the differences in the sizes of the generated fragments then serve as a representation of the polymorphisms or variation between individuals or populations. Data was analyzed using GenAlEx, to characterize genetic structure using dominantly inherited markers such as AFLPs. We found that despite the physical distance, the *Veratrum woodii* populations are maintaining a majority of their variation among populations, and may be outcrossing freely which supports our hypothesis that outcrossing is still occurring. In terms of conservation, this means that it would be prudent to maintain conservation efforts for all populations in the state.

Assessment of 5-Aminolevulinate Acid Synthase Expression & Purification Methods

Elizabeth May, CURO Scholar
Dr. Harry Dailey, Department of Biochemistry & Molecular Biology, University of Georgia

Heme is synthesized in a series of eight steps which, unlike many other biochemical pathways, occurs in both the cytoplasm and the mitochondria. The first enzyme in this pathway is of particular interest, 5-aminolevulinate synthase (ALAS), a pyridoxal phosphate-containing protein. Although it is translated in the cytoplasm of the cell, its catalytic activity takes place in the mitochondrial matrix. Thus, in addition to posttranslational modifications to the precursor enzyme, preALAS, there also exists some translocation mechanism by which the precursor is transported into the mitochondria. Past studies have demonstrated that heme forms a negative feedback loop to its own biosynthesis at this point by inhibiting the uptake of preALAS (Yamauchi, 1979). Three conserved heme regulatory motifs (HRMs) have been observed on the preALAS enzyme (Timko, 1993). Two of these are located in region I of the enzyme, the leader sequence which targets the protein for transport, and the last is located in region II, closer to the N-terminus. While it has been demonstrated that these motifs are required for heme inhibition, the mechanism behind this is not currently understood. Thus, the main purpose of this project has been to determine whether or not heme physically binds to preALAS to regulate its own biosynthesis. Methods used to determine this relationship included protein expression, through various recombinant E.coli plasmids, as well as protein purification, through affinity column chromatography. Unfortunately, obstacles arose in the effort to obtain a purified form of the protein, so further binding assays were unable to be performed. The focus of the project subsequently shifted towards method alterations for improved protein yield and quality.

Zot* as a Potential Virulence Factor for *Neisseria meningitidis

Lauren McLeod
Dr. Anna Karls, Department of Microbiology, University of Georgia

Neisseria meningitidis (meningococci, MC) is a Gram-negative diplococci that exists as normal flora in the nasopharyngeal mucosa. However, despite this commensal relationship, MC is also one of the leading causes of bacterial meningitis. In a study by Bille et al. (2005), a comparative analysis of MC genomes from invasive strains (isolated from patients with meningitis) and carriage strains (isolated from healthy individuals) revealed a sequence corresponding to a filamentous bacteriophage that is significantly associated with only invasive strains. This prophage was named the Meningococcal Disease-Associated prophage (MDAΦ). Our study focuses on an MDAΦ gene, *zot*, which is proposed to encode a zonula occludens toxin that can disrupt tight junctions in the Blood Brain Barrier (BBB). This potential virulence factor may allow paracellular passage of MC across the BBB. To test the hypothesis that MC *Zot* can disrupt tight junctions, this study will examine the effect of MC Δ*zot* mutants on human brain microvascular endothelial cells (HBMEC) that model the BBB. Southern blotting analysis was used to assess the number of copies of *zot* in *N. meningitidis* Z2491 (serotype A) and 6 un-sequenced MC isolates. These Southern blotting results will be confirmed using PCR. Each copy of *zot* will be deleted and the resulting Δ*zot* mutant strain will be used to infect polarized monolayers of HBMEC. If MC *Zot* disrupts tight junctions, further studies will be conducted to define the role of *Zot* in MC pathogenesis. MC *Zot* may become a target for therapeutic or vaccine strategies.

Legitimacy and Status in Mixed-Gender Task Groups

Trenton Mize, CURO Scholar
Dr. Dawn Robinson, Department of Sociology, University of Georgia

The present research examines status and legitimacy in task groups using theories

stemming from the Expectation States Theory paradigm. In the present study, three participants took several pre-tests that measured their creativity, job and academic histories, etc. In one condition, the experimenter assigned a supervisor and told the participants this was based on their pre-test scores. In the other condition the group was told the supervisor had been randomly assigned. In actuality, the supervisor was assigned randomly in both conditions. The other two participants were assigned the role of assistant. The three participants then took part in a collectively oriented task group. In this experiment, both legitimacy of the supervisor (based on the method of assignment) and the gender of the supervisor and assistants were manipulated. This allowed for a 2x2x2 experimental design. It is predicted that female supervisors will have lower status and legitimacy as leaders when compared with male supervisors, and that supervisors who were "randomly" assigned will have lower status and legitimacy compared to the supervisors who were assigned based on "merit". The present analyses will examine status of the supervisors in the traditional method of self-report surveys filled out by all participants after the group activity, but also look at behavioral measures of status such as words spoken, criticism levied, and praise given. It is predicted that there will be an observable effect of undermining female supervisors authority and legitimacy when examining behavioral measures that will not be present or be less evident in the self-reports.

The Orpheus Myth Over Four Hundred Years

Caleb Moreno
Dr. Dorothea Link, Hugh Hodgson School of Music, University of Georgia

The Greek myth of Orpheus has been the focus of much discussion in the musical world, often seen as both a dramatic story and an allegorical lesson. Orpheus was the subject of one of the earliest operas in 1607 and since then has been adopted in many variations for opera. While much of the literature in the field has both reviewed performances of Orpheus operas and critiqued the operas as compositions, little study has been made in relation to their Greek origins. The aim of this paper is to investigate how the myth's involvement in opera has changed over time and how this is reflected in the music. First I will establish the Greek history and context of the myth. Then, I will sequentially detail four specific operas representative of the 16th through 20th century styles, comparing each to the Greek myth and to each other as appropriate. In the process I will highlight key differences in plot and character. These distinctions will indicate several approaches to the Orpheus myth: Monteverdi's retelling, Gluck's re-imagining, Offenbach's satirizing, and Birtwistle's comprehensive presentation of the myth. I will show how the music of each opera supports these approaches according to the musical language of each time period on a large scale and also according to the conscious aesthetic choices of each composer in specific scenes.

Epidemiology of Equine *Staphylococcus aureus* in Georgia and Kentucky from 1995-2003

Tatum Mortimer
Dr. Susan Sanchez, College of Veterinary Medicine, University of Georgia

Staphyloccus aureus can infect many animal species. In horses, *S. aureus* can cause respiratory, joint, and wound infections. Antibiotic resistance is a growing problem in medical and veterinary fields, as antibiotic resistant infections are difficult to treat. While methicillin resistant *Staphylococcus aureus* (MRSA) began as a nosocomial infection, in the past decade the infection has become community associated (CA-MRSA). Infection by MRSA occurs in companion animals, including horses, which could serve as a potential reservoir for human infection. Our purpose was to study the epidemiology of equine *S. aureus* obtained from clinical samples from 1995 to 2003 in Kentucky and Georgia. We hypothesized that equine MRSA isolates from Georgia and Kentucky would be clonal and related to the CA-MRSA strain USA500, similar to results of equine MRSA studies in other locations. Isolates were characterized by presence of *mecA*, SCC*mec* type, and toxin genes by PCR. Pulsed-field gel electrophoresis

(PFGE) was performed to assess the genetic relatedness of the isolates, as well as twelve human control isolates. 59% of isolates were positive for *mecA*. MRSA was found to be present in the horse population in 1996, earlier than the first reported case of equine MRSA and the CA-MRSA epidemic in humans. 92% of MRSA isolates were SC*Cmec* type IVd. Analysis of PFGE results revealed that 78% of MRSA isolates were closely related to each other and USA500. This clone appears to be highly successful in horse populations and was circulating among the horse population before recognition as a community acquired pathogen.

"Cuando uno toma el agua del Tambopata…": Migration and the urban environment in Madre de Diós, Peru

Bryn Murphy
Dr. J. Peter Brosius, Department of Anthropology, University of Georgia

The region of Madre de Diós, Peru, contains the best-preserved area of the Amazon rain forest and the highest levels of biodiversity on earth. Because of this notoriety, Madre de Diós is also home to a high concentration of non-governmental organizations (NGOs) focused on conservation and sustainable development. These NGOs are predominantly staffed by non-local professionals who were raised and educated in urban areas of Peru and later migrated to Madre de Diós to work. The purpose of this study was to evaluate whether the non-local and originally-urban characteristics of these NGOs' workforces affect conservation outcomes in rural versus urban areas of Madre de Diós. Interviews were conducted on a sample of fifteen employees of NGOs in Madre de Diós. Interviewees' responses were analyzed with reference to the social constructivist school of thought in environmental anthropology, which argues that social constructs cause people to value rural landscapes over urban landscapes, resulting in greater investment of conservation resources into rural landscapes at the expense of urban landscapes. In contrast with the predictions of the social constructivist literature, interviewees' responses demonstrated approximately equal valuation of rural and urban landscapes. These results suggest the need for further research, including a larger sample of interviews, to determine whether Madre de Diós truly represents a counterexample to social constructivist predictions.

Epigenetic Effects of Bromate on p21 and Histone-2AX Expression in HEK293 Cells

Krelin Naidu, CURO Summer Fellow
Dr. Brian S. Cumming, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

The epigenetic effects of bromate (BrO_3^-) exposure in human embryonic kidney 293 (HEK293) cells were investigated. BrO_3^- is a byproduct of ground water disinfection procedures (oozonation). It has been designated a possible human carcinogen by the International Agency for Research on Cancer. BrO_3^- treatment (10 – 200 ppm) causes damage to HEK293 cells based on cell death assays and increased levels in specific regulatory proteins (p53, p38, cdc2, etc.) in HEK 293 cells over 72 hours. Immunoblot analysis indicates that BrO_3^- induced epigenetic changes as assessed by increased expression of phosphorylated histone-2AX (H2AX), a histone correlated with DNA damage that facilitates DNA repair. BrO_3^- exposure also led to a G2/M cell cycle arrest that correlated to increased expression of tumor suppressor gene, p-p53, and other regulatory genes p-p38, p21, cyclin B1 and p-cdc2. Treatment of cells at low concentrations (1 – 100 ppm) for 48 hours showed similar trends in protein expression levels suggesting that bromate's toxicity may lead to epigenetic alterations. Preliminary studies demonstrate that bromate treatment of human embryonic kidney 293 cells increases the phosphorylation of H2AX. This modification in histone expression level suggests the hypothesis that bromate, at low levels, induces epigenetic changes in *in vitro* models of toxicity.

Analysis of rRNA Maturation in *Escherichia coli*

Rakia Nasir
Dr. Sidney Kushner, Department of Genetics, University of Georgia

The maturation of ribosomal RNA (rRNA) in the bacterium *Escherichia coli* generates the functional species necessary for ribosome assembly. The rRNA genes in *E. coli* are organized into seven distinct operons that are comprised of 16S, 23S, and 5S precursors transcribed as a 30S precursor. Previously, it has been demonstrated that the 30S precursors are cleaved into four discrete pre-rRNAs with the help of endoribonuclease III (RNase III). Studies have shown that RNase III cleave sites on the double-stranded RNA in order for the maturation process to begin. However, our lab has demonstrated that additional enzymes participate in the separation of 16S and 23S rRNA species from the larger precursor. Our goal is to determine the ribonuclease(s) responsible for rRNA processing in the absence of RNase III. We hypothesize that a backup pathway involving multiple enzymes dependent on an RNA helicase unwinding the double-stranded RNA allow cleavages by other ribonucleases that cleave single-stranded RNA. To test this hypothesis, we are constructing specific *E. coli* strains, which are defective in potential and known ribonucleases that may affect the rRNA processing. RNA extractions will allow us to visualize the effect on rRNA in the absence of enzymes possibly involved in the rRNA maturation process A better understanding of rRNA maturation may facilitate the development of new antimcirobials that specifically target this pathway in bacteria.

The Effects of Manganese on Human Neural Stem Cell Cultures

Muktha Natrajan, CURO Scholar
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Human Neural Stem cells (hNSCs) have the potential to replace brain cells in patients with neurodegenerative disorders. Neural cell adhesion and development depend on integrins, so using integrin activation, hNSCs can adhere to a substrate or implant in the brain to replace degenerated cells. Through activation of integrins, it is hypothesized that manganese (Mn2+) will direct cells to a glial fate more rapidly than random differentiation. This study's objective is to obtain an increased rate of gliogenesis due to integrin activation, which will result in a purified glial cell population. To increase the rate of gliogenesis, 0.03 mM MnCl2 differentiation media was added. Glial cell gene expression was determined by Real Time Polymerase Chain Reaction. Results indicated that five of the seven genes were positive with MnCl2. Immunocytochemistry was performed using standard immunofluoresence protocols. Antibodies against glial proteins were used, but only one was positive. Higher concentrations of manganese have been shown to cause symptoms similar to Parkinson's disease, but a challenge now is to identify the neurodevelopmental consequences of manganese exposure. We will also determine the point where manganese causes a lethal dose response. Neural Progenitor cells provide an excellent developmental avenue for understanding the effects of common materials/toxins that are present in development. I performed dose response testing using an Alamar Blue proliferation assay, which indicated a definitive dose-response to manganese. Ultimately, we will know how manganese can potentially increase neural cell adhesion and growth at lower levels and how it is toxic at higher concentrations.

Emotion Regulation in Children: Implications for Affect and Childhood Psychopathology

Cody Nichol, CURO Scholar
Dr. Cynthia Suveg, Department of Psychology, University of Georgia

Within the scope of emotion research, much attention has been paid to the role of negative emotions in youth psychological functioning, but only a scant amount to the role of positive emotions. Yet, theory and preliminary empirical research with adults suggest that positive emotions can facilitate cognitive and psychological functioning. With implications for treatment outcome, i.e., more effective clinical interventions, research which examines the role

that emotion plays in one's psychosocial functioning is crucial. The purpose of this study was to examine the specific role of positive emotions in relation to emotion regulation (ER) and the presence of psychopathology in children ages 7-12. The following hypotheses were generated. First, it was expected that situational appropriate displays of positive affect during the negative emotion tasks would positively correlate with ER. Second, it was hypothesized that displays of negative effect in the positive emotion task would negatively correlate with ER. Third, it was anticipated that ER would function as a mediator between affect and psychopathology. Overall, ER was expected to be negatively correlated with symptoms of psychopathology. To conduct this research, children and their parents independently completed measures of the child's ER and symptoms of psychopathology. Children and their parents also participated in a behavioral observation task that required the family to discuss a time when the child felt happy, angry, anxious and sad. Behavioral observations were coded using Observer XT, and frequencies of positive and negative affect were obtained. Data were analyzed with correlational and mediational analyses.

Dust and Breath - Works of Art and Technology

Brittany Norman
Prof. Martijn Van Wagtendonk, Lamar Dodd School of Art, University of Georgia

In *Genesis*, the creation of man is twofold: "And the LORD God formed man of the dust of the ground, and breathed into his nostrils the breath of life." My studies in art and technology both grow out of the same desire to create--to take the matter around me and give it form and give it life. Whereas my studies in art have given me the tools to bring shape to my ideas and give them form, my studies in technology have given me the tools to breathe life into these forms--to give them the ability to move, sense, and respond to their environment. This body of artwork is born out of a culmination of four years of interdisciplinary studies in computer science, engineering, digital media art and sculpture. Creation methods have involved a combination of studio art practices, computer programming, electronics design and mechanical design.

LysR-type Transcriptional Regulators

Melesse Nune
Dr. Cory Momany, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

There are over forty LysR-type transcriptional regulators, LTTRs, in *Acinetobacter* sp. strain ADP1. According to the DEG (Database of Essential Genes), five of the many LTTRs in ADP1 have been predicted to be essential under specific growth conditions. The five essential LTTRs are ACIAD0461, ACIAD0746, ACIAD2511, ACIAD1539, and ACIAD2384. Only ACIAD2384 has homology to an LTTR with known function, MetR, which controls methionine biosynthesis in bacteria. *Acinetobacter baumannii* is a pathogen that is resistant to most antibiotics. As a result of its resistance to drug treatment, the bacterium kills tens of thousands of hospital patients each year, and specialists say that this pathogen is an emerging threat. The essential LTTRs in ADP1 are present in *A. baumannii* and, thus, may represent novel drug targets in the pathogen *A. Baumannii*. The investigation of the role of these LTTRs has been initiated by evaluation of the DNA sequences encoding the LTTRs, followed by the introduction of the essential LTTR genes into a plasmid that adds a polyhistidine C-terminal purification tag for simple protein purification from *E.coli* BL21(DE3) "Codon Plus" competent cells. All four LTTRs have been amplified by PCR and inserted into the expression vector. Successful protein purification of ACIAD0461 using metal-chelate chromatography has transitioned to crystallization studies in anticipation of providing valuable structural data. The structural and functional studies done on these LTTRs, improve our understanding of microbial metabolism and transcriptional regulation, and also help us identify novel drug targets that may lead to an important drug discovery.

The Effect of N-Back Stimuli Type on Performance

Laura O'Neill, CURO Apprentice
Dr. Rebecca S. Marshall, Department of Communication Sciences & Disorders, University of Georgia

Aphasia is a multimodal language deficit that results from damage to the language areas of the brain. Recent research in aphasia has considered the role of working memory. Working memory can be assessed using the N-back, a computerized task composed of alternating images that recur at specified intervals. In recent aphasia research, two different versions of the N-back have been used, one using fruit and the other using faces. The current study seeks to determine if stimulus type (fruit or faces) influences task performance of individuals with aphasia. For instance, if individuals engage in sub-vocal rehearsal of presented items, the task becomes linguistic. This is far more likely to occur with the fruit stimuli, for it is unlikely that individuals will be able to name face stimuli, making the task nonlinguistic. Results from the current study will aid in determining how to most accurately measure working memory in aphasia. In the current study, the fruit-back and faces-back were compared in healthy and aging populations. Individuals with aphasia (N=3, Mean age=62.3) and neurologically intact controls (N=18, Mean age=82.27) were recruited. Both the fruit and faces tasks consisted of three levels correlated to increasing working memory load. Data were analyzed based upon the number of correct responses, errors of omission, and errors of commission. A difference in performance between healthy individuals and IWA is expected in the linguistic task, but not in the nonlinguistic. A better understanding of working memory's role in aphasia can lead to improved assessment and ,therefore, rehabilitation of aphasia.

Investigating Early Warning Signals and Critical Slowing Down in Changing Environments

Tierney O'Sullivan
Dr. John Drake, Odum School of Ecology, University of Georgia

Extinction has long been a fascination of scientists but is incredibly difficult to study comprehensively. It is becoming an increasingly important topic due to habitat fragmentation and climate change throughout the world. The difficulty of studying extinction is that scientists often predict it, but are unable to reverse it because of late detection. The problem is that extinctions result from bifurcations, when a small change in a parameter creates a significant change in the system's behavior. Once a bifurcation occurs, the result is often irreversible. We used Daphnia magna as a test subject to investigate the presence of early warning signals in the form of increases in statistical patterns such as variance, autocorrelation, and standard deviation from the mean. These changes can predict extinction before the bifurcation occurs. The Daphnia populations were assigned to 96 chambers, and each chamber was assigned one of four treatments where all environmental conditions were kept constant except temperature. The temperature treatments divided the chambers into four categories: constant, increasing, periodic, and decreasing. Population sizes in the chambers were recorded daily, and the data were analyzed to determine the presence of the early warning signals of the critical slowing down phenomenon using statistical tests in R. The analysis uses a range of window sizes to detect increased levels of the indicators, which can predict bifurcations that lead to extinction. Additional analysis must be done to determine if the presence of the signals in the data is conclusive.

Expression of the DBL3x domain of VAR2CSA in *E. coli*

Oluremi Ojo, CURO Apprentice
Dr. David Peterson, Department of Infectious Diseases, University of Georgia

Plasmodium falciparum, the parasite that causes the most virulent type of malaria, results in nearly one million deaths annually. Our research focuses on pregnancy-associated malaria (PAM), which accounts for 10,000 annual maternal deaths and 3% to 8% of infant mortality in Sub-Saharan Africa. PAM results from infected erythrocytes binding to chondroitin sulfate A (CSA), a receptor on the placenta, preventing nutrient exchange between the mother and fetus. Infected erythrocytes express the protein VAR2CSA, which mediates binding to the placenta. VAR2CSA is a large protein and consists of six different domains called DBL1-DBL6. We primarily focus on studying the DBL3x domain, which has been shown to mediate parasite binding within the placenta. Our goal is to characterize the binding of DBL3x in an effort to further understand the mechanisms of the parasite's adhesion to the placental CSA. In our study, we have isolated variants of the DBL3x domain from blood samples obtained from pregnant women in Kenya. Our goal is to understand how binding of the DBL3x domain differs between these samples. To achieve this goal, we use PCR based methods to amplify the DBL3x region from our samples and ligate them into a plasmid that allows expression of this protein in *E. coli*. The purified protein will be used in binding studies to placental CSA to analyze its binding properties. Understanding the binding properties is important as a disruption at this step could prevent infected erythrocytes from binding to the placenta and, ultimately, decrease the virulence of Plasmodium falciparum in PAM.

Evaluation on Blood Flow Velocity and Arterial Diameter Produced by Compression Therapy

Rebecca Parker, CURO Scholar, CURO Summer Fellow
Dr. Kevin McCully, Department of Kinesiology, University of Georgia

Exercise is an effective treatment for cardiovascular disease. A proposed mechanism for the benefits of exercise is the increase in blood flow and subsequent increase in arterial vasodilating capacity. Some have difficulty performing adequate exercise due to disabilities and, therefore, suffer from cardiovascular disease. This study was designed to determine the optimal body position during leg compression therapy to augment blood flow resulting in arterial vasodilation. Twelve able-bodied control subjects completed a round of compression therapy—termed muscle pump (90mmHg @ 5s) in the supine position, and twelve subjects were in a seated position. Ultrasound velocity measurements of the femoral artery were taken during: 3 minutes baseline, 8 minutes compression and 2 minutes recovery. Femoral artery diameter was recorded at baseline and immediately after compression ended. Average blood velocity was 129.7 Â± 68.9% (meanÂ±SD) of baseline while in the supine position and 138.7 Â±49.4% for the seated compression tests (both not significant, $P > 0.05$). Femoral artery diameter after the supine test was 103.5 Â±0.47% of baseline, while the diameter after the seated tests was 99.4 Â±5.3% of baseline (both not significant, $P > 0.05$). Preliminary evidence suggested that neither the supine nor the sitting positions resulted in a significant increase in average blood flow velocity. However, the trend for an increase in diameter while in supine position suggests that the velocity oscillations could have physiologically important effects on diameter. If confirmed, "muscle pump compression" could be a viable method for improving arterial health in people who have difficulty exercising.

Pronunciation of Word-Final [ə] by Older Male Speakers from the South of France

Matthew D. Passarello
Dr. Diana L. Ranson, Department of Romance Languages, University of Georgia

A notable feature of Southern French dialects is the variable pronunciation of word-final mute *e*, which is almost never pronounced in the North, so that a Southern speaker might say [kɹməsa] rather than [kɹmsa] for *comme ça* 'like that'. Even though this vowel is subject to variability in the South, little attention has been paid to the factors affecting its pronunciation. The goal of the present study therefore is to analyze the possible linguistic factors favoring the pronunciation of mute *e* by Southern speakers. The corpus consists of 236 tokens of mute *e* in recorded conversations with seven men over 40 years of age from the South of France. The linguistic factors tested are the mode of articulation, point of articulation, and voicing of the consonants preceding and following the potential mute *e*. The results indicate that the following consonant affects the pronunciation of mute *e* while the preceding consonant does not. Whereas the total rate of pronunciation of word-final mute *e* is around 40% for preceding consonants, regardless of their mode of articulation (whether stop, fricative or liquid) or voicing (whether voiced or voiceless), these rates range from 25% to 57% for following consonants. The highest rate of pronunciation occurs before stops, especially when the preceding consonant has a different mode of articulation. Rates of pronunciation are also higher when preceding and following sounds differ in voicing. It appears then that mute *e* is more often pronounced between dissimilar sounds perhaps in order to facilitate the articulatory transition.

The Role of Histidines in pH Dependence of Human Equilibrative Nucleoside Transporter 3

Bhavi Patel, CURO Scholar
Dr. Rajgopal Govindarajan, Department of Pharmaceutical & Biomedical Science, University of Georgia

Human equilibrative nucleoside transporter 3 (hENT3) is one of four members of the equilibrative nucleoside transporter (ENT) family, a conserved family of solute carrier (SLC) proteins that allow for facilitated diffusion of nucleosides and anti-cancer and anti-viral nucleoside analogs. hENT3 differs from other members, which are predominantly cell surface transporters, in that it functions exclusively intracellularly, localizes to organelles such as the lysosome and the mitochondria and shows maximum transport activity at an acidic pH range of 5.5-6.5. In this study, we will determine the amino acid residues that are responsible for hENT3's pH dependence. Histidine has a pKa of approximately 6.0, and has been shown earlier to regulate pH dependent ligand-binding of many membrane proteins and receptors. Histidine has a positive charge at pH 5.5, where hENT3 shows maximum transport activity. At pH 6.5 and greater, however, histidine does not and hENT3 transport is inhibited. Therefore, we hypothesize that changes in the ionization of one or more histidine residue(s) (e.g. positions 132, 268, 294, 403 and 473) in the predicted translocation pore of hENT3 protein are likely regulating its activity. To study this, we will mutate, either singly or in combination, histidines in hENT3 to neutral, positive and negative amino acids through site-directed mutagenesis. Subsequently, we will perform radio labeled transport studies on mutant RNA injected Xenopus oocytes to study alterations in known endogenous substrates (e.g. adenosine). These studies are expected to lay groundwork in understanding the mechanisms of hENT3 transport of nucleoside drugs used in clinics.

Characterization of Striated Fiber Assemblins in *T. gondii*

Jay Patel, CURO Summer Fellow
Dr. Boris Striepen, Department of Cellular Biology, University of Georgia

In *Toxoplasma gondii*, an obligate intracellular parasite, there is a unique set of proteins known as striated fiber assemblins (SFAs). The tachyzoite stage of this Apicomplexan parasite contains three distinct SFA proteins: SFA2, SFA3 and SFA4. Although SFAs are yet to be characterized in Apicomplexans, one such SFA protein has been described fairly well in the algal ancestor of Apicomplexans, *Chlamydamonas reinhardtii*. Immunofluorescence assays (IFAs) using an anti-SFA antibody in *Chlamydamonas* have shown that SFA is dynamic over the cell cycle and may play a structural role during division. Fluorescent microscopy of the SFAs in *T. gondii* under the strong and constant t7s4 promoter has shown possible localizations and structures for SFA2 and SFA3. These results might not be reliable due to overwhelming background fluorescence within the cell. Also, microarray data shows strict regulation of SFA2 and SFA3 during the cell cycle. The results of these experiments suggest that SFAs are sensitive to the time they are promoted and the strength with which they are expressed. With antibodies against *T. gondii's* SFAs, more accurate localizations and structures of the SFAs during different stages of the cell cycle were identified. The results of the experiments will provide a deeper understanding of the biology of *T. gondii* and the disease that it causes. Furthermore, insight into the function of SFAs could have implications for other Apicomplexan diseases such as malaria and cryptosporidiosis.

Battling With Bytes: A Cybersecurity Doctrine for the United States

Tony Pelli, Katherine Arnold, Yuliya Bila, Rohan Mukhopadhyay, Shyam Shanker, Patrick Smith & Seth Taylor, Roosevelt @ UGA
Dr. Dan Everett, Department of Computer Science, University of Georgia

Cyber security is becoming an important security issue, as the recent attack on Iranian nuclear centrifuges by the computer virus called "Stuxnet" demonstrated. In terms of U.S. vulnerabilities, many experts fear that cyber attacks could cripple critical infrastructure in the electricity and banking industries. Despite the increasing importance of cyber security to the United States' national interest, there has been little comprehensive research on the danger posed by cyber attacks. Current research on the issue is focused too narrowly on the threat posed by cyber-terrorism or "lone wolf" hackers. This paper presents a database of known major cyber attacks by both state and non-state actors. It further identifies the type of cyber attack, which nation or group it originated from, and the intended target. In addition, this paper presents an evaluation of the cyber security capabilities of several key countries including Russia, China and EU member states. Upon examination of this data, we conclude that the threat of cyber attacks is indeed serious, but should not be overstated. Following this conclusion, the paper identifies several areas in which the United States can improve its cyber security and outlines a cyber security doctrine to guide future policies. In particular, public-private coordination and budgetary changes are suggested. Additionally, special attention is paid to the possibility of cooperation between states over cyber security issues.

Cognitive X's and O's: First Steps in the Resolution to the Offensive-Defensive Realist Debate

Chad Peltier
Dr. Jeff Berejikian, Department of International Affairs, University of Georgia

The offensive and defensive realist debate is primarily over how states prioritize security preferences. Do states seek to defend the status quo, as loss aversion would predict, or do they constantly feel the pressure to expand in a gain-seeking manner? I contend that states' grand strategies contain both types of behavior. This study bridges the gap between the offensive and defensive realist camps by using loss aversion, which was recently supported by studies in cognitive neuroscience, as the decision making structure instead of rational choice theory. I conducted an ordered logistic regression analysis

of the COW militarized interstate dispute dataset in order to determine how states prioritize their security preferences as either gain-seeking (offensive) or loss aversive (defensive).

A Flow Cytometry-Based Method of Glycosylation Profiling

Emily Peng
Dr. Robert Woods, Department of Biochemistry & Molecular Biology, University of Georgia

Glycoproteins are polypeptides that have oligosaccharide chains, or glycans, covalently attached to their surfaces. These polymers play essential regulating, functional, and structural roles in biological systems by providing a means for cell-to-cell interactions. Determining the types and amounts of glycans present on the surface of a glycoprotein provides key information about the function and development of the protein. In order to be accepted as therapeutic agents, glycoproteins must have their glycosylation states thoroughly characterized. Currently, procedures for glycosylation profiling involve combinations of mass spectrometry and high-performance liquid chromatography. These methods are complex, time consuming, and do not always give a complete characterization of a protein's glycans. We are developing a more efficient and complementary flow cytometry-based method of glycan analysis. In this method, proteins that bind specifically to certain glycan linkages (lectins) were covalently attached to microspheres, or beads, with discrete levels of red fluorescence. The lectin-bead conjugates were incubated with a solution of oligosaccharide labeled with green fluorescence. The amount of glycan bound to each lectin bead was measured in a flow cytometer. The higher green fluorescence intensity of a lectin bead relative to the other beads confirmed that the glycan of known linkage bound specifically to its lectin, and shows this method can correctly indicate the types of glycans present in solution. The results also show that this method has potential for identifying glycans on the surface of glycoproteins.

Oil Palm Proliferation in Latin America

Rachel Perez, CURO Apprentice, CURO Summer Fellow
Dr. J. Peter Brosius, Department of Anthropology, University of Georgia

This project examines the environmental and social effects of the oil palm/palm oil industry throughout Latin America by reviewing literature from a variety of sources in order to create a concise report. Palm oil, extracted from the African oil palm, is a highly profitable product whose diverse uses have most recently expanded to include bio-fuel. Cultivation of the palm occurs primarily in Southeast Asia, but is rapidly expanding to Latin America, largely to the detriment of the region. Oil palm cultivation occurs chiefly on large-scale monoculture plantations, a practice that causes ecological damages including deforestation, decreased biodiversity, and air, soil and water pollution. Cultivation practices also have negative social effects: local populations (often composed of marginalized groups such as racial/ethnic minorities) suffer land rights violations, displacement, unhealthy living and working conditions, decreased political representation and threats of violence among other afflictions. The oil palm mega-plantations create land scarcity, causing a significant decrease in food crop cultivation and a subsequent increase in food prices throughout the region. Large-scale growers use political and economic power to continue unsustainable practices in the name of short-term economic efficiency, while opposition groups, a demographic including conservationists, human rights organizations, universities and local populations, struggle with coordinating a united front in order to confront industry abuses. This project aims to bring more attention to a lesser-known environmental issue and present the findings and possible resolutions to interested parties in the hopes of addressing this issue before it progresses in to a more advanced state.

The Use of PCR Assays to Determine the Extent of Zones of Hybridization of *Culex pipiens quinquefasciatus* and *Culex pipiens pipiens* in Georgia

Katherine Perofsky, CURO Scholar
Dr. Daniel Mead, Department of Population Health, University of Georgia

In Georgia, *Culex pipiens quinquefasciatus* has been identified as the primary vector of West Nile virus (WNV). Statewide WNV surveillance data collected between 2001 and 2008 indicates that during the peak transmission period (July through late September) WNV infection rates in *Cx. p. quinquefasciatus* are high. However, in Georgia the low number of reported human cases of West Nile virus does not correlate with the *Culex* mosquito high infection rate. A study conducted on Georgia mosquitoes in 2003 reported the occurrence of *Cx. p. quinquefasciatus* and *Cx. p. pipiens* hybrids in an area within the state which is outside of the previously recognized hybridization zone (the northern region of Georgia). Hybrids of these species may have an alteration in host feeding preferences which could account for the low number of human WNV cases in the state. We hypothesize that the *Culex* hybridization zone is more widespread in the state as opposed to limited to Northern regions. To redefine the hybridization zone in Georgia, we used a previously described PCR protocol to analyze specimens of *Culex pipiens quinquefasciatus* and *Culex pipiens pipiens* that were collected from various regions of Georgia and identified based on morphology. The results of this study show the extent of hybridization between *Cx. p. pipiens* and *Cx. p. quinquefasciatus* to be small, yet suggest the hybridization zone in Georgia encompasses a wider area than previously considered.

Expression of Heat Shock Proteins 27 & 72 in Canine Intracranial Meningiomas

Grant Perry
Dr. Simon Platt, College of Veterinary Medicine, University of Georgia

Meningioma is the most common type of brain tumor in dogs and the most likely to be treated. Heat shock proteins (HSPs) are up-regulated during times of environmental stress and are associated with tumor maintenance via stabilization of tumor proteins. HSPs 27 and 72 have previously been shown to be present in human tumors, which make these HSPs a reasonable target for tumor therapy. The goal of this study was to see if HSPs 27 and/or 72 are expressed in canine intracranial meningiomas and, thus, potentially a therapeutic target. The study also sought to determine any similarity between human and canine tumors. This was a retrospective study of forty-one tumor samples from dogs. Immunohistochemistry (IHC) was performed using anti-HSP 27 or 72 antibodies to detect the presence of each HSP. Control samples used were canine mammary carcinoma and squamous cell carcinoma, both of which express HSPs. Staining intensities and percentages of tumor area were determined for each protein by semi-quantitative methods. HSP 27 was expressed in greater than 1/3 of cases (36%). HSP 72 was expressed in greater than 1/2 of cases (52%). Additionally, both HSPs were expressed in 21% of cases. This shows that expression of HSPs 27 and 72 does occur in canine intracranial meningiomas and deserves further investigation. Their potential as a target for treatment is also being evaluated further in association with markers of cell proliferation and dedifferentiation.

Women with Naturally Bright Red Hair Report Higher Pain in Response to Thermal Stimuli and Reduced Pain in Response to a Mild Muscle Injury Compared to Dark-Haired Women

Akil Piggott, CURO Apprentice
Dr. Pat O'Connor, Department of Kinesiology, University of Georgia

Variations in the melanocortin-1 receptor gene that result in bright red hair also are associated with a greater sensitivity to cutaneous thermal pain among women. It is of practical significance to learn whether women with bright red hair also are more sensitive to other noxious stimuli that cause pain. This study aimed to compare the cutaneous thermal and muscle pain responses of women with naturally bright red hair to women with dark-hair in response to a mild muscle injury. Red (n=5)- and dark-haired

(n=5) women were tested on 3 successive days. Measures of inflammation, pain and function of the non-dominant arm were obtained before and after 18 eccentric actions of the elbow flexors which induced a mild muscle injury. Changes in inflammation, arm function, forearm flexor strength, and both muscle pain and cutaneous thermal pain were induced by 2-second heat exposures of 45, 47 and 49°C presented to the skin of the non-dominant forearm and posterior lower leg using a 30x30 mm thermode. Compared to dark-haired women, women with bright red hair reported: (1) higher pain intensity (arm = 19% & leg 23% higher) and pain affect (arm = 34% & leg 15% higher) ratings, and (2) a greater reduction in pain ratings in response to the muscle injury (effect size deltas of .15 to .61). Effects on inflammation and arm function were smaller. The primary novel finding is that red-haired women show a greater reduction in pain ratings in response to muscle injury compared to dark-haired women.

Witch-Doctoring Tolstoy: Applying Traditional Healing Philosophies to *The Death of Ivan Ilych*

Ryan Prior, CURO Summer Fellow
Dr. Katarzyna Jerzak, Department of Comparative Literature, University of Georgia

As the humanities provide us with a rich reservoir of wisdom on what it means to be human and to live a good life, viewing the body and illness from a perspective beyond the merely biochemical can yield not only better doctors but also a better society. Throughout history, different civilizations have had widely varying medical philosophies, stemming from their religion and philosophy as much as their art and literature. Studying notions of sickness and death in Western literature, we can find yearnings for a more humane medicine, one that realizes that healing must be as spiritual and emotional as it is physical. In Tolstoy's meditations on sickness and death in *The Death of Ivan Ilyich,* we find a character whose attempts to find healing through relationships are condemned by a medical doctor as "foolishness." Yet Ayurvedic practitioners in India, valuing community, inquire about a patient's social well-being in the initial consultation. Ivan Ilyich comes to realize that his moral failings, family relations, and bitterness are as much to blame for his illness as his actual physical make-up. His internal monologues seem as if taken from sociological and anthropological case studies of Ayurvedic practitioners, healers who might tell victims of anxiety not to take Xanax, but to gain perspective by spending time with the poor. In comparing Ayurvedic case studies with passages from Tolstoy's text, this study will construct an Ayurvedic "treatment" for Ivan Ilych, one that aligns with the character's own judgments of himself, a philosophical cure that succeeds where science could not.

The Effect of Parasite Infection on Monarch Butterfly Mating Behavior

Malavika Rajeev, CURO Summer Fellow
Dr. Sonia Altizer, Odum School of Ecology, University of Georgia

Monarch butterflies (*Danaus plexippus)* are commonly infected by a debilitating protozoan *Ophryocystis elektroschirra*, which can inhibit growth and decrease survival of individuals in wild populations. This study examined the effect of parasite infection on monarch mating contests and mating success. Monarchs have a unique mating behavior (called 'forced copulation') whereby males chase and force themselves onto passing females. Although female monarchs do not actively choose their mating partners, females can struggle to avoid mating with certain males, and males may abandon attempts with certain females. Because infected monarchs are often in poorer condition than healthy butterflies, and mating with an infected partner poses the risk of spore transmission to offspring, infected male and female monarchs might mate less often than healthy butterflies. Lab-reared healthy and experimentally infected adults, equally distributed across sex and infection status, were placed in large outdoor enclosures. Mating contests and successful matings were recorded over 10 days. Our results showed that both healthy males and females mated more frequently than infected butterflies; however, this effect did not reach statistical significance. While the average number of contests per day was slightly higher for healthy versus infected

males, infection status did not have a significant effect on mating attempts. Most successful matings were between healthy males and infected females. Collectively, these results suggest that monarchs do not discriminate between healthy and infected mates, which should benefit parasites by allowing continued transmission via mating contacts.

Development of a System for Targeted Mutagenesis in *Mycobacterium Tuberculosis*

Akanksha Rajeurs, CURO Scholar
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

One third of the world population is infected with *Mycobacterium tuberculosis*. Annually, 7 to 9 million infected individuals suffer from active tuberculosis disease (TB) resulting in ~ 2 million deaths. The current TB vaccine, *Mycobacterium bovis* BCG, is rarely used in the U.S. because of variable efficacy (0-80%) against pulmonary TB. Attenuating *M. tuberculosis* to produce a more effective, safe, live vaccine will require deletion of multiple virulence factor genes from the chromosome. Current selection systems to delete genes from this bacterium utilize homologous recombination to replace a target gene with an antibiotic resistance gene. As a vaccine strain encoding multiple antibiotic resistances may lead to transfer of antibiotic resistance genes to other bacteria, we are developing a modified system to first replace the chromosomal gene with a cassette of genes encoding a selectable marker, a fluorescence marker and a counter-selectable marker. The first enables selection for the mutant. The second aids microscopic analyses of the mutant. The third provides a means for subsequent deletion of the cassette from the chromosome resulting in an unmarked, drug-sensitive mutant. Efforts are in progress to use this system to target a natural antibiotic resistance gene in *M. tuberculosis* and *M. bovis* BCG. Deletion of this gene will result in bacteria that can be killed by the antibiotic.

Kinetic, Temperature Dependent and Structural Analyses of YqhD, an Escherichia coli NADPH Dependent Oxidoreductase Enzyme

Cortney Ralston
Dr. William Lanzilotta, Department of Biochemistry & Molecular Biology, University of Georgia

YqhD is an $NADP^+$ dependent oxidoreductase that is of extreme importance to the cell. In general, YqhD catalyzes the reduction of toxic aldehydes produced from aerobic respiration in an NADPH dependent reaction. Buildup of toxic aldehydes in humans has been linked to diseases such as cancer, diabetes, emphysema and arthritis (Perez et al 2008). Our laboratory has determined the specific activity as well as the K_M and V_{max} of YqhD for propionaldehyde by performing assays that monitor the NADPH dependent reduction of propionaldehyde using UV-Visible spectroscopy. Our laboratory also elucidated a crystal structure for YqhD in order to address substrate specificity. Our hypothesis was that YqhD must also have an "open" confirmation, in contrast to what was originally reported. Our structure confirms this hypothesis and provides an explanation for the observation that YqhD can reduce several aldehyde substrates. A second hypothesis was focused on the application of YqhD, in combination with *Pyrococcus furiosus* hydrogenase I (PFH-I), in hydrogen-driven production of 1,3-propanediol, a compound used to manufacture a polymer that can be spun into a strong but flexible fiber. PFH-I is unique in that it can be used in the production of NADPH through the oxidation of hydrogen gas. Given that *P. furious* is a hyperthermophilic anaerobe, and recent evidence for YqhD genes in thermophiles with high homology to YqhD from *E. coli,* we proposed that YqhD may demonstrate some temperature stability and be applicable in hydrogen-driven production of 1,3-PD. An investigation of YqhD activity at elevated temperatures is presented herein.

Victory over the Sun: The Russian Futurist Transcendence over Materiality

Joanna Reising
Dr. Nell Andrew, Lamar Dodd School of Art, University of Georgia

Victory over the Sun, a Russian Futurist opera performed in St. Petersburg in 1913, was the combined effort of three prominent Russian Futurists: Kazimir Malevich, who designed the sets and costumes; Alexei Kruchenykh, who wrote the dialogue; and Mikhail Matiushin, who wrote the music. The Three Futurists were out to reform Russian theater, to transform it in the ways of the new art. This opera, with the combined efforts and innovations of three important Russian futurists, was a pivotal moment in the history of Russian Futurism. Although it was something uniquely Russian, its creators relied on inspiration from the west, namely Cubism and Italian Futurism. *Victory over the Sun* is the culmination of Russian Futurist theories that collaborate in a performance not meant to lead the audience to a clearer image of forms in space as with their French and Italian counterparts, but into a particularly Russian utopia of nonsense, through transcendence over the Sun, the personification of the material and rational. This is an important point to make when considering the avant-garde as a whole as it was developing across Europe. The styles and ideas borrowed from French Cubism and Italian Futurism fully entrench Russian Futurism in the Western tradition. But the opera in particular proved that Russian Futurism was not limited to painting or sculpture or poetry; it was a cacophonous combination of all media that lent itself to a pre-revolutionary Russian moment.

Design of a Computed Tomography Scanner with Components from an Existing DEXA Machine

Katherine Riccione, CURO Scholar, Ryan Boelter, Tina Carson & Chase Mooney
Dr. Mark Haidekker, Department of Biological & Agricultural Engineering, University of Georgia

A computed tomography (CT) scanner is to be designed with a number of components obtained from an existing dual-energy x-ray absorptiometry system (DEXA). These components include a dual-energy x-ray generator, a detector consisting of a scintillator crystal connected to a photomultiplier tube, and the necessary electronics for the x-ray source. The design was given a number of requirements, including a point spread function of at least 5 mm, volumetric scan ability, pencil beam geometry with an x-ray intensity of no greater than 140 keV, and a shielding apparatus that no more than doubles the background radiation at a distance of 1 m. With the x-ray source, detector and electronics provided by the existing DEXA system, the remaining components to be designed include a rotational sample stage capable of translational movement along the x-, y-, and z-axes; suitable sample holders that allow for observation of the sample during operation; a proper shielding apparatus; and any necessary software for calibration and image collection. Once complete, this CT scanner will be available for researchers in the UGA engineering department and will be capable of scanning various samples including, but not limited to, small animals, bones, plant materials and geologic matter. The benefits of this CT device over its original DEXA forerunner include faster image acquisition time, better image resolution, and the ability for selectable projections.

Effects of *Ligustrum sinense* Presence and Removal on Nitrogen Mineralization Rates

Rebecca Risser
Dr. Paul Hendrix, Odum School of Ecology, University of Georgia

Chinese Privet (*Ligustrum sinense*) is a common invasive in the southeastern United States, particularly in low lying riparian areas. Other invasive shrub systems have been found to have effects on soil characteristics and processes. As a result, nutrient cycling is often affected. This study explores the effects of privet removal on nitrogen mineralization rates at sites in the Oconee River basin. Four sites were selected and treated four years ago, each containing three plots: 1) The control in which privet was present; 2) privet felled by chainsaw; and 3) privet chipped by a mulching machine. In

addition, three reference, or desired future condition sites which are naturally privet free, were sampled. Soil samples were collected from these sites and were incubated for 28 days to determine net ammonia and nitrate mineralization rates. Preliminary results indicate that mulched plots have higher mineralized nitrogen than control plots and plots where privet is removed by felling. High biomass input into the mulched system combined with smaller particle size may have lead to this result, along with flooding in 2008 which washed away debris from the felled sites particularly.

Using Fluorescence to Identify Insect Damage to Cotton Bolls

Erin Roberts, CURO-Engineering Participant
Dr. Mark Haidekker, Department of Biological & Agricultural Engineering, University of Georgia

Every year, cotton crops across the Southeast United States are damaged by stink bugs feeding on the cotton bolls, rendering them unusable. When a stink bug feeds on a cotton boll, it can create three types of damage: lint damage, "warts" on the inner carpal wall and exterior puncture marks. As cotton is a vital industry, a fast and easy method of detection of infestations is needed. We discovered that this damage is associated with blue-green fluorescence under ultraviolet excitation. The purpose of this research is to determine whether fluorescence can be used in the field to diagnose cotton bolls as either damaged or undamaged. We examined cotton bolls that were grown in a greenhouse, some of which were exposed to stink bugs and others which were not. Images of all sides of the cotton bolls were then taken under ultraviolet light and blue LED light using a highly sensitive camera. Then the cotton bolls were manually opened and inspected for any signs of damage. We have found that there is a specific pattern of fluorescence on the outer carpal wall that is indicative of interior lint damage. This information can be examined with image analysis methods to predict if a cotton boll has internal damage without opening the boll.

Improving the Claims-Making Process in Context to the 2010 Deepwater Horizon Oil Spill

John Rodriguez, Roosevelt @ UGA
Dr. Leara Rhodes, Grady College of Journalism & Mass Communications, University of Georgia

The 2010 *Deepwater Horizon* Oil Spill decimated the tourist-dependent economies of the five affected states (Texas, Mississippi, Louisiana, Alabama, and Florida), and shattered the livelihoods of those who lived there. At the behest of President Obama, the responsible party created a $20 billion escrow fund in order to compensate affected individuals and businesses. This project analyzes the shortcomings of the Gulf Coast Claims Facility (GCCF) in an effort to create a more effective alternative claims process. We hypothesize that anecdotal evidence will support the data that summarizes the difficulty (both on a logistical and administrative level) of the claims procedure. The anecdotal evidence and qualitative data collection was gathered through interviewing individuals who were affected by the Spill and who had a first-hand experience of the claims process. The GCCF failed in the following ways: it was unprepared to handle the vast amount of claims; it did not have an established protocol in handling claims; and it also had close ties BP. The research concludes that in the case of future incidents, a governmental agency needs to be established to handle the response process, equipped with an agreed-upon procedure and appointed administrator to impartially judge individual claims. The only involvement the responsible party will have in the agency will be in funding the claims. The agency's claims analyst staff should be increased so as to assist claimants both quickly and effectively. With such an agency in place, future claims processes will be handled more transparently and promptly.

Morphological Changes Accompanying Killing of *Trypanosoma brucei brucei* by Human Serum

Carla Rutherford, CURO Summer Fellow
Dr. Stephen Hajduk, Department of Biochemistry & Molecular Biology, University of Georgia

Trypanosoma brucei brucei is a eukaryotic parasite that infects mammals, but is unable to infect humans due to the cytotoxic activity of human serum, mainly as a consequence of a minor subclass of serum high-density lipoprotein called Trypanosome Lytic Factor (TLF-1). Conflicting observations have complicated our understanding of the mechanism of *T. b. brucei* killing by human serum. To elucidate the killing mechanism, we analyzed morphological changes associated with human serum treatment, using both fixed cell imaging and time-lapse microscopy of live cells. Treatment of *T. b. brucei* with human serum suggests two distinct cellular mechanisms are associated with cell lysis. Using freshly collected, high specific activity human serum, we observed that *T. b. brucei* rapidly undergoes morphological changes appearing "kite-shaped" prior to cell lysis. The morphology of *T. b. brucei* incubated with low specific activity human serum was dramatically different. Three conditions produced low specific activity human serum: 1) The presence of elevated levels of haptoglobin, 2) prolonged storage at 4°C, and 3) brief incubation at 62°C. Using low specific activity serum, we observed the gradual formation of a large cytoplasmic vacuole and a delay in trypanosome killing, which immunofluorescence microscopy confirms is not the cell lysosome. These studies support the hypothesis that human serum killing of *T. b. brucei* may require the activity of multiple proteins, and that one of these proteins may be selectively inactivated by haptoglobin, heat treatment or storage, resulting in the distinct morphologies observed. Understanding this mechanism will allow us to better understand human innate immunity.

Attuning to Positive Social Cues as an Effortful Process for Socially Anxious Individuals

Raha Sabet
Dr. Michelle vanDellen, Department of Psychology, University of Georgia

The purpose of this project is to investigate the impact of anxiety on responses to social threat. In general, people attend to positive cues after social threat. However, these attention processes may not operate similarly for people at varying levels of social anxiety. At low levels of social anxiety, attuning to positive cues should occur naturally and should not involve effort. However, at high levels of social anxiety, attending to positive social cues may be effortful. This project involves two studies designed to investigate whether the regulation of positively oriented social attention requires effort by people high in social anxiety. Both studies will be conducted on male and female college students. In each study, I will measure trait social anxiety and manipulate the extent to which participants' ability to exert effort is reduced. Study 2 builds on Study 1 by including a manipulation of social threat such that some participants will be led to believe that they will be evaluated while reading a passage from Shakespeare's Hamlet. In each study, attention to positive social cues (e.g., attention to happy faces) is the primary dependent variable. All participants will be fully debriefed.

Reducing Water Usage by Repowering Plants in Georgia

Hank Schwartz, Roosevelt @ UGA
Dr. Laurie Fowler, Odum School of Ecology, University of Georgia

From 1970 to 2009, the metro Atlanta population exploded from 1.7 million to 5.3 million, and during the same period, farming irrigation in Georgia has increased from 200,000 to 1.4 million acres. The competition for resources is evident: a 2007 drought led to a decrease in $1.3 billion of economic output, and Georgia currently has the largest proportion of imperiled freshwater fauna in North America. Additionally, based on a 2009 U.S. federal court ruling, Atlanta will not be able to make

withdrawals from Lake Lanier past 1970 levels, effectively reducing the city's water supply by half. In order to dramatically reduce water consumption, certain aged power plants in Georgia should be "repowered." When an existing plant is repowered, boilers and generators are either replaced or revamped in order to increase efficiency, reduce emissions and lower water requirements by up to 97%. A review of scholarly journals, university research, business publications and other state water strategies indicates that repowering plants is the fastest and most efficient solution to Georgia's water shortage. While the initial cost will be significant, the payback on the investment will be achieved within four to six years. Considering that the power requirements are highest during the driest months of the year, repowering certain strategic plants in Georgia would reduce the adverse effect of droughts and ensure continued economic growth for the region.

A Cold Calculus: Spending in K-12 Education

Matthew Seitz, Roosevelt @ UGA
Dr. Catherine Sielke, Department of Lifelong Education, Administration & Policy, University of Georgia

Funding for Georgia's K-12 education system has plummeted by $4.3 billion over the last decade, $2.3 billion in the last two fiscal years alone. With revenue projections looking bleak, further cuts will be necessary in the future. Districts have already taken advantage of "easy" cuts; their task now is to make tough, practical decisions that minimally inhibit student opportunity. This paper scrutinizes the evidence for and against four common budget remedies—teacher pay reductions, increased property tax rates, increased class size, and targeted cuts of upper-level and non-core classes—for cost-effectiveness, with an end goal of helping school districts manage funds available to them until tax revenues increase. Evidence on cost-saving measures from the public and private sectors is considered to harmonize the efficient methods of the business world with the "education at any cost" mentality that has dominated public life in recent decades. An across the board wage decrease to teachers and administrators in conjunction with an increase in local property tax is recommended as the most cost-effective solution. This is a temporary measure—both educator salaries and local millage rates will need to be reassessed once the economy recovers, and longer-term policies are enacted. Until then, our school systems must keep all options—however unpopular—on the table.

Every Man a King: Robert Penn Warren, Populism and Contemporary American Politics

Matthew Sellers, CURO Scholar, CURO Summer Fellow & Roosevelt @ UGA,
Dr. Hugh Ruppersburg, Department of English, University of Georgia

Robert Penn Warren writes extensively about politics and political personalities, and that discussion leads him to consider populism's impact on the southern political landscape. From the tobacco wars in *Night Rider* to his representation of demagoguery in *All the King's Men*, Warren examines the circumstances surrounding the genesis of populist movements, delves into the personalities that drive them, and speculates about their consequences and demise. In light of recent developments in American politics—the rise of the Tea Party, grounded in conservative populism, and the election of Barack Obama, founded on liberal populism—Warren's novels' treatment of populist politics takes on new significance. Using Warren's literary evaluation of populism, created in his novels and poetry, this thesis will analyze the significance of populism to contemporary American politics. It will draw comparisons between political rhetoric as presented in Warren's novels with that found in contemporary political speeches; the characterization of the crowd with the media's characterization of populist movement members; and the characters of the figures who lead Warren's fictional movements with the real leaders of movements, like Organizing for America and the Tea Party. This comparison will elucidate the role populist movements play in shaping policy and politics by contrasting Warren's vision of populism with the reality of populism in government. The thesis will

conclude with a discussion of the conflict between institution and individual, highlighting efforts to reform ethics in government using Willie Stark as an exemplar, as well as considering the long-term sustainability of populist movements.

Ty1 Element Antisense RNA Activity from Natural *Saccharomyces* Isolates

Alexander Sevy, CURO Scholar
Dr. David Garfinkel, Department of Biochemistry & Molecular Biology, University of Georgia

Retrotransposons are a class of mobile DNA elements found in most eukaryotic genomes. These elements replicate through an RNA intermediate and insert at various locations in the genome. Ty1 retrotransposons are present in *Saccharomyces cerevisiae* and related species, such as *S. paradoxus*. *S. cerevisiae*, otherwise known as baker's yeast, is an effective model organism for studying retrotransposons because of the powerful genetic and molecular systems developed for this organism. Ty1 elements produce long antisense RNAs that inhibit transposition *in trans* and confer copy number control (CNC). We hypothesize that Ty1 elements present in *S. cerevisiae and S. paradoxus* isolates contain sequence polymorphisms that affect antisense RNA synthesis, stability or function. Therefore, genomic Ty1 element sequences recovered from selected *Saccharomyces* genomes were assessed for their ability to confer CNC, using a test strain carrying a genetically marked Ty1*his3-AI* element. DNA sequence analysis is underway to determine the location of polymorphisms within the Ty1 CNC region. Future work will determine if the Ty1 polymorphisms affect antisense RNA expression or function. Since HIV and other retroviruses have a life cycle that is closely related to Ty1, mechanisms regulating Ty1 transposition may also inhibit retroviral replication, and lead to novel therapeutic approaches.

The Evolution of Aging in *Saccharomyces cerevisiae*

Sylvia Shin
Dr. David Hall, Department of Genetics, University of Georgia

Understanding aging remains a central question in biology; however, it is often ignored in microbes. So yeast (a "model organism" in biology) has proven to be exceptionally important in this study because it combines the advantages of microbes, while also being a eukaryote. In my project, I am addressing two questions to determine whether, at an optimal level, mutations will increase and/or decrease the lifespan of the budding yeast, *Saccharomyces cerevisiae*. First, I am determining whether a particular lab strain shows evidence for an evolved, intermediate aging rate. Second, I am addressing whether the aging trait can rapidly respond to selection. To answer the first question, I cultivated on agar media, and then transferred to liquid media, a set of 149 mutation-accumulation lines, and then determined how random mutations alter the pattern of aging. If most mutations have similar effects on aging, this indicates selection has favored extreme, as opposed to intermediate, aging. To answer the second question, I am examining whether the same strain has responded to many rounds of selection for extended aging. Using a Bioscreen C (Thermolab system), an automated incubator/spectrophotometer, I will be measuring the growth curves. For the results, I will use Excel® to create mortality curves with the collected data. I will compare the results of the 149 lines to the ancestors, deduce a pattern and compare the effects of the mutations in different media. Showing that aging is an evolved phenotype will demonstrate that it is an important trait in microbes, similar to other organisms.

Human Embryonic Stem Cell Derived Neurons as Biosensors for Neurotoxins

Anuj Shukla
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Many environmental toxins can cause serious damage to the human central nervous system. Neurotoxins can generate reactive oxygen species (ROS) which damage important signaling mechanisms in the body's neural network. Currently, there is a need for a human cell-based sensor that utilizes functional biology to detect hazardous neurotoxins and their ability to produce ROS. Human neural progenitor cells (hNPs) derived from human embryonic stem cells (hESCs) were successfully differentiated into neurons in our lab; these hNPs provide an unlimited source of differentiated neurons which have the potential to be reliable human cell-based sensors. In fact, neurons derived from hESCs have shown to be remarkably accurate for toxicological applications compared to the results of similar in vivo studies. Therefore, the purpose of this study is to develop a hESC-derived biosensor by analyzing the functional effects of various neurotoxins on hNPs and hNPs differentiated into neurons. ROS generation in the neurotoxin-treated hNP and neuronal cultures was detected by the addition of a novel dye that only fluoresces in the presence of ROS. After addition of Tempol, a known ROS quencher, the fluorescence intensity of the neurotoxin-treated cultures decreased to control levels. We are currently testing other functional effects of the neurotoxins in correlation with ROS production. For example, the differentiation potential of the neurotoxin-treated hNPs is being analyzed by staining for neuronal marker proteins normally present during differentiation. Our results thus far show that hNPs and neurons derived from hESCs can be potent sensors for ROS generating neurotoxins.

Italian Futurism and Interventionism

Jennifer Skinner
Dr. Nell Andrew, Lamar Dodd School of Art, University of Georgia

The Futurists were an avant-garde group of writers and artists who originally advocated for a break with tradition. Their leader F. T. Marinetti promoted the push towards modernity in his "Futurist Manifesto," wherein he described the experience of man mixing with machine. In addition to machinery, they believed violence represented the true spectacle of a frenetic and unstable urban life. Like most of Europe in 1913-14, the Futurists knew that war was approaching and advocated in their work for Italian intervention. These interventionist works are the turning point for the Futurists, and my paper argues that these works anticipated the upcoming rise in fascism, for which the Futurists became supporters and propagandists. I will show how the Futurists began to take little steps towards fascism through their artworks and their writings, and I will also track how the Futurists increasingly became a vital gear in the fascist machine. In addition, my argument demonstrates how under the right circumstances an avant-garde art movement can easily become a proponent in a nationalist dictatorship. This element of my argument is essential for understanding why a liberal artistic movement became a supporter of a conservative political movement. Finally, I will analyze the role the Futurists play in Italian Fascism and how their art prolonged the life of the Italian Fascist government. Ultimately, the Futurists turned to fascism because of their interest in Italian intervention.

Is Distraction an Effective Method for Tolerating Distress?

Laura Smart, CURO Summer Fellow
Dr. Rheeda Walker-Obasi, Department of Psychology, University of Georgia

Distraction is widely cited in the literature as a method for tolerating distress; however, the evidence on the subject is inconclusive. Previous studies investigating the efficacy of distraction have used different methods of inducing distress and different types of distracters, making

comparisons between studies difficult. The current study utilized a Cold Pressor Test (CPT) in order to induce stress in undergraduate participants. The CPT has been used in a plethora of studies and is an empirically validated method for inducing stress in the laboratory. It involves submerging the participants' non-dominant hands in 0-1˚ C water for three minutes in order to produce physiological arousal. Changes in blood pressure and heart rate were measured in order to assess participants' physiological responses to stress. Participants were randomly assigned to either a control or a distraction group for the task. The participants in the distraction group were allowed to watch a three minute film clip that has been empirically validated as positive-affect inducing, while the control group was not given any distraction. Data will be analyzed using a multiple analysis of variance to determine if the participants who engaged in the distracting task during the CPT showed less change in physiological arousal (as measured by heart rate and blood pressure) from baseline as compared with the control group. If the hypothesis is correct, it will provide evidence that distraction is an effective method of preventing increases in physiological arousal during times of distress.

In the Image of the Artist
Daniel Smith
Dr. Asen Kirin, Lamar Dodd School of Art, University of Georgia

All creations inevitably reflect some aspect of their creators. To better understand the underlying nature of art, I spent the past several months investigating the most dramatic instance of this phenomenon as evidenced in self portraiture. I researched a number of artists. I looked at Albrecht Durer's super-realistic, divine renditions; Michelangelo's monumental conceits; Rembrandt Van Rijn's humble and vulnerable paintings; and a number of other artists' works and writings. I questioned these masters' artistic philosophies and methodologies and constructed my own in a series of self portraits. As a genre, self portraiture removes all variables from the creative process except the basic reproduction of the image and likeness of the artist. This approach towards art is one of the earliest, and in its simplicity it is the most powerful. Ultimately, I reproduced my own image in a series of images, which hopefully communicate more than mere words. In this photographic series, I used both the integrity of film and the flexibility of digital technology. Some images I printed simply in the darkroom. Other images I photographed in parts and later compiled, distorted or fabricated the individual elements on a computer. Through these alternatively traditional and unconventional means, I compiled a number of realistic and surreal images. In constructing each image, I paid careful attention to symbolism, pose and art historical relevance. My images speak for themselves, presenting my own ideas about self portraiture, yet echoing the conceits of numerous self portraitists throughout history.

How Leadership Makes a Difference: The Predictive Role of Managerial Leadership Competencies in a Multi-National Company
Rebecca Stein
Dr. Karl Kuhnert, Department of Psychology, University of Georgia

Increasing size of organizations, coupled with the information/technology revolution and an ever-expanding global environment, has created complex organizational systems, which are impossible to fully grasp or completely control (Kotter, 1982b). Furthermore, senior executives of these large companies are expected to provide leadership in the midst of this complexity, and are held responsible for organizational outcomes. This potent environment demands reliable information to assist organizations in the development of their leaders. Unfortunately, many important questions remain unanswered. Do leadership competencies of mangers predict critical organizational outcomes? If so, which leadership competencies are more important than others? Three thousand managers from a Fortune 500 company were rated on 9 leadership competencies and performance and business objectives were collected. Analyses were conducted to determine whether leadership competencies were related to important business outcomes. Possible explanations for the results are discussed and recommendations for future research are proposed.

Changing Environments: Effect on Extinction Time and Distribution

Theresa Stratmann
Dr. John Drake, Odum School of Ecology, University of Georgia

In an era of increasing species extinctions, it is vital to understand processes of population extinction in hopes of eventually predicting and preventing them. We used the aquatic ectotherm, *Daphnia magna*, as a model organism to study how deteriorating environmental conditions caused by temperature change affected the populations' extinction times and distributions. Three sets of twenty-four chambers of *Daphnia* ($N_0 = 20$) were subjected to temperature regimes according to three treatments: 1) increasing temperature, 2) decreasing temperature by 0.1ºC/day from 20ºC and 3) constant 20ºC temperature (control). Each treatment pushed temperatures toward a different end of the *Daphnia*'s thermal tolerance. Therefore, we hypothesized that the treatments would alter extinction risk differently: if one increased risk, the other would decrease it. In contradiction to these predictions, inspection of the data with the Cox proportional hazards regression and linear models showed that temperature treatments did not explain differences in survival time. Further analysis showed that random contamination by algae determined extinction time, and chambers subject to temperature manipulations became contaminated significantly later than control chambers. As a result, the temperature treatments indirectly affected survival. The treatments also resulted in different distributions of extinction times. The decreasing temperature treatments had a distribution that was shifted to the right, which means that some populations persisted much longer than most. This controlled laboratory experiment allows us to gain understanding of mechanisms that can cause population extinction, and we are now working to put our findings into such a context.

Presence of Newcastle Disease through Immunohistochemistry in Tissues of Chickens Diagnosed with the Disease in the Field

Lauren Sullivan
Dr. Corrie Brown, College of Veterinary Medicine, University of Georgia

Newcastle disease is a familiar problem to most poultry producers. Many strains of the virus exist, and can cause a wide range of clinical signs in chickens. The most serious forms of the disease are foreign to the US. The less severe forms of the disease are thought to cause mild to moderate respiratory problems, leading to decreased productivity. Consequently, many producers vaccinate their birds. Often chickens with respiratory problems are submitted to diagnostic laboratories, where they are diagnosed with Newcastle disease through identifying the presence of virus. In our laboratory, we are examining the respiratory tracts through histology and immunohistochemistry. First, heat-induced antigen retrieval is performed in a buffer solution; then a commercial agent is used in a blocking procedure in order to ensure the specificity of the antigen. Lastly, both primary and secondary antibodies are applied in order to visualize the binding reactions. Although there is evidence of respiratory damage noted morphologically, in fact, very few of the tissues have Newcastle disease virus evident through immunohistochemistry within the inflamed tissue. Consequently, we believe that many of the diagnoses of Newcastle disease are erroneous, and the viral identification was of the vaccine virus. Further investigations are warranted to confirm and expand upon these findings.

Linguistic and Musical Coherence

Ai Taniguchi
Dr. Paula Schwanenflugel, Department of Educational Psychology & Instructional Technology, University of Georgia

The comparative study of linguistic and musical semantics has gained popularity in recent years, but researchers have yet to explore the potential commonalities in the processing of context-

based meaning of language and music. The purpose of this research is to investigate such connections by testing the effect of contextual coherence of music on linguistic memory. "Contextual coherence" in this study has been designated as the process of individual segments connecting to form a meaningful whole. In language, this is the inferencing process; the musical parallel of it is the periodic structure, in which two musical phrases must complement each other in structure or function to create coherence. Two poems were selected, and two versions of music were assigned to each--one coherent, and one incoherent. The coherent piece abides by the periodic structure defined above. The incoherent piece was achieved by rearranging the coherent piece so that adjacent phrases do not form ideal periods in terms of material and/or function. 40 healthy college students listened to two songs, one coherent and one incoherent, and recalled the words of each poem. Participants recalled fewer words in the incoherent version of the songs than in the coherent version, thus potentially indicating that musical incoherence disrupts memory for poetry. This may imply that coherent musical context acts as a scaffold to linguistic comprehension. The significance of this study lies in the possible revelation of processing commonalities of linguistic and musical discourse, with potential applications in facilitating first and second language instruction.

Intramolecular Friedel-Crafts Cyclization with Arylsilanes

Stephen Thompson, CURO Summer Fellow
Dr. George Majetich, Department of Chemistry, University of Georgia

An electrophile adds to the ipso carbon atom bearing the silyl substituent of an aryl silane to generate a carbocation stabilized by the silicon's well-established β-effect; the loss of the trimethylsilyl group produces a product in which the electrophile has replaced the silyl group. Electrophilic aromatic substitution reaction of aryl silanes are widely known and include halogenations, Friedel-Crafts alkylation, Friedel-Crafts acylation and nitrations. Not surprisingly aryl silanes are useful to prepare functionalized arenes. Majetich et al. showed that a Lewis acid-activated dienone (A-ring) can react with an arene (C-ring), undergoing cyclialkylation to produce a cyclopheptane (B-ring). Application of Friedel-Crafts cyclialkylation to silyl substituted arene-dienone systems allows for exploration of the reactivity of the silyl moiety. Treatment of this system with a Lewis acid under kinetic control should produce the cycloheptane while not affecting the silyl substituent on the arene ring. The introduction of the silyl functionality would potentially allow a handle for further transformations, leading to more diverse tricycles. The synthesis of the arene-dienone began with transmetalation of o-bromotoluene and the addition of chlorotrimethylsilane. The resulting aryl silane was then treated with NBS to form benzylic bromide. 6-methyl-3-ethoxycylcohex-2-en-1-one was then alkylated with bromide using the Stork-Danheiser protocol and then reacted with vinylmagnesium bromide to furnish the dienone. Treatment with TiCl4 only produced the tricycle in which the trimethyl silyl group had been lost. However, using BF3•Et2O as the Lewis acid produced cyclialkylation and retention of the silyl moiety. Re-exposure of this product to Lewis acid catalyst resulted in protodesylation.

The Effects of Lutein and Zeaxanthin Status and Macular Pigment Optical Density on Neural Efficiency

Sarah Thorne
Dr. Lisa Renzi, Department of Psychology, University of Georgia

Macular pigment is comprised of dietary carotenoids lutein and zeaxanthin that are intercalated within the macular region of the neural retina. Macular pigment has been shown to prevent retinal degeneration and improve visual function (Beatty et al, 2000; Wooten & Hammond, 2002). Although lutein and zeaxanthin are found in highest concentration in retinal tissue, they are not unique to the retina. For example, lutein and zeaxanthin have been located in the frontal and occipital cortices of the brain (Craft et al, 2004). Whether lutein and zeaxanthin also protect cortical tissue and enhance cortical function is an open question. The hypothesis of the current study is that the brain benefits from the protective effects of

lutein and zeaxanthin, resulting in better cognitive performance and increased neural efficiency. Macular pigment density was measured in both young and older adults non-invasively via heterochromatic flicker photometry. Given the fact that lutein and zeaxanthin in the neural retina are known to correlate with lutein and zeaxanthin cortical levels, macular pigment density was used as a biomarker of cortical lutein and zeaxanthin and was compared to performances on cognitive and visual measures used to determine neural efficiency. Cognitive measures consisted of a rapid categorization task and a standard battery used to evaluate cognitive vitality. Neural efficiency was measured via the temporal contrast sensitivity function (tCSF) and a visual masking task. Preliminary evidence shows that macular pigment density is correlated with performance on visual and cognitive measures, suggesting that lutein and zeaxanthin are related to neural efficiency.

The Role of Indoleamine 2,3-Deoxygenase in CD8 T Responses to Influenza Infection

Jeffrey Tran
Dr. Kimberly Klonowski, Department of Cellular Biology, University of Georgia

Current influenza vaccines are designed to generate antibody-specific immunity against predetermined strains of virus and are ineffective in protecting against novel or emerging strains. Targeting conserved T cell epitopes can provide protection against unexpected circulating strains of influenza; however, this protection wanes over time. Thus, understanding and exploiting the mechanisms involved in CD8 T survival and maintenance may aid in the development of a successful anti-influenza vaccine eliciting cell-mediated immunity. Indoleamine 2,3-deoxygenase (IDO) is a tryptophan catabolyzing enzyme up regulated following influenza infection, which suppresses naive T cell proliferation and induces the apoptosis of T cells. To determine whether IDO suppression may be a viable option to enhance T cell immunity to influenza infection, wild type and IDO knockout mice were infected with influenza, and the number, frequency and function of the influenza-specific CD8+ T response were monitored over time. IDO knockout mice demonstrated a more robust virus-specific T cell response to influenza in the lung and lung airways (the site of viral replication) compared to wild-type during the early effector phase of the response. However, both groups of mice harbored similar levels of influenza-specific CD8 T cells at later stages of the immune response. Future experiments will determine whether an IDO deficiency alters the phenotype and function of these memory cells when rechallenged with influenza. Together our data provides a detailed picture of how IDO regulates T cell responses to respiratory infection.

Cuticular Pheromones and Fire Ant Queens: Smells like Mom

Waring Trible
Dr. Ken Ross, Department of Entomology, University of Georgia

The Red Imported Fire Ant (RIFA), *Solenopsis invicta*, has been the subject of intense research because of its status as a serious invasive pest. One major emphasis of study in ant biology focuses on the question of how pheromones (chemical signals) are used for communication. This question applies especially to the polygyne (multiple-queen) and monogyne (single-queen) social forms of RIFA. Previous research has found strong genetic control for the organization of a RIFA colony into polygyne or monogyne societies. These two social forms feature specific genotypes at a single Mendelian locus and phenotypic differences in behavior, physiology and biochemistry. We studied the process by which colonies of each form accept new queens. Workers in queenless colonies will accept a new queen in certain circumstances, but polygyne workers only accept into their colony polygyne queens, and monogyne workers only accept into their colonies monogyne queens. Preliminary studies indicated that this behavior may be influenced by chemicals. We first showed that fresh polygyne and monogyne corpses elicited the same specific worker responses of queen acceptance and rejection according to queen genotype as do live queens, demonstrating that the queens are not accepted on a behavioral

basis. We then showed that chemically extracted queen pheromones, deposited onto inanimate surrogates (paper wicks), also elicited appropriate worker ant discrimination behavior. These results support the hypothesis that worker discrimination behavior is elicited by chemical differences between workers of the two social forms.

"I've got the rhythm, she's got the blues." Relations Between Temperament, Maternal Stress and the Development of a Sleep-Wake Rhythm in Infancy

Vivien Tsou
Dr. Anne Shaffer, Department of Psychology, University of Georgia

Although there is extensive literature on factors that may influence an established sleep-wake rhythm in adulthood, there is little published on factors that may influence the characteristics of developing sleep-wake rhythms in infancy. In this study, we will examine the situational (e.g., maternal stress, environmental cues) and dispositional (i.e., temperament) characteristics that may influence the onset and characteristics of a sleep-wake rhythm in infancy. We hypothesize that increased maternal stress and difficult temperament will lead to later sleep-wake rhythm onset and poorer sleep-wake characteristics. Data collection is currently underway. Approximately 30 mother-infant pairs will be participating in this longitudinal study. When their infants are three and six months of age, mothers will complete measures about themselves (i.e., Life Experiences Questionnaire, Daily Hassles Scale) and their infants (i.e., Infant Behavior Questionnaire, sleep and feeding diaries). At four and five months, mothers complete sleep-wake characteristics of interest, including presence of a circadian rhythm, infant sleeping quarters, longest sleep duration, number of awakenings and total nocturnal sleep time. From this data, we expect to see differences in onset and characteristics of the sleep-wake rhythm predicted by maternal stress or infant temperament and how the relation between situational and rhythm characteristics are moderated by infant temperament. We will conduct bivariate correlations to assess relations between maternal stress, maternal contact, infant temperament and infant sleep characteristics. Multiple regressions will examine how maternal factors predict sleep-wake rhythm onset and characteristics, and temperament will be examined as a potential moderator of this relation.

Preserving Georgia's Waterways: Tackling Interbasin Transfer in Georgia

Pranay Udutha, Roosevelt @ UGA
Dr. Laurie Fowler, Odum School of Ecology, University of Georgia

Georgia's population is unevenly distributed—almost 60% lives in metro Atlanta. Furthermore, Atlanta has consistently displayed one of America's highest growth rates over the past decade, causing a disproportionately concentrated demand for water by Metro Atlanta. This phenomenon has generated severe water management issues, resulting in increased interbasin transfers (IBT). Metro Atlanta spans several narrow river basins of differing elevations, rendering water transfer from higher basins into lower basins cheaper than pumping water back up to its source basin. Without careful management, IBTs may inflict substantial, sometimes irreversible, damage to ecosystems of both recipient and donor basins. IBTs facilitate introduction of non-native species to each basin, degrade water quality and decrease water supply for some areas. Currently, no effective comprehensive policy regarding IBT in Georgia exists. This paper recommends a per acre-foot tax on IBT. The mechanism of action is straightforward, internalizing spillover costs and decreasing IBT profitability, and precedent for such proportional taxes already exists. An analysis of economic literature, judicial reviews, and policies of neighboring states facing similar water management issues indicates that this is the most efficient and effective policy for controlling IBT. This policy can be expected to stem further species invasion and water quality deterioration.

Measurements of Inhibition: The Relation Between the Eriksen Flanker Task and the Stop Signal Task

Litty Varghese, CURO-BHSI Participant
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Inhibition is an important behavioral ability that is essential for proper functioning. When it deteriorates, it leads to problems that could result in clinical disorders or psychopathology. There are many tasks, which vary across laboratory and field of study, that test inhibition. Knowing how performance on these varied tasks is related, and which ones provide unique information, would help researchers reduce the number of tasks used in studies. Performance can be measured by the proportion of correct and incorrect responses, as well as the amount of time it took to respond correctly and incorrectly. One common test is the Eriksen Flanker task, in which subjects have to focus on the direction of one central arrow amidst flanking distractor arrows (which can face in any direction) and have to respond appropriately. Another measure of inhibition is the Stop Signal task (SST) in which subjects have to resist a primed motor response when they see a stop signal. The hypothesis is that the results of the two tasks will be highly correlated. Performance on the Flanker task will predict outcomes on the SST in terms of error rates and reaction times, with poorer performance being indicative of decreased inhibition. The study was conducted on 100 undergraduates at the University of Georgia. Future researchers will benefit from these findings as it will enable them to optimize their studies by conducting tests that are uniquely informative, while still being able to predict performance on similar tasks based on the high correlation rates.

Nutrient Enrichment Effects on Detrital Food Resources in Streams: Implications for Microbes and Consumers

Stenka Vulova
Dr. Amy Rosemond, Odum School of Ecology, University of Georgia

Excessive nutrient enrichment has become the primary water quality issue for most of the freshwater and coastal marine ecosystems in the world. In this study, we examined nutrient enrichment effects on detrital food resources of stream consumers. We measured nutrient content (nitrogen (N), phosphorus (P) and carbon (C)) of two resources utilized by stream detritivores: fine particulate organic matter (FPOM) and leaves. We tested whether nutrient enrichment in streams affects detrital nutrient content and determined the implications for stream consumers by comparing samples of FPOM and leaves collected from a reference stream and experimentally enriched stream (with N and P) at the Coweeta Hydrologic Laboratory. Reductions in carbon to nutrient ratios (C:N, C:P) indicate higher nutrient content and food quality for consumers. We found C:P became reduced in the nutrient-enriched stream for both leaves and FPOM (approximately 38% reduction in both cases). We compared the C:P food requirements of shredders (which feed on leaves) and collectors (which feed on FPOM) to observed C:P values and found that nutrient enrichment decreased P limitation for shredders and enhanced C limitation for collectors. Thus, runoff of nutrients to streams would increase production of shredders and potentially reduce production of collectors, which contribute differentially to ecosystem services provided by streams. Our results help lay the groundwork for understanding how excess nutrients entering streams will differentially affect food quality for different groups of stream organisms, with implications to ecosystem function.

Grand Strategy as it Pertains to the Korean Peninsula

Edward Wells, Jr., CURO Apprentice
Dr. Brock Tessman, Department of International Affairs, University of Georgia

The current diplomatic gridlock and military tensions on the Korean Peninsula are a product of the manner in which the key external actors in the region—China, Japan, Russia and the United States—define their national interest. All of the non-state actors involved have publicly claimed to support both non-proliferation and the reunification of the North and the South, yet their actions sometimes prove otherwise. Though leaders from these states may publicly

declare that they are motivated by interests such as peace and principle, their actions seem typically driven by a fundamental desire to maximize power and profit, even if it means delaying the reunification of the two Koreas. This difference in words and actions has led to a lack of progress in achieving the set goals of non-proliferation and reunification. The paper acknowledges that states conceive their national interests based on the framework of the 4Ps: power, peace, prosperity, and principles. Through analysis of diplomatic documents, official speeches and objective scholarly sources, it becomes clear that while each actor may publicly define its national interest in terms of peace and principles, many leaders ultimately make foreign policy decisions based on power and prosperity-based interests. Currently, the stalemate on the Korean Peninsula persists because the key external powers calculate that their power and prosperity are best served by promoting the status quo instead of reunification. This reality has kept the six parties involved in the Korean peninsula, despite over a half-century of negotiations, conflicts and compromises, from coming up with a solution for peaceful reunification that is acceptable to all sides.

Breastfeeding Practices among Hispanic Women in Athens

Caroline West
Dr. Susan Tanner, Department of Anthropology, University of Georgia

Breastfeeding is the optimal source of nutrition for newborns, with immediate and long-term effects on infant and maternal health. The numerous benefits, including protection from infant infections and obesity, and promotion of cognitive development and healthy infant growth, are well established in medical literature and government policy. Despite these benefits, national levels of breastfeeding are lower than goals set by US Healthy People 2010. As the fastest growing population in the United States, Hispanics are of particular concern when examining disparities in access to health care and health outcomes. While Hispanic women meet some of the national breastfeeding goals, rates of optimal breastfeeding among this population remain stagnant and low. A review of literature identifies national breastfeeding trends among Hispanic populations, including factors influencing breastfeeding decisions, various barriers women face to initiate and continue breastfeeding and general attitudes and beliefs concerning the practice. Narrative data collected from individual interviews with four Hispanic women in Athens was analyzed to illustrate the prevalence of these breastfeeding trends on a local level. Questions concerning breastfeeding were coded for frequently used phrases, which were subsequently categorized according to trends found in the literature review. Results demonstrate a consistency with national trends, including the common perception of insufficient milk supply and practice of combining breast milk and formula before the optimal weaning age. A comparison between national and local breastfeeding trends provides insight in promotion of healthy breastfeeding practices among Hispanics in Athens and the broader Hispanic community.

Academic Relevancy: A Focus Group Study

Taylor Whelchel
Dr. Christopher Pisarik, Division of Academic Enhancement, University of Georgia

Colleges and universities are under increasing pressure from parents, the government, and the business community to prove that their academic curriculum is relevant. Most of the stakeholders of higher education have well documented positions on why a college education is relevant. For example, the government's prominent position is that higher education is relevant because it perpetuates national economic growth. Faculty members often view academics as relevant because it facilitates social and civic responsibility. However, there is little literature that explores the relevance that college students find in their academic experience. In this focus group study, fourteen students in a life skills class with varying majors, discussed and defined the construct of academic relevance from their perspective. The transcript of the focus group was analyzed using a qualitative coding methodology. Analysis of the data produced two distinct types of academic relevancy—direct and indirect. Each of these types of relevancy was

found to exist in three life dimensions: academics, occupation and personal development. Thus, participants found their academic experience to be relevant in six distinct ways. The results of this study lays the foundation for future quantitative studies that will further analyze this construct of academic relevancy. This is important because it will enable researchers to explore the extent to which academic relevancy has an effect on important constructs such as motivation, persistence, academic performance and psychological well-being.

Clinico-pathological Characterization of Newly Isolated Newcastle Disease Viruses from Dominican Republic, Belize and Peru

Anna White
Dr. Corrie C. Brown, College of Veterinary Medicine, University of Georgia

Newcastle Disease Virus (NDV) is the causative agent of Newcastle Disease, a highly contagious and fatal poultry disease. The virus belongs to the family *Paramyxoviridae*, subfamily *Paramyxovirinae*, genus *Avulavirus*. New strains frequently arise, creating serious transboundary risks. Three NDV isolates from recent outbreaks in Peru (APMV1/poultry/Peru/1918-03/2008), the Dominican Republic (APMV1/chicken/Dominican Republic (Juan Lopez)/499-31/2008), and Belize (APMV1/chicken/Belize (Spanish Lookout)/4224-03/2008) were each characterized by phylogenetic analysis and clinico-pathological assessment. Complete sequencing of the F gene revealed that Peru and Dominican Republic isolates likely belong to a new genotype, while Belize is a member of NDV genotype V, which is commonly circulating within Central and North America. Intra-cerebral pathogenicity indices were 1.88, 1.78 and 1.75 respectively for DR, Peru and Belize. Experimentation was conducted by inoculating groups of 4-week-old, White Leghorn chickens via eye drops containing the three isolates. Subsequent to inoculation, birds were monitored clinically and euthanized sequentially. Tissues were collected for histopathological examination and immunohistochemistry for viral nucleoprotein. Disease was severe in chickens inoculated with all the strains, with each chicken dying before four (Peru, Belize) and six days post-infection (DR), due to acute systemic illness, necrosis of lymphoid tissues and detection of nucleoprotein in multiple tissues.

Business Model Generation and Energy Informatics

Tyler Williamson
Dr. Rick Watson, Department of Management Information Systems, University of Georgia

Sustainability needs to be tightly woven into the thinking of every senior executive if we are to develop a sustainable society. Furthermore, those businesses seeking to capitalize on "the Green Movement" must put sustainability at the forefront of all of their planning and product development. Our goal is to provide business leaders with an energy efficiency oriented framework to allow them to transform their organizations into sustainable enterprises. Through the review of existing literature and professional experiences, we have taken the business model generation canvas (Osterwalder & Pigneur, 2009) and developed a layer to stimulate Energy Informatics (Watson, Boudreau, & Chen, 2010) thinking. Business model generation is a technique to capture the essential features of an organization's business. It addresses such issues as value proposition, sources of costs and revenues, partnerships and customers in a concise and graphical manner. Osterwalder and Pigneur's book has quickly become an international best seller because the technique is powerful and collectively engaging. We have taken the business model generation canvas and created a group collaborative version on Cacoo, which is web-based software for creating diagrams collaboratively. One of the features of Cacoo is the ability to create layers, so we have augmented our initial two-layer model of a blank canvas and key questions with a layer containing questions to provoke Energy Informatics thinking within organizations. The resulting canvas will be made publicly available to advance the development of Green IS.

Diversity of Orchid Fungal Symbionts in Estonian Mine Tailings

Samuel Willis
Dr. Richard Shefferson, Odum School of Ecology, University of Georgia

Nutrient and water availability are two key requirements of plant survival. Mycorrhizal symbioses help orchids subsist in areas with apparently low soil nutrients and water availability—in this case, Estonian mine tailings that contain little more than burnt oil soaked shale and ash. We extracted all DNA in soil samples taken from multiple sites in the mine tailings in both the summer and the fall. The sample size for summer was 25 and the sample size for the fall was 62. We carried out Polymerase Chain Reaction (PCR) on purified DNA samples, and performed gel electrophoresis and Restriction Fragment Length Polymorphism (RFLP) pattern determination. We then sequenced non-identical RFLP patterns and carried out Basic Local Alignment Search Tool (BLAST) searches to determine the organismal composition of the areas. We found 20 unique RFLP patterns for the fall samples and 12 unique RFLP patterns for the summer samples. The dominant organisms found were mycorrhizal fungi in families Thelephoraceae and Cortinariaceae. The overall diversity of mycorrhizal fungi determined by Shannon's Diversity Index shows that for the fall, H=2.33, and for the summer, H=1.84. This is higher than the mycorrhizal diversity in the Brazilian rainforest where H ranges from 1.2 to .87. This is important because although the fungi in the mine tailings only associate with orchids, it shows that mycorrhizal fungi in general may assist in reclaiming and restoring environmentally decimated locations such as mine tailings, landfills and other nutrient poor areas.

Smart Moves: Avoiding Common Investing Mistakes

Munir Winkel
Dr. Swarn Chatterjee, Department of Housing & Consumer Economics, University of Georgia

For investors, the financial world can be overwhelming and confusing. Novice investors have little experience with financial markets. They often do not understand the implications of their actions when it comes to trading stocks, bonds, CDs, mutual funds or index funds. Worse, best-selling books, television hosts and internet articles often provide misleading or inaccurate advice, and investors fall prey to numerous psychological mistakes. We asked: "What mistakes do investors typically make" and "How can investors avoid making those mistakes?" To provide investors with scientific and understandable answers to those questions, we compiled and synthesized information from numerous scholarly articles and books. Based on our preliminary analysis, we found that investors trade stocks too frequently and have their profits unnecessarily eroded by commissions and taxes. The securities investors sell often outperform the securities they keep, and despite claims to the contrary, most investors fail at their attempts to "time the market." We also identified several psychological factors that negatively influence investor behavior, which include hindsight bias, projection bias and loss aversion. Based on our findings, beginning and experienced investors alike can gain confidence and learn which behaviors and trading strategies to avoid. Our findings will enable investors to avoid making costly investing mistakes.

Sexual Attitudes, Media Use and Norms: Sexually Explicit Media and Exposure Effects on Norm Distortion

Courtney Witt
Dr. Tom Reichert, Grady College of Journalism & Mass Communications, University of Georgia

This study sought to explore the relationships between two personality variables (sexual self-schema, sensation seeking), consumption of media with both light (e.g., Maxim magazine) and heavy (e.g., pornographic websites) sexual content, and respondents' perceptions of social

sexual norms. Both personality variables are related to a variety of sexual attitudes and behaviors, and therefore should predict exposure to sexual media. Additionally, a link has been shown to exist between pornography use and distorted perceptions of sexual practices (e.g., infidelity, group sex), such that sexual media use should be positively associated with estimates of sexual normative behavior. With this literature and these concepts as guides, an extensive online survey was developed that measured both personality concepts, sexual media exposure, and a range of sexual practices. Participants (N = 314), consisting of a convenience sample of female and male undergraduates at the University of Georgia, completed the survey with anonymity. Although the analyses are not yet complete, preliminary results suggest that both personality variables are related to sexual media use. More important, both variables and sexual media use are linked to inflated perceptions of sexual behavioral norms, such that participants who score high on these variables also perceive sexual activity to be at higher levels than participants with low scores. These findings are important because they show that exposure to sexually explicit media, even that which appears in popular magazines and network television, can influence perceptions about sexual practices that may ultimately influence behavioral expectations and outcomes.

Increasing Enrollment of Eligible Children in Georgia's Medicaid and CHIP Programs

Abby Wong, Roosevelt @ UGA
Dr. Angela Fertig, Department of Public Administration & Policy, University of Georgia

In 2010, approximately 193,000 children in the state of Georgia were eligible for either Georgia's Medicaid or CHIP program, PeachCare for Kids, but were not enrolled. The state of Georgia has an obligation under the newly implemented provisions of the Patient Protection and Affordable Care Act (PPACA) and the Children's Health Insurance Program Reauthorization Act of 2009 (CHIPRA) to increase the take-up of children into Medicaid and PeachCare for Kids. The objective of this research is to compare various policy alternatives for the implementation of a more rigorous enrollment program in Georgia. Through a comparative analysis of three policy alternatives currently being employed in other states, Express Lane Eligibility (ELE) is found to be the best policy option for the state of Georgia based on three criteria: cost, implementation feasibility and enrollment increases. Specifically, the Georgia Department of Human Services, through the authority granted to state Medicaid and CHIP agencies under Sec. 203 of CHIPRA, should utilize eligibility verification from other public programs, such as Supplemental Nutrition Assistance Program (SNAP), for Georgia's Medicaid and CHIP applicants. Enrollment increases will afford low-income children access to primary care physicians and preventative services that will not only avert the development of costly, chronic illnesses in the long-term, but also preempt the incurrence of high, uncompensated health care costs for the state of Georgia in the short-term.

Representations of the East German Secret Police in Contemporary German Literature

Laura Wynn, CURO Scholar
Dr. Martin Kagel, Department of Germanic & Slavic Studies, University of Georgia

The East German Secret police have long intrigued people because of their secrecy and the way in which they pervaded the lives of East Germans. It was estimated that at the end of the 1980's more than one in seven East Germans was either employed by the East German Secret Police or was asked, cajoled or coerced into becoming a confidential informant. The stories of how the Stasi, as they were commonly known, ruined the lives of normal citizens seeking a way to voice their opinions has become infamous worldwide, and many memoirs and journalistic pieces have delved into these issues. In her novel *Heute wär ich mir lieber nicht begegnet* (*The Appointment*), Nobel-prize winning novelist Herta MÃller looks deeper into the impact that the secret police in the eastern bloc had on its citizens. The novel, which has heretofore been largely ignored in favor of her more overtly political works, follows a woman whose appointments with the Secret Police in Romania demonstrate the

Stasi's ability to trap citizens without having to physically imprison them. The role that literature plays in adding to the discussion of the secret police in the Eastern Bloc is one of showing the confusion and terror that accompanied the lives of those who dared to oppose the strict rules of the communist regime. It is through literature that the Stasi come alive, not merely as a government bureaucracy, but as a living being which lay at the heart of East Germany.

Sanctity as a Means of Conservation: Tongariro National Park, New Zealand
Allegra Yeley
Dr. Fausto Sarmiento, Department of Geography, University of Georgia

Thousands of mountains across the world are sacred to many religions and societies. Additionally, mountains contain natural resources that sustain millions. Because these landscapes are spiritually significant one may assume that their protection is guaranteed. However, anthropogenic activity endangers both the natural and cultural aspects of mountain environments. In New Zealand, the Māori term for "sacred mountain" is *maunga tapu*. Tongariro National Park (TNP) is located on the North Island of New Zealand and is home to the sacred peaks Tongariro, Ngauruhoe and Ruapehu. In 1887, TNP became the first national park in New Zealand. In 1990, it was designated a UNESCO World Heritage Site. The sacred mountains are a popular tourist destination and an important source of drinking water and geothermal energy. I examined Māori and Pākehā (non-Māori) conservation methods and the effect of the mountains' spiritual significance on conservation practices in TNP, which is evident in the park's very existence. The park was created because the mountains were sacred and has protected them for 124 years. My methods consisted of literature review and interviews with academics and scientists in New Zealand. I found that Māori tribes, scientists and other actors are concerned with the high level of tourist traffic in TNP, which may harm the ecosystem and sacred sites. Although the mountains may be sacred only to Māori, clearly labeling them "sacred" may persuade others to respect the sanctity of the environment. Effective conservation in TNP will rely upon equal consideration of economic, environmental and spiritual factors.

Exploring the Life and Technique of Michael Chekhov
Jacob Young, CURO Summer Fellow
Prof. George Contini, Department of Drama & Theatre, University of Georgia

Michael Chekhov was a Russian actor and theatre theorist who lived during the early 1900s. His technique placed more emphasis on the actor's use of imagination and physicality than the naturalistic theatre of his day. Because of this difference, he was marked as a revolutionary mystic by the Russian government and was forced to flee the country to save his life. He traveled across Europe and finally fled to the United States. He died leaving behind only two autobiographies in Russian and a single training manual. The purpose of this research is to present the history of Michael Chekhov and his acting technique in the style of a solo performance. The performance will explore Chekhov's method of teaching as well as his method of acting, focusing specifically on the use of gesture to create and develop a character. Research has been gathered abroad at the international Michael Chekhov workshop in Windsor, Ontario, under the instruction of experts in Michael Chekhov's system of acting, including his last living student. Additional research was conducted in the Michael Chekhov archives of Windsor University. The results of the research are in mid-creation. The production is currently half-way written and is entering the rehearsal process now. The goal of the performance is to use a study of Chekhov's growth to show us how theatre allows people to grow themselves. This project revolves around the art of theatre and addresses its significance in our current era.

An Analysis of Green Buildings: Comparing Tsinghua University's Sino-Italian Ecological and Energy-Efficient Building and UGA's new Odum School of Ecology Building

Sheena Zhang
Dr. Laurie Fowler, Odum School of Ecology, University of Georgia

China has recently surpassed the United States as the highest emitter of carbon dioxide. In both countries, approximately 30% of total greenhouse gas emissions and nearly 40% of total energy consumption are due to the built environment (i.e. buildings and infrastructure). Because China's energy structure is coal-based, the rapid rate of urbanization and demand for new construction has resulted in significant environmental and public health effects. By improving energy efficiency in buildings, carbon emissions can be reduced by up to 22%. This study focuses on two green buildings–the Sino-Italian Ecological and Energy-efficient Building at Tsinghua University in Beijing and the Odum School of Ecology Living Building at the University of Georgia in Athens, GA. Green buildings in the public sector were selected for analysis because universities are at the forefront of the green building industry. Interviews with project managers, university administration, architects, and green building consultants were conducted, in addition to literature research to compare the two buildings and green building industries in China and the United States. Through comparison of the two buildings, insight will be gained into understanding how to overcome barriers to the further growth of the green building industry in these two countries. By addressing obstacles in the green building industry, green buildings can become the standard of building construction and have a reduced impact on climate change, the environment and public health.

Glare Disability, Photostress Recovery and Chromatic Contrast in Relation to Retinal Lutein and Zeaxanthin

Quincy Zhong
Dr. Billy Hammond, Department of Psychology, University of Georgia

Disability due to glare and recovery from photostress are particular problems for people with eye disease and for the elderly in general. Chromatic sensitivity is also affected by glare, due to color unsaturation by bright light, which can decrease the quality of images by obscuring borders. Previous studies have shown that dietary carotenoids, such as lutein and zeaxanthin, are linked to macular health. Recent data has also shown that preventing short wave light from hitting foveal cones results in improved glare disability, photostress recovery and contrast sensitivity. In this study we measured the macular pigment densities of 150 subjects, ages 21-40, using a standardized psychophysical technique. Glare disability, photostress recovery and contrast sensitivity were measured in Maxwellian view, where a real image of a light source is directly focused on the pupil, using a broadband xenon light source. Our results indicated that macular pigment density was significantly related to glare disability ($p<0.0015$), photostress recovery times ($p<0.01$) and contrast sensitivity ($p<0.00005$). These results confirm earlier reports of a strong relation between variation in retinal carotenoid concentrations and many aspects of visual function.

CURO

April 2, 2012

Dear Students, Faculty, and Guests:

Welcome to the 12th annual CURO Symposium, UGA's celebration of undergraduate research across the disciplines. Many individuals—administrators, faculty members, staff, graduate students, and, of course, undergraduates—have collaborated to make the CURO Symposium the premier undergraduate academic event at UGA, and the 2012 CURO Symposium is the largest to date. The first CURO Symposium featured a handful of students presenting to each other around a single table. Today, nearly 200 undergraduate researchers will communicate their substantial accomplishments to their peers, mentors, and the public at large.

From its inception, the CURO Symposium has showcased research and scholarship in all disciplines. The 2012 Symposium continues that commitment, featuring presenters from 49 departments in 14 colleges/schools. Thus, today evidences UGA's broad and substantial support of research, and the invaluable commitment of UGA's administration and faculty to mentoring and providing exceptional learning opportunities for our undergraduates.

Thank you for your continued support of undergraduate research and CURO.

Sincerely,

Dr. David S. Williams, '79, '82
Associate Provost and Director

Mr. Alexander Vaughn	Department of Chemistry

Oral Session Conveners for 2012 CURO Symposium

Ms. Lisa Bolding	Department of English
Ms. Joy Bracewell	Honors Program
Mr. Sean Buskirk	Department of Infectious Diseases
Ms. Rebecca Cheney	Honors Program
Mr. Douglas Eudy	Institute of Plant Breeding, Genetics & Genomics
Ms. Teneema Kuriakose	Department of Infectious Diseases
Ms. Adrienne Madison	Department of Biological Engineering
Ms. Cary McGinnis	Department of Pharmaceutical & Biomedical Sciences
Ms. Crystal Phillips	Department of Microbiology
Ms. Amanda Pretti	Honors Program
Dr. Martin Rogers	Honors Program
Mr. Alexander Vaughn	Department of Chemistry

Schedule

Monday, April 2, 2012

Oral Session I **9:05 a.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session II **10:10 a.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session III **11:15 p.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I

Oral Session IV **12:20 p.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session V **1:25 p.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I

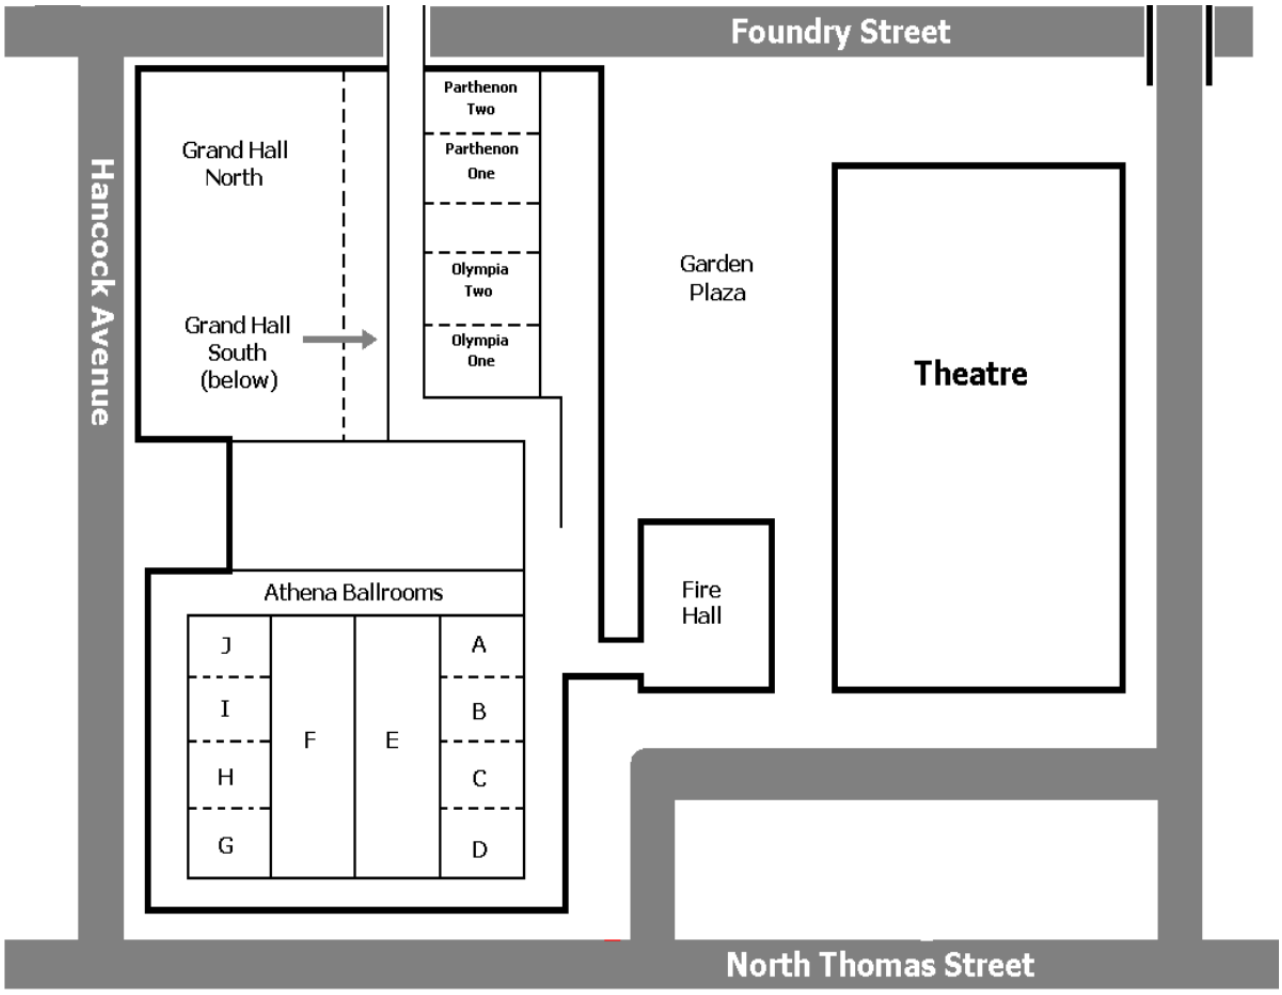
Oral Session VI **2:30 p.m.**
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I

Awards and Keynote Session **4:00 p.m.**
Classic Center, Athena Ballroom E

Poster Session and Reception **5:00 p.m.**
Classic Center, Grand Hall South (downstairs-use escalator in lobby)

The CURO 2012 Symposium will close at 6:00 p.m.

Classic Center Facility Layout



CURO Research Mentoring Awards

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the CURO Research Mentoring Award in 2001.

These awards recognize outstanding faculty who consistently make a concerted effort to engage undergraduate researchers and enhance the learning experience of undergraduates at The University of Georgia, especially through CURO. Award recipients have demonstrated superior research opportunities and mentoring programs for their undergraduate students, including outstanding teaching, supervision of undergraduate research courses and theses pursued through CURO, and collaboration on publications and presentations at professional conferences.

2012

Master Level Faculty Award
Dr. Lawrence Shimkets, Department of Microbiology
Early Career Faculty Award
Dr. Michael Yabsley, Warnell School Forestry & Natural Resources

2011

Master Level Faculty Award
Dr. Eric Stabb, Department of Microbiology
Early Career Faculty Award
Dr. John Drake, Odum School of Ecology
Program Award
Savannah River Ecology Laboratory
Dr. Kenneth McLeod, Interim Director

2010

Early Career Faculty Award
Dr. John C. Maerz, Warnell School of Forestry & Natural Resources

2009

Early Career Faculty Award
Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences
Dr. Anna C. Karls, Department of Microbiology
Dr. Dawn T. Robinson, Department of Sociology

2008

Master Level Faculty Award
Dr. John J. Maurer, College of Veterinary Medicine
Early Career Faculty Award
Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology
Program Award
Biomedical and Health Sciences Institute
Dr. Harry S. Dailey, Director

2007

Master Level Faculty Award
Dr. Timothy Hoover, Department of Microbiology

CURO Research Mentoring Awards

Early Career Faculty Award
Dr. Steven Stice, Department of Animal & Dairy Science

2006

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Department of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Department of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD candidate in Plant Biology

2005

Faculty Award
Dr. Gary Barrett, Odum School of Ecology
Dr. Sidney Kushner, Department of Genetics
Department Award
Department of Cellular Biology

2004

Faculty Award
Dr. William S. Kisaalita, Department of Biological & Agricultural Engineering

2003

Faculty Award
Dr. Jody Clay-Warner, Department of Sociology
Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator
Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Department of Plant Biology
Dr. Marie-Michèle Cordonnier-Pratt, Department of Plat Biology

2002

Faculty Award
Professor William D. Paul, Jr., Lamar Dodd School of Art
Dr. Katherine Kipp, Department of Psychology
Faculty Recognition
Dr. Susan Sanchez, College of Veterinary Medicine
Department Award
Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head
Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Department of Physics & Astronomy

Dr. Heinz-Bernd Schuttler, Department Head, Department of Physics & Astronomy
Dr. Jonathan Arnold, Department of Genetics
Dr. Susmita Datta, Georgia State University
Dr. David Logan, Clark Atlanta University
Dr. William Steffans, Clark Atlanta University

2001

Faculty Award

Dr. Marcus Fechheimer, Department of Cellular Biology

Faculty Recognition

Dr. David MacIntosh, Department of Environmental Health Sciences
Dr. Dean Rojek, Department of Sociology

Department Award

Department of Genetics
Dr. John MacDonald, Department Head

Program Award

Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

CURO Symposium Best Paper Awards

Since 2001, CURO Symposium Best Paper Awards have recognized excellence in papers developed from work being presented at that year's Symposium.

Applicants may submit in one or more of the following categories: arts, humanities, social sciences, civic responsibility focus, international focus, biological sciences, and physical sciences

Each recipient is recognized at the Symposium's Award and Keynote Session, and each award carries $100 in financial support, generously provided by the UGA Alumni Association. Winners from the 2012 CURO Symposium are listed below.

Arts:

Brendan Boyle	The New Western: Classical Genre Cinema in the 21st Century

Biological Sciences:

Tommaso Tosini	Characterization of Cone Degeneration in the Opn1.GFP Transgenic Mouse Retina

Civic Responsibility Focus:

Emily Fountain	Segregation in a Modern Age: Systematic Patterns and Consequences

Humanities:

Joshua Trey Barnett	We Are All Royalty: Narrative Comparison of a Drag Queen and King
Hope Rogers	No Triumph without Loss: Problems of Interracial Collaboration in Tolkien's Works

International Focus:

Logan Krusac	Individual Environmental Awareness and Urban Water Conservation in Kunming, China

Physical Sciences:

Christopher Sudduth	Measuring Chronic Ankle Instability in a Recreationally Active Population

Social Sciences:

Matthew Taylor	Teacher Evaluation Methods in Georgia Public Schools

Program

Monday, April 2, 2012

Concurrent Oral Sessions
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

9:05 – 9:55 a.m. Session I

Room A	**Caitlin McManemon**	Discrepancy Between Client Expectations and Doctor Reports of the Success in Treatment of Veterinary Patients
	Mark Zapata	Reversal of Acepromazine Sedation by Doxapram in Dogs
	Amita Nawathe	Gestational Diabetes Education Program
Room B	**Mark Rolfsen**	The Implementation of Effective Smoking Cessation Interventions for Drug and Alcohol Addicts in Substance Abuse Treatments
	Christopher Sudduth	Measuring Chronic Ankle Instability in a Recreationally Active Population
	Philip Oldham	Truth in Labeling: Nutritional Value Under NLEA
Room C	**Elena James**	Development of a Genetic Screen for Vitamin B12 Uptake Mutants in Mycobacteria
	Alexandra Dodd	The Role of Galacturonosyltransferase in the Acetylation and Methylation of Homogalacturonan During Pectin Biosynthesis
	Abby Weinberger	Cognitive Measures, Antisaccade Performance and Obesity in Children
Room D	**Natalya Haas**	A Piece of the Puzzle: Why People Wear Peace Signs Today
	Ransom Jackson	The Belle and the Behemoth: *Uncle Tom's Cabin* and the Southern White Woman
	Nicole Armbrust	Kathoey: Dress, the Only Opportunity for Success
Room G	**Catherine Debban**	Do Mushroom-Feeding *Drosophila* Self-Medicate with Alpha-Amanitin in Response to Nematode Parasitism?

	William Costanzo	Algae Biofuel Development: Growth Efficiency
	Matthew Smith	Determination of Virulence Factors Associated with *Histomonas meleagridis*' Cause of Blackhead's Disease in Gallinaceous Birds
Room H	**Alexis Garcia**	The Militarization of U.S. Intelligence?
	Sophie Giberga, **John Henry Thompson**	Drilling for the Future: Domestic Oil Production and Meeting America's Energy Needs
Room I	**Julian Rios**	DNA Hybridization in the Presence of Single-Walled Carbon Nanotube/ssDNA Complexes
	John Liu	The Relationship Between Macular Pigment and Neural Compensation
	Andrew Suddreth	Proteome Studies of the Interation Between *Botrytis cinerea* and Tomato Fruit
Room J	**Star Ye**	The Effect of Hypoxia on Transketolase in Breast Cancer Cells
	Patrick Wheat	U.S. Policy Alternatives to a Military Takeover in Egypt
	Dhillon Zaver	Photoimmunotherapeutic Nanoparticles for Combination Therapy of Breast Cancer

10:10 – 11:00 a.m. Session II
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Brittany Feldhaeusser**	Influence of Different Cell Storage/Culture Conditions on Spontaneous Proliferation and Tyrosine Kinase Receptor Inhibition in Two Feline Injection-Site Sarcoma Cell Lines, In Vitro
	Lauren Sullivan	Pathogenesis of Chicken Astrovirus as Studied by In-Situ Hybridization
Room B	**Justin Smith**	Characterization of a Putative Endonuclease-RNA Complex Involved in CRISPR-Mediated Viral Defense
	Jenny Brickman	Correlations Between Ankle Laxity and Dynamic Postural Stability

	Nathan Usselman	Optimization of Surface-Initiated Kumada Catalyst Transfer Polycondensation
Room C	**David Parker**	The Effects of Volume Removal on Values of Factional Anisotropy
	Stephen Robertson, Aaron Murray	An Examination of Communication and Employee Engagement
Room D	**Katherine Black**	Differences in Functional Movement Screen Scores Between Genders in NCAA Division I Athletes
	Suzanne Meller	Emotion Regulation and Childhood Depression: An Examination of Moderators
	Yiran (Emily) Peng	Reducing Costs and Maintaining Quality: Alternatives to Fee-for-Service in Federal Health Insurance Plans
Room G	**Rachel Bonds**	Outward Migration and the Kenyan Economy: Transforming the Brain Drain to a Brain Gain
	Dana Schroeder	Progress Toward Sustainability Goals at UGA's Costa Rica Campus in San Luis de Monteverde, Costa Rica
Room H	**Melissa McDaniel**	War, Peace, and Seduction: An Analysis of Tolstoy's Hélène Kuragin as a Symbol of Female Sexuality
	Audrey Glasgow	The Uses and Effects of Music in the Conflict in Northern Ireland
	Brittany McGrue	Public Art in Athens-Clarke County
Room I	**Malavika Rajeev**	Predictors of Tick Burden and Engorgement in Grant's Gazelle
	Jenna Grygier	Management of Marine Debris in the U.S.: A Survey of Options and Database for Decision-Makers
Room J	**William French, Ryan McLynn**	The Effect of Protein Kinase Inhibitors on the Growth of *Plasmodium falciparum*
	Cameron Zahedi	Addressing Students' Math Deficiencies in Introductory Physics with Online Scaffolded Problems
	Matthew Taylor	Teacher Evaluation Methods in Georgia Public Schools

Program

11:15 – 12:05 p.m. Session III
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I

Room A	**Daniel Smith**	Inferno
	Lea Rackley	Finding the Child in Children's Literature
	Meghan Russell	Architecture and Dress
Room B	**Elizabeth Crowley**	Racial Inclusivity and Exclusivity in HBO's *True Blood*: A Viewer-Response Critique via Hans Robert Jauss's "Horizon of Expectations"
	Lauren Anderson	The Legacy of Truth: Analyzing the TRC's Impact on South Africa's Millennial Generation
	Anisha Hegde	Increasing Breastfeeding Rates in Athens-Clarke County
Room C	**Marianne Ligon**	Characterization of the Tneap Complex in the CRISPR-Cas Viral Defense System of Prokaryotes
	Joshua Parker	Investigating Post-Translational Modification and Activity of Zebrafish Glycosidases
	Stephen Bocarro	The Characterization of Long Flagella 4 Protein in *Tetrahymena*
Room D	**Waring Trible III**	Manipulating Tropical Fire Ant Populations to Decrease the Coffee Berry Borer
	Katrina Egan	Effect of Anesthetic Variables on Recovery Time in Dogs
	Chelsea Renier	Does Eggshell Pigmentation Reflect Female Condition in Broiler Breeder Hens?
Room G	**Joshua Trey Barnett**	We Are All Royalty: Narrative Comparison of a Drag Queen and King
	Tyler Bugg	'All Truth is Bitter': Legacies of a Post-Apartheid, Post-TRC South Africa
	Emily Fountain	Segregation in a Modern Age: Systematic Patterns and Consequences

Room H	**JoyEllen Freeman**	A Portrayal of Power: Black Nationalism in the Documentary *Now Is the Time*
	Anna Beth Havenar	An Affect Control Theory Analysis of Islam and Christianity
	Connor Land	Information as Narrative Poison or Poultice in Ergodic Literature
Room I	**Benjamin Harris**	Race Relations in Brazil Between 1890 and 1920
	Samuel Kinsman	Private Equity in Brazil

12:20 – 1:10 p.m. Session IV
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Tyler Bugg**	Giving Voice to Silence: Theatre and Community in *He Said, She Said, Zhe Said: Gender Stories*
	Emily Jessup	Noah Webster's *American Spelling Book* as a Product of Colonial American Culture and Economics
	Brendan Boyle	The New Western: Classical Genre Cinema in the 21st Century
Room B	**Abid Fazal**	Production of Saccharification Enzymes by Recombinant Fungus Grown on Pectin-Rich Biomass Materials
	Charles Blair III	A Shot in the Dark: How Information Affects Consumer Light Bulb Purchases
	Heather Hatzenbuhler	Residential Electricity Consumption and Affordability of Efficiency and Clean Energy Upgrades
Room C	**Peter Sisk**	Proteomics Analysis of Canine Prostate Carcinoma Tissue: A Potential Animal Model of a Human Disease
	Sam Hempel	Developing Kinetic Genotype-Phenotype Correlations for Missense Point Mutations in Human Protein O-Linked Mannose β-1,2 N-Acetylglucosaminyltransferase (POMGnT1)

	Lindsey Megow	Effects of Helminth Infection on Local and Systemic Immunity
Room D	**Tanya Dieumegarde**	The Responsiveness of Mothers in Organic and Inorganic Nutrition in Ghanaian Children and the Social and Economic Implications
	Todd Pierson	Narcotics-Trafficking, Cloudforests, and a Killer Fungus: Amphibian Conservation in Central America
	Garrett Melick	Histological and Protein Expression Changes in Mouse Models of Early Dystroglycanopathy
Room G	**Anita Bhagavathula**	Vitamin D Deficiency in the African American Population
	Smitha Ganeshan	Access to Primary Care Services in Athens
	Bryn Murphy	Prospect Theory and Common Action Problems: Loss Aversion in International Riparian Treaty Compliance
Room H	**Erin Giglio**	The Role of Sensory Systems in *Drosophila* Courtship Across Populations
	Allyson Byrd	Comparative Genomics of Ribosomal RNAs in Malaria Parasites
	Daniel Guidot	Description and Measurement of Response to Osmotic Stress in *Toxoplasma gondii*
Room I	**Hope Rogers**	No Triumph Without Loss: Problems of Interracial Collaboration in Tolkien's Works
	Stephanie Talmadge	Social Media's Effect on the Arab Spring Revolutions
	Sarah Mitchell	Effect of Sugar on Brain Peptides
Room J	**Stephanie Wilding**	Expression of Secretory Phospholipase A2 in Prostate Cancer Cells Lines
	Lauren Titus	The Effect of Lipoic Acid on Inflammatory Cytokines and Messenger RNA Levels in Microglial Cells

	Michael Webber	*Methionine Sulfoxide Reductase* Gene Regulation in *Vibrio fischeri*

1:25 – 2:15 p.m. Session V
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I

Room A	**Debashis Ghose, Sr.**	Stability Analysis of the Inhibitor Resistant Phenotype of AJP50 in Biomass Fermentations
	Philip Grayeski	Genetic Manipulation of *Caldicellulosiruptor bescii* for Biomass Utilization
	Heather Hatzenbuhler	Legal Approaches to Addressing Water Pollution Risks Related to "Fracking" in the Marcellus Shale Region
Room B	**Brooke Bauer**	Organizational Commitment in the Workplace
	Anna Wilson	A Sociolinguistic Perspective on Roswell, GA
	Suze Valmé, Morgan Capps	An Investigation of the Role of Work Status in Relation to Company Growth
Room C	**Melanie Fratto**	Infection Modifies the Effects of Stress on Immune Function in Birds
	Daniel Pique	Regulation of the Cell Cycle in the African *Trypanosome* by Small Molecule Inhibitors and Serum Deprivation
	Jennifer Hegarty, Laura Hegarty	Recycling and End-Use Industries in Georgia
Room D	**Ashley Blackburn**	High Resolution Behavioral Economic Analysis of the Price Sensitivity of Smoking Cessation Motivation
	John Rodriguez	Combatting Obesity by Eliminating Food Deserts in Athens-Clarke County
	Dev Iyer	Prisons for Profit: A New Approach to the Private Prison Model in the State of Georgia
Room G	**Terese Gagnon**	Landscapes of the Interior: Ethnobotany and Senses of Place Among Karen Refugees

	Khai Nguyen	Post-Katrina Recovery Processes in the Vietnamese-American Community
	Cody Knapp	International Boundary Settlement and Domestic Conflict
Room H	**Kieran Maynard**	Lost Chapters in the *Wind-Up Bird Chronicle*: A Translation and Commentary
	Sarah Potter	Aporetic Structure in Marcel Proust's *In Search of Lost Time*
	Elina Kumykova	Exploring Medical Practice Through Chekhov's Literature
Room I	**Connor Sweetnam**	The Interaction of Tau Proteins and Hirano Bodies
	Farres Obeidin	Modeling Subtelomeric Growth and the Adaptive Telomere Failure Hypothesis
	Casey Love	Phospholipase Expression in Cocaine-Addicted Rats

2:30 – 3:20 p.m. Session VI
Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I

Room A	**Katherine Helmick**	Dietary Resource Partitioning of the Southern Flying Squirrel (*Glaucomys volans*)
	Brigid Burns	Anesthetic Complications in Dogs Undergoing Surgery for Liver Disease
	Kelsey Campolong	The Role of Coagulation in Cerebral Malaria in the Mouse Model
Room B	**Theresa Stratmann**	The Science of Monitoring Rare Species: Developing Methods to Locate and Survey for the Endangered Bog Turtle
	Ruth Davis	An Alternative Perspective?: Dora Mayer's Contributions to the Peruvian *Indigenismo* Movement
	Kayci Schoon	The Resistance Complex in Lyon: Politics, Memory, History

Program

Room C	**Hope Rogers**	The Skeleton in the Closet: Deadly Duplications in Mary Shelley's *Frankenstein*
	Christopher Bailey II	Computational Modeling of Emergent Dynamics in Language
Room D	**Tuiumkan Nishanova**	Assembly and Subspeciation of Haptoglobin-Related Protein Containing High-Density Lipoproteins
	Joseph Hill, Brittany Feldhaeusser	Effects of Platelet-Derived Growth Factor Receptor Inhibition on Feline Injection-Site Sarcoma Radiosensitivity
	Nakul Talathi	Characterization of *cis/trans* Phosphorylation Modes in a Eukaryotic Protein Kinase
Room G	**Eilidh Geddes, Avery Wiens**	Teacher Attrition: Possible Policy Solutions
	William Smith	Compelling State Interest: A Study of the Unequal Application of Strict Judicial Scrutiny
	Logan Krusac	Individual Environmental Awareness and Urban Water Conservation in Kunming, China
Room H	**Luben Raytchev**	Haemogregarines of Freshwater Turtle Species: Does Basking Behavior Influence Parasitemia Levels?
	Osama Hashmi	Analysis of the Legal Needs of Primary Care Physicians
	Allison Doyle	Increasing Access to Primary Care for Low-Income Rural Georgians
Room I	**Paul Havenstein**	Rastafari: Continuity, Discontinuity, and Present Identity
	Aaron Murray	Measuring Transformational Leadership in the NFL

4:00 p.m. Awards and Keynote Session
Classic Center, Athena Ballroom E

Welcome and Introductions	Dr. David S. Williams, Associate Provost and Director, Honors Program

Program

Remarks	Professor Jere W. Morehead, Senior Vice President for Academic Affairs and Provost
Introduction to Awards	Dr. William Kisaalita, Associate Director, CURO
CURO Research Mentoring Awards	Dr. David C. Lee, Vice President for Research
2012 Symposium Best Paper Awards	Dr. Laura Jolly, Vice President for Instruction Ms. Deborah Dietzler, Executive Director, Alumni Association
UGA Libraries' Research Awards	Ms. Caroline Barratt, Director, Miller Learning Center Library Commons
Introduction of Keynote Speaker	Ms. Dana Higgins, Foundation Fellow '12, International Policy
Keynote Address	Dr. Charles Bullock, Richard B. Russell Professor of Political Science "A Prospective Look at the 2012 Elections"
Closing Comments	Dr. David S. Williams, Associate Provost and Director, Honors Program

5:00 p.m. Poster Presentations
Classic Center, Grand Hall South (downstairs - use the escalator in the lobby)

Poster #1	**Aditya Aphale**	Test-Retest Reliability and Data Analysis for the NeuroCom Postural Stability Test
Poster #2	**Charlotte Ball**	Assessment of Fukutin's Biological Function by Identification of Associated Proteins
Poster #3	**Stephen Bocarro**	The Characterization of Long Flagella 4 Protein in *Tetrahymena*
Poster #4	**Kathryn Briggs**	Insertion of Hemagglutinin Gene from H5N1 into Parainfluenza Virus Type 5 (PIV5) Offers Immunity in Mice Against H5N1 Challenge
Poster #5	**Melissa Brown**	Black Stereotypes in Reality Television and the Reinforcement of Prejudiced Attitudes
Poster #6	**Allyson Byrd**	Comparative Genomics of Ribosomal RNAs in Malaria Parasites

Poster #7	**Neal Canlas, Michael Theobald**	Arterial Flow Pattern in People with Peripheral Arterial Disease
Poster #8	**Vinay Choksi**	Mating Regulates Germ Line Stem Cell Division Frequency in Testes of *Drosophila melanogaster*
Poster #9	**Dervin Cunningham, Jr.**	Proteomic Analysis of the Tomato/*Botrytis cinerea* Interaction
Poster #10	**Kasey Darley**	A Therapeutic Nanoparticle Platform for Targeting Mitochondrial Superoxide
Poster #11	**Tanya Dieumegarde**	The Responsiveness of Mothers in Organic and Inorganic Nutrition in Ghanaian Children and the Social and Economic Implications
Poster #12	**Alexandra Dodd**	The Role of Galacturonosyltransferase in the Acetylation and Methylation of Homogalacturonan During Pectin Biosynthesis
Poster #13	**Sarah-Bianca Dolisca**	The Sweet Connection: O-linked β-N-Acetylglucosamine Transferase and Cancer Stem Cells
Poster #14	**Abid Fazal**	Production of Saccharification Enzymes by Recombinant Fungus Grown on Pectin-Rich Biomass Materials
Poster #15	**Brittany Feldhaeusser**	Influence of Different Cell Storage/Culture Conditions on Spontaneous Proliferation and Tyrosine Kinase Receptor Inhibition in Two Feline Injection-Site Sarcoma Cells Lines, In Vitro
Poster #16	**Hope Foskey**	Identification of GABA-Responsive Neurons in the Zebrafish Brain
Poster #17	**William French, Ryan McLynn**	The Effect of Protein Kinase Inhibitors on the Growth of *Plasmodium falciparum*
Poster #18	**Nisha George**	The Role of Cysteine Residues in the Function of Ras Converting Enzyme
Poster #19	**Mina Ghobrial**	Testing Algorithms to Predict Onset of Cerebral Malaria in Murine Model
Poster #20	**Philip Grayeski**	Genetic Manipulation of *Caldicellulosiruptor bescii* for Biomass Utilization

Poster #21	**Daniel Guidot**	Description and Measurement of Response to Osmotic Stress in *Toxoplasma gondii*
Poster #22	**Tyler Haeffs**	Limb Morphology and Sequence Divergence in the *fgf* Genes of *Anolis* Lizards
Poster #23	**Hannah Hanley**	Digital Analysis of Feline Bone Marrow Fat Content
Poster #24	**Alexander Hansen**	Relationship Between Left Uncinate Fasciculus White Matter Integrity and Verbal Memory
Poster #25	**Jennifer Hegarty, Laura Hegarty**	Recycling and End-Use Industries in Georgia
Poster #26	**Alexander Herzog**	Protein-Glycosaminoglycan Interaction Studies Using Surface Plasmon Resonance (SPR)
Poster #27	**Rachel Johnson**	Examining Genetic Diversity in Peruvian Samples of *Plasmodium falciparum*
Poster #28	**Mathew Joseph**	Inflammatory Cell Markers' Gene Expression in Mouse Model of Placental Malaria
Poster #29	**Michael Klodnicki**	A New Approach to Histomoniasis: Data Mining and Targeted Drug Sensitivity
Poster #30	**Kelsey Kuperman, Suzanne Meller**	The Moderating Role of Romantic Relationship Satisfaction on the Relation Between Parenting Stress and Maternal Hostility
Poster #31	**SaiSudeepti Kuppa**	Development of a Vector to Delete the β-Lactamase Gene from Mycobacteria
Poster #32	**Monica LaGatta**	Construction of a vapB Deletion Mutation in a Swine Isolate of *Rhodococcus equi*
Poster #33	**Kellie Laity**	Development of Nut-Cracking Skills in Wild Bearded Capuchin Monkeys (*Sapajus libidinosus*)
Poster #34	**Christopher Lee**	Immortalization of Primary Swine Respiratory Epithelial Cells
Poster #35	**Michelle Lee**	The Contribution of Environmental Contamination with *Salmonella* to Human Illnesses in Georgia

Poster #36	**Hillary Liken**	Stimulation Current Does Not Influence NIRS Measured Metabolic Rate
Poster #37	**John Liu**	The Relationship Between Macular Pigment and Neural Compensation
Poster #38	**Katie Manrodt**	The Molecular Dynamics of Atomic Sticking Coefficients
Poster #39	**Lindsey Megow**	Effects of Helminth Infection on Local and Systemic Immunity
Poster #40	**Garrett Melick**	Histological and Protein Expression Changes in Mouse Models of Early Dystroglycanopathy
Poster #41	**Suzanne Meller, Sophie Arkin, Isabel Cohen**	Cumulative Risk and Child Psychopathology: Understanding the Role of the Parenting Relationship
Poster #42	**Hannah Muetzelfeld**, **Grace Cha**	Insecure Attachment, Low Self-Esteem, and Low Parental Warmth as Predictors of Substance Abuse
Poster #43	**Melesse Nune**	Protein Purification, Crystallization, and Functional Annotations of Five Essential LysR-type Transcriptional Regulators in *Acinetobacter baylyi* ADP1
Poster #44	**Philip Oldham**	Truth in Labeling: Nutritional Value Under NLEA
Poster #45	**Andrea Orton, James Ford, Kristen Whipple**	Development of Disability Awareness Assessment Scale
Poster #46	**Elliot Outland**	Finite-Difference Time-Domain Investigations of Metamaterials
Poster #47	**Akshita Parikh**	Affinity and Specificity Characterization of Fbs1 via Surface Plasmon Resonance and Glycan Array Screening
Poster #48	**David Parker**	The Effects of Volume Removal on Values of Factional Anisotropy
Poster #49	**Anisha Patel**	Cognitive Differences Between Objective and Subjective Memory Complaints

Poster #50	**Nisarg Patel, Christopher Lee**	Stable Cell Line Engineered with shRNA Against TMPRESS2 Protease to Reduce the Infection of Influenza Virus
Poster #51	**Todd Pierson**	Arabian Nights: Preliminary Survey of Herpetofauna and the Phylogeography of *Bufo dhufarensis* (*Bufonidae*) in Oman and the United Arab Emirates
Poster #52	**Daniel Pique**	Regulation of the Cell Cycle in the African Trypanosome by Small Molecule Inhibitors and Serum Deprivation
Poster #53	**Michael Rausher, Isabel Cohen**	Relations of Substance Use to Constructive Communication and Sexual Violence in Young Adults' Romantic Relationships
Poster #54	**Daniel Sharbel**	Assessing Rce1-Protease Inhibition in a Cell-Based Fluorescence Ras Localization Assay
Poster #55	**Andrea Sikora**	Intravenous Minocycline and Its Effect on Peripheral Interleukin-6 After Ischemic Stroke
Poster #56	**Lauren Sullivan**	Pathogenesis of Chicken Astrovirus as Studied by In-Situ Hybridization
Poster #57	**Nakul Talathi**	Characterization of *cis/trans* Phosphorylation Modes in a Eukaryotic Protein Kinase
Poster #58	**Korry Tauber**	Examining the Function of O-GlcNAc in Regulating Intracellular Signaling Pathways During *Drosophila* Development
Poster #59	**Lauren Titus**	The Effect of Lipoic Acid on Inflammatory Cytokines and Messenger RNA Levels in Microglial Cells
Poster #60	**Emma Torpy**	Global Web Advertising: How Different Countries Regulate Digital Advertisement
Poster #61	**Tommaso Tosini**	Characterization of Cone Degeneration in the Opn1.GFP Transgenic Mouse Retina
Poster #62	**Waring Trible III**	Manipulating Tropical Fire Ant Populations to Decrease the Coffee Berry Borer

Poster #63	**Kishore Vedala**	Analyzing the Kinetic and Thermodynamic Properties of O-Man Initiated Glycan Binding Alpha-Dystroglycan and Laminin-2
Poster #64	**Stephanie Wilding**	Expression of Secretory Phospholipase A2 in Prostate Cancer Cells Lines
Poster #65	**Star Ye**	The Effect of Hypoxia on Transketolase in Breast Cancer Cells

Abstracts

The Legacy of Truth: Analyzing the TRC's Impact on South Africa's Millennial Generation

Lauren Anderson, CURO Summer Fellow
Dr. Amy Ross, Geography, Franklin College of Arts & Sciences

Following years of racial violence and political negotiations, post-apartheid South Africa established the Truth and Reconciliation Commission (TRC) to investigate past human rights violations and develop a culture of peace. From 1996 to 2001, the TRC accepted over 21,000 victim testimonies and incorporated victim and amnesty hearings in an effort to collect a full and accurate historical record. However, since the release of the TRC's Final Report, few studies have sought to examine the long-term implications of the TRC's work, especially among young people who were not involved in the commission process. For this project, I conducted eleven semi-structured interviews with students at the University of Stellenbosch in Stellenbosch, South Africa. Utilizing questioning that gauged the participants' understanding of the TRC and contemporary racial and political realities, I implemented a qualitative analysis of the data, paying particular attention to commonalities in the responses. In general, the participants relayed favorable opinions of the TRC as an institution and indicated positive attitudes of present racial tolerance and social integration. Nevertheless, there is little evidence that the TRC has contributed to these progressive relations, suggesting that the TRC has failed to directly influence lasting reconciliation. While these results question the success of the TRC's efforts, I attribute this conclusion to the TRC's methodological practices as opposed to the truth commission itself. By illuminating the structural weaknesses of the TRC, this study ultimately seeks to provide insight for other post-conflict societies, as well highlight the limitations of truth in correcting socio-economic inequities.

Test-Retest Reliability and Data Analysis for the NeuroCom Postural Stability Test

Aditya Aphale
Dr. Michael Ferrara, Kinesiology, College of Education

Sport-related concussion accounts for about 5% of the injuries in intercollegiate football. A concussion occurs when a blow to the head affects neurological function. A multifaceted approach to concussion management includes self-reporting symptoms, neuropsychological testing, and balance testing. The NeuroCom Smart Master Balance System is an instrument used to assess postural stability following a concussion. The assessment tests responsiveness of the visual, vestibular, and somatosensory systems. In order to determine whether the NeuroCom can be used as a viable tool in concussion assessment, the reliability of the instrument must be assessed. The purpose of this project was to assess the test-retest reliability using clinically relevant time periods (Baseline, Day 45, and Day 50) which have been previously used to establish the reliability of neuropsychological testing. The NeuroCom consists of a force plate and a surround that sways in response to a person's movement. There are six different conditions administered that assess the various physiological systems involved with balance. Participants in the study were divided into two groups. The first group (Group A) had the test's conditions administered in a fixed order while the second group (Group B) had the conditions administered in a random order. Mean stability values and intraclass correlation coefficients (ICC) were computed. Group B had generally higher ICC values than Group A, with ICCs in the 0.7-0.8 range. While these ICC values are acceptable, the addition of self-report symptoms and neurocognitive test to the NeuroCom assessment would strengthen diagnosis and return-to-play decisions following sport-related concussion.

Abstracts

Kathoey: Dress, the Only Opportunity for Success

Nicole Armbrust
Dr. Katalin Medvedev, Textile, Merchandising & Interiors, College of Family & Consumer Sciences

In present day Thailand, there are over 100,000 transsexual males, termed Ladyboys or Kathoey, to whom dress and beauty play significant roles in displaying their true identities. Kathoey believe themselves to be women trapped inside male bodies and consequently dress and exude female personas (Forbes, 2002). Although Thailand is said to be accepting of their transgenders, Ladyboys are still denied political and legal rights to their womanhood in addition to being discriminated against and stereotyped frequently. By studying Thai religion and culture and analyzing journals and media on Kathoey livelihood, I have come to the conclusion that dress, appearances, and beauty are the most essential aspects of Ladyboys' lives and acceptance into Thai society. Throughout every stage in a Ladyboy's life, dress plays a vital role in the realization of their true nature and in changing them into what they want to be. The pinnacle of success for these Ladyboys is to become completely convincing women in every way, which is extremely difficult and only accomplished through dress practices. After studying the Kathoey of Thailand, it is evident that respect and acceptance is only attained if they are able to project perfect feminine beauty. Without dress practices, the discrimination and ostracism of transgenders would be significantly worse. Through this study, it is clear that members in any society who are deemed "different" use dress as a means of acceptance. I have ultimately found that dress and appearance play integral roles in societal approval, regardless of what culture one identifies with.

Computational Modeling of Emergent Dynamics in Language

Christopher Bailey II, CURO Summer Fellow
Dr. Bill Kretzschmar, English, Franklin College of Arts & Sciences

Computer simulation is the only way to study the adaptivity of language over time. There is no detailed diachronic source of language data with which to study the changes of language actually in use, leaving historical linguists to draw conclusions from inadequate remains. Consequently, this study uses a hand-crafted piece of software to unpack the mechanisms that contribute to the dynamic, emergent order found in language. The program's primary function is to run simulations according to user-specified, probabilistic rules, which take into account geographic and social factors (e.g., proximity, gender, race, age) sampled from actual linguistic survey data. My research consists primarily of exploring rule combinations in search of those rule sets that produce frequency distributions like those we know to exist, as found in the Linguistic Atlas Project. The simulation achieves success if such a rule set is found (i.e., one showing evolving, non-linear distributions of linguistic variants among the simulated speakers). There are two reasons this research is significant. First, it breaks new ground – no computer simulation of language has ever been validated against a data set as large and thorough as that contained in the Linguistic Atlas Project. Second, this simulation has the potential to provide insight into fundamental questions about language variation like "How important are social factors in influencing the way people speak?" and "What facilitates the spread of linguistic items within communities of different scales?"

Assessment of Fukutin's Biological Function by Identification of Associated Proteins

Charlotte Ball
Dr. Aaron Beedle, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Mutations in fukutin can cause congenital muscular dystrophy (CMD); however, the exact function of fukutin is still undetermined. The purpose of our research is to gather information about fukutin's biological role. Fukutin is known to be involved in the glycosylation of α-dystroglycan (αDG) because αDG is hypoglycosylated in fukutin patients. Proper αDG glycosylation is critical for maintaining the muscle cell membrane's association with the extracellular matrix (ECM) as the absence of sugar moieties prevents the αDG to ECM interaction, leading to decreased stability of the sarcolemma and increased muscle cell death. To expand our understanding of fukutin's role in αDG glycosylation, we will extract, purify, and identify proteins physically associated with fukutin. We used viral particles developed in-lab to deliver DNA encoding a tagged fukutin (3xHA) into fukutin-knockout mouse embryonic stem cells. From embryonic stem cell lysates, we have extracted fukutin and its associated proteins using the HA tag. Fukutin-associated proteins will be identified by mass spectroscopy, and known functions will be ascertained by database mining. Identification of fukutin binding proteins is critical to determining fukutin's function and developing therapeutic strategies for fukutin-dependent muscular dystrophy.

We Are All Royalty: Narrative Comparison of a Drag Queen and King

Joshua Trey Barnett, CURO Summer Fellow
Dr. Corey W. Johnson, Counseling & Human Development Services, College of Education

Drag performances have been studied as important visible cultural sites of gender transgression. Few studies, however, have sought to understand the ways in which drag performers—kings and queens—relate to and shape queer communities. In this manuscript we explore the narrative of a drag queen alongside a drag king in an effort to elucidate these relationships and the similarities and differences that become apparent between the two. Specifically, we are interested in how drag performers engage their drag personas for political and activist purposes as well as how the spaces they find themselves performing in influence their lived experiences. Seeking to understand drag performers through a genderqueer lens, which encourages engagement with the trans movement as a conduit for political expression, we employ narrative inquiry as a means by which to highlight and forefront the lived experiences of our participants.

Organizational Commitment in the Workplace

Brooke Bauer, CURO Summer Fellow
Dr. Robert Vandenberg, Management, Terry College of Business

Over the past thirty years commitment in the workplace has been researched and studied for the benefit of organizations. The results of measuring commitment in the workplace predict behaviors and attitudes of employees such as turnover, absenteeism, and performance. While the study of organizational commitment strengthens the organization's recognition of their employees' actions, the tools to measure commitment are highly outdated. The surveys used to measure commitment were developed during the post-depression era, and the questions within the survey focus more on earlier generations who were committed to their organizations for reasons that differ from the people entering in the workforce today. One of the most commonly used surveys is the Organizational Commitment Questionnaire. This questionnaire measures three different types of commitment: affective commitment, continuance commitment, and normative

commitment. What I question is how relevant each type of commitment is to society today, and if there is not another form of commitment that more accurately measures commitment in the workplace. One element that my mentor, Dr. Vandenberg, and I believe should be incorporated within the definitions of commitment is "transitional commitment," or the notion of remaining in an organization in order to further advance later in one's career. This past summer, Dr. Vandenberg and I created a new survey with additional questions on transitional commitment and sent the survey to full-time employees enrolled in the MBA programs at UGA. Currently, Dr. Vandenberg and I continue to question and quantify the significance of changed perceptions on attitudes in the workplace.

Vitamin D Deficiency in the African American Population

Anita Bhagavathula
Dr. Daniel Promislow, Genetics, Franklin College of Arts & Sciences

Vitamin D deficiency has been associated with Inflammatory Bowel Disease (IBD) in Caucasians. Hypovitaminosis-D is reported to occur among individuals of color including African Americans (AAs). One could hypothesize having two risk factors (IBD and AA race) would result in severe vitamin D deficiency. Our aims were to determine vitamin D status, as measured by 25-hydroxyvitaminD(25(OH)D) in AAs, and to compare these results to Caucasians with IBD. Serum 25(OH)D was determined in 86 AAs with Crohn's Disease(CD), 123 AA controls, and 62 Caucasians with CD(C-CD). Additional data (BMI, disease severity, and surgical history) were extracted following IRB approval. Vitamin D deficiency was defined as serum 25-hydroxyvitaminD≤20ng/ml based on the Institute of Medicine's dietary reference intakes. Vitamin D deficiency was present in 67% of AA-CD cases compared to 76% of the disease-free AA controls (P-value 0.17). Only 35% of C-CD had a vitamin D deficiency compared to 67% of AA-CD subjects (p-value <0.001). In addition, AAs-CD had much lower vitamin D levels (17.70ng/mL) than their Caucasian counterparts (24.38ng/mL) with the same diagnosis. Linear regression analysis showed that there were no differences in vitamin D levels among AA by BMI, disease severity, or surgical history. Vitamin D deficiency is common in all AA subjects. In addition, AAs-CD have almost 4 times greater odds of having vitamin D deficiency compared to Caucasians-CD (95% CI 1.89-7.50). Unlike in Caucasians, the vitamin D levels are not affected by disease severity or IBD phenotype in AA-CD. Further, prospective studies are warranted to better understand vitamin D metabolism in AAs.

Differences in Functional Movement Screen Scores Between Genders in NCAA Division I Athletes

Katherine Black
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Female athletes have documented differences in anatomical alignment of the lower extremity, and differences in strength may contribute to increased injury risk, including ligament sprains at the knee. The functional movement screen (FMS) is a quantifiable measure of athletes' performance in 7 fundamental movements. These include lunging, squatting, stepping, and stabilizing. Our objective was to determine if there was a significant difference between FMS scores of female and male NCAA Division I athletes. Differences in scores may provide rationale for increased injury risk in females. FMS data were obtained from males and females on the cross country, track/field, swimming, and tennis teams. Scores were totaled and averaged over genders across teams. Percent differences were calculated on the total and 7 individual sub-tests. A 49.0% difference occurred between male and female

scores on the push-up component of the FMS. Females had lower push-up scores than males. However, many of the female athletes had reported impingement pain while performing the task, so they were assigned a score of 0, not representative of their ability but of the presence of pain. The differences in the other tests were not clinically significant. It appears that male and female Division I athletes on those particular teams have comparable FMS scores in total and on sub-tests. The FMS may not provide rationale for or indicate why female athletes may be more at risk for specific injuries.

High Resolution Behavioral Economic Analysis of the Price Sensitivity of Smoking Cessation Motivation

Ashley Blackburn
Dr. James Mackillop, Psychology, Franklin College of Arts & Sciences

Tobacco use is the single largest cause of mortality in the United States, and understanding the factors that contribute to smoking cessation success is a priority for research. Previous research suggests that the cost of tobacco products plays an important role in successful smoking cessation. The purpose of this study was to better understand the relationship between cigarette price and smoking cessation motivation. A large sample of community smokers (n = 1074, 60.4% male, 67.5% Caucasian) were assessed using the Probability of Smoking Cessation Measure (PSCM), which assessed the estimated likelihood that an individual would quit smoking at a variety of cigarette prices ranging from free to $10/cigarette ($200/pack). Dependent variables from the PSCM included intensity (baseline quit motivation), breakpoint (price point corresponding to 100% quit probability), and P50 price (price point corresponding to 50% quit probability). Relationships between quit probability and demographic variables, measures of nicotine dependence severity, and self-reported smoking cessation variables were investigated. As anticipated, quit probability increased as a function of escalating cigarette price. Individual indices from the PSCM measure were correlated with each other (*r*s = .13-.45, *p*s < .001). Significant correlations were present between PSCM variables and a number of demographic and smoking variables. Higher nicotine dependence ratings were significantly associated with lower intensity (*r* = -.08) and higher P50 price (*r* = .10). These results provide further evidence that price plays an important role in smoking cessation motivation and that meaningful differences exist by nicotine dependence severity.

A Shot in the Dark: How Information Affects Consumer Light Bulb Purchases

Charles Blair III
Dr. Robert Nielsen, Housing & Consumer Economics, College of Family & Consumer Sciences

In light of the pending elimination of incandescent bulbs from the market to make way for less familiar, energy efficient light bulbs, I will investigate the role that information plays in the consumer's decision to purchase light bulbs by answering the following research question: *How does information affect consumers' decisions when purchasing energy efficient light bulbs?* This will be done through the execution of a controlled experiment using control and treatment groups. Participants in the study will be drawn from the UGA community (faculty, staff, and students) and will be randomly assigned to either the control or treatment groups. In each group, the participants will be shown five compact fluorescent light bulbs equivalent to 60-watt incandescent bulbs. Both groups will be encouraged to examine the product packaging and unit price before indicating their purchase choice from the selection. Treatment group participants will receive additional external information about the bulbs and explanation of the different

bulb qualities that are useful when shopping for light bulbs. It is anticipated that in the absence of more detailed information, consumers will decide based on price. However, when they receive more information, I expect them to choose the light bulb based on what characteristic they perceive to be most important, as well as comparisons and ratings provided by *Consumer Reports*. The findings will assist in the communication of pertinent product information and creation of a more consumer friendly market environment for light bulb purchases.

The Characterization of Long Flagella 4 Protein in *Tetrahymena*

Stephen Bocarro
Dr. Jacek Gaertig, Cellular Biology, Franklin College of Arts & Sciences

Cilia are microtubule-rich projections that determine a wide range of functions. Previous studies done in the flagellate *Chlamydomonas reinhardtii* identified LF4 (long flagella protein 4), a MAP kinase-like protein, as a negative regulator of cilia length. When overexpressed in growing *Tetrahymena thermophila*, GFP-tagged LF4 induced shortening of cilia associated with cell paralysis and arrest in cytokinesis (likely secondary to loss of cell motility). The phenotype of GFP-LF4 overproducing cells resembled that of mutants lacking the intraflagellar transport pathway (IFT), a pathway that operates within cilia and is required for ciliary assembly and turnover of ciliary proteins. This indicates that LF4 acts as an inhibitor of ciliary elongation and potentially an inhibitor of IFT. When GFP-LF4-overexpressed *Tetrahymena* were starved, the cilia showed paralysis but did not shorten. This suggests that in starved cells LF4 inhibits delivery of essential motility components, such as dynein arms. The paralysis phenotype may result from a higher turnover rate of dynein motors and relatively slow turnover of components required for ciliary elongation such as tubulin. Thus, LF4 could be a negative regulator of IFT, and its role in ciliary length regulation could be indirect due to its inhibition of IFT. Our goal now is to identify the specific protein(s) that is a substrate of phosphorylation by LF4. We will look for proteins that bind to LF4 using immunoprecipitation.

Outward Migration and the Kenyan Economy: Transforming the Brain Drain to a Brain Gain

Rachel Bonds
Dr. Jack Houston, Jr., Agricultural & Applied Economics, College of Agriculture & Environmental Sciences

The brain drain is a common phenomenon throughout the developing world, with Kenya sending some of the highest numbers of migrants from sub-Saharan Africa. Based on the assumption that the outward migration of Kenyan professionals will continue, this study will answer the following question: How can governments utilize the brain drain to maximize its economic benefits? Remittances are the most visible benefit of outward migration, representing an important source of foreign exchange, but additional benefits, such as an increased network of business professionals, also assist developing countries. This study will first identify these benefits with existing literature and economic modeling. Second, it will address policies that the government and the private sector can adopt to harness the positive externalities of the brain drain by examining the success of other developing countries' policies. Examples of potential findings include increased access and financing for higher educational research, the use of remittances to invest in education and business creation, and the utilization of the Kenyan diaspora to help finance development projects and raise awareness of domestic issues. This study is unique in economic policy and migration literature because it assumes the brain drain is a constant economic reality in the developing world. Using this assumption, this research

will make important advances on how the brain drain can be used to facilitate development in the sending country. Thus, it represents a departure from traditional brain drain research that focuses on how to inhibit the migration of professionals.

The New Western: Classical Genre Cinema in the 21st Century

Brendan Boyle
Dr. Christopher Sieving, Theatre & Film Studies, Franklin College of Arts & Sciences

The production of high-profile films in the Western genre has slowed dramatically since its classical period, from the 1940s to the early 1960s. Subsequent Hollywood-produced Westerns demonstrated strong revisionist tendencies and a critical attitude toward classical trends. Close viewings of several Westerns released in the last ten years, however, reveal a marked resurgence of interest in visuals and narratives which not only reference, but celebrate, the classical Western period. Additionally, a less conventional Western, Meek's Cutoff, turns a critical eye toward the cynical gender theory of the title character. These "New Westerns," viewed as a small, distinct group and removed from the glut of films released during the genre's Golden Age, demonstrate a reversal of revisionist attitudes in both mainstream and independent cinema. In particular, Meek's Cutoff, widely considered a "slow" and challenging art film, provokes with its dramatic breakdown of the Western form a consideration of the lingering potential of this neglected genre. The existence and box office success of more mainstream New Westerns prove these implications to be far more than idle musings or misplaced nostalgia.

Correlations Between Ankle Laxity and Dynamic Postural Stability

Jenny Brickman
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Ankle sprains are the most common injury in collegiate athletics, and approximately 40-70% of those who sprain their ankle will develop chronic ankle instability (CAI). CAI is defined as developing repetitive sprains and persistent symptoms after initial ankle sprain, and may be perpetuated secondary to laxity of the lateral ankle ligaments. Our objective was to determine if mechanical laxity secondary to sprain contributes negatively to dynamic postural stability. Twenty-three volunteer recreational athletes with a variable ankle injury history completed a jump landing task and had their ankle laxity quantified. Participants performed jump landings at 50% of their maximum jump height, and the dynamic postural stability index (DPSI) was used to quantify an individual's ability to maintain balance while transitioning from a dynamic moving state to a static standing state. Its four components include indices in the anterior-posterior (APSI), medial-lateral (MLSI), and vertical (VSI) directions. Higher scores indicated decreased dynamic postural stability. The Ligmaster instrumented arthrometer was used to measure ankle ligament laxity by measuring joint displacement to 150dN. Pearson bivariate correlation coefficients were calculated between DPSI indices and joint displacement. Composite DPSI was moderately significantly correlated to joint displacement ($r = 0.46$; $p < 0.001$). However, the directional dynamic balance indices, APSI, VSI, and MLSI were not significantly correlated with displacement. As laxity increases, so does composite DPSI, indicating that the ability to balance decreases. Increased laxity may play a role in development and perpetuation of CAI and may need to be addressed during rehabilitation to prevent later injury.

Insertion of Hemagglutinin Gene from H5N1 into Parainfluenza Virus Type 5 (PIV5) Offers Immunity in Mice Against H5N1 Challenge

Kathryn Briggs
Dr. S. Mark Tompkins, Infectious Diseases, College of Veterinary Medicine

Parainfluenza virus type 5 (PIV5) is a non-segmented, negative strand RNA virus in the Paramyxoviridae family. With few cytopathic effects on the host cell, PIV5 infects many cells types and lacks a DNA phase (excluding the possibility for viral gene insertion into the host genome). Importantly, while it is able to infect humans, it does not induce any known illness. To discern the viability of PIV5 as a vaccine vector, the hemagglutinin (HA) gene from highly pathogenic avian influenza virus (HPAIV) H5N1 was inserted into the PIV5 virion at various locations, taking advantage of the gradient of gene expression observed in paramyxoviruses. In the "base model" construct (ZL48), the transgene was inserted between the hemagglutinin-neuraminidase (HN) gene and the large (L) polymerase gene of PIV5. In the ZL46 construct, it was inserted closer to the leader sequence between the small hydrophobic (SH) gene and the HN gene. In the ZL47 construct, the transgene was inserted even further upstream between the V/P gene and membrane protein (M) gene. Insertion of the HA protein into PIV5 does not appear to increase virulence in mice and induces a robust immune response against influenza virus. The capacity for rPIV5-H5 as a live vaccine was examined in 6-8-week-old BALB/c mice, comparing the levels of transgene expression and assessing the dose required to elicit protection against HPAIV H5N1 challenge. Because gene expression in paramyxoviruses decreases in relation to proximity to the leader sequence, we expect the ZL47 construct to offer the best protection.

Black Stereotypes in Reality Television and the Reinforcement of Prejudiced Attitudes

Melissa Brown, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Kecia Thomas, Pscyhology, Franklin College of Arts & Sciences

Three studies examined depictions of Black Americans in reality television and factors that influence whether White Americans perceive these depictions as realistic. In Study 1, independent raters content analyzed reality dating shows. Depictions of Black Americans included invisibility, tokenism, stereotypical typecasting, and over-representation/idealization of the minority. In Study 2, 283 White undergraduate students viewed clips from four different shows before completing surveys of racial attitudes, interracial contact, and reality television show perceived realism. Afterward, they indicated their interest in engaging in interracial contact. Results indicated that shows depicting tokenism reduced a willingness to engage in interracial contact. Additionally, individuals who reported low interracial contact were more likely to perceive negative stereotypical images of Black Americans as true to life and support an anti-Affirmative Action petition. Stereotypical depictions of Black Americans viewed as "reality television" may fuel a self-perpetuating cycle of prejudice, stereotyping, and racial segregation that greater real-world interracial contact might counteract. Implications for stereotype maintenance, prejudice reduction, and the impact of television media on racial minorities are discussed.

Giving Voice to Silence: Theatre and Community in *He Said, She Said, Zhe Said: Gender Stories*

Tyler Bugg
Dr. Emily Sahakian, Theatre & Film Studies, Franklin College of Arts & Sciences

Community-based theatre is a field of arts practice in which theatre artists collaborate with people whose lives directly inform the subject matter to create collective meaning and heightened social dialogue about a social problem. This research explores the techniques of community-based theatre in the University of Georgia campus production of *He Said, She Said, Zhe Said: Gender Stories*. The production, authored and performed by the students of the university's Fall 2011 THEA4800 class, of which I was part, conducted surveys of scholarly writings and primary fieldwork in exploring issues surrounding themes of gender and sexuality. The research and fieldwork were then directly used in imagining, devising, and scripting stage scenes that responded to the discoveries within the research and fieldwork and employed community-based theatre techniques in communicating them to an audience. Now post-performance, this presentation aims (1) investigate how my particular research and fieldwork was transformed into a meticulously constructed scene entitled "26 Tellings: Rape on Repeat," (2) how it evolved within the context of the production's other pieces and broader message, and (3) based on observations from a post-show audience talk back, how the scene and its message were received by an audience. As a medium for dialogue and social and political engagement, the community-based theatre tactics used in the production represent a powerful method for facilitating a broader dialogue committed to social change on campus, in the surrounding community, and ultimately across the world.

'All Truth is Bitter': Legacies of a Post-Apartheid, Post-TRC South Africa

Tyler Bugg
Dr. Stacey Mitchell, International Affairs, School of Public & International Affairs

Early twentieth-century apartheid South Africa, defined by a systematic control of race relations in the hands of the intellectual and political elite, evolved into the darkest blot on the history of South Africa's reputation. Although the institutions of apartheid were abolished in the early 1990s, the legacy of apartheid continues to pervade political, economic, and cultural life in South Africa. This presentation seeks to examine how the ideologies that validated apartheid have been replicated in contemporary South African society, stunting the objectives of the country's Truth and Reconciliation Commission (TRC) in normalizing a post-racial, post-conflict society. The research takes a multi-sourced approach: surveys of scholarly writings addressing apartheid's long-term effects, collections of popular fiction, poetry, and media portrayals of apartheid, and primary court and victim testimony shed new light on the conditions of inequality at the center of apartheid, conditions that continue to divide a country along racial, ethnic, and socioeconomic lines. Analysis of each indicates that crime, rape, and assault rates are still among the world's highest; the government's deceptively progressive constitutional reforms are largely unseen; and poorly funded education and agricultural systems are largely ineffective and unequal. The resulting culture of inequality perpetuates the same rhetoric and ideology that sustained systems of apartheid for decades. In understanding the factors that made apartheid a force of power just a few decades ago, the hope for continuing to correct past wrongs and forge progress can be more positively and thoroughly fulfilled.

Anesthetic Complications in Dogs Undergoing Surgery for Liver Disease

Brigid Burns
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Liver disease affects several body functions of an animal that are important to consider from an anesthetic standpoint. A dog with ongoing gallbladder issues, such as cholecystitis (inflammation), rupture, or cholelithiasis (stones) associated with disease may undergo a cholecystectomy, in which the gallbladder is completely removed. Clinical experience has shown that patients with gallbladder disease have a higher risk of anesthesia complications, including a noticeable drop in blood pressure. This retrospective case-control study compared surgical records of dogs of similar breed, age, and weight that underwent liver surgery at the Small Animal Teaching Hospital at the University of Georgia to determine different rates of anesthesia complications between dogs that have their gallbladders removed and dogs that do not. Our hypothesis was that dogs that have their gallbladders removed would have a higher rate of anesthesia complications than those that do not. In order to detect possible correlation between cholecystectomies and anesthesia complications, we analyzed certain anesthesia-related variables in the hospital medical records. If there is any association upon completion of this study, in the future, anesthetists may be able to better predict any complications that may arise during liver or gallbladder-related procedures and develop a more efficient plan of action before the time of surgery. This study will also help the veterinary community better understand the role of the gallbladder and the effects of its removal in the dog.

Comparative Genomics of Ribosomal RNAs in Malaria Parasites

Allyson Byrd
Dr. Jessica Kissinger, Genetics, Franklin College of Arts & Sciences

Ubiquitous to all life, ribosomal RNAs (rRNAs) are components of protein-synthesizing ribosomes. In previously studied eukaryotic genomes, genes encoding rRNAs are distributed in multiple high-copy tandem arrays, each of which can contain dozens of copies of the rRNA three gene casette (18s, 5.8s, and 28s). Genome sequences from the parasitic genus *Plasmodium,* the causative agents of malaria, are atypical, differing in the copy number and organization of rRNA genes. There are only 4-8 non-tandem gene casettes per genome. *Plasmodium* species are also unique in having divergent rRNA genes that are differentially expressed during parasite developmental stages. The evolutionary history and genome biology of rRNAs within the *Plasmodia* have historically been under-investigated. I have used computational methods to investigate rRNAs from the sequenced genomes of the human-infecting *P. falciparum, P. knowlesi,* and *P. vivax,* and the rodent-infecting *P. berghi* and *P. chabaudi.* I have mined sequence, expression, and synteny data to identify full-length and partial rRNA genes in each genome. Curated genes were used to compare and contrast rRNA complements, distributions, secondary structures, and evolutionary histories within and between species, providing novel information on *Plasmodium* rRNA biology. Eventually, a better understanding of the nuances of *Plasmodium* rRNA biology and their role in parasite development may aid in determining their potential as antimalarial targets.

The Role of Coagulation in Cerebral Malaria in the Mouse Model

Kelsey Campolong
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Malaria caused by *Plasmodium falciparum* continues to be a major health concern, with nearly one million fatalities yearly. In severe manifestations, parasites adhere to the cerebral blood vessels. This condition is called cerebral malaria (CM) and typically occurs in children under five years. Although full recovery is possible, many patients die, and about one in four CM survivors suffers from long-term cognitive deficits. The development of CM is not well understood since it is difficult to study in humans; however, *Plasmodium berghei* ANKA infection in laboratory mice parallels the human disease. Coagulation in cerebral blood vessels is one mechanism thought to be involved in CM development. This study investigates the role of tissue factor, the protein that activates the coagulation cascade, in disease pathogenesis. Experimental mice genetically modified to lack mouse tissue factor (TF) and express 1% of the normal level of human tissue factor (low TF mice) were paired with control TF-intact mice. Following infection with *P. berghei* ANKA, mice were evaluated daily with behavioral and neurological tests. Test results indicating development of CM triggered immediate euthanasia. Non-CM mice were euthanized after twelve days. A total of 15 mice were infected: seven low-TF mice and eight control mice. Ten of the infected mice developed cerebral malaria by day six post-infection. Of the remaining five, three expressed low levels of TF. This preliminary data demonstrates that reduced levels of TF may offer protection against CM, but further experimentation is necessary.

Arterial Flow Pattern in People with Peripheral Arterial Disease

Neal Canlas,
Michael Theobald
Dr. Kevin McCully, Kinesiology, College of Education

Peripheral arterial disease (PAD) is a major form of vascular disease that contributes to poor health and a lower quality of life. A limitation to treating PAD is the imprecision of current detection methods. Previous studies have reported greater turbulence and velocity as well as a slower time course of reactive hyperemia. The current study analyzed the data from a previous study (6 subjects with PAD and 14 without PAD) and had two aims: 1) compare analyses of flow velocity data between a custom-written MATLAB program and the built-in ultrasound analysis program; 2) investigate the relationship between time course of reactive hyperemia as analyzed by the custom-written program and PAD severity measured with Ankle Brachial Index (ABI) test. A strong correlation was found between the two analysis programs when examining the time to peak ($R2 = 0.99$) and time to half-returned velocity ($R2 = 0.94$) in the femoral artery, suggesting that the custom-written program is a valid analysis technique. A moderate correlation was observed for both ABI compared to time to half-returned ($R2 = 0.4$) and time to peak velocity ($R2 = 0.6$), suggesting that time course of reactive hyperemia is a potential indicator of the disease severity. Subjects with a wider range of PAD severity will be needed to further confirm the correlation between the time course of reactive hyperemia and PAD severity.

Mating Regulates Germ Line Stem Cell Division Frequency in Testes of *Drosophila melanogaster*

Vinay Choksi
Dr. Cordula Schulz, Cellular Biology, Franklin College of Arts & Sciences

The replenishment of cells, such as skin cells, depends on the activity of stem cells. How stem cells divide to respond to the demand for specialized cells is not well understood. To explore this question, we use the model organism *Drosophila melanogaster*. In *Drosophila* testes, sperm cells are reproduced from germline stem cells (GSCs). To investigate if GSCs respond to the demand for sperm, we exposed males to females and control males and found that males have a significant increase in GSC division frequency in the presence of females compared to males. To explore possible pathways regulating this response, we investigated the effect of cuticular hormones on GSC division frequency. Cuticular hormones are signaling molecules that act as cues for mate choice. *Drosphila* males exposed to female cuticular hormones displayed an increase in GSC division frequency compared to males exposed to male cuticular hormones. We conclude that the presence of females induces a pathway that regulates SC division frequency in response to mating. Next we asked if mating leads to an increase in GSC division frequency. Mating behavior depends on the activation of specific neurons called fruitless neurons. Male fruitless mutants are not able to differentiate between sexes and attempt mating both sexes. Fruitless mutants also displayed an increase in GSC division frequency, suggesting that these neurons are part of the regulatory circuit for the response of the GSC to mating. The future direction of these experiments is to deduce the biological pathway that leads to GSC division.

Algae Biofuel Development: Growth Efficiency

William Costanzo, CURO Summer Fellow
Dr. K.C. Das, Biological & Agricultural Engineering, College of Agriculture & Environmental Sciences

The government has officially made the call for biofuels to replace traditional gasoline fuels. The Energy Independence and Security Act, passed in 2009, calls for "32 billion gallons of biofuels to be produced per year by 2022." Many of the traditional biofuel sources are either not efficient enough (energy density and productivity are too low) or would require too much of the U.S. cropland to be effective, Algae biomass is an attractive source for biofuels that concurrently satisfies both of those requirements. Previous work has shown that the biochemical stimulant *Naphthalene Acetic-Acid* (NAA) can cause the algae to grow at higher productivities and with more lipid content than when grown without the biochemical stimulant. My research sought to determine whether microalgae grow more effectively if that stimulant is administered as a single dose on a particular non-starting day of the 10-day cycle or as smaller doses spread over a period of time within the growth cycle. Across five different species (*Cso, Av, Ns, Db, Sb*) it was determined that adding *NAA* on a day other than day 0 (depending on the type of algae) produced the best increase in growth. Each species also concluded their cycles with an overall lipid content higher than that of the control. An average productivity increase of nearly 25% for all samples can be obtained with an additional cost of only $1.20/gram of stimulant (price of stimulant may vary depending on vendor).

Racial Inclusivity and Exclusivity in HBO's *True Blood*: A Viewer-Response Critique via Hans Robert Jauss's "Horizon of Expectations"

Elizabeth Crowley
Dr. Michelle Ballif, English, Franklin College of Arts & Sciences

In recent years, vampire fiction has swept the main stage of popular culture. Works like *Twilight* and *The Vampire Diaries* have embraced this trope, as *Dracula* did years before. Alan Ball's television series *True Blood*, though, is quite different from the other, largely simple, contemporary vampiric narratives. Although some critical work has been done on the series, especially in reference to LGBT parallels, no scholarship has yet examined how the show treats the two complex and opposing planes of humanity and supernaturalness. The human plane parallels a current colorblind ideology of complete inclusivity, while the supernatural one parallels historical periods of complete disenfranchisement—pre-Civil Rights America, the Holocaust, etc. The purpose of this study is to examine how the viewer uses this duality to interpret the series as a whole. Using Hans Robert Jauss's theory of reader response—"horizon of expectations"—I explore how these historical and contemporary references influence a viewer's interpretation. Ultimately, this thought experiment demonstrates a viewer's response to the human plane as an identification of the impracticality of a completely colorblind world and to the supernatural plane as an identification of the injustice of discrimination. The result of combining both interpretations is that the viewer paradoxically discerns a fictional/human plane and a non-fictional/supernatural one. This understanding revitalizes Jauss's theory, explains the complexities of *True Blood*, and encourages similar studies on other popular media outlets.

Proteomic Analysis of the Tomato/ *Botrytis cinerea* Interaction

Dervin Cunningham, Jr., CURO Honors Scholar, CURO Summer Fellow
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

*Botrytis cinere*a attributes to the post-harvest rot of more than 200 species of fruit and vegetables. As these produce ripen, their cellular wall drastically degrades, making them more susceptible to pathogens. Significant protein-protein interactions occur between the necrotrophic fungal pathogen, *Botrytis cinerea* (*B. cinerea*), and the tomato fruit. By describing host and pathogen proteomes simultaneously in infected tissues, the plant proteins that provide resistance and allow susceptibility and the pathogen proteins that promote colonization and facilitate quiescence can be identified. This study aimed to characterize the fruit and fungal proteins occurring in the *B. cinerea*/tomato interaction using shotgun proteomics. Mature green, red ripe, wild type, and *rin* and *nor* mutant tomato fruit were infected with *B. cinerea* B05.10. After 5 days the infected tomatoes were gently agitated in a 1.5M NaCl solution followed by a SDS and heat treatment to collect solubilized proteins. The collected proteins were separated on a one dimensional SDS-PAGE gel, followed by in-gel digestion. Peptides were then analyzed by LC-MS/MS on a linear ion trap mass spectrometer. Data was searched using Mascot algorithm. Proteins were identified by combining the *B. cinerea* BO5.10 (Broad Institute, MA), and T4 databases (Genoscope, France) with a tomato protein database (SOL Genomics Network, Cornell University, NY). A decoy database was constructed by reversing the sequences in this target database. Statistically significant proteins were determined at a 1% protein FDR. The composition of the collected proteins populations and their putative functions allow for a better understanding of

the plant-pathogen interaction mechanism.

A Therapeutic Nanoparticle Platform for Targeting Mitochondrial Superoxide

Kasey Darley
Dr. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Mitochondrial superoxide (O2-) has been implicated in the pathogenesis of human diseases including aging. It is important for the development of oxidative stress, and antioxidant strategies specifically targeting this organelle could have therapeutic benefits. One challenge of therapeutics targeting mitochondrial dysfunction is distributing drugs to the organelle. Commonly used antioxidants have proven ineffective in clinical trials because these agents are not adequately delivered to the mitochondria. Emerging insights into the molecular pathogenesis of aging suggest that inflammatory processes promote aging. We postulated that mitochondrial targeting of superoxide scavenging would have possible effects such as anti-aging, and the development of organelle-targeted delivery of antioxidants combined with anti-inflammatory agents could incite new therapeutic approaches to the anti-aging of cells. We speculated that a nanoparticle platform based on functionalized polymers could be beneficial for mitochondria-targeted anti-aging strategies. The biodegradable polymer poly (lactic-*co*-glycolic acid) (PLGA) is capable of encapsulating small- and macro-molecular payloads with a wide range of physicochemical properties, releasing them in a regulated manner. Polyethylene glycol (PEG) is a biocompatible polymer that promotes long-circulating nanoparticles and is used to create biodegradable PLGA-*b*-PEG copolymers possessing terminal lipophilic ligands, which can cross into the mitochondrial matrix space. These polymers will be blended to nanoparticles encapsulating combinations of antioxidants and anti-inflammatory agents by mixing targeting ligand-functionalized polymer with PLGA-*b*-PEG-OH. By combining controlled release polymer technology and targeted delivery approaches, we aim to deliver antioxidants to the mitochondria of cells along with anti-inflammatory agents in a regulated manner resulting in a more effective management of aging.

An Alternative Perspective?: Dora Mayer's Contributions to the Peruvian *Indigenismo* Movement

Ruth Davis
Dr. Oscar Chamosa, History, Franklin College of Arts & Sciences

The Peruvian *indigenismo* movement, spanning roughly from the 1880s until the 1950s, centered on the social and economic empowerment of the Peruvian indigenous peoples. During the 1920s and 1930s, under the influence of Marxists such as José Carlos Mariátegui and the often subversive rhetoric of Luis Eduardo Válcarcel, two of the most influential *indigenistas* during this period, participants in this movement acquired a particularly revolutionary character. In contrast, Dora Mayer de Zulen, one of the co-founders of the *Asociación Pro-Indígena* [The Pro-Indigenous Association] and a contemporary of these *indigenistas*, rejected revolution and condemned Marxism as another example of Western hegemony and instead opted for a more legalistic approach to socially uplift indigenous Peruvians. However, Mayer's writing was not limited to discussion on the plight of the indigenous peoples but also explored national and international intellectual currents, international policy, the World Wars, the War of the Pacific, and workers' rights. Nevertheless, while she was certainly a prolific writer and an active agent for national and international change, Mayer's contribution to the *indigenismo* movement was and has remained largely underappreciated. I am interested in examining how her marginalized position within the intellectual field of *indigenismo* interacts with the

expression of her ideas by comparing her nationalistic ideologies and opinions on the revival of the indigenous peoples of Peru to those of her contemporaries. Particularly, I am curious to explore how her position as a female, an immigrant, and a *limeña* [Limenean] seem to motivate these differences.

Do Mushroom-Feeding *Drosophila* Self-Medicate with Alpha-Amanitin in Response to Nematode Parasitism?

Catherine Debban, CURO Scholar
Graduation Distinction
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

Behavioral adaptations to parasites form an important component of host-parasite interactions. Self-medication is a behavioral adaptation in which animals change their feeding preferences in response to parasitism, resulting in decreased parasite virulence or transmission. Since mushroom-feeding *Drosophila* can tolerate the usually deadly toxin alpha-amanitin, but their *Howardula* nematode parasites cannot, I tested whether these flies might use the toxin to self-medicate in response to infection with nematodes. In this study, I used *Drosophila putrida* and *Howardula aoronymphium* to explore whether alpha-amanitin cures flies infected by *Howardula*, whether alpha-amanitin harms uninfected flies, and whether infected flies have an increased preference for alpha-amanitin. In addition, I tested whether flies from populations inside and outside the range of the nematodes have different toxin preferences. Considering the results of this study, it is unlikely that the flies self-medicate using alpha-amanitin. However, since there is some difference between the toxin preferences of flies from inside and outside the range of nematodes, it is possible that the flies somehow use the mushrooms to protect their offspring from nematode infection.

The Responsiveness of Mothers in Organic and Inorganic Nutrition in Ghanaian Children and the Social and Economic Implications

Tanya Dieumegarde
Dr. Alex Kojo Anderson, Foods & Nutrition, College of Family & Consumer Sciences

The objective of this study was to assess mothers' perceptions of the causes of their child's malnutrition and thus their responsiveness to the child's condition. This was a qualitative, cross-sectional study. In-depth interviews were conducted with mothers of children diagnosed with organic (n = 2) and inorganic (n = 6) malnutrition, as well as reviewing their medical chart for data extraction in the only children's hospital in Ghana. This was done in concurrence with the nutritional rehabilitation program of the Nutrition Rehabilitation Clinic. Of the eight mothers with malnourished children observed and interviewed, only one correctly attributed poor nutrition as the cause of malnutrition and admittance to the hospital, while the remaining seven did not have any idea of the role of nutrition. Overall, mothers of the organic cases were more responsive to the nutritional care of their child at the clinic, while some of the mothers of the inorganic cases withheld the PlumpyNut supplied by the clinic. This observation was consistent with the rate of recovery of the two organic cases compared to their inorganic counterparts, according to their respective medical charts. Our observation and interaction with the mothers suggested a lack of nutrition knowledge and awareness in child feeding. There is therefore a need for nutrition education in the area of child feeding in resource-poor areas and a rehabilitation program that strictly requires mothers' involvement.

The Role of Galacturonosyltransferase in the Acetylation and Methylation of Homogalacturonan During Pectin Biosynthesis

Alexandra Dodd
Dr. Debra Mohnen, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Homogalacturonan (HG) is an essential glycan domain in plant cell wall pectic polysaccharides. This project explored the range of enzymes activities that modify HG during synthesis, specifically, the addition of acetyl and methyl groups. Labeled HG oligosaccharides (oligogalacturonides, OGAs) were created by reaction with fluorescent 2-amino-benzamide. The resulting 2-AB-OGA was incubated with UDP-GalA and galacturonosyltransferase (GalAT) present in an SP-Sepharose purified solubilized membrane fraction from Arabidopsis suspension cultured cells which contains the GAUT1:GAUT7 GalAT complex. The fluorescently labeled-OGA was used as substrate to detect HG methylation and acetylation activity. Fluorecently labeled OGAs were incubated with crude microsomal membrane fractions, SP-Sepharose purified GAUTs, and GAUT1/GAUT7 complexes immunoprecipitated using monoclonal antibodies against either GAUT1 or GAUT7. Small scale reactions were used to verify enzymatic activity by polyacrylamide gel electrophoresis (OGA-PAGE), and large scale reactions were carried out with verified enzymes. The resulting product was eluted through a size-exclusion chromatography column and analyzed using thin- layer chromatography. Analysis by matrix-assisted laser desorption/ionization mass spectroscopy revealed the size of the labeled OGAs and the presence of acetyl groups, providing evidence for acetylation by native enzymes during HG production. Up to eight GalA residues with four acetylations have been observed thus far. Ultimately, our goal is to determine whether GalA addition is concurrent with the acetylation or methylation steps in HG biosynthesis. Knowledge about the enzymatic activity that builds pectic polysaccharides as well as other plant cell wall polymers may provide information needed to support the development of a sustainable bioenergy economy.

The Sweet Connection: O-linked β-N-Acetylglucosamine Transferase and Cancer Stem Cells

Sarah-Bianca Dolisca
Dr. Michael Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

There is increasing evidence that a variety of cancers are initiated and maintained by a small proportion of cells called cancer stem cells (CSCs). Recent results from our lab show that deletion of GnT-V, which catalyzes a specific modification of N-glycans with β(1,6) branching, reduced the size of the compartment of CSCs in the her-2 mouse model, consequently leading to inhibition of tumor onset. O-linked β-N-Acetylglucosamine Transferase (OGT) is an enzyme that catalyzes the transfer of O-linked β-N-Acetylglucosamine (O-GlcNAc) from Uridine Diphosphate N-Acetylglucosamine (UDP-GlcNAc) to serine and theronine residues of target proteins. OGT is upregulated in metastatic cancer cells in a highly context-dependent manner that may serve as a mechanism that enables tumorgenesis. The notable characteristic of cancer phenotype further supports the hypothesis of OGT's involvement in oncogenesis because the switch from oxidative phosphorylation to glycolytic pathway at the cellular level produces an increase in the necessary intermediates for the hexosamine biosynthetic pathway (HBP). HBP increases the amount of O-GlcNAc, an intermediate that induces the activity of OGT. In the present study, small interfering RNA is used to reduce OGT gene expression in colorectal and mammary cell lines. A series of comparative experiments will be conducted

on the control and cancerous cell lines to support the working hypothesis that downregulation of OGT will decrease the metastatic properties of cancerous cells by regulating the population of CSCs and ultimately bring insight about the link between OGT activity and CSCs maturation and proliferation.

Increasing Access to Primary Care for Low-Income Rural Georgians

Allison Doyle
Dr. Richard Schuster, Health Policy & Management, College of Public Health

A lack of primary care infrastructure and accessibility to affordable health care is a leading cause of adverse health outcomes in rural areas nationwide. In rural Georgia counties, this lack of infrastructure impedes access for all rural Georgians but most acutely for low-income, uninsured and underinsured Georgians, who have even more limited health care options. Rural Georgia counties have higher rates of chronic diseases and uninsured patients. They also have substantially higher rates of hospital emergency room usage by the uninsured than in metropolitan counties, indicating a lack of options in seeking health care. This paper examines three policy alternatives that Georgia state and local health care authorities can pursue to increase accessibility to health care in rural counties through the augmented use of federally qualified health centers (FQHCs). As they must provide health care services regardless of ability to pay, FQHCs are an optimal mechanism for providing high-quality health care to low-income populations and are heavily invested in by the Affordable Care Act. The effectiveness of the policy alternatives are evaluated through an analysis of health outcomes in several case studies according to four criteria: cost of policy implementation, increased quality of care provided, increased accessibility to health care, and political feasibility. The analysis indicates that when rural FQHCs and local rural hospitals pursue a policy of collaboration, they can provide expanded health care accessibility to the underserved in rural communities while strengthening their vital role in the rural primary care safety net.

Effect of Anesthetic Variables on Recovery Time in Dogs

Katrina Egan
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Knowing the most efficient route to recovery is important because not only does it help the aesthetician, it can reduce the amount of postoperative morbidity and mortality. The purpose of this retrospective study was to determine all the variables that may be associated with anesthesia recovery and see how they affect the speed of recovery in dogs that were anesthetized with isoflurane, desflurane, or sevoflurane. The hypothesis was that temperature, health status, anesthesia duration, and type of procedure would help predict the best route to recovery. Anesthetic records of dogs treatd at the Veterinary Teaching Hospital at the University of Georgia between July 1, 2008 and June 30, 2011 were included in evaluation for this study. Multiple linear regressions using backwards elimination were used to build a model for recovery, using all other measured variables as independent variables. For these data, significance was set at $p < 0.05$. The adjusted R2 value indicates how much variance in the dependent parameter is explained by the model. Nine hundred dogs were included in the study. The final model for predicting recovery time had an R2 of 0.117 with weight, acepromazine administration, and hypotension being significant predictors for a longer and butorphanol and propofol administration for a shorter recovery time. In conclusion, anesthesia-related variables had a significant but minor effect on recovery time. Only about 12% of recovery time was due to these anesthesia-related variables. This means that

the other percentage was due to other, unknown variables.

Production of Saccharification Enzymes by Recombinant Fungus Grown on Pectin-Rich Biomass Materials

Abid Fazal, CURO Summer Fellow
Dr. Joy Peterson, Microbiology, Franklin College of Arts & Sciences

Pectin-rich biomass such as sugar beet pulp (SBP), citrus waste, and apple pomace contain 15-30% pectin, a polymer of galacturonic acid. These materials are viable feedstock sources for alternative fuels, as they are not used for human consumption. In order for these feedstocks to be used, the polymers must be hydrolyzed so that monomeric sugar molecules are released, which the ethanologen can ferment. Commercial enzymes such as pectinase, cellulose, and hemicellulase are required to degrade the plant polymers, which increases the price of industrial ethanol production. Commercially, cellulase and hemicellulases are produced from the ascomycete *Hypocrea jecorina* and pectinase from *Aspergillus* species, as wild type *H. jecorina* produces insufficient amounts of pectinase. Thus, *H. jecorina* Rut-C30 was genetically engineered for the production of pectinase (Pec2) using the microprojectile bombardment method. Upon purification of the recombinant polygalacturonase enzyme (Pec2), the optimal pH and thermal stability was studied by measuring enzyme activity and compared against *A. niger* polygalacturonase (ANP). The recombinant conidia spores were grown in 5L flasks of SBP media containing lactose (as *cel7A* inducer), stabilizers, and other nutrients under saturated oxygen conditions with continual agitation at 28°C. After 7 days of proliferation, the enzyme cocktail was harvested and characterized for the production of a variety of saccharifying enzymes. Under similar conditions of growth, the recombinant strain of *H. jecorina* produced larger amounts of pectinase than its wild type counterpart. Further studies with this recombinant fungus can help decrease ethanol production costs, making ethanol a more efficient alternative to fossil fuel.

Influence of Different Cell Storage/Culture Conditions on Spontaneous Proliferation and Tyrosine Kinase Receptor Inhibition in Two Feline Injection-Site Sarcoma Cell Lines, In Vitro

Brittany Feldhaeusser
Dr. Robert Gogal, Jr., Anatomy & Radiology, College of Veterinary Medicine

Optimizing cell culture conditions is important when studying cell proliferation and viability, particularly when evaluating response to cytotoxic compounds. Situations can arise in which these cells are stored at less than optimal conditions prior to culture. A change in cell storage conditions can adversely impact proliferation and viability in mortal cell lines. However, little is known regarding the effects on immortal feline cell lines. In the present study, two feline injection-site sarcoma cell lines (KH and Hamilton) were evaluated under standard culture conditions and 3 alternate storage/culture conditions for spontaneous proliferation rate and sensitivity to a novel tyrosine kinase inhibitor, which was assessed by 7-aminoactinomycin D and cytology. Spontaneous proliferation did not differ across various FBS concentrations; however, the standard and delayed techniques showed higher rates of spontaneous proliferation, suggesting a need for prior cell attachment. When normalized to cells untreated with masitinib, the IC50 values for masitinib were comparable across all the different culture techniques. Our preliminary findings suggest that select feline sarcoma cell lines can be subjected to various storage/culture conditions yet yield similar proliferation and cytotoxicity data.

Identification of GABA-Responsive Neurons in the Zebrafish Brain
Hope Foskey, CURO Honors Scholar
Dr. Jim Lauderdale, Cellular Biology, Franklin College of Arts & Sciences

Over 2 million people in the United States have experienced unprovoked seizure activity or been diagnosed with epilepsy. While medication has been developed that can help some people control their seizures, the mechanism by which seizures occur is not well understood. Zebrafish (*Danio* rerio) is emerging as a vertebrate model in the study of seizure disorders. Seizures in zebrafish can be induced by exposure to the chemoconvulsant pentylenetetrazol (PTZ). PTZ blocks the A and C receptors of the major inhibitory neurotransmitter in the brain, GABA (GABAAR and GABACR). However, the neural circuits by which PTZ propagates seizure activity are unknown. The purpose of my experiments was to identify the neurons likely to be involved in generating PTZ-induced seizure activity. To do this, an adult zebrafish brain was cryosectioned transversely, and GABA-responsive neurons were identified by immunolabeling for GABAAR, GABA, and GAD65/67. GAD is the enzyme that catalyzes the decarboxylation of glutamate to GABA. Additionally, neurons that exhibited high levels of electrical activity during seizure were identified by immunolabeling for *c-fos*, a protein whose expression in neurons is increased when under stress. These experiments identified for the first time the neural pathways in the zebrafish brain that are affected by PTZ and provided insight into the pathways that normally are affected in human seizures.

Segregation in a Modern Age: Systematic Patterns and Consequences
Emily Fountain
Dr. Charles Bullock, Political Science, School of Public & International Affairs

This paper details the history of the desegregation of Tattnall County, GA, specifically examining the "deliberate speed" with which county schools complied with Brown v. Board of Education, as well as the emergence of a local private school and its impact on the local school system in terms of test scores, dropout rates, and graduation rates. A series of interviews with former students and school officials, from the public and private institutions, were conducted, yielding important perspective on history and attitudes, as well as relevant data on graduation rates, dropout rates, and test scores. Additional statistical information was collected from public records. The collected data suggests that desegregation led to the formation of a local private school, which may serve as a persistent form of segregation, especially with regards to class.

Infection Modifies the Effects of Stress on Immune Function in Birds
Melanie Fratto, CURO Summer Fellow
Dr. Vanessa Ezenwa, Odum School of Ecology

A paradox of the immune response to stress is that, under stress, the ratios of phagocytic leukocytes increases, but the ability of blood cells to kill bacteria decreases. In this study, house finches, *Carpodacus mexicanus,* infected with *Mycoplasma gallisepticum* and ones with no obvious infection were captured to study this paradox. This bacterial infection is common among finches and can be spotted by the development of red, swollen eyes. The effect of stress from capturing and holding wild house finches for two hours was assessed by counting white blood cells and running an assay in which plasma is exposed to E. coli to measure the innate killing ability of blood. The ratio of heterophils to lymphocytes is an accurate measure of stress and is frequently used in stress studies, and this ratio was compared in pre-stress and post-stress samples from the same bird. The results of this study show that the two hour holding period increased the stress levels of both

infected and uninfected birds, and that an existing infection alters the effects of stress on immune function. This study will add to the current understanding of how stress affects an animal's immune function and, therefore, risk of infection.

A Portrayal of Power: Black Nationalism in the Documentary *Now is the Time*

JoyEllen Freeman, Foundation Fellow, CURO Honors Scholar, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Barbara McCaskill, English, Franklin College of Arts & Sciences

"Now is the time." This phrase embodies the impatience that simmered within the black community during the late 1960s. Due to the slow progression towards racial equality and the subsequent emergence of Black Nationalism, many African Americans began to focus less on racial integration and more on racial solidarity as a means of achieving social justice. Hence, various media sources attempted to portray this new mood within the African American community by associating negative images and language with the Black Power Movement. The 1967 documentary *Now is the Time*, however, takes a different approach to Black Nationalism. Using microfilm copies of twentieth-century newspapers such as the *Philadelphia Inquirer* and the *New York Times*, multiple anthologies of African American literature, and scholarly books about Black Nationalism, I have found that *Now is the Time* uses selected works of canonized African American writers to legitimize the Black Power Movement. Although the film fails to include the voices of early African American writers, most likely due to the paucity of available sources, the words of writers such as Paul Laurence Dunbar (1872-1906), James Baldwin (1924-1987), and Langston Hughes (1902-1967) show that resistance and anger have characterized the African American experience since the earliest days of slavery. Examining *Now is the Time*'s normalization of Black Power addresses the conflicting portrayals of this movement in the late twentieth century and simultaneously probes questions about the way in which media sources portray Black Power in the post-Civil Rights Movement era.

The Effect of Protein Kinase Inhibitors on the Growth of *Plasmodium Falciparum*

William French,
Ryan McLynn
Dr. David Peterson, Infectious Diseases, College of Veterinary Medicine

Malaria is a serious, life-threatening disease that plagues the tropical areas of our planet, causing over 1 million deaths among adults and children annually. While treatments and medicines are available to combat the parasite that causes malaria in humans, *Plasmodium falciparum*, the issue of drug resistance is a dangerous problem in the effort to eradicate this disease. This research project, then, explores the effectiveness of recently developed protein kinase inhibitors on the prevention on *P. falciparum* growth. The project thus far has consisted of tests involving two of these drugs, which were originally developed for cancer therapy, with the hopes of their use in malaria treatment. *P. falciparum* parasites were grown *in vitro* and assessed for growth in micromolar and nanomolar drug concentrations over various time periods. The first drug, Sunitinib (generic name Sutent), is a receptor tyrosine kinase inhibitor and in these low concentrations clearly inhibited parasite growth. The other drug of interest, Akt inhibitor-IV, targets serine-threonine kinases and also demonstrated an ability to inhibit parasite growth at low drug concentrations. The experiments run as a part of this project, once the inhibiting effects of these drugs were observed, suggested an IC50 value for Sutent against *P. falciparum* of around 0.1 uM in a 4% hematocrit solution. The IC50 value for AKt inhibitor-IV appeared to be the same.

However, the exact mechanism of these drugs is unknown, and further studies are currently underway to determine whether the drugs have a target within the parasite or in the erythrocytes they invade.

Landscapes of the Interior: Ethnobotany and Senses of Place Among Karen Refugees

Terese Gagnon
Dr. Virginia Nazarea, Anthropology, Franklin College of Arts & Sciences

Though few are aware, Athens, Georgia is home to a small community of Burmese political refugees of the Karen ethnic group. Forced to leave their homeland by ongoing government persecution, they continue the process of remembering and reaffirming their cultural traditions while seeking meaning and belonging in their new environment. Through engaging in interviews and gardening practices with the Karen people, I seek to examine the anthropological phenomenon of the 'landscape of the interior,' particularly as experienced from a transnational perspective. Recognizing the value of preserving genetic biodiversity alongside culturally situated knowledge, I will record--through the process of memory banking--ethnobotanical traditions of the Karen and their cultural relationship to the natural environment. With information obtained from interviews I plan to produce a register of Karen plant species, including their characteristics, methods of cultivation, uses, and religious/cultural significance. In order to facilitate the clarity of interviews and build a reciprocal relationship, I will offer participants English language tutoring, focusing particularly on terms related to nature and gardening. My research will culminate in a thesis examining the role of 'interior landscapes' in shaping relationships with a new inhabited environment, an area of cultural anthropology largely understudied. This investigation seeks to benefit the Karen people and the community at large by encouraging the continuation of traditions, creating a sense of 'rootedness' and preserving ethnobotanical knowledge. I approach this research with the belief that practices of remembrance are often the strongest means of combating forces of oppression.

Access to Primary Care Services in Athens

Smitha Ganeshan, Foundation Fellow
Dr. Monica Gaughan, Health Policy & Management, College of Public Health

In Athens-Clarke County, 20% of the population is uninsured and 38% of the population receives Medicaid assistance. This 58% of the population faces severe financial and structural barriers in accessing primary care services. Most of the uninsured and Medicaid patients are seen in Athens Regional Medical Center's and Mercy Health Center's emergency departments, where the cost of care is mostly uncompensated and approximately three times higher than it would be in a primary care setting. Additionally, poor longitudinal care for chronic diseases results in repeated preventable hospitalizations. A thorough literature review was conducted to develop a policy proposal to make Athens-Clarke County more competitive for federal money and assistance through the Patient Protection and Affordable Care Act. After evaluating various policy alternatives based on a cost-benefit analysis, a proposal that calls for Athens to apply for a Health Professional Shortage Area (HPSA) designation was chosen. This designation will ultimately enhance Athens-Clarke County's applications for having a Federally Qualified Health Center (FQHC) and improve low-income patients' access to primary care services in Athens. An integrated health system that provides adequate access to primary care services for low-income patients in Athens-Clarke County would improve community health, reduce health disparities, and reduce health costs.

Abstracts

The Militarization of U.S. Intelligence?
Alexis Garcia, CURO Honors Scholar
Dr. Loch Johnson, International Affairs, School of Public & International Affairs

In his 2012 Defense Strategy Rollout, President Barack Obama declared, "the tide of war is receding." Yet, the U.S. is still spending one-third more on the military than the Cold War peak, and the United States is estimated to have almost 1,000 military bases abroad. It appears as if chief executives believe that the post-9/11 world is more dangerous than ever, brimming with existential threats. As Admiral Stansfield Turner remarks in *Burn Before Reading*, military officials "simply cannot overcome their conviction that the intelligence needed on the battlefield must always have number-one priority" (256). Considering that a large amount of the information the president uses to make foreign policy decisions comes directly from these intelligence leaders, it may be that the information these leaders have provided to the president is greatly influenced by their military backgrounds, which may in turn fuel the nation's concerns over defense issues rather than economic or political issues. In order to test this hypothesis, I will examine the occupational backgrounds of the past directors of the sixteen intelligence communities, as well as the Director of National Intelligence. The methodology of this study will be to use archival records to determine who has led these agencies. Based on this data, the study will contrast the extent to which military or civilian leaders have led the intelligence community. I predict that the project will reveal that a significant number of the nation's intelligence leaders have had military rather than diplomatic backgrounds. Thus, these findings should provide important insights that might help us understand America's large spending on defense.

Teacher Attrition: Possible Policy Solutions
Eilidh Geddes, Foundation Fellow, Avery Wiens
Dr. Sylvia Hutchinson, Language & Literacy Education, College of Education

Teacher attrition is a major problem facing the United States' education system. Almost half of all new teachers will exit the profession within their first five years. Estimates of the costs of continually replacing teachers run in the billions of dollars, and attrition has major implications for the quality of the teaching workforce, as teachers make their largest gains in their teaching ability in the first couple of years. Major solutions to the problem of teacher attrition in the literature include comprehensive induction, salary increases, improvement of pre-service training programs, and changes in working conditions. If a policy of comprehensive induction includes support and mentoring for new primary school teachers, as well as collaboration with the community and departments of education, then primary school teacher attrition rates will decrease. This paper will evaluate these policy alternatives in terms of the cost of implementing the program, the cost savings of the program, the reduction in the attrition rate, and the increase in the quality of the teaching workforce.

The Role of Cysteine Residues in the Function of Ras Converting Enzyme
Nisha George, CURO Summer Fellow
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Rce1p is a protease that is involved in the post-translational modification of Ras. Because of the well-recognized involvement of Ras in cancer biology, Rce1p, a Ras modifier, is considered an anticancer target. Despite its biomedical importance, Rce1p enzymology remains uncertain. Contrary to

the claim that Rce1p is a cysteine protease, recent investigations have demonstrated that Rce1p lacking all of its native cysteine residues remains functional in vivo. These investigations were performed using yeast Rce1p and a natural substrate, the **a**-factor mating pheromone. Notably, cysteine-less Rce1p is inactive in vitro against a synthetic **a**-factor-based substrate that is significantly shorter than the natural in vivo substrate. This study tests the hypothesis that cysteine residues are not involved in the Rce1p catalytic activity but are instead involved in substrate recognition by Rce1p in a manner that is influenced by substrate length. The ubiquitin fusion technique was used to create shortened **a**-factor substrates in vivo. We used quantitative mating tests to evaluate and quantify the ability of several Rce1p cysteine mutants, including cysteine-less Rce1p, to recognize these shortened substrates, named Ub-P2 and Ub-M, and yield mature **a**-factor. The tests reveal that the substrate recognition of cysteine-less Rce1p is comparable to that of wildtype Rce1p for the Ub-P2 substrate, while its selectivity is severely diminished to approximately ten percent of wildtype in the context of the Ub-M substrate. The results support the hypothesis that cysteine residues are involved in recognition of short substrates by Rce1p and clearly not involved in the catalytic mechanism of Rce1p.

Testing Algorithms to Predict Onset of Cerebral Malaria in Murine Model

Mina Ghobrial
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Malaria is an infectious disease caused by the parasite genus *Plasmodium,* which kills approximately 2.7 million people each year. 20-50% of all malaria cases develop into cerebral malaria (CM), but much of its pathology is not clearly understood. *Plasmodium berghei* ANKA induces CM in mice. Behavioral and neurological symptoms of mice experiencing CM are similar to those seen in humans. However, incidences of experimental CM are variable. In some experiments, nearly 100% of mice develop CM, yet in others, only 50% develop CM. Lack of understanding which and when infected mice will develop CM contributes to a weak understanding of the relationship between early pathological changes of CM and the resulting outcome. In our experiments, approximately 4-8 mice are infected with *P. berghei* ANKA and evaluated daily for symptoms suggesting the likelihood that they will develop CM. On days 4-7 post-infection, the mice were subjected to a battery of behavioral and neurological tests. Each test produced a numerical score that was inserted into a published algorithm designed to predict the chance that a mouse will develop CM. While the experiments are still underway, it appears that the published algorithm does not universally apply to all experimental conditions and mouse strains. However, assessment of an alternate predictive algorithm is being investigated. Creating an effective and reliable algorithm has a plethora of benefits. For example, it can predict CM development in its early stages and the corresponding approximate time of death. Composed of simple tests and inexpensive materials, the protocol for this algorithm can be reproduced easily. This could be helpful to future research concerning CM in murine models.

Stability Analysis of the Inhibitor Resistant Phenotype of AJP50 in Biomass Fermentations

Debashis Ghose, Sr., CURO Summer Fellow
Dr. Joy Peterson, Microbiology, Franklin College of Arts & Sciences

The United States' dependence on foreign oil and a desire to protect the environment have increased demand for alternative fuels. Lignocellulosic biomass can be fermented into fuel ethanol by a biocatalytic organism, such as *Saccharomyces cerevisiae*. Adapting *S. cerevisiae* to the harsh conditions found in biomass

fermentations would increase production. Strain XR122N was adapted by continuous pine fermentation to yield strain AJP50. AJP50 was able to grow and produce ethanol more rapidly than XR122N in pine wood fermentations. To determine if AJP50 retained its inhibitor resistant phenotype, the strain was cultured on YPD media. Growth curves were created to compare the growth of the newly cultured cells to the freezer-stock AJP50. Approximately 62% of the freshly cultured cells maintained the same level of resistance as freezer-stock; at other times they reverted to the parent or an intermediately resistant phenotype, indicating the resistant phenotype is not completely stable. AJP50 cells were grown on YPD plates with a mixture of 13 major inhibitors. Single colonies were subcultured onto fresh plates containing media with all 13 inhibitory compounds. Single colonies from this plate were then grown in liquid YPD with all 13 inhibitors. The cells in the flask were compared to the AJP50 freezer stock. Those that performed similarly were made into freezer stocks to be used in future pine wood fermentations. Developing culture techniques that will allow AJP50 to retain its phenotype would aid in study of the strain's genetics, and allow for the creation of strains with advanced fermentation capabilities.

Drilling for the Future: Domestic Oil Production and Meeting America's Energy Needs

Sophie Giberga, Foundation Fellow, John Henry Thompson
Dr. Rob McDowell, Public Administration & Policy, School of Public & International Affairs

Since the oil industry boomed in the 1930s, oil has provided the United States with a consistent and reliable fuel source while allowing it to prosper and establish a high quality of life. Oil is a rich natural resource that the United States is fortunate to have in abundance. Unfortunately, environmental fears blind us to the benefits of this resource that cannot be matched in any other fuel source. The federal government has imposed strict regulations on drilling that limit the areas in which drilling is allowed and rarely allow new permits to be administered, creating an uncertain business environment for oil companies. As a result, the government forgoes $803 billion in economic growth, $6 billion in tax revenue, 690,000 jobs and billions of barrels of domestically produced oil. After a thorough literature review of studies conducted by industry experts and a cost benefit analysis, this study proposes easing certain regulations on domestic oil production. Easing regulations would mean opening up the areas currently closed to drilling on the Pacific and Atlantic coasts, in the Gulf of Mexico, and on the Alaskan coast, increasing the rate of permitting, allowing further production of shale gas, and permitting the Keystone XL Pipeline. Several studies have compared the current path of oil production with that of the possible path if this policy were to be enacted, and all have shown tremendous economic benefits. Oil is simply a natural resource that the United States logically should take full advantage of in order to continue to prosper.

The Role of Sensory Systems in *Drosophila* Courtship across Populations

Erin Giglio, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

All species of *Drosophila* use distinctive courtship patterns to choose among potential mates. The purpose of this project is to examine the sensory systems used in courtship behavior by two closely-related *Drosophila* species. *D. recens* and *D. subquinaria* are two species which do not mate with one another in the wild but whose geographic ranges partially overlap. It is possible that they avoid intercrossing by using different sensory systems during courtship, such as wing-based

song, pheromonal smells, or visual displays. To test which of these hypotheses was correct, I performed a series of individual crosses to identify the emphasis on each sensory system within each species. I studied flies from *D. recens* and two populations of *D. subquinaria*—one population living alongside *D. recens*, and one population that does not overlap with *D. recens*. I studied the courtship behavior of flies from each population through observation of mating pairs. Four sensory system losses were assessed through surgical removal of wings, antennae, aristae, and through painting over of eyes. Finally, I looked at the sex-based differentiation of these categories by surveying the differences between courtship success with different combinations of intact or altered males with intact or altered females. This measured the importance of these systems on courtship success. I found that olfactory signaling was important to females and that wing status and vision were important to males in almost all populations. I also identified a shift from gustatory to olfactory signaling in males from the sympatric *D. subquinaria* population.

The Uses and Effects of Music in the Conflict in Northern Ireland

Audrey Glasgow, CURO Scholar Graduation Distinction
Dr. Jean Kidula, Ethnomusicology, Hugh Hodgson School of Music

For centuries, music has been and remains an integral part of Northern Irish culture. Music is used as an expression of celebration or mourning, as a means of remembrance or protest, and in a variety of cultural functions. Another defining aspect of modern culture in Northern Ireland is the traditional and continuing conflict between Catholics and Protestants. This conflict colors the culture, the politics, and everyday life in Northern Ireland. This thesis seeks to explain the role music, a visceral and emotional force, plays in this conflict in Northern Ireland. The work is based on ethnographic research including interviews and participant-observation in Northern Ireland, as well as independent historical and musical research. This research informs insights into the culture and music and provides a broad knowledge base on the background of Northern Irish music and the religious and cultural conflict. It is hypothesized that the Northern Irish music related to the conflict will serve specific purposes based on the performers' intentions and the effects on members of the group to which it belongs and the effect on the opposing cultural group. The messages, origins, material associated with them, and locations and situations in which they are performed will likely influence the analyses of songs. These analyses of the songs attempt to determine culture non-specific definitions of the roles of music in conflict. This analysis of the Northern Irish use of music in conflict may be applicable to other cultures in which music plays an important role in conflict.

Genetic Manipulation of *Caldicellulosiruptor bescii* for Biomass Utilization

Philip Grayeski, Foundation Fellow
Dr. Janet Westpheling, Genetics, Franklin College of Arts & Sciences

Caldicellulosiruptor bescii is a thermophilic anaerobic Gram-positive bacterium that grows optimally at 75°C and is capable of using untreated lignocellulosic biomass for growth. Its substrate range includes xylan, crystalline cellulose, hardwoods, grasses, populus, and switchgrass making it a model system for the study of biomass conversion to biofuels and bioproducts. Our lab recently developed a method for DNA transformation for *C. bescii*. We are using genetics as a tool to investigate its ability to use complex substrates as well as to engineer it to make products of interest. My role in this project has been to improve existing transformation methods and to generate deletions of genes predicted to be involved in plant cell wall deconstruction. We have shown that higher transformation

efficiencies are obtained by altering medium components, lowering phosphate concentrations, removing sodium sulfide, and using a pre-culture grown to an O.D. of 0.08. We also constructed a plasmid to introduce an extra copy of the cellulose A (CelA) gene, an enzyme important in crystalline cellulose degradation with a His-tag to facilitate protein purification. We have constructed gene deletions on non-replicating plasmids and introduced them into the chromosome by marker replacement. A deletion in a cluster of genes predicted to be important for pectin degradation results in a strain that shows significant growth defect on grasses. We will use constructed deletions to identify genes important for biomass deconstruction. Methods for transformation and marker replacement will be presented.

Management of Marine Debris in the U.S.: A Survey of Options and Database for Decision-Makers

Jenna Grygier
Dr. Jenna Jambeck, Biological & Agricultural Engineering, College of Agriculture & Environmental Sciences

Solid waste (e.g., garbage, trash, litter) that accumulates in the world's waters and shorelines of waterways is known as marine debris. Marine debris is a type of pollution in which land- or sea-based activities discharge waste into the ocean and its shorelines. Debris exists throughout every depth of the ocean and can be found even in the most remote areas. Stormwater runoff, rivers, streams, etc. help transport marine debris onto the land. Marine debris represents a complex problem in which aesthetic, environmental, human and animal health, and safety factors are of concern. The purpose of this research was to investigate and document current waste management programs of various marine debris projects (beach cleanups, etc.) and partnerships in the US. The result is a dataset that can act as a resource for decision makers for land based or open ocean marine debris projects. The dataset and information will be housed on the Southeast Atlantic Marine Debris Initiative website. Individuals can access this database as a guide for implementing original marine debris waste management projects; data summaries will provide information such as the percentage of marine debris projects that recycled, landfilled, or practiced waste-to-energy methods, including the location, description, contact information, sponsorship information, etc. for each project. This research encourages the development of innovative, potential debris management methods such as gasification and pyrolysis. This research encompasses many fields of study: engineering, environmental science, alternative energy, ecology and chemistry, which all work together to explore the challenging problem of marine debris.

Description and Measurement of Response to Osmotic Stress in *Toxoplasma gondii*

Daniel Guidot
Dr. Silvia Moreno, Cellular Biology, Franklin College of Arts & Sciences

Toxoplasma gondii is an Apicomplexan parasite that infects any nucleated cell and causes significant morbidity in immunocompromised patients and unborn fetuses. It is a great model parasite because, unlike other Apicomplexans, it is highly amenable to genetic modification. *T. gondii* can infect a wide host range because of robust homeostatic mechanisms, including homeostatic osmoregulation. However, methods are needed to evaluate osmoregulatory mechanisms in *T. gondii*. We observed *T. gondii* parasites of the RH strain using Differential Interference Microscopy videos as they responded to osmotic stresses and observed how these cells react in morphology and size. We additionally observed that cells scatter light in direct correlation to changes in cell size and morphology during hyposmotic stress. Using this approach, we developed a technique to

show an osmoregulatory defect of a *T. gondii* mutant strain lacking the vacuolar proton pyrophosphatase (TgVP1), an enzyme important for osmotic regulation in plants. We observed a 60% increase in swelling in these mutants compared to parental cells in identical osmotic stress, demonstrating decreased homeostatic osmoregulation. This result shows this technique to be a sensitive and robust method to measure osmoregulatory capacity. TgVP1 localizes to the Plant-Like Vacuole (PLV), an organelle whose function is not fully understood but is so named because it possesses many membrane proteins, like TgVP1, that are found in plant vacuoles. We performed Immunofluorescence Assays on fixed cells at time intervals after exposure to hyposmotic stress and found significant PLV rearrangment. Cells showed apparent PLV fission or possibly the creation of new PLVs in response to stress.

A Piece of the Puzzle: Why People Wear Peace Signs Today

Natalya Haas
Dr. Katalin Medvedev, Textile, Merchandising & Interiors, College of Family & Consumer Sciences

According to the anthropological symbolic theory, dress represents "the relationship of the individual to the cultural system" (Hamilton & Hamilton 141-2). Therefore, wearing the peace sign represents the values and beliefs an individual wants to convey to society. And many people wear peace signs today for the same reasons they did when it first became popular during the Vietnam War – to protest a war that continues against their wishes. To arrive at this conclusion, I researched a number of academic journals, books, and popular sources discussing the peace sign and why its symbolism continues to be so relevant. I discovered that the recent reemergence of the peace sign is linked to the increase in violence-related events around the world and reveals people's desire for these conflicts to end. Designers such as Tory Burch (in 2007) and Moschino (in 2010 and 2011, possibly in support of the withdrawal of more U.S. troops) featured peace signs in their collections in the midst of the Iraq War. The increasing number of celebrities that promote peace-related issues has also led more people to wear peace signs. My research concluded that the peace sign conveys the attitude of many people toward present political conflicts around the world and expresses their desire for such conflicts to be resolved without violence.

Limb Morphology and Sequence Divergence in the *fgf* Genes of *Anolis* Lizards

Tyler Haeffs, CURO Scholar Graduation Distinction
Dr. Douglas Menke, Genetics, Franklin College of Arts & Sciences

Fibroblast Growth Factors (FGFs) constitute a large family of secreted signaling proteins that are involved in many vital processes in the vertebrate body. In particular, the well-conserved *fgf8*, *fgf10*, and *fgf19* genes encode proteins that tightly regulate limb growth during embryonic development. However, currently it is not known whether changes in the expression levels or activities of these proteins contribute to the evolution of different limb morphologies among species. In order to better understand this connection, sequence divergence for *fgf* genes of interest was compared between closely related species of long and short-limbed *Anolis* lizards, a group of species that possesses a unique combination of repeated adaptive radiations and convergent evolution of similar limb morphologies. Isolation of the *fgf* genes was carried out on cDNA samples of two different *Anolis* species, and sequence analysis was then performed on the isolated fragments to identify divergences in *fgf* gene sequence between the two species. The amino acid sequences of the encoded *fgf* proteins were observed to be nearly identical between the

different *Anolis* species. Because of this sequence similarity, I speculate that protein divergence in these *fgf*s is unlikely to contribute to the dramatic difference in limb size observed between these species. Future work could examine the expression of these genes to determine whether differences in expression correlate with changes in morphology.

Digital Analysis of Feline Bone Marrow Fat Content

Hannah Hanley
Dr. Elizabeth Howerth, Pathology, College of Veterinary Medicine

Diagnosis of malnutrition in animals at postmortem can be difficult and in forensic cases requires objective criteria for legal purposes. Currently, chemical analysis of bone marrow fat is one objective standard for assessing nutritional status. However, alternative methods for quantifying bone marrow fat that do not rely on chemical analysis, such as quantitative microscopic analysis, are needed when fresh marrow is not available. The null hypothesis of this study is that bone marrow fat content determined by chemical analysis differs from fat content determined by microscopic digital imaging. To test this, both femurs were collected from 18 cats submitted to the Athens Veterinary Diagnostic Laboratory for necropsy. One was submitted for analysis of percentage marrow fat using a chemical extraction method. The other was fixed in formalin and hematoxylin, and eosin stained microscopic sections of marrow from head and mid-shaft regions were analyzed for percentage fat via microscopic digital imaging using Adobe Photoshop. Results of the two methods were compared; findings were also compared to body condition scores. Results from the two types of analyses were similar, but the marrow fat percentage from the mid-shaft region as determined by microscopic imaging more closely matched the chemical analysis. The majority of cats had less than 60% femoral fat content, which is less than normal, based on other domestic species. However, this generalization cannot be made in cats as low fat content did not necessarily correspond to a poor body condition score.

Relationship Between Left Uncinate Fasciculus White Matter Integrity and Verbal Memory

Alexander Hansen
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Processes of higher cognition, such as memory, ostensibly rely on the integrity of anatomical connections in order to function efficiently. Magnetic resonance imaging (MRI) is used to analyze the anatomy of the brain and can elucidate the connectivity of brain regions. Diffusion weighted imaging is an extension of MRI that measures the diffusion of water in tissues. In areas of dense myelination, diffusion parallels the length of the axons. To characterize directional diffusion along myelinated axons, software is used to calculate fractional anisotropy (FA) values, a measure of white matter integrity. Based on FA, white matter fibers can be tracked and rendered graphically, revealing the degree of connectivity between regions of the brain. In this study, we assessed the relationship between the degree of connectivity in the left uncinate fasciculus (UF), a fiber tract said to be involved with verbal memory and verbal memory performance. Diffusion weighted images (encoded in 30 diffusion gradient directions) for 20 participants (ages 8-11) were obtained using a GE 3T MRI scanner. Verbal memory was measured using the California Verbal Learning Test—Children's Version (CVLT-C). Fibers of the left UF were tracked using ExploreDTI software. Preliminary results indicate that the average FA values of the left UF are correlated with CVLT-C scores. The purpose of this study is to characterize the relationship between FA of the left UF and verbal memory performance. If a relationship

is found, it may suggest that proper development of this fiber tract is important for efficient memory processing.

Race Relations in Brazil Between 1890 and 1920

Benjamin Harris
Dr. Susan Quinlan, Romance Languages, Franklin College of Arts & Sciences

Brazil, the second-to-last country in the Americas to abolish slavery, sees itself as an extensive racial democracy. And at surface level, Brazil projects racial harmony. But analyzing the social constructions present in Brazilian society reveals that this democracy is a fallacy. This work dissects several historical, sociological, and literary texts that clearly demonstrate the precarious relationship between the Brazilian racial hierarchy: those of European, Indigenous, and African descent. In each work, the primacy of whiteness dominates through the subtle characterization of Europeans, while developing stereotypes that adversely affect the African, bi-racial, and indigenous populations. This work analyzes these representations in texts post-abolition until the end of the Old Republic in 1920. Through the historical and literary texts, it is possible to clearly see the steps that Brazil took in its formation and understanding of racial relations into the modern day. Ultimately, Brazilian society during that time utilized white-washing as a tool to eliminate racial hierarchy. Interpreting the literary texts further, it is then possible to understand the multiple, marginalized perspectives and project them as a reflection of Brazilian societal goals.

Analysis of the Legal Needs of Primary Care Physicians

Osama Hashmi, CURO Summer Fellow
Dr. Monica Gaughan, Health Policy & Management, College of Public Health

The American Medical Association has recently defined various legal issues physicians face, ranging from patient confidentiality to malpractice management. As the Patient Protection and Affordable Care Act goes into effect between now and 2014, physicians will need to navigate an even more complex and legal environment. During this time period, policy researchers around the United States will be asked to evaluate alternatives to improve and reform the current policy problems in healthcare delivery. As the legal issues physicians face become a more prominent aspect of physician life and primary care recruitment, this research will be crucial in promoting a better system of healthcare for the United States. My contribution to the study was to employ various policy analysis tools to analyze the legal needs of primary care physicians, and to provide a comprehensive evaluation of the physician payment system, as well as the networks which create our current system. This research also involved travelling to Washington, D.C to work on-site with various groups analyzing the current national health care policy environment, especially as it relates to the primary care labor force.

Residential Electricity Consumption and Affordability of Efficiency and Clean Energy Upgrades

Heather Hatzenbuhler
Dr. Andrew Carswell, Housing & Consumer Economics, College of Family & Consumer Sciences

Fossil fuel-generated electricity is artificially competitive in the energy market, which is excluding competition from renewable energy technologies such as wind, solar, geothermal, and tidal. In the U.S., coal is also the largest

source of fuel for electricity generation, generating more power than natural gas and oil combined.**1** Coal is the largest contributor to greenhouse gas emissions in the country, and it releases dangerous pollutants such as arsenic, lead, and mercury into the air and water supply. This pollution has significant environmental and human health costs that are not accounted for in the market price of coal-generated power. These economic conditions make household investments in clean energy and efficiency technologies cost-prohibitive for the average consumer. Residential efficiency and clean energy (RECE) upgrades that could reduce energy costs and improve environmental conditions are not feasible for most homeowners. Similarly, most consumers are uninformed about the origin of electricity and ways to conserve power. Through a review of government data, academic studies, and existing policies and outcomes, I have crafted a policy that addresses the barriers to RECE investment in Georgia. It includes a package of tax incentives, financing options, and education to be implemented as a pilot program in Athens-Clarke County.

1 U.S. Energy Information Administration, U.S. Coal Supply and Demand, 2009 Review, April 2010. Retrieved at <http://www.eia.doe.gov/cneaf/coal/page/special/overview.html>

Legal Approaches to Addressing Water Pollution Risks Related to "Fracking" in the Marcellus Shale Region

Heather Hatzenbuhler
Dr. Terence J. Centner, Agricultural & Applied Economics, College of Agriculture & Environmental Sciences

Hydraulic fracturing, or "fracking," is an industrial process used to harvest fossil fuel reserves that lie deep underground. By digging wells and injecting them with large quantities of water mixed with specially selected chemicals at high pressures, the rocks that store these natural resources are cracked open, allowing their contents to flow to the surface. This process has led to a significant increase in the economic reserves of natural gas in the United States. The once unreachable shale gas is now being piped out by the ton, and natural gas prices in all sectors—commercial, residential, and industrial—are at 5-year lows. However, there is growing concern about evidence of negative environmental impacts from fracking. The potential for water contamination, land destruction, air pollution, and geologic disruption at every step in the process has brought the safety of this extraction method into question. States such as New York, New Jersey, Maryland, and North Carolina have banned fracking until further research and review of environmental and human health impacts are completed. This paper looks specifically at the impacts that these processes have on local water supplies and seeks to identify the best legislative or regulatory approach to mitigating these risks in the Marcellus shale region. Existing state and federal laws, government data, and peer-reviewed academic studies and articles will provide a base of information for analysis and development of policy alternatives. Criterion such as ecological impacts, political feasibility, and operational practicality will establish framework for evaluation and ultimate policy recommendations.

An Affect Control Theory Analysis of Islam and Christianity

Anna Beth Havenar, CURO Honors Scholar, CURO Summer Fellow
Dr. Dawn Robinson, Sociology, Franklin College of Arts & Sciences

While western scholars have studied the languages and cultures of many groups, Arabic linguistic culture remains sorely under-investigated. My research employs semantic analysis of Arabic and English words to examine the role of religion in shaping linguistic culture. Utilizing Affect Control

Theory, I will analyze the way that sentiments affect other sentiments (impression change). I focus on three universal dimensions of sentiments: evaluation (good to bad), potency (powerful to weak) and activity (lively to quiet). These generalized sentiments are widely shared across a culture, and it is our agreement upon them that allows us to communicate with others. My data is derived from surveys of 500 native English speakers and 470 native Arabic speakers currently residing in North Carolina. These data, collected during the summer of 2010, serve as a pilot study for a new international data collection project to begin in the summer of 2012. I expect to see an emphasis of potency over evaluation in Arabic speakers, perhaps due to the deeply rooted Islamic ideals of shame and honor. Once our data is collected in the U.S. and the Middle East, we can use it in simulation programs to predict the outcome of social actions in various situations. By comparing our results with previous and current English ACT studies, we will be able to explore key differences in American and Arab cultures. This research is funded by the U.S. Naval Academy and will hopefully aid soldiers in their interactions with Arabic-speaking civilians during conflict in the Middle East.

Rastafari: Continuity, Discontinuity, and Present Identity

Paul Havenstein
Dr. Reinaldo Román, History, Franklin College of Arts & Sciences

Despite its global reach**,** Rastafarianism is one of the most misunderstood religions in the world. Since the 1970s, Rastafarians have grown from a Jamaican peasant cult to a worldwide socio-political, religious, and cultural phenomenon. This transformation has not gone unnoticed, but as UCLA historian Robert A. Hill points out, "there is an urgent need to reintegrate the study of Rastafarians into the dynamic flow of popular social movement in a manner that is sensitive to both the complex aspects of continuity and discontinuity in the overall historical process." My thesis is aimed at addressing this need with a study of select Rastafarians groups from around the globe. The object is to determine second-generation communities' engagement in the Jamaican tradition, and to what extent they represent distinct social movements rooted in new dynamics. The paper will cover the continuities and discontinuities as the religion spread and ask the question of who today is an authentic Rastafari? My work focuses much on the current state of Rastas in Washington, DC and includes in-depth personal interviews with Gary Himelfarb, partly responsible for bringing reggae music to DC, and Dr. Jake Homiak, a leading expert on Rastafari and curator of the "Discovering Rastafari!" exhibit at the Smithsonian. My thesis will clarify how and why the religion transformed from a deviant and sometimes violent cult in Jamaica to a worldwide proclamation of universal love and respect.

Recycling and End-Use Industries in Georgia

Jennifer Hegarty,
Laura Hegarty
Dr. Anne Marie Zimeri, Environmental Health Sciences, College of Public Health

A study by the Georgia Recycling Commission found that 16 Georgia paper mills use recycled content, with 9 of the mills relying exclusively on recycled fiber. Because Georgia does not recycle enough paper to meet production demands, Georgia's end-use industries are currently buying recycled material from other states, yet they still often do not have enough supplies to keep up with production demands. The GRC study also found that Georgians throw away an estimated 1.9 million tons of paper a year -- paper that could be recycled and purchased by end use markets within the state. Although many Georgians recycle, many more do not because they deem it too inconvenient and

expensive, and perceive a lack of facilities available to accommodate such recycling. The lack of paper recycling within the state of Georgia causes market failure by way of externalities through pollution and through the limitations it places on the development of Georgia's end-use industries. This policy proposes that Georgia implement a state-wide recycling initiative to increase the volume of paper recycled with the goal of enhancing and increasing the end-use industry within the state, which would in turn stimulate the state's economy. With use of a thorough literature review as well as a cost benefit analysis, alternatives to the status quo will be evaluated on the basis of efficiency, economic growth, political acceptability, the interest of future generations, and improvability. The proposed policy will be the one that stands up best to this evaluation.

Increasing Breastfeeding Rates in Athens-Clarke County

Anisha Hegde, Foundation Fellow
Dr. Alex Kojo Anderson, Foods & Nutrition, College of Family & Consumer Sciences

Breastfeeding is linked to improved child and maternal health. Low breastfeeding rates contribute to poor health outcomes and an estimated $3.6 billion in superfluous costs to health care providers and patients--markers compounded by the unavailability of breastfeeding support to those in the bottommost social strata. Breastfeeding rates in the U.S. are lower than those in most of the developed world; only 14.8 percent of U.S. mothers breastfeed exclusively for six months. Georgia's breastfeeding rates are amongst the lowest in the U.S. (only 10 percent of Georgian mothers exclusively breastfeed at 6 months). These rates are even lower in Athens-Clarke County, which currently offers sparse and costly or underfunded breastfeeding services through St. Mary's, Athens Regional, and the Supplemental Nutrition Program for Women Infants and Children. To better this status quo, a policy recommendation to establish a breastfeeding peer counseling program in the two hospitals was constructed through literature reviews, cost-benefit analysis, and interviews with healthcare personnel. By implementing a counseling program in hospitals, targeted at but not limited to mothers living 185 percent or more below the poverty line, an efficient partnership and mutually beneficial relationship amongst patients, hospitals, and Athens-area organizations would be fostered. The program would potentially increase the number of women breastfeeding for one year by 15 percent--likely an underestimate because it is based on numbers from Hartford Hospital, which serves a larger minority, disadvantaged population than do Athens-area hospitals. According to Healthy People Goals, an increase of 15 percent is enough to improve the health of a community by making infants less susceptible to illnesses such as gastroenteritis and reducing risks for diseases such as breast cancer and heart conditions in mothers.

Dietary Resource Partitioning of the Southern Flying Squirrel (*Glaucomys volans*)

Katherine Helmick
Dr. Gary Barrett, Odum School of Ecology

Understanding feeding habits of the Southern flying squirrel, *Glaucomys volans*, is limited to few scientific studies. We investigated dietary preference of *Glaucomys volans* by computing daily rate of ingested energy, and ranking food preference. Five food resources were provided to 10 individual flying squirrels (6 male, 4 female) for 5 consecutive days. Individuals were contained in separate experimental tanks. Each *G. volans* was provided with fruits of *Cornus florida*; acorns of *Quercus alba*, *Q. nigra*, and *Q. velutina*; and nuts of *Carya glabra*. *G. volans* ingested the most grams of *Q. alba*, averaging 53.6 Kcal·day-1 of *Q. alba*. The average rate of ingestion for the Southern flying squirrel was 109.8 Kcal per day; thus *Q. alba,* constituted 49% of their

daily diet. *Q. velutina* , *Q. nigra*, and *C. glabra* respectively were ranked next in dietary preference. Southern flying squirrels consumed 16.9 Kcal·day-1 of *Q. velutina*, 15.5 Kcal·day-1 of *Q. nigra*, and 10.7 Kcal·day-1 of *C. glabra*. There was no clear overall pattern in food preference concerning these 3 foods: preferences varied among individuals. The least preferred food of *G. volans* was fruits of *C. florida*, averaging 9.1 Kcal·day-1. These findings suggest that the survivorship of *G. volans* relates to a diversity of food resource availability.

Developing Kinetic Genotype-Phenotype Correlations for Missense Point Mutations in Human Protein O-Linked Mannose β-1,2 N-Acetylglucosaminyltransferase (POMGnT1)

Sam Hempel, CURO Honors Scholar
Dr. Lance Wells, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Human protein O-linked mannose beta-1,2 N-acetylglucosaminyltransferase, also known by its acronym POMGnT1, is a type II transmembrane glycosyltransferase found in the Golgi apparatus. POMGnT1 is one protein that plays a role in the larger pathway of O-mannosylation that is found in many different types of human tissues, most prominently in skeletal muscle, brain tissue, and the eyes. We are developing genotype-phenotype correlations for missense mutations in POMGnT1, a glycosyltransferase found in the mammalian O-mannosylation pathway. Several cases of POMGnT1 mutation in humans have been previously documented; however, the direct relationship between genetic mutation, molecular phenotype, and clinical presentation has yet to be well characterized. Muscle-Eye-Brain disease (MEB, OMIM 253280) is the predominant phenotype of genetic mutations in the POMGnT1 gene, yet the phenotypic variation that has been observed in POMGnT1 enzymatic mutants is too diverse to categorize under one "umbrella" – there is a growing need for more specific genotype-phenotype correlations in POMGnT1 mutants. One exemplary missense mutation (R311G) presents as classical MEB: severe muscular dystrophy, mental retardation, and unique eye deformations. However, a different missense mutation in the enzyme (D556N) results in limb-girdle muscular dystrophy (LGMD, OMIM 613517), a mild form of congenital muscular dystrophy with *normal* brain function. Developing these correlations is the ultimate aim of the project. Towards this goal, we are using genetic techniques such as site-directed mutagenesis to develop several mutants of interest, and eventually we intend to measure enzyme stability and kinetics to characterize the ultimate molecular phenotype of each mutant.

Protein-Glycosaminoglycan Interaction Studies Using Surface Plasmon Resonance (SPR)

Alexander Herzog
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Glycoaminoglycans (GAGs) are complex polysaccharides that display unique binding and regulatory properties in the presence of specific proteins. These molecules are prevalent in the extracellular matrix, and they are sometimes referred to as mucopolysaccharides due to their viscous, mucous nature. Three of the sulfur containing GAGs, heparin, heparan sulfate, and chondroitin sulfate (CSA), contain structural similarities that significantly impact the physiological regulation of an organism. In this study, we biotinylated heparin, heparan sulfate and chondroitin sulfate through the reducing terminus of the GAG chain, immobilized the GAG on a sensor chip, and studied the interaction with GAG-binding proteins, SDF-1 and Slit3, through Surface Plasmon Resonance (SPR). SDF-1, an *a*-chemokine that binds to G-protein-coupled CXCR4, acts as an inhibitory

factor that deters emigration of premature B cells out of bone marrow and interacts with heparin. The other GAG-binding protein, Slit3, is a large, secreted repulsive axon guidance molecule. Recent genetic studies reveal that Slit3 is dispensable for neural development, but required for non-neuron related developmental processes (where heparan sulfate is absolutely required for Slit-Robo signaling). Analysis of affinity constants for GAG-SDF-1 and GAG-Slit3 attachment, as well as their non-covalent interacting partners, is expected to provide a reasonable initiation for therapeutic intervention.

Effects of Platelet-Derived Growth Factor Receptor Inhibition on Feline Injection-Site Sarcoma Radiosensitivity

Joseph Hill,
Brittany Feldhaeusser
Dr. Michelle Turek, Anatomy & Radiology, College of Veterinary Medicine

Platelet derived growth factor receptor (PDGFR) is a protein kinase that has been shown to be important in feline injection-site sarcoma (ISS) cell survival and signal transduction. Masitinib is a tyrosine kinase inhibitor that specifically targets multiple growth factor receptors including PDGFR. The objective of this study is to evaluate the effects of masitinib on the radiosensitivity of ISS cells. Clonogenic assays were performed using ISS cell lines to determine the effects of masitinib and radiation on cell survival. ISS cells were irradiated with a single radiation exposure (0, 3, 6, 9, 12 Gray). Survival was defined as the ability of the cells to maintain clonogenic capacity and to form colonies. After irradiation, cells were plated for colony formation and colonies consisting of ≥ 50 cells were counted following incubation. Clonogenic experiments were carried out in triplicate in two ISS cell lines, KH and Hamilton. For each cell line, radiation experiments were performed in control cells (without masitinib) and in cells exposed to 6 μM masitinib for 72 hours before irradiation. Results indicate that masitinib and radiation decrease cell survival in a radiation-dose-dependent fashion. Masitinib at the dose and duration of exposure used here does not appear to alter the radiosensitivity of ISS cells. Based on these data, masitinib may not have a role in the management of ISS in combination with a single dose of radiation. Additional in vitro investigation may be warranted to explore the temporal effects of combination therapy.

Prisons for Profit: A New Approach to the Private Prison Model in the State of Georgia

Dev Iyer
Dr. Jody Clay-Warner, Sociology, Franklin College of Arts & Sciences

The issue of prison reform and recidivism rates is a growing issue in the state of Georgia. Currently, Georgia operates the fifth-largest prison system in the nation, a majority of which is privately owned. At a cost of $1 billion a year, the private prison system has absolutely no incentive to reduce the rate of incarceration and recidivism. Despite the growing problems of the Georgia prison system, little research has been conducted to accurately frame the issue and offer an alternative. This paper analyzes the business model of privately run prisons and isolates the factors that are inputs and outputs to the process. After an extensive cost/benefit and impact analysis review of various policy alternatives, a specific tool will be offered for identifying low-risk inmates as well as qualifications for community-based treatment programs. This researcher will also recommend a new business model for private prisons that eliminates the role of politics and corporate influence on profitability. These policy alternatives will ensure a more stable prison system that will be focused on helping rather than profiting.

Abstracts

The Belle and the Behemoth: *Uncle Tom's Cabin* and the Southern White Woman

Ransom Jackson, CURO Summer Fellow
Dr. John Inscoe, History, Franklin College of Arts & Sciences

In a paternalistic society like the antebellum South, women were not expected to have an opinion on politics or slavery. Yet *Uncle Tom's Cabin* blazed through the South, influencing many women to make a final decision on slavery one way or the other. Some saw it as a retched institution ruled by rich white men and governing over women with a brutal fist. Others remained loyal to its ideas of class, race, and downright way of life that the South had become accustomed to. This paper discusses the ways in which Harriet Beecher Stowe's characters influenced southern white slaveholding women. It will show that women indeed had an opinion about the "peculiar institution." Finally, it will show that their anger developed into attempts at changing the world they belonged to. The influence of *Uncle Tom's Cabin* on southern white women is crucial in showing that they had a voice and did attempt to make a change.

Development of a Genetic Screen for Vitamin B12 Uptake Mutants in Mycobacteria

Elena James, CURO Honors Scholar, CURO Summer Fellow
Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Tuberculosis, a disease in humans resulting from infection by *Mycobacterium tuberculosis*, kills approximately 1.4 million people annually. Vitamin B12 is a cofactor in various *M. tuberculosis* metabolic enzymes. Utilization of vitamin B12 by this pathogen when added to culture suggests possible uptake of B12 from humans. Thus, *M. tuberculosis* vitamin B12 uptake proteins may serve as useful targets for antitubercular drug development. My project is to develop a genetic screen for vitamin B12 transport mutants in mycobacteria. I created a plasmid in which an antibiotic-resistance gene is under the control of a B12 riboswitch, an RNA structure that blocks gene translation upon binding of vitamin B12. This plasmid, which can replicate in mycobacteria and *E. coli*, has DNA elements in this order: a transcription terminator, the promoter and B12 riboswitch from the *M. tuberculosis metE* gene, and a promoterless apramycin-resistance gene. This plasmid was introduced into a related species *Mycobacterium smegmatis*. We hypothesized that this plasmid would confer resistance to apramycin in mycobacteria only when vitamin B12 is absent from the culture medium. However, expression of the apramycin resistance gene is too high even when vitamin B12 is added. To reduce expression, the same DNA elements have now been cloned into a plasmid which is maintained in mycobacteria at a single copy per cell. If this plasmid confers tight vitamin B12 control of apramycin resistance in *M. smegmatis*, the next step will be to perform transposon mutagenesis in this strain and select for mutants defective in vitamin B12 uptake.

Noah Webster's *American Spelling Book* as a Product of Colonial American Culture and Economics

Emily Jessup
Dr. Bill Kretzschmar, English, Franklin College of Arts & Sciences

Noah Webster's *The American Spelling Book* was the most popular book of its time in America. The "blue-backed speller" shaped American education and culture, selling over 15 million copies in the years following its first publication in 1783. The success of Webster's speller is apparent; however, why he experienced such success is the question that still seeks an answer. The *American Spelling Book* could not have been produced successfully if Webster had not carefully considered different aspects of the text's

physical publication and distribution, as well as how to distribute the text, once published, to those who would make up the intended audience. Webster's efforts to distribute his speller in the more urban and densely populated northern states ensured his speller would have greater and more immediate success as opposed to the southern states where the population was less dense and more diffuse. In addition, the culture of American education was ripe for change as nationalism swept the country in the post-Revolutionary War years. It was an opportune time for the introduction of a speller like Webster's, full of religious and nationalistic sentiments. An examination of the location and economics of the printing industry, the population diversity of the possible audiences for Webster's book, and the changing culture and educational structure of the late-eighteenth century demonstrates that Webster's success, while in part due to the educational material the speller introduced, was in larger part owing to his considered and calculated distribution.

Examining Genetic Diversity in Peruvian Samples of *Plasmodium falciparum*

Rachel Johnson, CURO Honors Scholar
Dr. David Peterson, Infectious Diseases, College of Veterinary Medicine

Plasmodium falciparum is a causative agent of Malaria, a disease which affects hundreds of millions of people annually. VAR2CSA is a member of the Duffy-Binding like (DBL) protein superfamily which has been shown to mediate binding of the parasite to a unique host receptor. VAR2CSA is a highly polymorphic protein, a target of the immune response, and understanding the level of diversity in this protein is important. Previously, we cloned the DBL3x domain of VAR2CSA from Kenyan blood samples into plasmids, which were then sequenced. In collaboration with the CDC, we now seek to characterize diversity among *P. falciparum* from Peruvian samples. DBL3x was first amplified from sixteen different Peruvian samples, followed by ligation into a plasmid vector. After transformation of the PCR product into chemically competent *E.coli* cells, positive colonies were indentified and sequenced using conventional sequencing methods. The DBL3x region was confirmed and located in the sequencing results. At the conclusion of this project, we plan to have DBL3x-positive sequences from at least ten of the original sixteen samples. All sequencing results will be analyzed in order to characterize the diversity among the Peruvian *Plasmodium falciparum* population. Furthermore, we seek to quantify the genetic differences between the Peruvian samples and the previously studied Kenyan samples. By studying the genetic variation of the DBL3x domain, we seek to come to a deeper understanding of the mechanisms by which parasites, specifically *Plasmodium falciparum*, bind to their host and cause infection.

Inflammatory Cell Markers' Gene Expression in Mouse Model of Placental Malaria

Mathew Joseph
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

One of the foremost health issues in the developing world during pregnancy is malaria, with nearly half the world's population living in high-risk areas. *Plasmodium falciparum*, transmitted by the Anopheles mosquito, is the deadliest protozoan parasite which causes malaria in humans. We have recently initiated studies on malaria during pregnancy using *Plasmodium chabaudi* AS (a rodent plasmodium species) to infect C57BL/6J (B6) and A/J mice as model platforms for understanding the immunopathogenesis of malaria during pregnancy. On day zero of pregnancy, mice are infected with *P. Chabaudi* inoculum. Throughout gestation, secreted cytokine and chemokine proteins are assayed by ELISA. Tissues from mice spleens and fetoplacental units are homogenized and RNA is isolated. cDNA is made from the RNA and real-time

PCR is performed to assess levels of T cell markers with specific primers. The data obtained show that *CD3e (*T cell marker), *Hprt2* (B cell marker*), Mgcl2* (macrophage marker), and *Klrd1* (natural killer cell marker) are upregulated in infected pregnant A/J and B6 mice relative to their respective uninfected counterparts. This implies that *Plasmodium chabaudi* induces a local placental inflammatory response as does human malaria during pregnancy. Our research analyzes the mechanistic basis for malaria-induced compromise of pregnancy, especially mid-gestation, when high parasitic density is coincidental with pregnancy loss in our model. Continued study promises to reveal common and critical mechanisms that contribute universally to malaria-induced compromise of pregnancy.

Private Equity in Brazil

Samuel Kinsman
Dr. Jeff Netter, Banking & Finance, Terry College of Business

This research broadly analyzes the development of financial markets in Brazil with specific focus on private equity (PE) investment. Private equity's well-known absence of public company regulation and reporting requirements have appealed to investors because of the opportunities for increased returns. Likewise, PE investments in private companies can connect investors with high growth companies not listed on public exchanges. Recent trends in PE fundraising suggest investors in developed economies are allocating more capital to emerging economies to take advantage of higher growth opportunities. This research project seeks to document important trends in Brazilian PE deal financing structure including equity vs. debt ratios, minority stake vs. majority stake investments, and foreign vs. domestic capital sources. Controlling for other relevant factors, regression tests will link the data to key macroeconomic indicators to create a model for prediction of PE investment trends in Brazil. Initial research suggests declining macroeconomic indicators such as declining inflation rates have impacted the structure of PE investment by lowering the cost of debt for investments. Research findings may explain why PE investors are turning to Brazil and how monitoring readily available macroeconomic indicators can be a useful tool to quickly estimate the expected growth of Brazilian PE funds from both domestic and foreign investors.

A New Approach to Histomoniasis: Data Mining and Targeted Drug Sensitivity

Michael Klodnicki
Dr. Robert Beckstead, Poultry Science, College of Agriculture & Environmental Sciences

Histomonas meleagridis, the causative agent of blackhead disease in gallinaceous birds, is an anaerobic parasite that lacks mitochondria. Few treatment options exist for *Histomonas* infection, the most effective of which is banned in the United States and Europe for application in livestock bound for human consumption. Previous studies on closely related organisms have revealed certain details of their anaerobic, hydrogenosomal-centered metabolism, providing a clear target for drug treatment that is distinct from the host's metabolism. Using a multi-disciplinary approach, we have generated a cDNA library of the *H. meleagridis* genome and an annotated contiguous DNA sequence database to study virulence factors and specific metabolic components. Additionally, we examined the potential and efficacy of novel methods of controlling infection by targeting the hydrogenosome. In this study, we demonstrate through a series of sensitivity assays that application of variable concentrations of zinc in solution significantly inhibits in vitro growth by acting on the hydrogenosome. Furthermore, we evaluated potential methods of zinc delivery in vivo to begin treatment development for livestock application.

Abstracts

International Boundary Settlement and Domestic Conflict
Cody Knapp, CURO Honors Scholar
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

After they settle their borders, do states intensify repressive practices and experience a higher rate of intrastate violence? Previous studies have shown that states with unsettled borders experience higher levels of militarization, centralization, and social cohesion relative to states with settled borders. Theoretical arguments, however, are indeterminate regarding the precise effect that international border settlement has on domestic uses of violence. In this study, I will test the expectations of these divergent theoretical arguments. I will identify complete border settlement as a potential influence on the occurrence of intrastate conflict and confirm an empirical relationship between the two variables. I test the arguments using data on international border settlement and civil conflict during the period 1816-1997. Through its findings, this study will demonstrate the previously unrecognized implications of the positive action of state border settlement for a state's susceptibility to civil conflict. If complete border settlement renders a state more or less likely to experience internal unrest in subsequent years, then recognizing this correlation would enable policy makers to take steps to address the potential influences associated with this action.

Individual Environmental Awareness and Urban Water Conservation in Kunming, China
Logan Krusac, Foundation Fellow
Dr. Larry Nackerud, School of Social Work

Although the majority of water use in China occurs in the countryside, the responsibility for water conservation flows from the urban population centers outward. This research employs surveys of urban residents in Kunming, Yunnan Province in order to illustrate China's urban centers' growing impact on water conservation. This study determines what contributes to effective environmental awareness and analyzes the relationship between an individual's awareness and his or her in-home water conservation methods. The results show that first-hand environmental awareness is significantly more effective in encouraging conservation than is traditional environmental education. In addition, the survey reveals a pervasive lack of awareness in urban Kunming, with only 4 percent and 13 percent of respondents correctly identifying the price and source of their water, respectively. Only 59 percent of those surveyed believed they could have any influence in solving China's water crisis—a statistic that must change in order to promote greater urban water conservation.

Exploring Medical Practice Through Chekhov's Literature
Elina Kumykova, CURO Scholar Graduation Distinction
Dr. Elena Krasnostchekova, Germanic & Slavic Studies, Franklin College of Arts & Sciences

The relationship between literature and medicine has been reflected in many great literary texts. Doctors often become involved in the stories of their patients' lives. Literature, too, has the human being for its object. Many physician-writers explored their feelings and concerns about individual characters or patients in their writing. Medical practice has served as a rich source of material for some well-known authors, such as Arthur Conan Doyle, Anton Chekhov, and William Carlos Williams. The first purpose of this reseach is to examine the influence of Anton Chekhov's medical practice on his writing. The study will describe Chekhov's medical practice and his daily routine of seeing patients. Using biographical materials, the period of 1892-1897 when Chekhov served as the "Country Doctor" in Melikhovo will receive specific

attention. At this stage, the study seeks to understand why some existing research depreciated Chekhov's medical practice. The second purpose is to describe insights into the art of medicine offered by Chekhov's writing and particularly by "Ionych," "A Case History," "Ward Six," and "Uncle Vanya." At this stage, the study will describe Chekhov's insights into the doctor-patient relationship, specific diseases, medical ethics, etc. As a result, I seek to understand why Chekhov called medicine his "lawful wife" and literature his "mistress."

The Moderating Role of Romantic Relationship Satisfaction on the Relation Between Parenting Stress and Maternal Hostility

Kelsey Kuperman,
Suzanne Meller
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

Prior research has established an association between high parenting stress and parental hostility (i.e, harsh, punitive discipline; Sturge-Apple et al., 2010). Additionally, research has identified romantic relationship satisfaction as a moderator on the relation between self-reported parenting stress and mothers' report of parenting hostility (Deater-Deckard & Scarr, 1998); however, few studies have examined observed parent hostility toward children during middle childhood.
The current study examines the moderating role of mothers' romantic relationship satisfaction on the association between maternal stress and observed maternal hostility in a diverse community sample of 39 mother-child dyads (child ages 8-11). Dyads completed a conflict discussion task, attempting to reach compromise on a topic of current conflict (e.g., homework, fights with siblings, chores). These discussions were video recorded and later coded for maternal hostility with adequate interrater reliability. Indicators of hostility included rejecting statements, cynicism, and mothers' disregard for her child. Mothers completed the Parenting Stress Index (PSI-SF; Abidin, 1995), and indicated their current level of relationship satisfaction on a seven-point scale. We hypothesized that under high parental stress, high romantic relationship satisfaction will buffer maternal hostility and low relationship satisfaction will exacerbate levels of maternal hostility. The overall model that examined relationship satisfaction as a moderator was significant (F (3, 35) = 6.27, $p < .01$; $R2 = .59$). The main effects of parenting stress ($t = 3.24$, $p < .05$) and relationship satisfaction ($t = 2.15$, $p < .05$) on hostility were significant, as well as their interaction ($t = -3.21$, $p < .05$), indicating moderation.

Development of a Vector to Delete the β-lactamase Gene from Mycobacteria

SaiSudeepti Kuppa
Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Mycobacterium tuberculosis causes tuberculosis, a disease which in 2010 claimed 1.4 million lives, out of which 350,000 individuals were also infected with the HIV virus. This bacterium is resistant to β-lactam antibiotics, such as penicillin, because it carries the *blaC* gene encoding a β-lactamase which cleaves and inactivates this class of drugs. The live vaccine strain *Mycobacterium bovis* BCG carries an identical *bla*C gene and can cause disease in people infected with HIV. A live vaccine that is sensitive to penicillin is considered to be safer as this drug could be used to treat people who develop disease from the vaccine. Therefore, the goal of this project is to delete the *blaC* gene from *M. bovis* BCG and from *M. tuberculosis*. A former student in the lab created plasmid pAR17, which is designed to facilitate deletion of any targeted mycobacterial gene by specialized transduction. Upon testing the system by targeting a specific gene, it was discovered that pAR17 may be too large after combining with transducing mycobacteriophage DNA to be stably

packaged into phage capsids. To address this, plasmids pSK1-pSK4 were generated by deletion of nonessential regions from pAR17. Plasmids pSK3 and pSK4 are currently being modified to target deletion of *blaC*. The resulting plasmids will be useful in evaluating if smaller plasmid size addresses the in vitro packaging problem observed with pAR17 and in mutating the *blaC* gene in pathogenic mycobacteria.

Construction of a vapB Deletion Mutation in a Swine Isolate of *Rhodococcus equi*

Monica LaGatta
Dr. Mary Hondalus, Infectious Diseases, College of Veterinary Medicine

Rhodococcus equi, a Gram-positive facultative intracellular bacterium, is a pathogen of foals, pigs and immunocompromised people. In foals and humans, *R. equi* typically causes bronchopneumonia, whereas in swine the predominant clinical presentation is lymphadenitis. The ability of virulent strains of *R. equi* to replicate intracellularly in host macrophages and establish chronic disease is dependent on the possession of a large extrachromosomal virulence plasmid. This virulence plasmid contains a pathogenicity island (PAI), which encodes a novel family of genes called virulence associated proteins (*vaps*). The PAI of foal plasmids possess *vapA*, a gene encoding a surface-expressed lipoprotein shown to be essential for intracellular replication and establishment of a chronic infection in a murine model system. In contrast to equine isolates of *R. equi*, swine isolates are vastly unstudied. It is known however, that the virulence plasmid of swine isolates has significant homology to that of foal isolates. Nonetheless, swine plasmids do not contain *vapA*, rather they possess the related gene, *vapB*, which shares ~80% sequence identity at the amino acid level. VapA and VapB are hypothesized to be functionally equivalent proteins in their respective hosts. To determine if *vapB*, like *vapA*, is essential for intracellular replication, we used a two-step allelic exchange strategy employing a single crossover intermediate and counter-selection to construct a marked deletion mutant of *vapB*. The requirement of *vapB* for intramacrophage growth will be assessed by comparison of the intracellular growth phenotypes of the *vapB* mutant and wild type *R. equi* using standard in vitro macrophage infection assays.

Development of Nut-Cracking Skills in Wild Bearded Capuchin Monkeys (*Sapajus libidinosus*)

Kellie Laity, CURO Summer Fellow
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Bearded capuchin monkeys crack nuts using large stones as hammers. This behavior is thought to be traditional. Juvenile capuchins (birth to four years old) are not directly taught by adults how to crack nuts, nor can they crack nuts open themselves, yet they spend a lot of their time for several years participating in percussive activities. We set out to study adult and peer facilitation on nut-cracking behaviors of juvenile capuchins. Our hypothesis is that nut-cracking activities of group members support young monkeys' practice with nuts and stones during the years that they cannot open nuts themselves. We collected data in Piauí, Brazil on a group of nineteen capuchin monkeys. Behavioral data were collected for eleven juvenile monkeys (4 – 54 months) by observing consecutive focal juveniles and their neighbors for 20 minute periods over eight weeks (393 focal samples). Manipulation of nuts increased with age ($R2 = 0.78$, $N = 11$, $p < 0.001$). Within-subject analyses are in progress; currently we know that for five individuals, manipulation of nuts increases when two or more other individuals in the group are concurrently manipulating nuts. These data support the hypothesis that juveniles' practice related to nut-cracking is promoted by group activities. Further analyses will be conducted to find if a) specific individuals' activities, b)

hearing (but not seeing) others crack, and/or c) encountering artifacts of previous cracking (nut shells, stones) promote percussive activity by juveniles. Research supported by the National Geographic Society and CURO.

Information as Narrative Poison or Poultice in Ergodic Literature

Connor Land
Dr. Richard Menke, English, Franklin College of Arts & Sciences

This presentation focuses on the impact of information on the narratives of ergodic texts, conventionally known as videogames. In *The Storyteller,* Walter Benjamin explains that information and narrative differ in that "the value of information does not survive the moment in which it was new. It lives only at that moment," whereas "a story is different. It does not expend itself. It preserves and concentrates its strength and is capable of releasing it even after a long time." Most modern games contain both information and narrative. Games will often stream statistics on a heads-up-display in the game while simultaneously involving the player in narrative events. From a background in narrative studies, I will try and discover if information has as dire an effect on games' narrative content as Benjamin would contend. Using reading materials from previous research, supplemented with those in the areas of information and narrative minimalism, I will discuss how storytelling in gaming is either hurt or helped by information. The bourgeoning field of ludic studies contains a few notable works in its own right, but it lacks papers addressing one narrative issue with a perspicacious focus. Thus this presentation seeks to start a more nuanced dialogue about the games we take for granted as toys and link videogame studies with other narrative media such as film, photography, and the novel.

Immortalization of Primary Swine Respiratory Epithelial Cells

Christopher Lee
Dr. Ralph Tripp, Infectious Diseases, College of Veterinary Medicine

Influenza A viruses pose a significant risk to human health due to their continuous evolution and zoonotic potential. Swine are thought to be a mixing vessel for generation of reassortant influenza viruses because they can be infected with both avian and human influenza A viruses, and unlike humans, readily support replication of avian influenza viruses. To advance disease intervention strategies, there is a critical need to better understand the innate antiviral responses of swine respiratory epithelial cells to avian influenza virus infection. Unfortunately, few if any immortalized swine bronchoalveolar epithelial cell lines exist which are need to facilitate these studies. In this study, we harvested and isolated primary normal swine lung epithelial (NSBE) cells from a healthy pig and attempted to immortalize the cells using various procedures. After isolating the NSBE cells from all other components of the lungs, the cells were infected them with a lentivirus construct carrying a simian virus 40 (SV40) T antigen to induce immortalization by suppressing the p53 tumor suppressor protein. The results suggest that this method of cell transformation has the capability to immortalize NSBE cells, and we have isolated several colonies of immortalized cells. Prospective studies with these transformed NSBE cells will be performed to identify pathways and mechanisms that influenza virus uses to infect and undergo reassortment with other influenza A viruses in host swine respiratory epithelial cells.

Abstracts

The Contribution of Environmental Contamination with *Salmonella* to Human Illnesses in Georgia

Michelle Lee
Dr. John Maurer, Population Health, College of Veterinary Medicine

In the US, *Salmonella* causes 1.4 million illnesses each year. While most cases in the past have been attributed to the consumption of fecally-contaminated food, *Salmonella* infections by non-food borne strains, more specifically environmental strains, have been increasing in humans. The environment has a potential role in the lifecycle of *Salmonella*, and consequently, it can affect its geographic distribution. By investigating the distribution of *Salmonella enterica* serovars in the environment, specifically from surface waters and wildlife species inhabiting the collection sites, as well as collecting relevant geographical information, we can determine the ecological interactions that contribute to salmonellosis in humans. Monthly surface water samples from the Little River (three sites) and the North Oconee River (three sites) were collected and sampled for *Salmonella*. A total of 13 *S. enterica* serovars among 197 *Salmonella* isolates were compared genetically using pulsed- field gel electrophoresis (PFGE). Several *Salmonella* strains from this study were identical to human isolates in the CDC PulseNet database. PFGE patterns of *S. Braenderup*, type Br2, and *S. Muenchen* isolates were identical to human isolates in the CDC Pulsenet database, providing further support for the contribution of environmental contamination to human illness.

Characterization of the Tneap Complex in the CRISPR-Cas Viral Defense System of Prokaryotes

Marianne Ligon, CURO Honors Scholar, Ramsey Scholar, CURO Summer Fellow
Dr. Michael Terns and Dr. Rebecca Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The CRISPR-Cas (**C**lustered, **R**egularly-**I**nterspaced, **S**hort **P**alindromic **R**epeats and **C**RISPR-**as**sociated genes) system is a recently discovered defense system present in approximately 40% of bacteria and 90% of archaea. Small RNAs and ribonucleoprotein (RNP) complexes provide the basis of this adaptive, genetically-heritable immune system that protects prokaryotes against viruses, plasmids, and other genome invaders. There is a wide variety of both conserved and subtype-specific *Cas* genes, but little is known about the biochemical activity of the majority of these gene products and RNP complexes. In this study, the *Tneap* subtype proteins are investigated in how they function within the CRISPR-Cas system to confer immunity. Recombinant proteins and synthetic RNAs cloned from the thermophilic archaea *Pyrococcus furiosus* and *Thermococcus kodakaerensis* are used to acertain structural and functional components of the *Tneap* RNP consisting of three proteins, Cst1, Cst2, and Cas5t, and a crRNA (CRISPR RNA). I show that these proteins form an RNP complex with crRNAs of varying length and are able to bind ssDNA and dsDNA in a crRNA- and homology-dependent many.. Further work involving a predicted nuclease, Cas3, must be done to determine the function of the *Tneap* RNP complex. The *Tneap* RNP requires few genes to assemble, and therefore may be useful in applying the CRISPR-Cas system to a variety of industries, including the biofuels, biotechnology, dairy, and gene therapy industries.

Stimulation Current Does Not Influence NIRS Measured Metabolic Rate

Hillary Liken
Dr. Kevin McCully, Kinesiology, College of Education

Near infrared spectroscopy (NIRS) has been used to evaluate skeletal muscle oxygen levels and metabolic rates. This study tested the effect of different electrical stimulation current levels on NIRS measured metabolic rate. Healthy subjects (six females, ages 23-32) were tested. A dual channel NIRS device (Oxymon, Artinis) was used with separation distances between 3.0-4.5 cm, placed over the medial gastrocnemius or vastus lateralis. Surface electrical stimulation produced muscle activation. Each subject was stimulated for three two-minute stimulation periods at 4 Hz with randomized current levels. Between levels, a 10 second ischemic period was used to measure metabolic rate. A five-minute duration ischemic cuff with reactive hyperemia was used to calibrate NIRS signals. Oxygen saturation during stimulation was not significantly different ($F(2,15) = 0.02$, $p = 0.980$) between current levels (70.1 + 8.6 %, 69.7 + 13.4 %, 71.0 + 9.4 % low, med, high current) and was similar to resting oxygen saturation (65.9 + 11.9 %). Metabolic rate was not significantly different ($F(2,15) = 0.085$, $p = 0.919$) between current levels (1120%, 1118%, 1118% of resting metabolic rate for low, med, high current). Longer separation distances gave results similar to those reported for shorter separation distances. Small differences in current levels at or above 50 mA did not influence muscle oxygen saturation or metabolic rate following electrical stimulation. Separation distance also did not influence these measurements. This suggests that electrical stimulation is a feasible method of activating skeletal muscle for NIRS-based measurements of muscle metabolism.

The Relationship Between Macular Pigment and Neural Compensation

John Liu
Dr. Lisa Renzi, Psychology, Franklin College of Arts & Sciences

Macular pigment is a collection of dietary carotenoids within the central retina, which is known for its ability to improve visual function by filtering short-wave light. MP optical density varies widely in the population; consequently, some individuals filter the majority of the short-wave light that enters the eye from a combination of MP and a yellowing lens, while others with little to no MP and a relatively clear lens must transduce the majority of short-wave light that enters the eye. Despite these differences in the amount of short-wave (blue) light that reaches the retina and, consequently, the amount of visual improvement that can be achieved as a result of having MP in the retina, past research suggests that the majority of individuals are similarly sensitive to short-wave light. The purpose of this project is to determine whether or not compensation within the central nervous system is responsible for the relatively uniform short-wave sensitivity seen in the population, despite differences in the amount of light that reaches the retina.

Phospholipase Expression in Cocaine-Addicted Rats

Casey Love
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Recent studies from our laboratory show that exposure of rats to cocaine, followed by withdrawal and re-exposure significantly alters the expression of several different types of phospholipids in multiple brain areas. Alterations in select phospholipids correlated to increased sensitization to cocaine and increased intensities of initial responses to cocaine re-exposure. The expression of several types of phospholipids in the brain is

controlled by a class of enzymes called phospholipase A2 (PLA2). We hypothesize that the exposure of rats to cocaine will alter PLA2 expression. Four of the many isoforms were chosen for this experiment: iPLA2 beta, iPLA2 gamma, NTE, and GAPDH was used for the control. Expression was assessed using reverse transcriptase and quantatative-polymerase chain reactions (RT- and qPCR, respectively), which also assess the level of mRNA expression. We found that NTE, iPLA2 beta, and iPLA2 gamma were expressed in control brains at different levels depending on the brain region. NTE seemed to be expressed more in the Cerebellum with the other three areas(ventral striatum, dorsal striatum, and Hippocampus) close behind. NTE was expressed the least in the Hippocampus of the control brains which is where the phosphatidylcholine levels were found to be increased after cocaine exposure, withdrawal, and re-exposure. iPLA2 beta had the highest levels of all three enzymes in all four regions of the brain with the hippocampus second to last in its levels. Furthermore, the difference in expression of these enzymes were little to none for the hippocampus area and the cerebellum had a greater expression of all of the enzymes in the cocaine addicted brain tissues verses the saline treated tissues out of four different tissues of the same brain area.

The Molecular Dynamics of Atomic Sticking Coefficients

Katie Manrodt, CURO Honors Scholar, CURO Summer Fellow
Dr. Steven Lewis, Physics & Astronomy, Franklin College of Arts & Sciences

Interstellar dust has been shown to be a common mechanism for the formation of molecular hydrogen; however, the "sticking probability" of atomic hydrogen impinging on these surfaces remains somewhat controversial. This project aims to provide continuity between two conflicting past studies. In 1998, Takahashi, Masuda and Nagaoka preformed a computational study of the sticking probability of atomic hydrogen. A study done in 2002 (Al-Halabi, Van Dishoeck, and Croes) cited experimental data showing an error in the previous study: the sticking probability was actually much lower than the 1998 study determined. This project utilized the code from the 1998 computational study, modified it according to the methods cited in the 2002 paper, with the intention of comparing results to that of the 2002 study. Computations were carried out using the classical molecular dynamics technique. Our corrected sticking probability is higher than the one found in the 2002 and 1998 paper, which was not expected. We are currently looking into what could have this affect, exploring the properties the slab of water ice used, etc. Ultimately, this project will be used as the starting point for more simulational studies of the sticking probability of carbon and nitrogen.

Lost Chapters in the *Wind-Up Bird Chronicle*: A Translation and Commentary

Kieran Maynard
Dr. Masaki Mori, Comparative Literature, Franklin College of Arts & Sciences

Murakami Haruki is the most translated living Japanese author. His longest novel, *Nejimakidori kuronikuru* (1994, 1995), has been translated into English as *The Wind-Up Bird Chronicle* (1997) by Jay Rubin, who cut about 61 of 1,379 pages, including three chapters (Book 2 Chapters 15, 18, and part of 17; and Book 3 Chapter 26). Other sections were rearranged or altered. I will translate the omitted sections, compare my reading of the altered sections and the entire work to Rubin's, and comment on the effects of translation practice on the English language text as a literary work. My theory of translation practice is drawn primarily from Venuti (1998) who proposes a "foreignizing" translation practice to counter 'domestication' that occurs when a work is translated between

cultural contexts. Translation "approximates" the experience of a literary work in another language; the "source text" and the translation have a "performative relation" (Venuti 1998). I have completed translating Chapters 15 and 17, and part of 18, and have noted that the most frequently omitted character is one Rubin claims detracts from the book. I expect the omitted chapters will invite a new interpretation of the novel, despite Rubin's claim, "We are *not* talking about huge textual differences between the Japanese original and the English translation" (Rubin 2002); that choice of translation practice will be found to have artistic and ethical implications; and that a better understanding of these choices as they relate to Japanese and to literature will benefit translation studies as a whole.

War, Peace, and Seduction: An Analysis of Tolstoy's Hélène Kuragin as a Symbol of Female Sexuality

Melissa McDaniel
Dr. Charles Byrd, Germanic & Slavic Studies, Franklin College of Arts & Sciences

In the tradition of the Greek epics *The Iliad* and *The Odyssey*, Leo Tolstoy's masterpiece *War and Peace* observes and re-interprets the impact of fate (what Tolstoy calls "history") on personalities, from the high and virtuous to the low and deceitful. Hélène Kuragin of *War and Peace*, a deviation of Helen of Troy, is too often dismissed as little more than a typical femme fatale by critics who gloss over her connection to the epic Helen. An analysis of her treatment as symbol of violent sexuality in terms of the epic tradition reveals what the vilification of Hélène means about the relationship of men and women in a world of both war and peace. While others have analyzed the depiction of women in Tolstoy's literature, they have more often focused on the novel *Anna Karenina* or Natasha Rostov, the girlish heroine of *War and Peace*, and Hélène's place within the events of the novel is often overlooked. This investigation will compare the vilified Hélène to victimized Helen of Troy in order to point out how Tolstoy prevents Hélène from receiving the same sympathy as her precursor. In the few scenes in which she appears, Tolstoy focuses on Hélène's body as an instrument of war, revealing the novel's underlying connection between wealth, murder, and unnatural sexual promiscuity. Through Natasha, Tolstoy illustrates his admiration for the fortitude and fertility of Russia, but Hélène displays fear of the corrupting violence of female sexuality.

Public Art in Athens-Clarke County

Brittany McGrue, CURO Honors Scholar
Dr. Marilyn Wolf-Ragatz, Lamar Dodd School of Art

Public art refers to any piece of artwork meant to be displayed and enjoyed in the public sphere, and pertains to all the arts. Public art can be funded through government channels, private funding, or philanthropic efforts. Important benefits of a public art program include those of education, aesthetics, job stimulation and economic development. Although Athens-Clarke County is considered an arts community with some established public art, the community was interested in structuring a program that would build upon that foundation. In order to explore the possibilities of creating a program, the mayor's office appointed a task force in April of 2010 and charged the group with researching public art programs, identifying possible funding sources and inventorying established public art. A 1% for art ordinance was recommended by the task force and approved by the Mayor and County Commissioners late in 2010. The Athens Cultural Affairs Commission, a 9-member commission of community volunteers that works in tandem with the government, was created in March of 2011. My research has involved participating in meetings of both the task force and the ACAC, facilitating communication, researching the topic of public art, and most importantly, observing the process of creating a public art program.

A final responsibility of my participation in this progression was to create the foundation and procedure for inventorying the County's present art collection. This was done using PastPerfect museum software provided by through the County's Arts and Leisure Department.

Discrepancy Between Client Expectations and Doctor Reports of the Success in Treatment of Veterinary Patients

Caitlin McManemon
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Numerous factors affect patients' expectations after a consultation with their doctors regarding various illnesses. The patients themselves, their degree of worrying, the number and types of problems and symptoms they encounter, and the previous knowledge and experience they have with their condition can all play a role. This could lead to the patient either overestimating or underestimating his or her likely chance of successful recovery. Such a disconnection could also result when patients regard other important matters, such as their animals. This experiment intends to establish whether or not an analogous disagreement exists, and then to delve into and understand the reasons behind why the dissonance may occur. The study consists of two separate surveys, one that will be given prior to the first consultation, and one that will be administered immediately following the consultation during the same visit. The surveys include the Depression-Anxiety-Stress Scale 21, the Comfort from Companion Animals Scale, and the Illness Worry Scale. By utilizing these select scales, the study aims to find a potential correlation between various degrees of depressive, anxious, and worry-related symptoms characteristic of the participants themselves, as well as their subjective assessment of their bond with their pets, which may illuminate sources affecting their future outcome appraisals. These results may uncover new ways to lessen the gap and promote more effective veterinarian-client consultations with regards to the expected outcome of the animal patients.

Effects of Helminth Infection on Local and Systemic Immunity

Lindsey Megow, CURO Summer Fellow
Dr. Kaori Sakamoto, Pathology, College of Veterinary Medicine

Bovine tuberculosis, caused by *Mycobacterium bovis*, is a serious, reportable, zoonotic problem primarily affecting bovids worldwide. Control of *M. bovis* infection requires an effective T helper (Th)1 response. On the other hand, infection by intestinal helminths, a common problem in wild bovids, triggers a Th2-skewed immune response. We therefore hypothesize that when an animal is infected with intestinal nematodes, the resulting systemic Th2-skewed environment created by the immune system down-regulates the Th1 response, decreasing the ability of the animal to fight the mycobacterial infection. We are developing a mouse model to study this effect. The mice are co-infected with the intestinal nematodes *Heligmosomoides bakerii* and *Nippostrongylus brasiliensis*, followed by intratracheal instillation with *M. bovis*, in order to mimic the conditions found in an African buffalo study by our collaborators, the Ezenwa laboratory. At specific time points after infection, tissues from the lung, intestines, and regional lymph nodes will be harvested for histopathology, flow cytometry (to determine recruited leukocyte subsets), and ex vivo cytokine production. Serum will also be collected to study the systemic cytokine responses. Preliminary results have shown an increased local pro-inflammatory cytokine response in the lungs, with increased eosinophil recruitment and perivascular cuffing. Results have also shown greater T lymphocyte recruitment to the lungs and intestines with nematode co-infection as compared to single nematode infection. Co-

infection also exhibited a suppressive effect on *H. bakerii* egg production. After optimizing the helminth co-infection, mice will be intratracheally infected with *M. bovis*.

Histological and Protein Expression Changes in Mouse Models of Early Dystroglycanopathy

Garrett Melick
Dr. Aaron Beedle, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Dystroglycanopathies, characterized by progressive muscle weakness and wasting, are associated with abnormal glycosylation of alpha-dystroglycan (αDG). Fukutin is one of six proteins known to be important for αDG glycosylation (Barresi, Campbell 2006); and we have shown that knock out of the mouse fukutin gene early in skeletal muscle development (Myf5-cre/Fktn KO) elicits severe dystroglycanopathy. Here, we hypothesize that loss of dystroglycan function during skeletal muscle differentiation disrupts muscle signaling pathways to promote the severe disease phenotype. To address this research question, we studied skeletal muscle fiber type specification, which is a downstream readout of differentiation pathways, using immunofluorescent imaging of myosin heavy chain genes in knockout (K) and littermate control (LC) mice at 4 and 8 weeks of age. We then correlated myosin heavy chain expression, to indicate muscle fiber type, with disease severity. Preliminary data suggests altered fiber type distribution in KO mice that is correlated with mouse age. As expected, the iliopsoas muscle showed considerably different fiber isotype content than quadriceps muscle. Thus, fiber type specification appears altered in dystroglycanopathy mice in an age- and muscle-group-dependent manner. These data are significant because they suggest that differentiation signaling pathways are altered and may contribute to disease severity in our mouse model. Further analysis of these abnormal signaling pathways may provide targets for new therapeutic strategies.

Emotion Regulation and Childhood Depression: An Examination of Moderators

Suzanne Meller
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

Emotion regulation is the ability to modify or maintain emotions in order to successfully navigate emotional experiences (Gross & Thompson, 2007). Children experiencing significant deficits in emotion regulation have an elevated risk for developing psychopathology (Zeman et al., 2002), including childhood depression (e.g., Betts et al., 2009). The majority of studies examined middle-class Caucasian samples (e.g. Silk et al., 2003), while other potential moderators (i.e. child gender, parent perceived child difficulty) have yet to be investigated in diverse samples. In order to understand whether the association between child emotion regulation and child depressive symptoms differs depending on ethnicity, child gender, family income, and parents' perceived child difficulty, we propose a series of moderation models. Participants include 64 mother-child (ages 8-11; 40.6% male;) dyads from a diverse sample (i.e. Caucasian, 40.6%; African American, 51.6%; yearly income < $20,000, 49.9%). Children's emotion regulation was assessed using the self-reported Child Emotion Management Scale (CEMS; Zeman et al., 2001) and via behavioral coding of the interaction tasks. Child depressive symptoms were assessed via the Child Depression Inventory (CDI; Kovacs, 1992). Perceived child difficulties were measured using the Parenting Stress Index subscale (PSI-SF; Abidin, 1995). Results showed that children's problems with emotion regulation were consistently associated with depressive symptoms for all examined moderators (i.e. gender, parent perceived child difficulty, ethnicity, income). The association between

emotion regulation and depressive symptoms regardless of gender, perceived difficulty, ethnicity and SES stressed the importance of children's development of adaptive emotion regulation abilities in the prevention of depressive symptoms.

Cumulative Risk and Child Psychopathology: Understanding the Role of the Parenting Relationship

Suzanne Meller,
Sophie Arkin, Isabel Cohen
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

Children experiencing multiple risks throughout development have elevated likelihood of experiencing psychopathology (Flouri et al., 2009). Cumulative risk, the combined effect of several risk factors (e.g. single parenthood, low income; see Obradovic et al., in press), is a greater predictor of negative child outcomes than any single risk factor alone; thus, it is important to examine risks in combination versus isolation (e.g. Sameroff, 2006). Although children experiencing multiple risks have greater chance of experiencing psychopathology, positive parent-child interactions have potential to mitigate these negative effects (Trentacosta et al., 2008). This study expanded on literature by examining the positive relation between cumulative risk and child psychopathology in a demographically diverse sample, and predicted positive parent-child interactions would moderate (i.e., buffer) this association. 64 mother-child (8-11 years) dyads completed interaction tasks recorded for subsequent coding. Positive parent-child interactions were assessed using observed shared positive affect (e.g., mother laughed and child shared in the experience by smiling/laughing). Cumulative risk was calculated based on previous research (e.g. Grant et al., 2003), and included eight mother-reported risk factors (e.g., recent life stressors; annual income under $20,000; clinical levels of psychopathology assessed via the Symptom Check List-90-Revised; Derogatis, 1994). Child psychopathology was assessed via maternal self-report (Child Behavior Checklist; Achenbach, 1991). Cumulative risk was related to more externalizing problems in children only when there were low levels of shared positive affect between mother and child (β = -.220; t(53) = -1.793, p = .079), indicating the importance of interventions targeting the parent-child relationship in high-risk environments.

Effect of Sugar on Brain Peptides

Sarah Mitchell, CURO Honors Scholar
Dr. Silvia Giraudo, Foods & Nutrition, College of Family & Consumer Sciences

The role of sweets and palatable foods within the context of the overweight and obese can be explored by examining the effect of fructose intake on orexigenic signals and hormones, such as ghrelin. Changes in the amount of ghrelin affects satiety and hunger levels, which can cause weight gain and even lead to obesity. Previous studies indicate that fructose may cause an increase in ghrelin levels that other sugars do not. Our main objective is to see what difference there is between the effects of dextrose and fructose on ghrelin levels. We are looking at how different sugars affect ghrelin levels in rats over a twelve week period, using three groups of rats and the sugars dextrose (a mixture of sucrose and glucose) and fructose with one control group. During the study, we measured the weight fluctuations and food intake over the twelve-week period. We harvested brain tissue to determine via immunohistochemistry changes in ghrelin receptor activation. This information will lead us to more knowledge about the effects of fructose versus other sugars on brain peptides regulatories of consumatory behavior. The interactions between our diet and ghrelin might lead us to develop new strategies to prevent overeating and more effective weight management therapies to treat obesity.

Insecure Attachment, Low Self-Esteem, and Low Parental Warmth as Predictors of Substance Abuse

Hannah Muetzelfeld,
Grace Cha
Dr. Joshua Miller, Psychology, Franklin College of Arts & Sciences

Given the increasing rate of marijuana use and the consistently heavy alcohol abuse among college students, and the resulting societal impact (e.g., Pentz, 1999), an empirical investigation of risk factors and predictors of such abuse is imperative. Previous studies have demonstrated a relationship between marijuana and alcohol abuse and both low self-esteem (e.g., Donnelly, Young, Pearson, et al., 2008) and parental warmth (e.g., Johnson & Pandina, 1991). To expand on this existing research, the present study explores insecure romantic relationship attachment in addition to parental warmth and low self-esteem, and their potential relationship with marijuana and alcohol use. This broadens an idea used by Kassel, Wardle, and Roberts (2007), in which it was proposed that adult attachment style plays an influential role in the prevalence of drug use, in addition to self-esteem and parental variables. It is hypothesized that low self-esteem, low parental warmth, and insecure attachment styles will all account for a significant amount of variance in both alcohol and marijuana use. To examine these relationships, self-reports from 342 college students were collected. Simultaneous regression analyses revealed that the model significantly predicted substance use ($t = 2.23$, $p < .01$). In terms of the individual relationships between independent variables and substance use, only parental warmth predicted substance use ($t = -.346$, $p < .01$). Together, these three variables contributed 22.3% in shared variability.

Prospect Theory and Common Action Problems: Loss Aversion in International Riparian Treaty Compliance

Bryn Murphy, Foundation Fellow
Dr. Peter Brosius, Anthropology,
Franklin College of Arts & Sciences

This paper attempts to apply cognitive science findings on loss aversion to identify best practices for treaties governing common pool resources. Prospect theory demonstrates that decision-makers are loss-averse: decision-makers overvalue losses relative to comparable gains. Consistent with this finding, international treaties governing common pool resources should achieve greater compliance when they are structured to provide an immediate gain (commons protection treaties) than when they demand an immediate loss (public goods treaties). This paper will test this hypothesis through regression analysis on an adapted version of the Transboundary Fluvial Dispute Data set. In the interest of maintaining an interdisciplinary perspective, these findings will be analyzed in the context of anthropological literature on common action problems and riparian politics. The findings could suggest more effective structures for treaties governing international rivers specifically, and common pool resources generally.

Measuring Transformational Leadership in the NFL

Aaron Murray
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

Transformational leadership has become a popular leadership style with several distinct characteristics. In theory, transformational leaders influence followers by raising follower self-awareness, establishing a sense of purpose and vision, and influencing followers to assume lower-order goals for the long term benefit of the organization (Bass, 1985). A myriad of research also suggests that

transformational leadership leads to a variety of benefits for groups, such as creating more innovative teams, increasing behaviors that have positive contributions to team environments, and overall leading more effective teams (Keller, 1992, 2006; Piccolo & Colquitt, 2006; Podsakoff & MacKenzie, 1997; Judge & Piccolo, 2004). Although few would debate the strong influence of leadership in professional sports, research is lacking as to the measurability of such leadership characteristics among this unconventional demographic. Our study hopes to analyze the key behaviors of transformational leadership in quarterbacks from the National Football League. Specifically, we hope to construct and test a behavioral coding system to measure levels of transformational leadership among these team leaders. In order to test this, we will develop our coding system based on assessment center methodology, which research has found to be sufficiently valid (Klimosky & Strickland, 1977). Using archival data from past seasons in conjunction with game footage of starting quarterbacks, we will examine the effects of these transformational leadership behaviors on team success, as well as if situational factors play a role in the presence of such behaviors.

Gestational Diabetes Education Program
Amita Nawathe
Dr. Fazal Khan, School of Law

Gestational diabetes is one of the most common health issues that arise during pregnancy. It is currently estimated that 26 million American women have gestational diabetes. It is also estimated that one of every two to five women with gestational diabetes will develop Type II diabetes within a decade of giving birth. The rising epidemic of obesity, minority ethnic populations becoming the majority, and increasing levels of socioeconomic disparity make it more important than ever to analyze alternatives to the current system of delivering gestational diabetes care. Through a thorough literature review and cost benefit analysis, this paper proposes that Georgia implement a Gestational Diabetes Education Program (GDEP) to help curb the problem of gestational diabetes. The GDEP will be funded both federally (Medicare) and locally (Medicaid) and will incentivize the creation of more primary care residency seats in rural and underserved areas of Georgia, the education of patients and the establishment of strong relationships between healthcare providers and patients. Implementing a state-wide GDEP can help prevent spending approximately 100 billion federal tax dollars on diabetes related costs over the next decade, while also helping residents of Georgia live healthier, happier and more fulfilling lives.

Post-Katrina Recovery Processes in the Vietnamese-American Community
Khai Nguyen
Dr. Steven Holloway, Geography, Franklin College of Arts & Sciences

The paper examines the recovery process of the Vietnamese community around the Gulf Coast in the aftermath of Hurricane Katrina. It focuses on cities with large Vietnamese populations such as Biloxi, Mississippi and New Orleans, Louisiana. Its framework is based on three major factors: intra-member relationships within the Vietnamese community as well as external interactions with the African-American community, the news media portrayal of the recovery and re-building process, and broader implications for federal disaster management. In addition to academic journals, the paper relies on sources such as newspaper articles, available census data and statistics from interviews with NGOs, to evaluate federal intervention as compared to community-based assistance. This study will also attempt to track the migration trends of evacuees from the Gulf Coast to urban areas around the US which contain significant Vietnamese populations (i.e. Houston, Texas and Atlanta, Georgia).

Preliminary research finds that the federal handling of disaster aid, by not taking into account the historical background of marginalized minorities and the geographical importance of communal support, exacerbated the fragmentation of communities. The model minority myth, which overstates the speed and success of the recovery of the Vietnamese community, was reinforced by the media. This ultimately interfered with allocation of disaster aid at the expense of black Americans and caused the notable cooperation between the two communities to go largely unacknowledged. It is therefore irresponsible and counterproductive to advocate for self-reliance in disaster recovery because help does not go to the people and places that need it most.

Assembly and Subspeciation of Haptoglobin-Related Protein Containing High-Density Lipoproteins

Tuiumkan Nishanova
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The purpose of this research is to define the mechanisms of High-Density Lipoprotein (HDL) subspeciation. Specifically, we are seeking to understand how the retained N-terminal signal peptide of Haptoglobin-related protein (Hpr) mediates association and distribution of Hpr amongst HDLs. We propose that HDL lipid fluidity affects the ability of signal peptides to associate with HDLs. We have addressed the first question by performing HDL-binding studies with native Hpr and recombinant Hpr that lacks the N-terminal signal peptide. To study how HDL fluidity affects the ability of apolipoproteins with retained signal peptides to associate with HDLs, we have utilized a model system in which we can modify liposome fluidities and observe how Hpr interacts with each of the liposomes. We show that the retained signal peptide of Hpr is necessary and sufficient to associate Hpr with HDLs. We also show that HDL fluidity affects HDL- association of apolipoproteins with retained signal peptides. We found that liposomes with lower fluidities have tighter binding with Hpr, while liposomes with higher fluidities have faster binding with Hpr. It is significant to understand how HDLs assemble and factors affecting this assembly process because it will help us determine the best ways to treat patients with disorders, for example cardiovascular and metabolic diseases, where the levels and or composition of their HDLs are affected.

Protein Purification, Crystallization, and Functional Annotations of Five Essential LysR-type Transcriptional Regulators in *Acinetobacter baylyi* ADP1

Melesse Nune, CURO Scholar Graduation Distinction
Dr. Cory Momany, Pharmaceutical & Biomedical Sciences, College of Pharmacy

There are over forty LysR-type transcriptional regulators (LTTRs) in *Acinetobacter baylyi* ADP1. Five of the LTTRs in *A. baylyi* are essential under defined growth conditions (Database of Essential Genes <http://tubic.tju.edu.cn/deg/>). These five essential LTTRs are ACIAD0461, ACIAD0746, ACIAD2511, ACIAD1539, and ACIAD2384. Only ACIAD2384 has homology to an LTTR with known function, MetR, which controls methionine biosynthesis in bacteria. *Acinetobacter baumannii*, a closely related organism to *A.baylyi*, is a multidrug-resistant pathogen that kills tens of thousands of hospital patients each year and is considered an emerging threat. The essential LTTRs in ADP1 are present in *A.baumannii* and thus may represent novel antibiotic targets for drug discovery in the pathogen *A.baumannii*. Studies have been initiated to better characterize these essential LTTRs. The genes have been cloned into an expression plasmid that adds a polyhistidine C-terminal purification tag for simple protein purification

from *E. coli*. Successful protein purification using metal-chelate chromatography has transitioned to crystallization studies. Bioinformatic analysis (evaluation of shared synteny and multiple sequence alignments) and functional studies (EMSAs) are being used to identify the regulated metabolic targets. The structural and functional studies done on these LTTRs will improve our understanding of microbial metabolism and transcriptional regulation and may provide avenues to develop new classes of antibiotics.

Modeling Subtelomeric Growth and the Adaptive Telomere Failure Hypothesis

Farres Obeidin, CURO Summer Fellow
Dr. David Hall, Genetics, Franklin College of Arts & Sciences

In many organisms, subtelomeric regions, the sequences near the ends of chromosomes, have a variety of features including an abundance of duplicated sequences, epigenetic silencing of genes, very high rates of evolution, and enrichment for genes involved in rapid adaptation to novel environments. These features are due in large part to a greater tolerance of subtelomeric regions to recombinational exchanges. The adaptive telomere failure hypothesis proposes that telomeres may have evolved to partially fail at a certain rate in some or all conditions to accelerate recombinational exchanges in subtelomeric regions. To determine the viability of this hypothesis, we constructed a Mathematica model to simulate evolution of individuals in environments with varying degrees of selection. This selection acts on a class of genes known as contingency genes. The model follows an organism through a set number of generations, recording the genomes of each individual and the number of contingency genes in subtelomeric regions at each time step in relation to the total number of these genes. Subsequent additions to the model allowed for increased recombination near the telomeres, an effect of telomere dysfunction, to address whether a high rate is favored in a population undergoing selection on contingency genes because of an inherently higher ability to rapidly alter gene dose. Data from these simulations will most directly examine the adaptive telomere failure hypothesis.

Truth in Labeling: Nutritional Value Under NLEA

Philip Oldham
Dr. Robert Nielsen, Housing & Consumer Economics, College of Family & Consumer Sciences

Obesity rates are climbing and the health risks associated with obesity are alarming. Providing consumers with nutritional content such as fat, sugar, and salt has become increasingly important to combat this health epidemic. Nutrition labels are the primary method by which consumers account for nutrient content. Food labeling policy, however, has not been addressed since the Nutrition Labeling and Education Act of 1990 despite the increased complexity of food over the past two decades. Research suggests that consumers find it difficult to understand current labels and that there are more effective ways to display nutrient content for consumers. To better understand consumers' ability to interpret nutrition labels, this study convened a focus group of consumers who provided feedback on the use of new tools that clarify the nutritional value of food products. I expect the results to indicate that food labels are more comprehensible when the nutrient content is displayed graphically and in color. These data have important implications for consumer policy. In understanding what consumers comprehend, policymakers can shape labeling policy to reduce the asymmetry of information between consumer and producer in the food market.

Development of Disability Awareness Assessment Scale

Andrea Orton,
James Ford, Kristen Whipple
Dr. Kevin McCully, Kinesiology, College of Education

Enhancing social awareness of individuals with disabilities is important among students at UGA in contributing to their education. The purpose of this study was to test version 1 of a disability awareness assessment scale. A 34-item scale was developed, and IRB approval was granted to use this scale at the beginning and end of an academic semester. The questionnaire included 16-items with a 1-5 range focused on disability awareness, and 16-items with a 1-5 range focused on drug use in sports. Participants were recruited from two freshmen First Year Odyssey seminar (FYOS) classes. The disability group consisted of freshmen students in a First Year Odyssey course on disability awareness (n = 5). The control consisted of freshmen students in a First Year Odyssey course on Drugs and Sports (n = 13). The test scores on the questions related to disability awareness were 49.0 + 5.6 pre and 51.0 + 2.7 post class for the experimental group and 40.4 + 4.2 and 41.6 + 4.8 for the control group. The disability class had higher awareness scores than the control group ($p = 0.001$). However, there were no differences between initial and final scores in either group ($p = 0.231$). The results suggest that students selected the disability course based on previous knowledge and experience with individuals with disabilities. The lack of change in the disability awareness scores in the disability group suggests that the test battery was not sensitive to change, as by self-report, the students reported significant increases in disability awareness and a high degree of satisfaction in the course. Future studies are needed to test more participants, in particular students with low scores on disability awareness prior to a disability awareness course.

Finite-Difference Time-Domain Investigations of Metamaterials

Elliot Outland, CURO Honors Scholar
Dr. William Dennis, Physics & Astronomy, Franklin College of Arts & Sciences

Metamaterials, artificially engineered materials possessing properties not normally found in nature, have a variety of applications, such as miniaturized antennas, superlenses, and cloaking devices. In order to put these novel materials to their best uses, it is necessary to understand how and why they work as they do. The finite-difference time-domain (FDTD) method is one way of achieving such understanding; by solving electromagnetic equations one time step at a time, one can gain information about the way that waves interact with the material in question for all future time-steps. Our research uses the MIT Electromagnetic Equation Program (MEEP) to perform FDTD calculations on the behavior of electromagnetic waves as they propagate through various metamaterials in comprised of nanostructures in different configurations After we specify the material and geometric parameters and run the simulation, MEEP produces an output file from which we can obtain quantitative data about the light-material interaction. By analyzing these results, we can gain a better understanding of how the nanomaterial parameters ad geometry affect the optical properties of the metamaterials; this will aid in the designing of new metamaterials with desired optical properties.

Affinity and Specificity Characterization of Fbs1 via Surface Plasmon Resonance and Glycan Array Screening

Akshita Parikh
Dr. Robert Woods, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Ubiquitin-mediated proteolysis of misfolded proteins occurs through the systematic cascade of three types of enzymes: an activating enzyme (E1), ubiquitin-conjugating

enzyme (E2), and ubiquitin-ligating enzyme (E3). The SCF complex, comprised of Skp1, Cul1, Roc1/Rnx1 and a variable F-box protein, is a well-characterized ubiquitin-ligating E3 enzyme complex. Fbs1 (97-297) is a glycoprotein specific F-box protein which interacts with glycoproteins containing high-mannose oligosaccharides (N-glycans). Specifically, Fbs1 recognizes the internal diacetylchitobiose structure in N-glycans. Since the internal chitobiose of N-glycans in native glycoproteins is not accessible, denatured glycoproteins exposing the N-linked oligossacharides serves as a signal which is recognized by Fbs1. The objective of this research is to characterize the affinity and kinetics of Fbs1 for denatured RNAse B through Surface Plasmon Resonance (SPR) and to further investigate its specificity for related N-glycan structures via glycan array screening. Fbs1 is expressed and purified using an engineering pGEX-6P-1 plasmid. It is first expressed as GST fusion protein into E.coli BL21 (DE3) Codon Plus RIPL strain and purified using a GSTrap FF 1ml column through on-column cleavage of Fbs1 from GST by PreScission Protease cleavage at an engineered cleavage site. High purity Fbs1 is obtained through Size Exclusion Chromatography (SEC) and verified by SDS-PAGE, Western blot analysis, MALDI Mass Spectrometry (MS) and peptide MS fingerprinting through LC-MS/MS. SPR affinity and kinetic analysis of Fbs1 for target denatured RNAse B containing a single N-glycan site indicates a disassociation constant (KD) of 13 uM and disassociation rate (koff) rate of 9.87 e-3 s-1. Additionally, the specificity of Fbs1 is further investigated by screening fluorescently labeled Fbs1 on glycan arrays provided by the Consortium for Functional Glycomics. These results will help determine the utility of Fbs1 as an affinity capture reagent for N-glycan bearing peptides and glycoproteins.

The Effects of Volume Removal on Values of Factional Anisotropy

David Parker
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Diffusion Tensor Imaging (DTI) is a form of Magnetic Resonance (MR) technology that allows for non-invasive characterization of brain anatomy by measuring the diffusion of water molecules within the brain tissues. DTI is especially useful for examining connectivity between brain regions and is a new analysis technique that will have important clinical relevance towards a variety of brain pathologies that affect the integrity of these connections. In order to quantify the degree of connectivity between brain regions, fractional anisotropy (FA) values are calculated based on the average magnitude and direction of water diffusion. During data collection, a common problem is that slight movements can cause artifacts among the many brain images that contribute to the average FA value, which compromises the data. Standard practice is to visually inspect the data and to eliminate images with artifacts. Our goal is to examine the effects of volume reduction (i.e. elimination of poor quality images) on FA. Quality diffusion weighted images (30 diffusion encoded directions) from a single subject were chosen from a larger study and used as a baseline. From these baseline images, we systematically altered the number of diffusion weighted directions that contributed to that image in order to examine the effect of volume removal on FA. By comparing a complete data set that has no artifacts with a data set that has had volume reduction, we hope to determine a reasonable threshold for the number of diffusion encoding directions needed to preserve the validity and quality of data.

Abstracts

Investigating Post-Translational Modification and Activity of Zebrafish Glycosidases

Joshua Parker, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Richard Steet, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Zebrafish (*Danio rerio*) has emerged as a popular model organism to study human diseases including lysosomal storage disorders. In order to better understand the regulation and function of lysosomal hydrolases in this system, the activity and post-translational modification of specific glycosidases has been investigated using wild type and mutant zebrafish lines. A characterization of a novel beta-galactosidase enzyme with a pH optimum near neutral was conducted. The results show that this activity is tissue-specific, distinct from the lysosomal beta-galactosidase and does not depend on the presence of soluble co-factors. A potential role for this nuetral glycosidase activity could be extracellular remodeling of cell surface sugar chains. The maternal deposition of N-acetylglucosamine-1-phosphotransferase, the enzyme responsible for initiating the addition of mannose 6-phosphate residues to lysosomal hydrolases, was also investigated. A mutant zebrafish line deficient in its gamma subunit was utilized for genetic and biochemical analysis. Following a series of genetic crosses, the embryonic activity of four glycosidases was measured at different stages. These experiments provide strong evidence for the maternal deposition of N-acetylglucosamine-1-phosphotransferase into zebrafish eggs and set the stage to explore the function of mannose phosphorylation in the development of oocytes and embryonic growth.

Cognitive Differences Between Objective and Subjective Memory Complaints

Anisha Patel
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

Mild cognitive impairment (MCI) is a term used to define an older adult who has a deficit in a specific cognitive domain that is greater than expected for their age. This category includes problems with memory, language, attention, or reasoning. Recently, an area of contention has been whether objective and subjective memory complaints differ cognitively, which is of particular importance given subjective memory complaints are a requirement for MCI. My hypothesis is that older adults with subjective memory complaints would not differ from individuals without complaints. I suggested that personality factors may account for the complaints, particularly neuroticism which has been previously researched and seems to be an indication of memory loss. We evaluated 57 older adults aged 65-85 on several factors. Using the Immediate and Delayed memory scores from the RBANS, I conducted a two tailed Spearman correlation, a regression, as well as a t-test. I also completed a two tailed Spearman correlation and independent samples t-test to see whether the personality factors were related subjective memory complaints. I found that there is no difference in immediate or delayed memory between someone reporting a memory problem and someone who isn't. Interesting, personality factors did not account for the difference. This suggests subjective memory complaints may not need to be required in order to determine if a patient suffers from MCI. Further research must be done to verify what may be accounting for subjective memory complaints, given there were no memory performance differences or personality differences as I had expected.

Stable Cell Line Engineered with shRNA Against TMPRESS2 Protease to Reduce the Infection of Influenza Virus

Nisarg Patel,
Christopher Lee
Dr. Ralph Tripp, Infectious Disease, College of Veterinary Medicine

The cleavage of hemagglutinin (HA) protein with the use of host cell protease is required for influenza virus to gain entry into the cell. Previous studies have found that TMPRSS2 protease plays a significant role in the infectivity of influenza virus. During this study Lentivirus was used for the insertion of shRNA against TMPRSS, Red fluorescent expression, Puromycin selection gene, as well as Doxycycline induction to create a stable cell line which can be tested to determine the role of TMPRSS in influenza infection. The cell line was passage through fluorescent cell sorter as well as Puromycin selection to create clone cell lines. Gene silencing was validated with the use of PCR which demonstrated that there was a significant difference in the level of TMPRSS2 between Doxycycline induced and non-induced clones. Upon induction with Doxycyclin, TMPRSS2 silencing RNA is produced which blocks the production of TMPRSS2 RNA. The blocking leads to a decrease translation of TMPRSS2 and without the protease activity of TMPRSS to cleave influenza hemagglutinin (HA), the infection of host cell is reduced. The assay results demonstrated that the induction of the clone does decrease the infection of influenza virus.

Reducing Costs and Maintaining Quality: Alternatives to Fee-for-Service in Federal Health Insurance Plans

Yiran (Emily) Peng, Ramsey Scholar
Dr. Phaedra Corso, Health Policy & Management, College of Public Health

The fee for service system (FFS), the current way federal health insurance programs reimburse physicians, encourages financial waste and lowers the quality of U.S. healthcare. In 2009, the U.S. spent $2.5 trillion or 17.3% of its annual gross domestic product on healthcare, ranking number one in spending compared to all other industrialized countries. Despite this large investment, the World Health Organization ranks the U.S.'s healthcare system 37th out of 191 countries in performance and quality. FFS exacerbates the divide between cost and quality in a few significant ways. Payment by service provides incentives for excess spending and fraud. This rise in spending leads to health inequities by denying care to those who cannot afford it. In addition, FFS is a barrier to integrated care in that it rewards individual procedures, fragmenting patients into separate symptoms. To address these problems, Medicare should implement a capitated system that integrates insurance companies, hospital systems, and provider networks to cut costs and improve quality. A cost benefit analysis, as well as a thorough literature review indicates that replacing the FFS payment schedule removes incentives for physicians to order unnecessary procedures that increase waste. Paying physicians at a fixed, capped rate curbs health costs by eliminating the incentive for unnecessary procedures and offers more affordable care. At the same time, HMOs increase spending regulation and reduce fraud. To improve quality, a capped and integrated system gives incentives to hospitals, physicians, and insurance companies to collaborate and better serve their patients. Although the U.S.'s overall spending on health care will not dramatically change under this new policy, patients will receive increased quality per dollar under a capitated system, ultimately reducing the disparity between spending and quality-care in the U.S.

Narcotics-Trafficking, Cloudforests, and a Killer Fungus: Amphibian Conservation in Central America

Todd Pierson
Dr. John Maerz, Warnell School of Forestry & Natural Resources

Amphibians are the most threatened group of vertebrates, and the highlands of Central America are home to one of the greatest diversities of salamanders worldwide. In addition to the ubiquitous effects of deforestation, an epidemic fungal infection—chytridiomycosis—has led to the extinction of dozens of species in the region. Despite great losses in the amphibian diversity of neotropics, the number of nominal species continues to increase as taxonomic studies reach their maturity. In the last sixteen months, I have joined the Museum of Vertebrate Zoology of the University of California Berkeley on three expeditions to Guatemala and Honduras to search for new species of amphibians, assess the status of remaining forest, and plan for the conservation of these threatened species. Here I present the results of these expeditions, a complicated success story of conservation in the Sierra Caral, and a plan for future conservation.

Arabian Nights: Preliminary Survey of Herpetofauna and the Phylogeography of *Bufo dhufarensis* (*Bufonidae*) in Oman and the United Arab Emirates

Todd Pierson
Dr. John Maerz, Warnell School of Forestry & Natural Resources

Amphibians and reptiles of the Arabian Peninsula are composed of groups of both African and Asian origin and previous phylogeographic studies have revealed radically different histories for different taxa. I spent six weeks in June and July 2011 collecting herpetofauna from Oman and the United Arab Emirates on an expedition with the Museum of Vertebrate Zoology. We collected more than 300 specimens of more than 45 species, including both amphibian species of this arid region—*Bufo arabicus* and *Bufo dhufarensis*. The latter species is of particular interest, as its affinity for oases creates a highly disjunct geographic range across the region, and further analysis of interpopulation genetic variation may reveal some cryptic diversity. Here, I present a summary of previous herpetological phylogeographic research done in the region, the results of our 2011 expedition, and outline a phylogeographic study of *Bufo dhufarensis* that I will conduct in the summer of 2012.

Regulation of the Cell Cycle in the African Trypanosome by Small Molecule Inhibitors and Serum Deprivation

Daniel Pique, CURO Scholar Graduation Distinction
Prof. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts & Sciences

Human African trypanosomiasis, a disease caused by the protozoan *Trypanosoma brucei,* lacks safe and effective treatment options. Cell-permeable molecules can serve as lead anti-trypanosome chemicals or tools for cell cycle studies. Current protocols for *T. brucei* cell cycle synchronization use hydroxyurea to arrest in S phase. Herein, we present a new serum deprivation protocol that arrests trypanosomes at G1, as verified by two independent methods: flow cytometry evaluation of DNA content per cell and organelle duplication analysis by microscopy. Trypanosomes lack epidermal growth factor receptor (EGFR) and vascular endothelial growth factor receptor (VEGFR). However, we discovered that AEE788, a small molecule that inhibits EGFR and VEGFR tyrosine kinases in human cells, blocks Tyr phosphorylation in the trypanosome and arrests *T. brucei* in G1. Since *T. brucei* lacks EGFR and VEGFR, we used chemical proteomics approaches to identify three novel protein kinase targets of AEE788. With AEE788 and serum-deprivation both

arresting at G1, the possibility of synergism between the drug and serum factors was explored. Surprisingly, serum-starved trypanosomes are no longer susceptible to AEE788 inhibition. We present a new hypothetical model that links a serum factor to AEE788-susceptible protein kinases in regulation of the trypanosome cell cycle.

Aporetic Structure in Marcel Proust's *In Search of Lost Time*

Sarah Potter
Dr. Andrew Zawacki, English, Franklin College of Arts & Sciences

By researching works of literature, theory, and criticism by Georges Bataille, Maurice Blanchot, Roland Barthes and others, I will investigate an aporetic structure—an impasse that is inherent in the nature of a situation or being—recurrent throughout my primary source, Marcel Proust's *In Search of Lost Time*. For Proust, nothing is truly experienced because of an aporia of presence and time. An event is not realized until experienced a second time, in a reincarnation that imparts meaning to the original experience. The latter becomes real by its dependency on this secondary experience, when Proust cannot be present for the original. While the essence of the first instance is preserved, Proust witnesses it outside of its place in time. He is torn between living in the present, building experiences without perspective in time, and reiterating his past to gain significance. This aporia futures capacity for experience, since it requires an impossibility in time. Applying this structure to experiences of color, travel, architecture, romantic love, writing, and more, Proust's narrator replicates a series of "little deaths," or limit experiences, that mimic the grandest iteration of aporetic experience: one's own death. Knowing one's death is impossible, for the moment it takes place, one is no longer present. This thesis will define the limit experience and nature of Proust's aporias before proving this structure and its fundamental importance across themes and dynamics threaded throughout Proust. I hope that my findings will cast new understanding on Proust's work and its nuances.

Finding the Child in Children's Literature

Lea Rackley, CURO Summer Fellow
Dr. Katarzyna Jerzak, Comparative Literature, Franklin College of Arts & Sciences

As a child of twelve I was disengaged not just from school, but also from the world and its possibilities as I saw them. Coincidentally, the child protagonists of the books I read were similarly disengaged. As an English Education major, I have wondered how I might have responded, at twelve, to portrayals of children not stereotypically disengaged but enamored of the world. In this autoethnographic study, I draw on experiential knowledge to consider the importance of how literature is chosen for children–with particular consideration of their individual needs—both within the classroom and outside of it. I compare various portrayals of the child protagonist throughout world children's literature, examining their orientations to issues identified as fundamental to the emotional and developmental needs of children. I consider the child portrayed as recognizing love as responsibility, the child seeing loss, fear, grief, and sorrow as enabling growth, strength, and endurance, and the child seeing learning not as compartmentalized within the classroom, contained within homework, but inseparable from the child's world. By contributing to the discussion about children's literature from this interdisciplinary perspective, and by suggesting standards upon which works are chosen for students, I also hope to contribute to thinking about the way children's literature is taught. With children's emotional and developmental needs as the primary focus of my work, reading, and analysis, this study looks for works that help children see themselves and their strengths more clearly.

Predictors of Tick Burden and Engorgement in Grant's Gazelle

Malavika Rajeev, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Vanessa Ezenwa, Odum School of Ecology

Despite the negative effects of tick infection and the widespread distribution of ticks in African ungulates, very little is known about the factors that affect patterns of tick infestations in this group of hosts. Our study examined possible predictors of tick burden and engorgement rates in the Grant's gazelle (*Nanger granti*). We captured 61 gazelle at the Mpala Research Centre, Kenya in June 2011; and sex, age, body weight, body size (body length and neck circumference), overall tick burden, and number of engorged ticks were assessed for all individuals. We found that females and younger animals had a higher average tick burden than males and older individuals. Body weight was negatively associated with tick burden, while body size was positively associated with tick burden. Body weight and body size were also significantly correlated with the proportion of engorged ticks, whereas sex and age had no significant effect. Our results support previous studies examining tick infestations in small mammals, which show that tick burden typically increases with body size. On the other hand, the negative correlation between body weight and tick burden may reflect the effect of body condition rather than size. Our results also suggest that body size and weight may affect tick engorgement. Overall, our study contributes to a better understanding of the relationship between intrinsic host factors and tick parasitism.

Relations of Substance Use to Constructive Communication and Sexual Violence in Young Adults' Romantic Relationships

Michael Rausher,
Isabel Cohen
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

The present study aims to better identify the relations between marijuana use, communication patterns, and interpersonal violence in young adults' dating relationships. Research suggests substance use may contribute to negative relationship outcomes and impact adults' abilities to form and maintain romantic relationships (e.g., Fals-Stewart, 2003). Additionally, current research indicates substance use may serve as a proxy for other deviant behaviors (e.g., Kilpatrick et al., 1997). While evidence supports relations between alcohol use, cocaine use, and sexual violence, less is known about if, how, and to what extent marijuana use may relate to interpersonal communication and sexual violence in college students' romantic relationships (e.g., Fals-Stewart, 2003; Ramisetty-Mikler et al., 2007). This paucity of information is important considering marijuana is one of the most readily available and frequently used drugs on college campuses. The present study utilized a sample of 62 undergraduate dating couples. Marijuana use was defined as reporting using marijuana three or more times during your life. Results indicate that there are significant differences between marijuana users and non-users regarding self-reports of Constructive Communication, measured by the CPQ, $t\,(60) = 2.98$, $p = .004$, and self-reports of perpetrated sexual violence, measured by the CTS, $t\,(60) = -2.90$, $p = .005$. Future research should explore the possible mechanisms through with the relation between marijuana and interpersonal violence functions.

Haemogregarines of Freshwater Turtle Species: Does Basking Behavior Influence Parasitemia Levels?

Luben Raytchev, CURO Summer Fellow
Dr. Michael Yabsley, Warnell School of Forestry & Natural Resources

Haemogregarines are intracellular blood parasites of freshwater turtles. These parasites are considered nonpathogenic and are transmitted by leeches. Although common, many aspects of the parasite-host relationship have yet to be elucidated. This project seeks to compare the parasitemias of haemogregarines among common species of freshwater turtles. We hypothesize that behavior (basking vs non-basking) will influence parasitemia levels with baskers having lower numbers of parasites. Turtles were trapped and bled at numerous locations in Georgia (Baker Co., in South Georgia and Clarke and Madison Cos., in North Georgia) and various ponds in Ingham Co., Michigan. In total, 90 turtles of 10 species from Georgia and 94 turtles of 5 species from Michigan were tested. Thin blood smears were made, fixed in methanol, and stained with Giemsa. Smears were analyzed under a light microscope (100x) to determine 1) whether haemogregarine parasites were present and 2) the parasitemia level within each turtle (based on number of infected cells per 7,000 cells examined). To date, no differences were noted in the parasitemias detected in Georgia or Michigan turtles, in general ($p = 0.338$), or by basking behavior (baskers, $p = 0.2766$; non-baskers, $p = 0.3382$). In contrast, significantly higher parasitemias were noted in non-baskers compared with baskers (Georgia and Michigan combined, $p < 0.0001$; Georgia only, $p = 0.004$; Michigan only, 0.003). These results indicate that basking behavior has a significant impact on the haemogregarine parasitemia levels in turtles. Currently it is unknown if basking reduces parasite burdens by limiting exposure to leeches or by increasing the immune response of the host.

Does Eggshell Pigmentation Reflect Female Condition in Broiler Breeder Hens?

Chelsea Renier
Dr. Kristen Navara, Poultry Science, College of Agriculture & Environmental Sciences

Brown eggshell pigmentation varies substantially among chicken eggs and is generated by the pro-oxidant protoporphyrin, a metabolite intermediate formed during the biosynthesis of heme. Protoporphyrin can cause oxidative stress damaging cells and tissues, creating reactive oxygen species, and inhibiting antioxidant systems. The hen's ability to sustain high levels of protoporphyrin in the blood for deposition into eggshells may convey information about female condition. Due to the costs of protoporphyrin generation and deposition, a positive correlation might be expected to exist between female condition and egg color. To test this, six consecutive eggs were collected from each of thirty-one broiler breeder hens and colors were analyzed using a 10 megapixel digital camera and Adobe Photoshop software. During the period of egg collection, the condition of each hen was assessed through weighing, tarsus length measurements, and blood collection for subsequent analysis of circulating levels of corticosterone (a stress hormone), heterophil/lymphocyte ratios (a measure of stress and immunity), and total antioxidant capacity of blood. Condition indices were then related to average measures of hue, saturation, and brightness to determine whether darker egg colors reflect better female condition. We predicted that hens laying darker eggs would weigh more, have lower stress indicators, and a better antioxidant capacity. Results may help determine hen quality in the poultry industry.

DNA Hybridization in the Presence of Single-Walled Carbon Nanotube/ssDNA Complexes

Julian Rios, CURO Honors Scholar
Dr. Marcus Lay, Chemistry, Franklin College of Arts & Sciences

Single walled carbon nanotubes (SWNTs) are cylindrically shaped carbon molecules that have exceptional structural, electrical, and thermal properties. Due to their unique characteristics, SWNTs may form reliable and efficient biosensors for proteins, sugars, and DNA. Single stranded DNA (ssDNA) readily binds to SWNTs because the positively charged base pairs on the DNA are attracted to the loosely bound sp2 hybridized electrons in a SWNT. Due to this electrical interaction, DNA unwinds and wraps around a SWNT, allowing the nanotube to act as a mediator during the formation of double stranded DNA. The DNA/SWNT complex not only allows for SWNTs to readily dissolve in water, but also enhances the detection of DNA using Raman spectroscopy through surface enhanced Raman scattering (SERS). The DNA/SWNT complex is formed by adding ssDNA to a solution of dispersed SWNT in sodium dodecyl sulfate (SDS). The SDS was later removed through dialysis. After binding was detected by UV-Vis spectroscopy, the complementary strand of ssDNA was added and allowed to hybridize to the DNA bound to the nanotubes. All unbound DNA was then removed from the solution using dialysis. The final suspensions were analyzed using UV-Vis-NIR spectroscopy. The suspensions were also deposited on copper nanoparticles for characterization with SERS. Once functionalized, the increased solubility and enhanced detection allow the DNA/SWNT complex to be an excellent biosensor which can lead to the more effective detection of early treatment of diseases such as diabetes and Parkinson.

An Examination of Communication and Employee Engagement

Stephen Robertson,
Aaron Murray
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

The present study seeks to examine the relationship between management communications and employee engagement. More specifically, we propose to focus on manager relations as a mediating variable in the relationship between communication and engagement. The current literature on organizational leaders and perceived organizational support provide a theoretical background for the relationship between communication and manager relations. As salient representations of the organization, leaders play an important role in establishing perceived organizational support through giving meaning to organizational activities (Baranik, Roling, & Eby 2009; Cherniss, 1995; Drath & Palus, 1994; Smircich & Morgan, 1982). Utilizing literature from Blau's (1964) social exchange theory support can be found for the relationship between manager relations and engagement. The present study sample includes 2,557 participants from a large Fortune 50 company. From these participants, we will compare the nature of the mediated relationship for both managers and non-managers.

Combatting Obesity by Eliminating Food Deserts in Athens-Clarke County

John Rodriguez
Dr. Gail Hanula, Foods & Nutrition, College of Family & Consumer Sciences

Athens-Clarke County mirrors the rising trend in obesity seen at national and state levels. From 2004 to 2008, the adult obesity rate in Athens increased from 24.7% to 27.1%–a rise of 10% in just over four years. Excess body fat is detrimental to individuals and societies, fostering chronic health conditions and causing higher annual medical costs. More

and more, research and policy interventions are targeting community-level environments as a way to address the persistence of obesity. Of particular importance in Athens-Clarke County is the food desert, which is any low-income tract where a high percentage of individuals face limited financial and geographical access to a full-service grocery store. Approximately 20% of the Athens population lives in such conditions, relying on convenience stores that do not provide for an adequate, balanced diet. This project attempts to analyze the shortcomings of current policy in Athens-Clarke County to combat rising obesity rates. It draws on literature examining community-wide intervention obesity initiatives, supplementing it with expert opinions from Athens officials. The project proposes three possible courses of action to eliminate food deserts as a method of combatting obesity in Athens-Clarke County: (1) implementing farm to school programs; (2) funding a mobile farmers market; and (3) expanding community gardens. After a multigoal (effectiveness, cost, feasibility) analysis, the research concluded that a combination of farm to school programs and a mobile farmers market would be the best policy to decrease the obesity trend and encourage healthier lifestyles.

No Triumph Without Loss: Problems of Interracial Collaboration in Tolkien's Works

Hope Rogers, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Jonathan Evans, English, Franklin College of Arts & Sciences

Tolkien peopled his fantastic world of Middle-earth with various races, from Elves and Dwarves to Hobbits and Men, and further subdivided those races into different ethnicities and cultures. Although many critics have discussed Tolkien's races, few have taken a comprehensive look at them from a real-world perspective, and still fewer have gone beyond praising Tolkien's celebration of diversity to explore the loss that accompanies it in his stories. Through an exhaustive study of Tolkien's works and letters, as well as relevant criticism, this study examines how the interactions of Tolkien's races relate to modern race issues. It focuses on his portrayals of the causes of conflicts and the problems that accompany other racial interactions, such as trade inequalities and acculturation. Tolkien uses Middle-earth as an arena to play out issues of prejudice, exploitation, and globalization and to explore possible responses as different as isolationism and intermarriage. He thus challenges readers to look at the ultimate consequences of such responses and to reevaluate supposedly ideal solutions. Far from being escapist fantasy, Tolkien's works have a unique relevance to the real world with their all-too-real pictures of the complexities of racial interactions.

The Skeleton in the Closet: Deadly Duplications in Mary Shelley's *Frankenstein*

Hope Rogers, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Michelle Ballif, English, Franklin College of Arts & Sciences

Pieced together from the bodies of men and beasts, the monster from Mary Shelley's *Frankenstein* has fascinated casual readers and critics alike. And of the many critics who have written about the novel, a small yet significant number have explored its themes of race and miscegenation, describing the monster as a racially Other or miscegenated being. These critics, however, have failed to notice the book's overriding drive for homogeneity that ultimately characterizes the monster not as the Other but as Victor's double. In my in-depth analysis of the novel, I first establish how the Frankensteins and other characters preserve the integrity of their homogenous community and prevent contamination by difference by constantly duplicating themselves, absorbing and thus effacing difference through semi-incestuous

relations and assimilatory practices. These doublings threaten the Hegelian dichotomy between Self and Other, in which the Self can only exist by being defined against an Other. This threat is realized in Victor's unnatural creation of the monster, his perfect double, which totally destroys the Other, breaking the dichotomy and resulting in the death of Self, a consequence acted out through the monster's murders. Shelley's novel is thus a tale not of difference, racial or otherwise, but of the destructiveness of forced homogeneity, a reading that both highlights the novel's complexities and provides a forceful reflection on our own world.

The Implementation of Effective Smoking Cessation Interventions for Drug and Alcohol Addicts in Substance Abuse Treatments

Mark Rolfsen, CURO Summer Fellow
Dr. Jessica Muilenburg, Health Promotion & Behavior, College of Public Health

The prevalence of smoking among individuals in substance abuse facilities is very high, between 70%-95%. However, only 51.3% of drug treatment facilities in this study offered either medication or counseling for nicotine dependence. Previous research demonstrates that addiction to nicotine may affect the brain in a way that decreases the chance of prolonged sobriety. Understanding what characteristics of treatment facilities allow them to most effectively implement smoking cessation practices would be highly cost effective versus the alternative of dealing with patient relapses. The study that I worked with conducted telephone interviews with 850 directors of substance abuse facilities. I looked at two aspects of these interviews: factors that might influence a facility's likelihood of offering smoking cessation, and factors that are associated with a strong attitude towards smoking cessation. Three factors- staffing, training, and financials -were measured using questions answered on a 5-point scale. Out of these three areas, financials was the only factor that had a significant correlation ($p < .05$) with the prevalence of a smoking cessation program. Likewise, program director attitude was measured on a 5-point scale. Neither recovery status, time in the field, nor educational level had any correlation with a director's attitude towards the effects of smoking cessation on sobriety. However, the majority, 67.4%, of directors felt that smoking cessation increased a patient's chance of sobriety. Further analysis of which factors are important in implementing smoking cessation practices will hopefully yield higher levels of nicotine treatment, and therefore enhance the nation's ability to promote prolonged sobriety.

Architecture and Dress

Meghan Russell
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

My research investigated how architecture and dress (defined as modifications and supplementations to the body) are related, beyond both being essential for human survival. In order to explore modern collaborations between architects and designers, I closely studied art exhibits and investigated scholarly projects and ideas of fashion designers whose designs emulate architecture. From my research, I concluded that space and the way it is connected to the human body is the main driving force that links architecture and dress. We as humans not only conceive space as our environment in which we are located, but also view our bodies as our personal space. We wrap ourselves in clothing and enclose ourselves in a room within our homes or public buildings in similar ways. Both architecture and dress help us stay protected from the elements or the mocking of societies that often harshly judges the human form.

The Resistance Complex in Lyon: Politics, Memory, History

Kayci Schoon
Dr. Steven Soper, History, Franklin College of Arts & Sciences

Considering the essential role of the city of Lyon in the French Resistance, surprisingly little has been written specifically on this subject. The French Resistance movement and occupied France have been contentious topics ever since the release of Robert Paxton's *Vichy France: Old Guard and New Order*, which tore down decades of denial about France's collaboration with Germany. Lyon, as "the Capital of the Resistance," was Charles de Gaulle's base for the movement, placing Lyon's activities and prime résistants at the center of France's Gaullist myth – the idea that France was a nation of heroic résistants. This myth was useful for inspiring national unity and popularizing de Gaulle, but it also seeped its way into historical studies and memoirs, producing many misunderstandings about the nature of the Resistance. My goal is above all to demonstrate the true complexity of the Resistance in Lyon – that it did not comprise simply Lucie Aubrac and other idealized non-Jewish liberals, but it included Catholics, Communists, Jews, as well as a variety Gaullist movements, that struggled to reconcile their differences. When achieved, unity often meant to ignore their differences at the cost of nuance and accuracy, as is reflected in the language of Gaullist clandestine newspapers and de Gaulle's vague speeches. I also demonstrate the breadth of the Lyonnais Catholic resistance movement, which has often been overlooked despite its significant achievements and drawbacks. In so doing, I hope to emphasize Lyon's role in the formation of the French Resistance myth, and how breaking down the myth through the Lyonnais paradigm will help us better understand the reality of the Occupation.

Progress Toward Sustainability Goals at UGA's Costa Rica Campus in San Luis de Monteverde, Costa Rica

Dana Schroeder, CURO Summer Fellow
Dr. Quint Newcomer, Odum School of Ecology

Since its inception in 2002, UGA Costa Rica (UGA CR) in San Luis de Monteverde has operated under a business model that heavily emphasizes environmental, social, and economic sustainability. Hosting an average of 27 students, faculty, researchers, and tourists per night in 2010, this cloud-forest campus has been developed to protect the surrounding ecosystem, support the local economy, and immerse guests in the local culture. Progress toward sustainability goals is investigated and reported in an annual sustainability report. Documents including management plans, protocols, accounting records, and resource use data compiled for the *2011 Sustainability Report* show that UGA CR is meeting monthly targets for resource use in 10 months out of the year, 82.5% of waste is being diverted from landfills, and some organic waste is even being converted to cooking fuel in the campus's new biodigestor. After interviewing staff and hosting departmental meetings to complete the Earth Charter Ethics-Based Assessment Tool, we have indicated potential areas for improvement. Specific focus could be placed on improving commitment to poverty eradication, expanding on-site renewable energy generation, and raising awareness for environmental issues through mass media. Indicating these areas for improvement and making recommendations for future initiatives will ultimately help UGA CR reach its goals listed in the *Vision for 2015*, earn a higher rating in the Certification for Sustainable Tourism, and set an example for the UGA community in Athens to incorporate more sustainable practices into its operations.

Abstracts

Assessing Rce1-Protease Inhibition in a Cell-Based Fluorescence Ras Localization Assay

Daniel Sharbel, CURO Summer Fellow
Dr. Timothy Dore, Chemistry, Franklin College of Arts & Sciences

Ras proteins function at the plasma membrane to induce several intracellular pathways, some of which are involved in cell proliferation. If the Ras gene is mutated to become constitutively active, cell cycle misregulation and rampant cell growth may occur, leading to tumorigenesis. In the second of three post-translational modifications to the Ras carboxy-terminus CaaX motif, Rce1p endoproteolytically cleaves the -aaX sequence after prenylation of the free cysteine thiol. Rce1p is an ideal target for Ras inhibition since it is a universal modifier of proteins in the Ras superfamily. Previous findings show that small molecule inhibition of Rce1p activity in *S. cerevisiae* causes Ras mislocalization, but investigation of inhibition in mammalian cell culture has not been conducted. Our study utilized a simple fluorescence-based cell culture assay to assess the ability of small molecule inhibitors of Rce1p to cause Ras mislocalization in mouse embryonic fibroblast (MEF) cells. We transfected both null *(Rce1-/-)* and wildtype (*Rce1+/+*) cells with a green fluorescent protein-tagged Ras isoform (GFP-KRas4B) plasmid construct as positive and negative controls, respectively, and observed the degree of Ras localization to the plasma membrane with fluorescence microscopy. A distinct, binary difference in phenotype between *Rce1-/-* and *Rce1+/+* MEFs was not initially observed, so we conducted a time-trial transfection and imaged cells under a confocal microscope at 24, 36, and 48 h. Our assay shows that the GFP-KRas4B construct is not ideal for studying Rce1p inhibition. Other GFP-tagged Ras family members, like GFP-Rnd3 and or GFP-RhoB, may be more suitable to quantify inhibitor activity.

Intravenous Minocycline and Its Effect on Peripheral Interleukin-6 After Ischemic Stroke

Andrea Sikora, CURO Scholar Graduation Distinction
Dr. Susan Fagan, Clinical & Administrative Pharmacy, College of Pharmacy

Due to a favorable safety and pharmacokinetic profile, anti-inflammatory activity, demonstrated compatibility with t-PA, and efficacy in multiple pre-clinical stroke models, minocycline shows potential to improve therapeutic outcomes in ischemic stroke. In this early phase trial of intravenous minocycline in acute ischemic stroke patients, blood samples were collected to quantify the effect of minocycline on inflammatory biomarkers. IL-6 levels have been associated with stroke severity and clinical outcome. Following an open-label, dose-escalation design, minocycline was administered intravenously within 6 hours of stroke symptom onset in preset dose tiers of 3, 4.5, 6, or 10 mg/kg daily over 72 hours. Blood samples for biomarker analysis were drawn at 24 after symptom onset and analyzed using ELISA techniques. The effects of minocycline on interleukin-6 were subsequently compared to a historical control group and literature values of IL-6 in acute ischemic stroke. A statistically significant association was found between patients that received minocycline and non-detectable IL-6 levels, with patients receiving minocycline 7.16 times (95% CI 2.64-19.38) more likely to have a non-detectable IL-6 level than those patients that did not receive minocycline. In conclusion, minocycline shows robust anti-inflammatory activity and prevents the rise in IL-6 levels due to ischemic stroke

Proteomics Analysis of Canine Prostate Carcinoma Tissue: A Potential Animal Model of a Human Disease

Peter Sisk
Dr. Ron Orlando, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Animal models have often been used in cancer research due to neoplasms that exhibit similar characteristics to human cancers. Male humans and canines are the only large mammals that spontaneously develop prostate cancer, exhibiting a potential model for human prostate cancer. In this work, a GeLC-MS proteomics approach was used to identify protein expression from normal and carcinoma canine prostate tissue. Soluble proteins were extracted from tissue samples and analyzed using an Agilent 1100 LC system interfaced online to a Thermo-Fisher LTQ mass spectrometer. Resulting LC-MS/MS files were database searched via Mascot, with identifications analyzed using ProteoIQ software. DAVID bioinformatics software was used to determine biological significance of identified proteins. Previously published proteomic data used MALDI MS/MS to analyze only proteins displaying more than a 2.5-fold difference between carcinoma and normal tissue samples using 2-D DIGE spots, leading to only 9 proteins being analyzed. Using the GeLC-MS/MS strategy, all potential proteins were analyzed in the carcinoma and normal prostate samples. Preliminary data shows that 942 total protein groups were identified with 863 of the proteins overlapping between the normal and carcinoma samples. Using differential analysis, 69 proteins were found only in the carcinoma samples, while 10 unique proteins were found in the normal cells. All identified proteins will be run through DAVID Bioinformations Resource to look for any biological pathways these proteins may be associated with.

Inferno

Daniel Smith, CURO Summer Fellow
Prof. Michael Marshall, Lamar Dodd School of Art

In his 14th-century masterwork, *Inferno*, Dante Alighieri describes a place where people exist entirely out of contact with God, having only each other and their own, self-willed damnation for comfort. In today's increasingly secular culture, Dante's *Inferno* retains a resonance less present in Purgatorio and Paradiso, precisely because the characters' utter isolation from God relates to contemporary culture's existential awareness. With the resources of a 2011 CURO Summer Fellowship, I investigated the literature and art surrounding Dante's poem to inform the creation of a large-scale, photographic illustration of the work. I quickly realized the difficulty in photographing the impossible images that I envisioned, and so I invented a method of photographic compositing emphasizing contemporary art techinques for contemporary audiences. The ultimate result of two semesters using this new method is "Inferno," a 5'x27', Last Judgment-themed photomural, illustrative of ideas and aesthetics in Dante's masterwork, numerous Italian and Northern European Renaissance artworks, and historic photographic practices. In my photomural I attempt to portray many of Dante's characters, while reinventing them and structuring my own vision of the world that they inhabit. This world is not merely relevant to the wicked but to all people. "Inferno" is more than a recapitulation of Dante's hell; it is a contemporary, human hell which tells the divine tragedy of man's story.

Characterization of a Putative Endonuclease-RNA Complex Involved in CRISPR-Mediated Viral Defense

Justin Smith, CURO Summer Fellow
Dr. Michael Terns & Dr. Rebecca Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Genomes are under the constant threat of deleterious alteration or disruption from exogenous genomic elements such as viruses, transposable elements, or plasmids. Consequently, evolution has led to the creation of defensive systems that function to protect cellular genomes from attack. One such system, the CRISPR-Cas System, discovered in prokaryotic organisms has the ability to not only silence invaders but also to acquire heritable immunity from genome invaders. My focus resides with a prokaryote that outlines a well-studied CRISPR-Cas system. This bacterium, *Streptococcus thermophilus*, has recently been shown to have the ability to acquire resistance to a number of bacteriophages through destruction of invader-derived dsDNA1. The Cas protein, Csn-1, has been found to be required for this invader silencing, however its precise role in defense has yet to be determined. My goal is to determine the role that Csn-1 plays in defense of silencing invaders, possibly through direct cleavage of invader dsDNA and/or a potential role in the crRNA biogenesis. I will test the ability of Csn-1 to cleave invader-derived dsDNA using a crRNA guide to determine if Csn-1 functions in the Invader Silencing Stage of the CRISPR-Cas immune pathway. If catalytic activity is observed directly by Csn-1, the putative catalytic residues will be substituted through site-directed mutagenesis to assess whether these amino acids are required for catalysis as well as which predicted endonuclease active site is responsible for cleavage. Finally, to ensure the findings are physiologically relevant, I plan to reintroduce the mutant Csn-1 proteins into a mutant strain of *Streptococcus thermophilus* that lacks Csn-1, and assess effects on crRNA biogenesis and invader (phage and/or plasmid) silencing. These findings will provide the first molecular details of CRISPR mediated silencing of invader-derived dsDNA.

Determination of Virulence Factors Associated with *Histomonas meleagridis*' Cause of Blackhead's Disease in Gallinaceous Birds

Matthew Smith
Dr. Robert Beckstead, Poultry Science, College of Agriculture & Environmental Sciences

Histomonas meleagridis is the causative agent of Blackhead Disease in gallinaceous birds. It causes cecal inflammation and can spread to the liver leading to liver failure and death. This disease is known to have 80-100% mortality in turkey flocks. In a previous study, *H. meleagridis* was shown to lose virulence upon passage in culture suggesting a variation in pathogenicity that is also observed in the field. Our lab has identified potential virulence factors whose expression is lost upon passaging in laboratory cultures. To test the ability of these genes to cause disease, we are designing experiments to express putative virulence factors in a non-virulent strain of *H. meleagridis* via transgenesis. We are currently designing a transformation protocol specifically for *H. meleagridis*. My research project has been to design, generate and test this expression system. To do this, we cloned the *H. meleagridis* beta-tubulin promoter upstream of the neomycin resistant gene. A polyadenylation signal sequence was also cloned downstream of the neomycin gene to promote stable mRNA expression. Currently we are testing several electroporation

conditions to assess the ability of this construct to confer resistance to G418. Upon successful transformation of *H. meleagridis,* we will generate new vectors that contain sequences encoding virulence factors in place of the neomycin resistance gene, and test their affect the pathogenicity of *Histomonas meleagridis* in turkeys. Virulence genes identified in these studies will be targets for future drug development and vaccine production.

Compelling State Interest: A Study of the Unequal Application of Strict Judicial Scrutiny

William Smith
Dr. Peter Hoffer, History, Franklin College of Arts & Sciences

The concept of judicial scrutiny surrounding the free exercise clause has created an extremely esoteric and controversial method for determining the outcome of particular cases in the Supreme Court. For centuries, Court Justices have struggled to find a procedure that effectively protects the free exercise of religion, while still maintaining the integrity of the federal and state legislatures. Eventually, the Supreme Court developed a balancing test known as "compelling state interest," which would place the burden on the state to prove that the law in question was necessary to protect the state's interest. Originally, this balancing test was widely accepted by religious and secular pundits, as it appeared to be a method designed primarily to protect religious rights while still allowing the state a process for overriding that right if necessary. However, this paper will discuss recent cases decided by the Court, which reveal that the justices do not use this balancing test objectively. Through the study of the justices' opinions in two Court cases involving the rights of Christian interests, as well as their opinions in two cases involving the similarly exploited rights of Native American interests, it is apparent that strict judicial scrutiny is not applied equally. In this paper I argue that law itself is not as impartial as it is often believed to be, and that the justices of the Supreme Court are often guided by the same economic interests and inherent racism the judicial system is designed to prevent.

The Science of Monitoring Rare Species: Developing Methods to Locate and Survey for the Endangered Bog Turtle

Theresa Stratmann, CURO Summer Fellow
Dr. John Maerz, School of Forestry & Natural Resources

North America's smallest turtle, the bog turtle (*Glyptemys muhlenbergii*), resides in the bogs of the eastern United States. Habitat loss and deterioration, as well as illegal collection for the pet trade, have resulted in this turtle being listed as Critically Endangered under the International Union for Conservation of Nature (IUCN) Red List. Cryptic and rare, it is extremely difficult to assess their population status. In addition, monitoring efforts are often done in a manner that cannot be used to estimate species detection rates, population abundance, or population viability. Time-effective methods of surveying for new populations are also largely lacking. To address these deficiencies several mentors and I are (1) developing a species distribution model (SDM) for the bog turtle to better predict where populations should occur, (2) determining the best methodology and minimal effort required to determine with confidence whether bog turtles are present at a site, and (3) testing the SDM and trapping methodology in South Carolina where bog turtles have not been seen in over a decade. Current analyses are based on what we have learned from a basic SDM and a season of mark/recapture data collected in Georgia using the new methodology. We hope this project will help state wildlife agencies in their efforts to conserve bog turtles. More generally, it is a case study that will contribute to designing robust monitoring of rare and cryptic species.

Proteome Studies of the Interation Between *Botrytis Cinerea* and Tomato Fruit

Andrew Suddreth
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Botrytis cinerea is a pathogenic filamentous fungus that infects more than 200 plant species, many of which are of agricultural interest. *B. cinerea* secretes enzymes that degrade pectin, a major component in plant cell walls. This study tries to identify what proteins are secreted by the fungus at different time points during the growth period by using pectin as carbon source. To do this, a model system was constructed. We prepared a liquid pectin media to culture *B. cinerea* and we used tomato fruit, a known plant that *B. cinerea* infects, as our agricultural crop of interest. The first part of the project will be the standardization of protein extraction using a model system (liquid media). Once the protein extraction protocol had been standardized, we could identify the secreted proteins from the interaction between tomato fruit and *B. cinerea*. The liquid pectin media was inoculated with *B. cinerea* and samples were obtained every 24 hours for seven days. We followed a protocol to concentrate the secreted proteins for analysis. The concentrated proteins were then subjected to TCA protein precipitation, Bradford protein assay, SDS-PAGE gel electrophoresis, tryptic digestion, mass spectrometry and database searching. Proteins were identified by using a target database created by combining the *B. cinerea* BO5.10 (Broad Institute, MA), and T4 databases (Genoscope, France). A decoy database was constructed by reversing the sequences in the target database. Statistically significant proteins were determined for all of the samples at a 1% protein FDR using ProteoIQ Software.

Measuring Chronic Ankle Instability in a Recreationally Active Population

Christopher Sudduth, CURO Summer Fellow, CURO Scholar Graduation Distinction
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

After suffering a lateral ankle sprain, a significant number of people report residual symptoms such as pain, swelling, instability, and a feeling of the ankle joint "giving way" during activity. These recurring symptoms have been coined Chronic Ankle Instability (CAI). This definition is vague and does not empirically quantify the degree of ankle instability. The aims of this study were to establish the reliability of the LigMaster, an instrumented ankle arthrometer, in assessing ligament laxity and to characterize CAI by evaluating the relationships between ankle laxity and self-reported ankle function. Twenty-four participants had lateral ankle ligament laxity assessed using the LigMaster. They self-reported scores of ankle function using two questionnaires. Two testers measured ankle laxity on multiple days for a subset of participants. Intraclass correlational (ICC) values were calculated to measure the reliability of the LigMaster. Correlation coefficients were calculated to measure relationships between ankle self-report function and ligament laxity. ICC values ranged from 0.00 to 0.90 on the LigMaster. Significant correlation coefficients were found between lateral displacement and questionnaire scores ($R=-0.476$ and -0.506; $p<0.05$). The LigMaster can be considered a reliable tool between testers on a single day and within a single tester on the same day. However, reliability across days is low to moderate. As ankle instability increased, self-reported ankle function decreased, in a moderate relationship. It appears the LigMaster can be reliably used to measure ankle laxity, and increased laxity is associated with poorer ankle function.

Pathogenesis of Chicken Astrovirus as Studied by In-Situ Hybridization

Lauren Sullivan, CURO Scholar Graduation Distinction
Dr. Corrie Brown, Pathology, College of Veterinary Medicine

The purpose of this study is to characterize the pathogenesis of disease caused by chicken astrovirus(CAstV). CAstV is a single-stranded positive-sense RNA virus reported to be a contributing agent in the runting-stunting syndrome (RSS) in broilers. Key features of RSS include diarrhea, delayed development, and increased mortality; however, little is known about the pathogenesis of the disease. For this study, chicken embryos were inoculated with CAstV, at 17 days of embryonation. The negative control group was inoculated with phosphate-buffered saline (PBS). Tissues were harvested at day of hatch (three days post-infection). In-situ hybridization was performed using a negative-sense digoxigenin-labeled riboprobe complementary to the polymerase gene of CAstV. In the CAstV-infected group, intestinal tissue from all infected birds demonstrated positive signal. Preliminary analysis indicates that the virus infects and replicates predominantly in the cells lining the sides of the villi.

The Interaction of Tau Proteins and Hirano Bodies

Connor Sweetnam, CURO Honors Scholar, CURO Summer Fellow
Dr. Marcus Fechheimer, Cellular Biology, Franklin College of Arts & Sciences

Alzheimer's disease (AD) is the fastest growing neurodegenerative disease in the world and is characterized by memory loss, dementia, and difficulty in communication. AD has two hallmark pathologies, amyloid plaques and tau tangles. In addition, Hirano bodies are observed with AD. Hirano bodies (HBs) are actin-rich inclusions that occur in the brains of patients with neurodegenerative diseases. Although the function of these pathologies is not known, tau- and beta-amyloids are linked to cell death. Mutant forms of tau are well known to contribute to cell death in diseases like Parkinsonism-linked frontotemporal tau dementia (FTDP). Hyper-phosphorylated tau increases cell death and may play a role in Alzheimer's disease as well as other tauopathies (diseases attributed to tau). Previous studies in the Fechheimer lab show that Hirano bodies dramatically reduce cell death due to hyper-phosphorylated tau. These results and the fact that tau binds well to F-actin, the main constituent of HBs, have led me to ask whether tau affects Hirano body size and formation. In my experiments, H4 astroglioma cells were transfected with CT-GFP, a construct that induces HB formation, with and without mutant or wild type tau. Cells were examined using fluorescence microscopy, and images were analyzed to compare the different actin and Hirano body structures in a cell with or without tau. I have found that different forms of tau affect Hirano body size. This study enhances our understanding of the mechanism of how Hirano bodies protect against tau-induced cell death and contributes to our understanding of neurodegenerative disease.

Characterization of *cis/trans* Phosphorylation Modes in a Eukaryotic Protein Kinase

Nakul Talathi, CURO Summer Fellow
Dr. Natarajan Kannan, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Most eukaryotic protein kinases are activated via phosphorylation of a residue in a loop called the activation loop, which allows the kinase to adapt an active conformation. Interestingly, some kinases are autophosphorylated, including the Aurora kinase, a protein involved in spindle formation. Mechanistically, autophosphorylation could be *trans,* where one molecule phosphorylates another, or *cis,*

in which the same molecule is both substrate and enzyme. In order to determine the mode of autophosphorylation in the *Aurora* kinase, wild type protein was combined in solution with a kinase dead mutant and a phospho-Aurora antibody was used to check phosphorylation of the mutant. Lack of phosphorylation on kinase dead mutant suggested that the mode of autophosphorylation is not *trans*. *Cis* autophosphorylation is characterized by the rate of reaction being concentration independent. The *cis* autophosphorylation was examined by autophosphorylation levels in two different concentrations of *lambda phosphatase* treated wild-type protein. The preliminary data suggests that the kinase undergoes *cis* autophosphorylation. The current understanding of the activation loop phosphorylation is that it is part of a signaling cascade of kinases. However, because of the similarities of the *Aurora* kinase and its phosphorylation loop to other kinases, the fact that it undergoes *cis* autophosphorylation could be indicative of some other kinases undergoing similar mechanism. This would be important in the field of cancer, because some kinases could activate themselves and cause disease. Additionally, because the *Aurora* kinase is an oncogene, this *cis* autophosphorylation could lend insight into its malfunctions.

Social Media's Effect on the Arab Spring Revolutions

Stephanie Talmadge
Dr. Leara Rhodes, Grady College of Journalism & Mass Communication

Social media has opened up a new realm of journalism, which has been particularly important for the countries of the Arab Spring Revolutions. In this study, the government overthrows in Egypt, Libya and Syria were examined to determine whether or not these events occurred before these three countries were ready to implement a more democratic form of government. "Democracy" is defined by the presence of three factors: a strong leader, free elections, and an independent media where citizens can freely exchange ideas. I hypothesize that if the countries were not ready, social media would spur protesters to action, but the following revolution would be messy and not have a clear outcome. If the countries were ready, however, I posit that the revolutions would happen quickly, involving a smooth government ousting, and have a clear outcome. Newspaper articles were retrieved from the International Herald Tribune, The Daily New Egypt, Syria Today and The Tripoli Post using the key words "social media and uprising" between January 2011 and August 2011 to produce empirical data. Ultimately, I concluded that the implementation of social media could have caused the Arab Spring Revolutions to happen before Egypt, Libya and Syria were ready to receive democracy because the outcome in all three is still unclear and no obvious leaders have emerged.

Examining the Function of O-GlcNAc in Regulating Intracellular Signaling Pathways During *Drosophila* Development

Korry Tauber, CURO Summer Fellow
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The addition and removal of O-linked N-acetylglucosamine (O-GlcNAc) at serine and threonine residues is an essential regulator of intracellular signaling pathways. Like phosphorylation, O-GlcNAc modification acts to significantly alter the function of the protein to which it is attached. There has been considerable research documenting the functional implications of phosphorylation; such as acting as a regulator of cell growth and differentiation. Contrarily, the functions of O-GlcNAc are still being discovered and relatively little attention has been paid to the involvement of O-GlcNAc in cell processes.

As with kinases and phosphatases, O-GlcNAc modification is controlled by regulated and compartmentalized enzymes; O-GlcNAc transferase (OGT) and O-GlcNAcase (OGA). Currently, it is impractical to study the function of O-GlcNAc in mammalian species because the loss of O-GlcNAc is lethal. However, the genetic tools provided by Drosophila allow us to examine the effects of increasing and decreasing O-GlcNAc levels in specific tissues. This project aims to better understand the function of O-GlcNAc by altering the expression of OGT and OGA within specific cells of *Drosophila melanogaster*. Our results indicate that diminishing the attachment of O-GlcNAc to intracellular proteins in engrailed-expressing cells reduces the amount of wingless protein the cells secrete. Coupled with previous preliminary analyses, now reproduced and optimized here, that revealed the loss of the entire posterior wing section in O-GlcNAc deficient wing discs, it is becoming increasingly clear that O-GlcNAc is essential for normal wingless signaling. Further research will aim to examine phenotypic penetrance in larval wing discs and quantify protein expression in both wing discs and embryos.

Teacher Evaluation Methods in Georgia Public Schools

Matthew Taylor
Dr. Sally Zepeda, Lifelong Education, Administration & Policy, College of Education

Students in Georgia's public schools are lagging behind the rest of the nation. According to the National Assessment of Educational Progress (NAEP), a nation-wide test of 4th and 8th graders, Georgia ranks among the bottom 15 states of the nation in reading and math. While numerous variables influence students' educational outcomes, the most important school-related factor is the quality of teachers.

In order to assess the ways in which teacher evaluation methods could be improved to increase the quality of teachers in Georgia's public schools, I reviewed relevant scholarly research and conducted interviews with education scholars and policy experts. Over the course of the research, it was discovered that the current system of Georgia Public Schools identifies very few ineffective teachers, does not incentivize good teaching, and does not have accurate information on which to base employment and compensation decisions. In addition, the value-added tests currently in place to measure teacher effectiveness are in many cases inaccurate due to the small sample size involved. In the wake of these findings, I suggest that the formation of an independent body of teacher evaluators would increase the quality of teachers by providing unbiased feedback to the teachers, as well as accurate qualitative information to be used in schools' employment and compensation decisions. These findings are important because they embody a critique of the status quo, as well as a viable alternative to it. By improving teacher evaluations, we improve the quality of teachers, and thereby give Georgia's students the education they deserve.

The Effect of Lipoic Acid on Inflammatory Cytokines and Messenger RNA Levels in Microglial Cells

Lauren Titus
Dr. Nick Filipov, Physiology & Pharmacology, College of Veterinary Medicine

Parkinson's Disease is a crippling neurodegenerative disorder, whose symptoms are caused by dopaminergic cell death in the substantia nigra. The cause(s) of this cell death is still largely unknown, but numerous studies have demonstrated that reactive oxidative species and inflammatory cytokines produced in brain microglial cells damage neighboring dopaminergic neurons, possibly by triggering apoptosis. Microglia could be activated by

multiple factors, one of them being lipopolysaccharide (LPS), an endotoxin from gram(-) bacteria. When microglia are activated by LPS, they secrete inflammatory cytokines such as TNF-a and IL-6, as well as reactive oxygen and nitrogen species. My research focuses on the anti-oxidant lipoic acid, a non-essential fatty acid able to pass through the blood-brain barrier and its anti-inflammatory effects. Because certain antioxidants also exhibit anti-inflammatory properties, I hypothesized that lipoic acid would neutralize damaging reactive oxygen species, decreasing inflammatory cytokines produced. If neuroinflammation of microglia can be reduced by lipoic acid, then, potentially, the severity of PD could be lessened. To test this hypothesis, I pre-treated microglial cells with varying amounts of lipoic acid and then activated them with LPS. I performed ELISAs and quantitative PCRs to determine how lipoic acid affects the expression and transcription of two inflammatory cytokines, TNF-a and IL-6. The results showed that lipoic acid pre-treatment decreased the expression of TNF-a and IL-6 (24hr) and that this decrease at the protein level correlated with a decrease in mRNA levels of these two cytokines, particularly TNF-a (4hr). This suggests lipoic acid decreases inflammatory cytokine transciption or mRNA stability.

Global Web Advertising: How Different Countries Regulate Digital Advertisement

Emma Torpy
Dr. Leara Rhodes, Grady College of Journalism & Mass Communications

In an increasingly globalized market, corporations and organizations are increasingly utilizing to the internet as a platform to build relationships. This process especially manifests itself in online advertising. Since the internet is a worldwide medium—it is the most efficient for a global market. The question is: Do advertisements on the web fall under different laws and jurisdictions in different countries? With so many countries, and their varied laws, able to access one site—how do we regulate and protect content? Thus far, most guidelines for digital advertising have been based on laws pertaining to print. These laws differ from country to country. For example, while in the United States advertising is regulated by the Federal Trade Commission, the United Kingdom monitors its advertising through "self regulation" (in which the industry itself decides fair practices). Yet, in Singapore, historically the emphasis has been less on protecting the consumer and more on nation-building and monitoring sensitive themes. They do not yet have a legal framework for advertising regulation (Hoy 2008). International corporations need to be aware of the differences between communication laws in countries. In this paper, we will take a brief look at the web advertising laws of the major economic powers in the world—the G8 countries. These countries—Canada, France, Germany, Italy, Japan, Russia, the United Kingdom, and the United States—are the most industrialized and thus the most likely to come in contact with each other in trade. Thus it is important for these eight to be familiar with the communication—notably advertising—law of their foreign partners. This paper hypothesizes that, although most of the globe operates by the guidelines of international organizations such as The International Chamber of Commerce or The Committee for Consumer Policy, there are significant differences that we must learn about in order to practice business properly abroad. By looking at these major countries, we can produce guidelines to help corporations plan their online advertising.

Characterization of Cone Degeneration in the Opn1.GFP Transgenic Mouse Retina

Tommaso Tosini
Dr. Jim Lauderdale, Cellular Biology, Franklin College of Arts & Sciences

Many eye diseases, particularly those with an underlying genetic cause, have no current

form of treatment. In order to develop new treatments, good animal models of human disease are required. The Opn1.GFP mouse, which has green fluorescent protein (GFP) expressed in the L/M-cone photoreceptors only, has previously been used in research into *retinitis pigmentosa* (RP) and is the focus of this research project. It has recently been reported that there is a slow decline in GFP-expressing cells, which had been attributed to GFP-mediated toxicity. Preliminary findings suggested that cell death was not limited only to GFP-expressing cells, but was also due to a global cone degeneration, perhaps due to an underlying genetic cause, as a result of insertional mutagenesis of a cone-specific gene during insertion of the Opn1.GFP transgene. To characterise this degeneration, we made retinal sections stained by immunocytochemistry (ICC) which indicated that the degeneration was not limited to L/M-cone photoreceptors but extended to S-cone photoreceptors; this was confirmed statistically by flat-mounted retina cone counts, thus suggesting an underlying genetic cause. To further investigate this, we used various PCR strategies to precisely map the insert location to investigate the effects on neighbouring genes, but they were not successful in locating the insert. This mouse is a new model of a cone-specific degeneration, useful for research into *retinitis pigmentosa*, in addition to being useful for cone survival analyses for early cone degenerations.

Manipulating Tropical Fire Ant Populations to Decrease the Coffee Berry Borer

Waring Trible III, Foundation Fellow
Dr. Ron Carroll, Odum School of Ecology

The coffee berry borer, *Hypothenemus hampei*, is the greatest pest in coffee production worldwide. Ants are the primary known predators of the coffee berry borer and some research has been conducted into which ant species are the most efficient predators. The tropical fire ant, *Solenopsis geminata*, is common throughout Central American coffee farms, but *S. geminata* is not known to be a strong predator of the coffee berry borer. We conducted an experiment in two shade farms in Costa Rica to test the hypothesis that *S. geminata* indirectly protects the coffee berry borer by suppressing populations of other ant species. Here we show that removal of *S. geminata* from a coffee plot can lead to a significant increase in the disappearance rate of coffee berry borer beetles from coffee berries on the ground over a 72 hour period compared to control plots.

Optimization of Surface-Initiated Kumada Catalyst Transfer Polycondensation

Nathan Usselman, CURO Summer Fellow
Dr. Jason Locklin, Chemistry, Franklin College of Arts & Sciences

Conjugated polymer films are capable of influencing the electrical properties of a surface, and films of these polymers have potential uses in biofuel cells, solar cells and other organic electronic devices. Surface-Initiated Kumada Catalyst Transfer Polycondensation (SI-KCTP) was developed to grow polymer films from surfaces functionalized with a reactive monolayer, a single molecule-thick layer of initiators. Repeated oxidative addition and reductive elimination of a Ni(0)/Ni(II) catalytic group in the presence of monomer initiates a chain growth polymerization from the surface. Each step of this polymerization, however, must be optimized for controllable polymer growth. Cyclic voltammetry was used to analyze the quality of monolayers constructed on indium tin oxide (ITO). These tests determined that the number of holes in monolayer coverage is substantially reduced by the addition of an annealing step to promote coupling after initial deposition. Also, cyclic voltammetry can quantify the Ni(II) groups present on the surface through the addition of a ferrocene based capping agent. Time-dependent studies into deposition conditions indicate that Ni(II)

reaches a maximum coverage density on a functionalized surface after only a few minutes in solution. These optimization steps have assisted in the consistent growth of conjugated polymer films via SI-KCTP, and further investigation may allow for additional control in the polymer growth.

An Investigation of the Role of Work Status in Relation to Company Growth

Suze Valmé,
Morgan Capps
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

The predictors of positive employee attitudes and work behaviors have long been of interest to industrial/organizational psychologists. Social exchange theory (Blau, 1964) and more recently psychological contract theory (Rousseau, 1998) suggest that employees feel obligated to reciprocate when they receive social or transactional benefits from their organizations. This research examines two aspects of satisfaction with the workplace, compensation satisfaction and communication satisfaction, which lie at either end of the psychological contract continuum, representing transactional and relational benefits respectively (Rousseau, 2001). The primary hypothesis of this study is that, when employees are satisfied with levels of compensation and communication within the organization, this obligation will impact employee's attitudes toward behaviors that grow the company. We investigate the role of work status (full-time or part-time employment) as a potential moderator of this relationship. Existing research informing the direction of the moderation is inconclusive, such that we will develop and test three alternative models. The first model suggests that full-time employees will feel a stronger obligation for growth than part time. The second model suggests that part-time employees will feel a stronger obligation for growth than full-time, while the third suggest that obligations to reciprocate will not differ between part-time and full-time employees. This study utilizes survey data collected at a large U.S. based shipping and packing company. The results from this study will enrich current understanding of the psychological contracts and extra role performance in the workplace.

Analyzing the Kinetic and Thermodynamic Properties of O-Man Initiated Glycan Binding Alpha-Dystroglycan and Laminin-2

Kishore Vedala, Foundation Fellow
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Alpha-dystroglycan is a heavily glycosylated cell-surface protein that functions as a transmembrane linkage from the cytoskeleton to the extracellular matrix. The defective binding of alpha-dystroglycan to laminin-2 is one cause of congenital muscular dystrophy. A phosphorylated o-mannose glycan on alpha-dystroglycan is required for this binding to occur. Defects in the post-phosphoryl modification of the protein, which is mediated by multiple established and yet unknown glycosyltransferases, are what lead to the defective binding and, by extension, congenital muscular dystrophy. The exact structure of the o-man initiated glycan is not known, but it is hypothesized to have an HNK-1 capped keratan sulfate-like domain. The purpose of this study was to obtain a purified, isolated sample of the FC region of alpha-DG (DGFC4) and run a surface plasmon resonance study to determine the kinetic and thermodynamic parameters binding a DGFC4 chip to laminin, helping determine the structure. The sample was isolated utilizing the transformation of DH5-alpha cells with DGFC4 plasmid, amplification and isolation of the plasmid, transfection of HEK293T and C2C12 cells, purification of the DGFC4 protein from the cells through affinity chromatography, expression of the epitopes, and confirmation

of purification. The results showed confirmation of DGFC4 expression through the presence of bands in the 95-135 kDa region of SDS-PAGE western blots using IIH6 antibody and wFa treatment. However, analysis using silver stain and coomassie dyes showed a purity of about 80-90%. In order to further purify the protein for use in the SPR study, isoelectric focusing and subsequent ion-exchange chromatography will be used.

Methionine Sulfoxide Reductase Gene Regulation in _Vibrio fischeri_

Michael Webber
Dr. Eric Stabb, Microbiology, Franklin College of Arts & Sciences

Living cells exposed to reactive oxygen species (ROS) undergo oxidative stress, which damages macromolecules within the cell, including nucleic acids, lipids, and proteins. Cells use various strategies to diminish the harmful effects of ROS including detoxification enzymes, antioxidants, and enzymes that reduce oxidized products. *Methionine sulfoxide reductases* (*msr*'s) are repair enzymes that act on the amino acid methionine (Met) after it has been oxidatively damaged in prokaryotes and eukaryotes. *Msr*'s reverse oxidative damage by reducing the oxidized sulfur atom on Met. We are investigating transcriptional regulation of *msr* genes to better understand oxidative stress responses in bacteria and during host-microbe interactions. The bioluminescent marine bacterium *Vibrio fischeri,* which forms a mutualistic relationship with the Hawaiian bobtail squid *Euprymna scolopes*, contains three *msr* proteins encoded by three distinct genes. Transcriptional regulators of these genes were targets in this study. We created a random mutant library of *V. fischeri* using a Transposon. Then, we inserted plasmids with transcriptional fusion between each *msr* promoter and a β-galactosidase gene to identify changes in *msr* promoter activity. Future work will include identifying the site of Transposon insertion to find and characterize regulators of *msr* genes. The identification of *msr* regulators will allow us to better understand how cells respond to damage caused by oxidative stress.

Cognitive Measures, Antisaccade Performance and Obesity in Children

Abby Weinberger
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Obesity is a rapidly increasing epidemic. Previous studies have found relationships between obesity, fitness and cognition. In children, increased obesity and decreased fitness have been associated with lower performance on tests of aptitude, achievement and executive control (EC). An ongoing study is investigating these relationships in children. Participants are 175 sedentary, overweight (BMI ≥ 85th percentile) children, 8 - 11 years old, who are tested at the Georgia Health Sciences University. Participants undergo behavioral and cognitive measures that differentially assess inhibition. The antisaccade task requires inhibition of a glance, and the flanker task requires inhibition of a response to competing stimuli. A correct antisaccade requires inhibition of a reflexive glance towards a peripheral visual cue and generation of an eye movement to its mirror image location. One type of trial assessed in this task is a trial in which the initial glance is an error but is then corrected. This measure and other behavioral inhibition measures can be correlated with well-known measures of cognition, including the Cognitive Assessment System (CAS) and Tower of London (TOL). Preliminary exploratory analyses indicate that children who correct their errors more often and more quickly have higher scores on other cognitive measures. For example, faster reaction times were associated with better performance on the CAS subscales, which have been impacted by chronic exercise in previous intervention studies. Cognitive performance was also related to measures of obesity and fitness. In sum, this study

provides important information regarding the relationship between effective inhibition and various cognitive measures.

U.S. Policy Alternatives to a Military Takeover in Egypt

Patrick Wheat
Dr. Sherry Lowrance, International Affairs, School of Public & International Affairs

Since the resignation of President Hosni Mubarak, the Supreme Council of the Armed Forces (SCAF) has led the government of the Arab Republic of Egypt. Recent actions by the SCAF have raised concern that the SCAF will not surrender power upon the conclusion of the 2012 election cycle. These conclusions were drawn as a result of the continued use of Emergency Law, the continued use of military trials on civilians and the detainment of international citizens, including citizens of the United States (U.S.). As a result of these observations, the U.S. must anticipate an attempt by the SCAF to hold on to political authority rather than transfer it to the elected officials of the new government. To plan an appropriate reaction to this event, the U.S. should consider previous military controlled governments, including the Republic of Haiti and the Republic of Poland, to chart a response. Effective options the U.S. should consider include enforcing political and economic sanctions, which may range from the reevaluation of military foreign aid, the rescindment of military weapons sales, economic sanctions and continued support for the democratic movement within the Egypt, in an attempt to transfer power from the SCAF to a democratically elected government.

Expression of Secretory Phospholipase A2 in Prostate Cancer Cells Lines.

Stephanie Wilding
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Secretory phospholipase A2 (sPLA2) are calcium activated esterases that are secreted to the extracellular side of cells. Recent studies show that sPLA2 expression in prostate cancers correlates to metastasis and poor prognosis. There are several isoforms of sPLA2, which are categorized into groups (e.g. Groups I, II, III, V and X). Few reports have examined the differential expression of sPLA2 in cancer cells. Thus, we used reverse transcriptase-polymerase chain reaction (RT-PCR) and quantitative PCR (qPCR) to study the expression of sPLA2 in prostate cancer cell lines (PC-3, LNCaP and DU-145 cells). Our sPLA2 studies included Groups IB, IIA, V and X. Group IB sPLA2 was expressed in all three cell lines. Group IIA sPLA2 was detected in LNCaP and DU-145 cells, with lower levels detected in PC-3 cells. Group V sPLA2 was detected in LNCaP and PC-3 cells. In contrast, Group X sPLA2 was detected in all cells but was highest in PC-3 cells. RT-PCR does not allow for a quantitative comparison of mRNA levels between cells; therefore, we used qPCR to show that Group IB sPLA2 had higher levels of expression in PC-3 cells compared to LNCaP cells, which had higher levels of expression than DU-145 cells. Group IIA sPLA2 and Group V sPLA2 followed the same pattern of expression in all three cell lines. Group X sPLA2 expression was highest in PC-3 cells, followed by DU-145 cells, with low levels in LNCaP cells. Collectively, these results show the differential expression of sPLA2 isoforms in prostate cancer cells.

Abstracts

A Sociolinguistic Perspective on Roswell, Georgia

Anna Wilson
Dr. Bill Kretzschmar, English, Franklin College of Arts & Sciences

Where once Spanish was relegated to historically Hispanic-influenced parts of the country, it can now be heard in virtually every corner of our nation. Hispanics, or *Latinos* as they prefer to be called, have profoundly impacted the size, look, and feel of our cities. Knowing this, I began working with Dr. William Kretzschmar's *Roswell Voices* project, as well as the Roswell Convention and Visitors Bureau, in Fall 2011, in an attempt to describe the sociolinguistic experience of the Latino community of Roswell, Georgia. In order to achieve this goal, I have tried to elicit community, volunteer-based participation in a series of interviews. Entering into the Latino society of Roswell proved difficult. Thus, as a byproduct of my original research inquiry, I have collected qualitative data about the closed nature of Roswell's Latino community. These observations are pertinent to the fields of Sociolinguistics and Spanish in the United States U.S., as they provide insight into the nature of Latino communities outside the Southwestern and Northeastern U.S., and are important if we are to understand the changes taking place in Georgia's culture and for Latinos in the Southeastern U.S.

The Effect of Hypoxia on Transketolase in Breast Cancer Cells

Star Ye, CURO Summer Fellow
Dr. Jason Zastre, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Due to the hypoxic microenvironment of solid tumors, breast cancer cells preferentially rely on anaerobic glycolysis for ATP generation. Paralleling the rapid growth of tumor cells, an increase in glucose uptake is one of the most recognizable phenotypic changes in cancer. Glucose is required for glycolysis and is subsequently metabolized to glucose-6-phosphate prior to entering the pentose phosphate pathway (PPP). The principal function of the PPP is to generate ribose-5-phosphate for nucleic acid synthesis and NADPH for reductive biosynthetic reactions. Within the nonoxidative branch of the PPP, the thiamine-dependent enzyme transketolase (TKT) is rate-limiting. TKT catalyzes a reaction that produces glyceraldehyde-3-phosphate and fructose-6-phosphate, which can be shunted into the glycolytic pathway. Essential for TKT activity is the enzyme cofactor thiamine pyrophosphate (TPP), produced by the conversion of thiamine by thiamine pyrophosphokinase 1 (TPK1). Our research has shown that hypoxia induces increased glucose consumption, thiamine uptake and TPK1 expression in breast cancer cells. We hypothesize that TKT activity increases with increasing expression of TPK1 in hypoxia. Preliminary results from transketolase assays show an increase in transketolase activity in hypoxic breast cancer cells. Also, RT-PCR and western blotting reveal that hypoxia does not change TKT mRNA and protein expression, suggesting that increased TKT activity may be a result of increased TPP availability. This study demonstrates the implications of thiamine in breast cancer, indicating that TPP may be a key enzyme cofactor in anaerobic cancer metabolism.

Addressing Students' Math Deficiencies in Introductory Physics with Online Scaffolded Problems

Cameron Zahedi, CURO Honors Scholar
Dr. Craig Wiegert, Physics & Astronomy, Franklin College of Arts & Sciences

Introductory physics courses are mathematically demanding, even those for non-physics science majors. Students must become adept at solving a wide variety of quantitative problems. However, even students with calculus experience often lack facility with basic pre-calculus skills. A large

contributing factor to the problem is the students' generally poor retention of working math skills, but they also struggle to transfer their math knowledge to unfamiliar problem domains. These students should benefit from early intervention that continues to scaffold throughout the term. We report on our efforts to create and evaluate math-related, online formative assessment modules for first semester introductory physics. These online tutorials target specific mathematical skills that are essential to success in physics, and are designed to progress from a purely math-centered review of each basic skill, to problems of increasing generality and complexity, and ultimately toward a transfer of these skills to physics problem domains.

Reversal of Acepromazine Sedation by Doxapram in Dogs

Mark Zapata
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Acepromazine generally produces long-lasting, mild to moderate sedation and depresses the central nervous system. Doxapram works as a non-selective central nervous system stimulant that directly works at the respiratory center in the brain stem. The purpose of this study was to evaluate the effectiveness of two doses of doxapram to reverse acepromazine sedation in dogs. Dogs were randomly assigned to one of three treatment groups. Each group was administered acepromazine followed 30 minutes later by saline solution with 1.25mg/kg doxapram or 2.50mg/kg doxapram. Sedation scores were obtained at 0, 15 and 30 minutes after acepromazine administration and at 5, 15 and 30 minutes after treatment administration. Comparison of sedation scores for all time points and groups revealed a significant correlation between use of doxapram and decreased sedation scores. Dogs were noticeably more alert and interactive after doxapram treatment. There was not a significant difference between the effects of the 1.25mg/kg dose and 2.50mg/kg doses of doxapram. This study determined doxapram to be effective in reversing the behavioral effects of acepromazine for a short period of time. We recommend a 1.25mg/kg dosage of doxapram to reverse the effects of acepromazine sedation in dogs.

Photoimmunotherapeutic Nanoparticles for Combination Therapy of Breast Cancer

Dhillon Zaver
Dr. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Cancer is among the leading health problems in society today. Though there are several methods of treatment, the combination of photodynamic therapy, using light to activate a complex in a specific area, and immunotherapy, the activation of the host's immune system to fight the cancer, has largely remained unexplored. Thus, the effective formation of a nanoparticle based complex for the wide delivery of drug and activation of specific immune response to combat this issue is an ideal place to explore. To this end, a nanoparticle platform that has a photosensitizer to destroy localized cancer in the visible light and a dissociating dendritic cell activator to initiate an immune response against the cancer, as well as possible cancer metastasis, can be imagined. Construction of such a platform, using chemical, biological, and nanotechnology based tools and its characterization will be presented. Preliminary in vitro studies will be used to verify the potential of such a platform for cancer therapy. If this platform can be proved effective, a new alternative therapeutic option for metastatic cancer can be envisioned.

CURO

April 1, 2013

Dear Students, Faculty, and Guests:

Welcome to the 13th annual CURO Symposium, UGA's celebration of undergraduate research across the disciplines. Many individuals—administrators, faculty members, staff, graduate students, and, of course, undergraduates—have collaborated to make the CURO Symposium the premier undergraduate academic event at UGA.

Each year, the Symposium has grown larger, and the 2013 Symposium is the largest to date, with 211 undergraduate researchers communicating their substantial accomplishments to their peers, mentors, and the public at large.

From its inception, the CURO Symposium has showcased research and scholarship in all disciplines. The 2013 Symposium continues that commitment, featuring presenters from 51 departments in 13 colleges/schools. Thus, today evidences UGA's broad and substantial support of research, and the invaluable commitment of UGA's administration and faculty to mentoring and providing exceptional learning opportunities for our undergraduates.

Thank you for your continued support of undergraduate research and CURO.

Sincerely,

Dr. David S. Williams, '79, '82
Associate Provost and Director

Dr. Martin P. Rogers, '01, '11
Associate Director

Reviewers for 2013 CURO Research Mentoring Awards

Dr. David S. Williams	Associate Provost and Director of Honors and CURO
Dr. Martin Rogers	Associate Director of Honors and CURO

Reviewers for 2013 CURO Summer Research Fellowships

Dr. Brian Cummings	Department of Pharmaceutical and Biomedical Sciences
Dr. Monica Gaughan	Department of Health Policy & Management
Dr. Timothy Hoover	Department of Microbiology
Dr. Patricia Hunt-Hurst	Department of Textiles, Merchandising, & Interiors
Dr. William Kisaalita	College of Engineering
Dr. Martin Rogers	Associate Director of Honors and CURO

Reviewers for 2013 CURO Symposium Best Paper Awards

Dr. Carl Bergmann	Department of Biochemistry & Molecular Biology
Dr. Pamela Orpinas	Department of Health Promotion & Behavior
Dr. Martin Rogers	Associate Director of Honors and CURO
Dr. Brock Tessman	Department of International Affairs

Oral Session Conveners for 2013 CURO Symposium

Ms. Lisa Bolding	Department of English
Mr. Sean Buskirk	Department of Infectious Diseases
Ms. Lindsay Coco	Honors Program
Mr. Douglas Eudy	Institute of Plant Breeding, Genetics & Genomics
Ms. Michelle Johnson	Academic Advisor, Honors Program
Ms. Teneema Kuriakose	Department of Infectious Diseases
Mr. Bill McDowell	Odum School of Ecology
Ms. Emily Myers	Administrative Associate, Foundation Fellowship Office, Honors Program
Ms. Jessica Reichard	Honors Program

Acknowledgements

Mr. Greg Roundtree	Administrative Associate, Office of Recruitment, Honors Program
Ms. Elizabeth Sassler	Honors Program
Mr. Alexander Vaughn	Department of Chemistry

Schedule

Monday, April 1, 2013

Oral Session I **9:05-9:55 a.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session II **10:10-11:00 a.m.**
Athena Breakout Rooms A, B, C, D, G, H

Oral Session III **11:15-12:05 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I

Oral Session IV **12:20-1:10 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session V **1:25-2:15 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session VI **2:30-3:20 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Awards and Keynote Session **4:00-5:00 p.m.**
Grand Hall Atrium (downstairs-use escalator in lobby)

Poster Session and Reception **5:00-6:00 p.m.**
Grand Hall South (downstairs-use escalator in lobby)

The 2013 CURO Symposium will conclude at 6:00 p.m.

CURO Research Mentoring Awards

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the CURO Research Mentoring Awards, formerly the EURM awards, in 2001.

These awards recognize outstanding faculty who consistently make a concerted effort to engage undergraduate researchers and enhance the learning experience of undergraduates at The University of Georgia, especially through CURO. Award recipients have demonstrated superior research opportunities and mentoring programs for their undergraduate students, including outstanding teaching, supervision of undergraduate research courses and theses pursued through CURO, and collaboration on publications and presentations at professional conferences.

2013

Master Level Faculty Award

Dr. Jennifer McDowell, Department of Psychology, Franklin College of Arts & Sciences

Early Career Faculty Award

Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

2012

Master Level Faculty Award

Dr. Lawrence Shimkets, Department of Microbiology, Franklin College of Arts & Sciences

CURO Symposium Best Paper Awards

Since 2001, CURO Symposium Best Paper Awards have recognized excellence in papers developed from work being presented at that year's Symposium.

Applicants may submit in one or more of the following categories: arts, biological sciences, civic responsibility focus, humanities, international focus, physical sciences, and social sciences.

Each recipient is recognized at the Symposium's Award and Keynote Session, and each award carries $100 in financial support, generously provided by the UGA Alumni Association. Winners from the 2013 CURO Symposium are listed below.

Arts:

Brendan Boyle	The "Darlton" Initiative: Serial Complexity, Parallel Media Narratives and Showrunner Tactics in *LOST*

Biological Sciences:

Lauren Titus	The Anti-Inflammatory Effects of Lipoic Acid on Inflammatory Cytokines

Civic Responsibility Focus:

Dalton Mark	The First Rule of Camorra Is You Do Not Talk about Camorra: An Investigation into the Rise of the Organized Crime Syndicate in Naples, Italy

Humanities:

William Prigge	"Is Black So Base a Hue?" An Examination of Aaron and Racial Dynamics in *Titus Andronicus*

International Focus:

Patrick Wheat	Justice for All: The Vitality of Addressing Judicial Structures During Reconstruction Period

Physical Sciences:

Miriam Perryman	Embodied Energy Requirements for Meat Calorie versus Non-meat Calorie Production: A Comparative Study of Nine Countries

Social Sciences:

Meghan Foley, Katryna McCann	Managers vs. Employees: The Differing Effects of Communication Strength and Supervisor Support on Work Engagement

Program

Monday, April 1, 2013

Concurrent Oral Session I: 9:05 – 9:55 a.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Emily Vermillion**	An Analysis of the Effect of Phytase Phosphorous Absorption and Growth in Nursery Pigs
	Brigid Burns	Anesthetic Complications in Dogs Undergoing Surgery for Liver Disease
	Steven Mathew	The Use of Scheduled Combination Treatments of Etoposide and Doxorubicin to Treat Feline Injection Site Sarcoma Cells
Room B	**John-Jordan Nunnery**	Removing Barriers to Vision Services for School Children
	Terese Gagnon	On Memory's Tidewater: Sapleo Island Documentary Project
	Christine Bassett	Popular and Folk Medicine: Towards an Understanding of the Latino Health Paradox
Room C	**Maria Cox**	When is a Kiss a Thimble? Sexuality in Adaptations of *Peter Pan* over Time
	Jared Stepp	Sitcom Technology through the Ages
	Brendan Boyle	The "Darlton" Initiative: Serial Complexity, Parallel Media Narratives and Showrunner Tactics in *LOST*
Room D	**Nicholas Ramos-Franklin**	Democratic Peace Theory: An Accurate View or Team Alliance
	Conner Blackwell	The Aversion to Condom Use in an HIV-saturated World
	Kameel Mir	Civil Society Collaboration between the U.S., E.U., and Turkey
Room G	**Kelly Tucker**	The Role of Cognitive Tasks in the Conceptualization and Assessment of ADHD
	Hania Bisat	Election Triggers: How a Sip of Water Can Ruin a Campaign

	Brett McCardel	Performance on a Saccade Task under Varying Cognitive Load
Room H	**Callan Brownfield, Robert Ashley**	Synthetic and Enzymatic Decarboxylation of Tyrosine Derivatives
	Elena James	Targeting the *Mycobacterium smegmatis* cobU Gene to Study Vitamin B12 Biosynthesis
	Lauren Titus	The Anti-inflammatory Effects of Lipoic Acid on Inflammatory Cytokines
Room I	**Dalton Mark**	From Feudalism to Democracy: Using Political Philosophy to Reframe Traditional Distinctions between the Great Ages of Europe
	Dalton Mark	The First Rule of Camorra is You Do Not Talk about Camorra: An Investigation into the Rise of the Organized Crime Syndicate in Naples, Italy
	Kangkyu Lee	Rekindling the Hermit Kingdom
Room J	**Brittany Truitt**	Determining a Method for Pharmacologic Rescue of Mutations that Affect Tissue-specific Glycan Expression in *Drosophila melanogaster*
	Mathew Joseph	Autophagic Responses in the Murine Model of Placental Malaria
	Nicholas Richwagen	Algae Biomass Production Using Compost Leachate Water and Evaluation of Biomass Harvesting Techniques

Concurrent Oral Session II: 10:10 – 11:00 a.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Michelle Norris**	*Dormant*: A Photographic Series
	Samuel Smith	Multiple Marlows: Intertextuality and Irony in Conrad's Marlow Tales
	Jacqueline Van De Velde	A Critical Examination of Anglicanism in the Life of Laurence Sterne and Its Implications within *Tristram Shandy*

Room B	**Chelsea Sexton**	*Pseudo-nitzschia* in the Diet of *Paraprionospio pinnata*, a Polychaete in the Gulf of Mexico Hypoxic Zone: Potential Mechanism for Toxin Bioaccumulation
	Na Hyung Choi	The Origin of Unusual Phosphate Deposits on the Venezuelan Island of Gran Roque, Leeward Antilles
	Ian Karra	Developing a Sustainability Policy for the University System of Georgia
Room C	**Peter Melampy**	Components of Economic Freedom and the Institutional Approach to Economic Growth
	Colin Dungu	Analyzing Linkages between Economic Development Models and Food Security: Comparative Case Study of Thailand, Vietnam, and the Philippines
Room D	**Katherine Arnold**	Music, Metaphorical Language, and Expanding Thought Networks in Shelley's "To a Skylark"
	Fiona Sheehan	The Unpublished Letters of Elizabeth Bishop
	Daniel LoPilato	Mapping Narrative: The Structure and Composition of a Short Story Cycle
Room G	**Ashton Garner**	Compensatory Exercise and Thinness Expectancies
	Jake Moskowitz	Occupational Complexity as a Predictor of Cognitive Reserve
	David Parker	Understanding the "Gap" Effect in the Generation of Express Saccades
Room H	**Patrick Wheat**	Justice for All: The Vitality of Addressing Judicial Structures during Reconstruction Period
	Terese Gagnon	Landscapes of the Interior: Ethnobotany and Sense of Place among Karen Refugees
	Aveek Sarker	Chinese Foreign Direct Investment in the United States: A New Game

Concurrent Oral Session III: 11:15 – 12:05 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I

Room A	**Hannah Klevesahl**	Fanny Kemble: A Juliet of a Different Era

	Gloria Kim	The Birth of Metrosexuality in South Korea
	Margaret Touchton	The Women of *Richard III* Revisited
Room B	**Elijah Staggers**	The Black Youth Vote in the 2012 Presidential Election: Disillusioned or Reenergized?
	Madison Lamar	Grandparenting from the Dump
	Emily Peng	Increasing Access to Specialty Services in Community Health Centers: Policy Alternatives and Implications for Minority Communities
Room C	**McKinley Alden**	German Inalienable Possession Constructions
	Minh Ngoc Nguyen	Vietnamese Language Attitudes, Use, and Identity: Determining a "Fobby" Vowel Quality
Room D	**Melinda Johnson**	Drug and Mental Health Courts in Georgia's Criminal Justice System
	Aditya Aphale	The Relationship between Dynamic Postural Stability Index Composite Scores and Talar Tilt Average Scores
	Carol Conroy	Exploring the Use of Comprehensive Nutrition Education Programs as a Means of Reducing Food Insecurity in Georgia
Room G	**Todd Pierson**	Traditional and Environmental DNA Detection of a Rare Amphibian
	Ridwan Mahbub	Development of a PCR-based Marker to Identify Overwintering Sites for *Exobasidium* sp. on Blueberries in Georgia
	Cameron Prybol	Discover Life Mothing Project
Room H	**Krista Ritchie**	Identifying Possible Roles for Structural Proteins in Thymus Morphogenesis
	Travis Williams, Jr.	Comparison of Two Biocatalysts for Ethanol Production from Pectin-rich Biomass with Varying Levels of Industrial Processing
Room I	**Rebekah Myrick**	Three Dimensional Cell Based Assay Standard for Pharmaceutical Testing

	Natalie Levey	Pharmacological Manipulation of the Neuromuscular Junction between Stem Cell Derived C2C12 Muscle Cells and Motor Neurons

Concurrent Oral Session IV: 12:20 – 1:10 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Ashley Thompson**	There's Another Side to the Story: Examining the Blacklist Resulting in the HUAC Hearings of the 1950s
	William Murdock, Jr.	Story-gathering and Community Performance
	Emily Hoskins, Dakota Nesbitt	Converting Culture: Relating 19th Century Women's Dress to a 1960s Society
Room B	**Matt Burns**	Where a Kid Can Be a Kid, Even When She's an Adult – The Internet's Role in Sustaining Engagement with Children's Television
	Adam Samples	The Epistle of James: Discovering Its Conception of Faith and Works and Its Call for Social Justice
	Charles Hicks	How the White Protestant Church Should Respond to Issues Affecting Lesbian, Gay, Bisexual, and Transgender People
Room C	**William Austin II**	Groundwater in Sub-Saharan Africa
	Amelia Watson	Navigating Sickle Cell Disease in Africa
Room D	**Dervin Cunningham**	Proteomic Analysis of the Tomato/*Botrytis cineria* Interaction
	Alexandra Auger	Evaluation of Live Virally-vectored Vaccine for Malaria in Murine Model
	Savannah Pena	Lipid Association Improves Hemoglobin-binding Capacity by Haptoglobin Related Protein
Room H	**Savannah Colbert**	Democratic Dialogue: Comparing Presidential Debate Content and User-generated Comments in Online News
	Mackenzie McRae	Policy Analysis: US-Afghanistan Reconstruction Efforts
	Kirstie Hostetter	Affordable Housing in a Poverty-stricken Community

Room I	**Emily Stubbs**	For the Love of God: Damien Hirst and a Room with a Corpse
	Joanna Caffrey	The Excommunication of Early Jewish Christians and Its Interpretive Value for the So-called Temple Cleansing in the Gospel of John
	Lindsay Ullrich	Major Clarity in a Minor Paradox: The Role of Mark 9:24 in Illuminating the Markan Conception of Faith in the Context of Discipleship
Room J	**Katherine Hsieh**	Relationship between Approximate Entropy and Dynamic Postural Stability in Ankle Instability
	Phillip Ogea	Classification of Protein-ligand Interactions of *P-glycoprotein*

Concurrent Oral Session V: 1:25 – 2:15 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Richard Gardiner**	The Death of the Death Penalty
	Travis Miller	Trade-offs: The Effects of Contiguous Rivalries on International Decision-making
	Jinny Park	Leading from Behind: A Progressive Outlook on U.S.-North Korean Relations
Room B	**Alexandra Prather**	The Few. The Proud. The Marines.
	Jeanette Kazmierczak	Pervasiveness of Science News in First-world Countries vs. in Emerging Economic Powerhouses
	Olivia Gorbatkin	Science Lecture Classrooms: Extending the Bounds of Creative Teaching and Learning
Room C	**Carley Borrelli**	Examination of Age as a Moderator of the Relationship between Sleep Quality and Job Satisfaction
	Sarah Evans	Comparison of an Embedded Effort Measure on CNS Vital Signs between Older and Younger Adults
	Rachel Callery	Vocal Intonation as a Social Referencing Cue in Infants and African Grey Parrots

Program

Room D	**Theresa Stratmann**	Developing Methods to Locate and Survey for Rare Species: a Case Study Using the Endangered Bog Turtle (*Glyptemys muhlenbergii*)
	Brent Zurcher	Understanding Ecological Networks: A Mathematical Approach to Ecosystem Balancing and Analysis
	Victoria Staples	Body Size and Temperature: A Report on Moth Activity in Clarke County
Room G	**Zachary Holmes**	Top-down Control by Bonnethead Sharks in Oyster Reef Communities through Consumptive and Non-consumptive Effects
	Kelly Murray	Investigating the Indirect Effects of Guppy Introduction on Populations of a Shredding Caddisfly in Trinidadian Streams
	Megan Sheehan	Effects of the Amazon River Plume on Subsurface Waters: Measuring the Effectiveness of the Plume's Uptake of Atmospheric CO_2
Room H	**Grant Moody**	Conformational Preferences of a Prototype Biomolecule in Liquid Helium Nanodroplets
	Kasey Darley	A Therapeutic Nanoparticle Platform for Ischemic Brain Injury

A Disease Ecology Project without the Disease: A Survey of Trichomoniasis in House Finches in Athens, GA

Heather Abernathy
Dr. Andy Davis, Odum School of Ecology

Trichomoniasis is an infection caused by the protozoan *Trichomonas gallinae* and is known around the world to cause morbidity and mortality in columbiform species and birds of prey (Bondurant and Honigberg 1994). It is now believed that the infection is spreading in North America and primarily affects members of the finch family (Fringillidae). In this study we captured and sampled house finches for the presence of *Trichomonas gallinae* in the Athens, GA area. We used two methods to detect the parasite: wet-mounts and commercial kits designed to culture Trichomonid parasites. We sampled a total of 34 house finches, and of these, 9 birds had visible signs of mycoplasmal conjunctivitis. We did not detect *T. gallinae* in any of the birds, which indicates it is not present in this area, or that birds with the disease are removed from the mobile population.

German Inalienable Possession Constructions

McKinley Alden
Dr. Vera Lee-Schoenfeld, Germanic & Slavic Studies, Franklin College of Arts & Sciences

In German, possessive constructions with inalienable prepositional phrase-embedded objects yield either an accusative- or dative-marked possessor. The construction in question is defined by the seemingly random interchangeability of the accusative and dative case, for example, "Der Junge hat ihn/ihm in die Nase gebissen" ("The boy has him-*Acc/Dat* in the nose bitten" or, less literally, "The boy bit him in the nose"). Previous studies suggest that degree of affectedness was the direct cause of this apparent equivalence of case— namely, that a more heavily affected object will be taken in the accusative case (Draye 1996, Lamiroy and Delbecque 1998). However, a lack of reliable objective quantification of affectedness and the inability of this theory to explain examples when parts of speech not directly present in the construction change degree of affectedness— for example, adjectives "increasing" affectedness do not change case marking— show that this established idea cannot be true. Here we take the position that the ability to use either case is dependent on the presence of verb-specified directed motion, the endpoint being a goal prepositional phrase. A combination of corpus search, interview, and survey will be used on subjects who were either born, raised, or currently reside in Germany, or speak the language as their mother tongue. This methodology should yield results that will, when superimposed on preordained German case laws, generate valuable syntactic information and aid in the further construction of German grammar.

The Relationship between Dynamic Postural Stability Index Composite Scores and Talar Tilt Average Scores

Aditya Aphale
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

In the United States, about 25,000 lateral ankle sprains occur per day, with 74% of those afflicted developing chronic ankle instability (CAI). Increased mechanical laxity, or looseness, of the ankle ligaments may influence the development of CAI, as can deficits in postural stability. These two constructs may interact to increase severity of CAI. The purpose of this study was to determine whether there was a correlation between Dynamic Postural Stability Index (DPSI) composite scores and talar tilt scores. Seventy-eight recreationally active college-aged participants completed a forward hop onto a single leg and balanced on a force plate. Participants also had talar tilt measured using the instrumented LigMaster device, which applies a known inversion force to the

ankle and calculates resultant tilt in degrees. Pearson R correlations were calculated for talar tilt and DPSI composite scores. There was no significant correlation between the variables, (R= 0.10, p=0.37). Ankle ligament laxity does not appear related to DPSI composite score, indicating these are two distinct constructs. Future studies should correlate medial-lateral postural stability indices to talar tilt, since the ankle's ligaments protect it from medial-lateral instability during a jump in the same direction as talar tilt.

Music, Metaphorical Language, and Expanding Thought Networks in Shelley's "To a Skylark"

Katherine Arnold
Dr. Casie Legette, English, Franklin College of Arts & Sciences

Percy Shelley was a Romantic poet and literary figure interested in the sources of a poet's creativity and the inner processes of the imagination. He developed his ideas in a poem, "To a Skylark," in which he invokes music as a metaphor for inspiration. Through the metaphors and metre of language, the poem attempts to affect the reader's thought pattern in a manner similar to the musical forms composed concurrently by Felix Mendelssohn. This paper examines sources in musical criticism, literary criticism, and cognitive science in order to identify the similarities in Shelley's and Mendelssohn's works. Specifically, Mendelssohn's musical forms interact with a listener's working memory and rely on the listener to develop a musical theme across movements of a composition. This interaction relates to the cognitive processes pertaining to metaphors like those created in Shelley's poem. Both artists, responding to the intellectual movements of subjectivity and organicism, created works that convey a unity of thought while resulting in a thematic transformation across a piece. Placing Shelley's poem in a medium both literary and musical allows for a new interpretation and understanding of the poem's abstract images and sources of energy in relation to the reader's cognitive process.

Evaluation of Live Virally-Vectored Vaccine for Malaria in Murine Model

Alexandra Auger
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Malaria is a vector borne infectious disease common in tropical regions caused by *Plasmodium falciparum*. Nearly a million people, the majority children, die from the disease each year. The majority of cases occur in developing nations where prophylaxis medications and treatments may be too costly or difficult to administer. Despite the great need, no effective vaccine is currently available. This study evaluates the effectiveness of a live viral vector vaccine administered intranasally. MSP 4 and 5 are merozoite surface proteins that were chosen to target infection and incorporated into the parainfluenza virus, PIV5. In the current experiment, ten mice were administered the vaccine, ten mice received only the vector without MSP 4 and 5, and ten mice received PBS as a control. The thirty mice were then infected with 10^3 *Plasmodium Berghei* ANKA, which parallels human malarial infection, to evaluate the effectiveness of the vaccine. The mice were monitored daily for anemia, parasitemia levels, weight loss, behavioral changes, and development of cerebral malaria. All but one of the vaccinated mice succumbed to cerebral malaria by day eight of infection. Currently, the antibody response of the vaccinated mice is being evaluated through immunofluorescence assay. Although the vaccine did not prevent fatality, the vector may still be useful with a different antigen if an antibody response is present. More research is needed to determine if the vaccine has the potential to be effective against malaria.

Groundwater in Sub-Saharan Africa
William Austin II, CURO Summer Fellow
Dr. William Kisaalita, College of Engineering

Global warming and climate change have greatly impacted small-scale farmers in Sub-Saharan Africa. The continent's populations traditionally relied upon groundwater. Groundwater has very slow natural replenishment rates, inevitably causing continental water tables to sink as water sources are exhausted. The declining water tables have led towards even faster climatic change for various regions, particularly East Africa. New practices are slowly being adopted within Sub-Saharan Africa. We collected field data in Tanzania to measure the adverse effects of the changing climate on small-scale farmers while analyzing and promoting alternatives to combat the negative environmental outcomes. Much of the data was collected in an effort to decrease dependence on ground water through sustainable sources—primarily rain catchments and water storage tanks. We were able to calculate the additional energy placed into an environment through the utilization of roof catchments. Additionally, we are analyzing the benefits of small-scale conservation agriculture to trap water within the soil, preventing environmental degradation. Our research has confirmed that small-scale farmers are at the mercy of changing weather patterns and that the adverse effects can be overcome through a shift away from groundwater towards alternative sources of water. If stronger affirmative action is not adopted in the near future, mass water shortages will likely become magnified.

Perspectives on Postnationalism in Chilean *Nueva Canción*
Christina Azahar, CURO Honors Scholar, CURO Graduation Distinction
Dr. Susan Thomas, Hugh Hodgson School of Music

The Chilean *nueva canción* movement provides in its rich artistic innovation and far-reaching sociopolitical influence a unique opportunity to examine the theories and questions of postnational musical scholarship. This paper uses the framework of Ignacio Corona and Alejandro L. Madrid's book *Postnational Musical Identities: Cultural Production, Distribution, and Consumption in a Globalized Scenario* to study *nueva canción*'s role in the formation of Chilean nationalist identity. The authors argue that "the invention of narratives of tradition, heritage, and myth" to construct a nationalist identity is an essential component of postnational scholarship, and in the context of Chile in the late 1960s and 1970s, these narratives were invented largely through the cosmopolitan practices of prominent *nueva canción* figures such as Violeta Parra and Victor Jara. Both artists used genres and traditions from a wide variety of marginalized cultures throughout Latin America to inform their socially conscious musical output. This cosmopolitan perspective on social and cultural issues, as well as the movement's national and international political affiliations, caused Chilean *nueva canción* to play a major role in the construction of pan-Latin American identity – ultimately making it transcend classification within the nation-state of Chile. Violeta Parra's early ties with Andean folkloric-popular music in Argentina and France, Victor Jara's move towards nationalism and political activism, and Luis Advis's innovative *Cantata Santa María de Iquique* are each demonstrated in this study to be a response to the postnational condition of Chile and Latin America as a whole.

Popular and Folk Medicine: Towards an Understanding of the Latino Health Paradox

Christine Bassett
Dr. Susan Tanner, Anthropology, Franklin College of Arts & Sciences

Social science and anthropology recognize that local perceptions, social expectations, and behavior shape human health. The Latino health paradox references an epidemiological phenomenon where Latino immigrants, despite low socioeconomic status, exhibit good health outcomes while second generation Latinos with similar socioeconomic status experience deteriorating health outcomes. Research indicates that a loss of cultural knowledge associated with migration facilitates these outcomes. This study proposes that traditional medical knowledge serves as a buffer to environmental stressors and, in its absence, produces differential health outcomes in Latino communities. Data was collected using qualitative methods, largely structured and semi-structured interviews, with women living in Georgia who self-identified as Mexican. Interviews on topics related to maternal and child health were conducted in Spanish or English, transcribed, translated if necessary, and analyzed to identify key themes on health care practices. Results indicate that Mexican migrants integrate both biomedical and traditional remedies into their healthcare regimen. Results also imply that social networks, primarily family, serve as a vital source of health-related information. Finally, the study suggests a need for more intense research that would seek to recognize if higher reliance on traditional medical knowledge produces differential health outcomes compared to those who predominantly access biomedical healthcare strategies. A deeper understanding of the Latino health paradox would assist in transitioning towards a more holistic, individualized healthcare system and consequently facilitate better health outcomes in migrant communities.

Expression of PECAM in EHD

Elizabeth Beadles
Dr. Elizabeth Howerth, Pathology, College of Veterinary Medicine

Epizootic hemorrhagic disease (EHD), caused by a midge-transmitted orbivirus, is the most prevalent and often fatal infectious disease of white-tailed deer in the United States. The causative virus, epizootic hemorrhagic disease virus (EHDV), infects and destroys endothelial cells lining the microvasculature causing hemorrhage, but this destruction curiously elicits very little inflammation. Failure to elicit an inflammatory response may allow the virus to spread within the microvasculature and may help explain why infection is often fatal. CD31 (PECAM) is a cell adhesion molecule that plays a fundamental role in maintaining homeostasis in blood vessels through the transport of white blood cells into and out of the cell and is found on the surface and around intercellular junctions of endothelial cells. We hypothesize that low baseline levels of PECAM, or its destruction or impairment by viral infection, is partially responsible for the susceptibility of deer to EHDV. Our objective was to develop methods to quantitate expression of PECAM in deer (both normal and EHDV infected) in order to determine its specific role and/or any correlation between its expression and the disease. We have developed and are standardizing an immunohistochemical technique to quantify PECAM protein and a rtPCR technique to evaluate its mRNA in deer tissues. These techniques will allow us to evaluate PECAM expression in a wide range of tissues from normal and EHDV infected deer in order to address our hypothesis. Our findings may also help explain the pathogenesis of certain viral hemorrhagic diseases of humans.

Effect of Muscadine and Concord Grape Juice Phenolics on the Oxidation of LDL

J. Taylor Bellamy
Dr. Phillip Greenspan, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The oxidation of LDL is an important contributor to the pathogenesis of atherosclerosis and heart disease. In this disease state, oxidized LDL is thought to promote both the accumulation of cholesterol in macrophages and the recruitment of immune cells into the atherosclerotic plaque. One intervention that may preclude the accumulation of atherosclerotic plaque and therefore arrest the development of heart disease is the dietary consumption of antioxidant foods. Muscadine and Concord grape juices contain significant amounts of phenolic compounds known to have substantial antioxidant effects. To analyze and compare the effect of these grape juices on LDL oxidation, a model system of LDL oxidation was employed using cupric sulfate, a transition metal. The amount of oxidation was determined by measuring the formation of lipid oxidized products employing the TBARS (thiobarbituric acid reactive substances) assay. At equal phenolic concentrations of 10 and 25 μg phenolics/mL (concentrations less than 5% v/v), the Concord grape samples exhibited substantial inhibition of oxidation while the muscadine grape samples were not effective. At equivalent antioxidant capacities, the muscadine grape samples again failed to inhibit LDL oxidation; Concord grape samples at the same concentration demonstrated significant inhibition. However, at a 5% (v/v) concentration, muscadine juice did inhibit LDL oxidation. While the presence of significant amounts of polyphenolics in muscadine grapes would suggest an ability to inhibit LDL oxidation in vitro, these experiments demonstrate that muscadine juice is a relatively ineffective inhibitor of LDL oxidation. Further research will analyze the specific constituents found in muscadine juice and examine whether any of them possess pro-oxidative properties.

Election Triggers: How a Sip of Water Can Ruin a Campaign

Hania Bisat
Dr. Leonard Martin, Psychology, Franklin College of Arts & Sciences

Sometimes, candidates for political office rise or fall in popularity based on seemingly insignificant events (e.g., Mark Rubio taking a sip of water during his speech). Other times, they remain popular no matter what happens to them (e.g., Clinton, Reagan). We wanted to understand why. We presented participants with brief descriptions of five fictitious candidates and asked them to rank order the candidates in terms of preference. Then, we presented them with additional information about their first and third choice candidates. This information came in the form of news stories, or "triggers," covering succeeding weeks of the campaign. Participants evaluated the candidates after each set of stories. For the last story, participants read that either their first or third choice candidate had referred to his constituents as hillbillies (questioning the candidate's electability) or had ignored his sick mother to stay on the campaign trail (questioning the candidate's values). We submitted the participants' ratings to a 2 X 2 X 2 repeated measures ANOVA (1st or 3rd choice candidate X electability or values trigger X Week 1 and Week 2). Preliminary analysis suggested that although participants gave higher ratings for their first vs. third choice candidate both initially and after the negative trigger, only their opinion of their first choice candidate dropped significantly. Also, the effect of the values-related trigger was stronger than the trigger pertaining to electability. These findings could be useful to campaign managers as they try to help their candidates cope with events that could derail their candidacy.

The Aversion to Condom Use in an HIV-Saturated World

Conner Blackwell, CURO Summer Fellow
Dr. Darius Ornston, International Affairs, School of Public & International Affairs

The Human Immunodeficiency Virus (HIV) has grown to become a pandemic since its first diagnosis in 1981. Since then, the virus has become a plague in the impoverished world. In Tanzania, the focus of this research, 3.3% of the population is living with the virus, but in some regions, the rate climbs to 16%. On the other hand, only .4% of Americans are currently living with HIV. The only way to prevent the transmission of the virus while remaining sexually active is through the use of a condom. However, the Tanzanian government reports "low and inconsistent" condom use despite its large sex education and condom distribution campaigns. What societal factor is holding Tanzanians from using condoms? My research aimed to expel all possible differences between America (90% of sexually-active Americans report having used a condom) and Tanzania that could explain the discrepancy in condom use in order to find a singular factor that unified all of the effects through one over-arching cause. Through analysis of HIV reports from the World Health Organization and UNAIDS, and by utilizing anthropological observations from fieldwork in Tanzania, I have concluded that this over-arching factor blocking condom proliferation is gender inequality. By recognizing the cause, it becomes easier to locate a solution to the low condom use.

Striated-Fiber Assemblin in Tetrahymena

Conner Blackwell, CURO Summer Fellow
Dr. Boris Striepen, Cellular Biology, Franklin College of Arts & Sciences

Prior research into the role of the Striated-Fiber Assemblin (SFA) protein has shown that it plays an essential role in the placement of Micro-tubule Organizing Centers (MTOC). In some organisms, this has totally depleted the possibility of reproduction. To confirm these previous findings, we have extended the study into Tetrahymena, a ciliate protozoan whose cilia grow from MTOC's that are similar to the ones from previous studies. We hypothesized that knocking out the SFA protein would disrupt the placement of MTOC's and thus immobilize the organisms. The knock-out comes from recombination of a plasmid that we construct containing Neomyacin resistance instead of coding for the SFA protein. The successful transformations will survive on a Neomyacin-coated plate and will be qualitatively studied for loss of cilia or loss of function. These results are not yet available due to the time it takes to construct the plasmid. If the SFA protein performs the hypothesized function, it will be a drug target for such diseases as malaria, cryptosporidosis, and toxoplasmis.

The Overexpression of Long Flagella Protein 4 in *Tetrahymena thermophila*

Stephen Bocarro, CURO Summer Fellow
Dr. Jacek Gaertig, Cellular Biology, Franklin College of Arts & Sciences

Microtubules mediate the majority of the movements of organelles in eukaryotic cells. One of the organelles in cells that microtubules directly mediate the movement of is the cilium. Studies in *Chlamydomonas reinhardtii* have shown that the Long Flagella protein 4(LF4) is a negative regulator of cilia length. Using a GFP tag, LF4-GFP was overexpressed in the protist, *Tetrahymena thermophila,* and shown to also negatively regulate cilia length in a pathway similar to that of Intraflagella transport (IFT) mutants. IFT proteins work in complexes near the axoneme, the base of the cilium in the main cell body. Due to the similarity between IFT and LF4 mutants, it can be elucidated that LF4 works as an inhibitor of cilia elongation and possibly of the IFT complex. By comparing the rate of growth of growing versus starved cells, we were able to establish

that the turnover rate of proteins transcending the cilia is being affected by the overexpression of LF4. We went on to establish a time at which LF4 had stopped movement in *Tetrahymena* cells while the cells still retained some length in their cilia. This would show that LF4 is affecting the turnover rate in cilia and actively stopping their movement.

Examination of Age as a Moderator of the Relationship between Sleep Quality and Job Satisfaction

Carley Borrelli
Dr. Lillian Eby, Psychology, Franklin College of Arts & Sciences

Prior studies have indicated that sleep loss results in decreased overall mood (Blagrove & Akehurst, 2001; Mastin et al., 2005). By extension, spillover theory (Staines, 1980) predicts that poor sleep quality may likewise predict lower job satisfaction. The current study examines this relationship. Moreover, existing studies have not examined how factors such as age affect the relationship between sleep quality and affective reactions, such as job satisfaction. One body of research has shown that the effectiveness of the circulatory system declines with age, resulting in lower core body temperature and disrupted sleep at night (Patlak, 2005). The purpose of this study is to determine how age moderates the relationship between sleep quality and job satisfaction. This study includes data collected from 1054 counselors from substance abuse treatment centers across the United States. The results showed that while age (B=.061, p <.045) and sleep quality (B=.203, p<.00) are negatively related to job satisfaction, age does not moderate the relationship between sleep and job satisfaction (F Change = 16.43, n.s.). Therefore, the study does not support the hypothesis that the relationship between sleep and job satisfaction is moderated by age. This research helps to develop a better understanding of the relationship between sleep, job satisfaction, and age.

The "Darlton" Initiative: Serial Complexity, Parallel Media Narratives, and Showrunner Tactics in *LOST*

Brendan Boyle
Dr. Horace Newcomb, Grady College of Journalism & Mass Communication

ABC's *LOST* was a rare success for network television that drew a wide and enthusiastic audience for six seasons despite a complex narrative involving one of primetime's largest acting ensembles, high-concept science fiction storytelling, and weekly episodic structure that built in regular trips back and forward in time. Showrunners Damon Lindelof and Carlton Cuse, who acted as head writers and executive producers throughout the series' run, helped fans engage with the show's complexity through the creation of their own media personalities. An examination of their appearances on panels at events like Comic-Con and their official podcast, as well as the industrial circumstances surrounding the showrunners' decision to fix the series' end date in advance, grants a greater understanding of how Cuse and Lindelof were able to use the complexity of the narrative to engage with fans both as part of a larger

public relations exercise and a way to achieve greater influence in dealings with network executives. This case study works as a paradigmatic example of how television's new breed of creative-executives gain power within existing management structures during a period of upheaval in the traditional network model, a synthesis of two roles in the production process at a level of exposure which may never be repeated.

Spousal Healthcare Disparities between LGBTQ Federal Employees and Their Heterosexual Coworkers

Kathryn Bridges
Dr. Meghan Skira, Economics, Terry College of Business

This presentation will highlight the methodologies and findings of my current research project focused on spousal healthcare disparities between LGBTQ federal employees and their heterosexual coworkers. This research seeks to predict and analyze the costs that federal LGBTQ employees must incur to cover spouses' healthcare. While their heterosexual counterparts can either opt into a federal plan for their spouse or receive a tax break on the dollar amount that they contribute toward an insurance plan, LGBTQ individuals, even when legally married, do not get this benefit as a result of Section 3 of the Defense of Marriage Act (DOMA). First, I seek to use the 2012 Federal Employee Viewpoint Survey (FEVS) to identify the number of LGBTQ employees currently working in the federal government. From here, I will seek to address health concerns faced by LGBTQ individuals, specifically highlighting the costs of purchasing private market individual plans for spouses. Lastly, I seek to estimate a lump sum that this coverage costs LGBTQ families ever year, and discuss the strain that puts on families, as well as the economic effect it would have on the government if they chose to provide benefits. This estimate will be based largely in current court cases addressing this disparity, including plaintiffs in "Pederson v. OPM," set to be heard by the Supreme Court in March. In addition, the study situates this disparity within larger current federal legislation concerning lesbian and gay individuals' marriage and domestic partnership rights.

Synthetic and Enzymatic Decarboxylation of Tyrosine Derivatives

Callan Brownfield, Robert Ashley
Dr. Richard Morrison, Chemistry, Franklin College of Arts & Sciences

L-DOPA, a derivative of the amino acid tyrosine, is converted to the neurotransmitter dopamine in the human body by the DOPA decarboxylase enzyme. Extant laboratory methods for comparable decarboxylations are laborious, inefficient, and few in number. We describe the development of a microwave-promoted method to accomplish a high yield and facile decarboxylation of L-DOPA and other amino acid precursors to their corresponding amines. The amino acid or amino acid derivative is placed in a glass microwave vessel along with a catalyst in a methanol solution, and refluxed until no visible amino acid remains. Upon completion, the catalyst can then be completely recovered from the reaction. Amines are purified by simple extraction and isolated as HCl salts of the desired neurotransmitters. The method is general for most natural amino acids and for all tyrosine derivatives that were studied. Recent research involves efforts to determine if structurally similar tyrosine derivatives can be converted to their respective amines enzymatically by DOPA decarboxylase. As potential drug targets, these compounds could theoretically be delivered in amino acid form and decarboxylated to the corresponding amine in vivo. Future research efforts entail analysis of the bioactivity of unnatural derivatives of the amino acid tyrosine. HPLC comparison of the enzyme digests to the synthetic amine standards will reveal the

general efficacy of our synthetic methodology.

Developing a Nutrition Intervention Program for College Female Freshmen Using Social Media

Alixanna Burg
Dr. Rebecca Mullis, Foods & Nutrition, College of Family & Consumer Sciences

For many college freshmen this is the first time they have been solely responsible for their nutritional well-being. However, many of them have little knowledge of nutrition and healthy eating habits, making it difficult for them to navigate the myriad of food choices within a busy academic and social schedule. This study investigated whether having easily accessible and relevant nutrition information during the first year of college helped increase healthy eating habits. A focus group was conducted and ten topics were identified for the intervention to address. A social media intervention was developed using a blog to post the content of the nutrition lessons. The blog was then linked to a Facebook group that reminded participants to view the lessons. A pre- and post-test were administered online to ten study participants to measure their improvement in both knowledge and behavior. Results showed that five out of six participants who completed at least one of the blog lessons improved their overall knowledge and behavior score. Topics that showed improvement in knowledge included dining hall symbols (17.5% increase) and food labels (10% increase), and topics that showed improvement in behavior changes included dining hall information (20% increase), dietary guideline requirements (18.8% increase), and eating out (43% increase). Though the results from this study are limited by a small sample size, they show the potential that a nutrition intervention using social media can improve access to and use of reliable nutrition information for college freshmen. Further study using a larger sample size is recommended.

Anesthetic Complications in Dogs Undergoing Surgery for Liver Disease

Brigid Burns
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

A dog with ongoing biliary disease may undergo a surgical procedure called a cholecystectomy, in which the gallbladder is completely removed. In the authors' clinical experience, patients with gallbladder disease tend to have a higher incidence of complications during anesthesia, including hypotension during manipulation of the gallbladder or following cholecystectomy. The purpose of this retrospective case-control study is to determine if there is a difference in the incidence of anesthetic complications between dogs with hepatic disease undergoing cholecystectomy compared to dogs undergoing other types of hepatic surgery. The hypothesis was that dogs that receive cholecystectomies would suffer a greater number of anesthesia complications than dogs that do not undergo cholecystectomy. By analyzing the medical records of dogs that underwent exploratory laparotomy for surgical management of liver disease at the UGA Small Animal Teaching Hospital, it was found that dogs that had cholecystectomy had longer anesthesia durations and longer surgery durations than dogs that did not have cholecystectomy. No significant differences existed for temperature nadir (94.6 vs 95.6 ºF; non-cholecystectomy vs cholecystectomy), final temperature (96.1 vs 96.7 ºF), time to extubation (29.5 vs 48.9 min), duration of hypotension (26.8 vs 20.8 min), or blood pressure nadir (53.3 vs 51.4 mmHg). Hypotension occurred in 66% and 74% and inotropes were used in 64% and 53%, for non-cholecystectomy and cholecystectomy patients, respectively. Dogs undergoing liver surgery for cholecystectomy did not suffer a greater number of anesthesia complications than dogs without cholecystectomies.

Abstracts

Where a Kid Can Be a Kid, Even When She's an Adult - The Internet's Role in Sustaining Engagement with Children's Television

Matt Burns
Dr. Alison Alexander, Grady College of Journalism & Mass Communication

For years, programming models insisted that children's television series aired 65 episodes, re-ran for a few years, and then disappeared into the recesses of viewers' memories. Now online video streaming allows nearly any television episode ever produced to be viewed instantly at any time, and social media outlets encourage users to share, discuss, and demand this content. With several media corporations currently riding a wave of nostalgia by reviving children's television franchises from the 1990s, this research sought to discover how and why college students are engaging with children's television, and if this sustained engagement can impact the ways media companies consider their programs' lifespans. This article reports the findings of an online survey (n = 332) that assessed methods and motivations, as categorized by Askwith (2007), that college students reported for engaging with children's television. Engagement with children's television in college is common (69%), but students are unlikely to pay for the content. Traditional television broadcasts remain an essential component of a show's longevity. Drawing from Uses and Gratifications Theory, respondents' motivations for viewing children's television in adulthood revealed three unique factors labeled Entertainment, Nostalgia, and "Closeted Masters." At a small but significant level, childhood engagement with children's television predicted adult engagement. More specifically, students who as children played in imaginary worlds, called paracosms, based on children's television were much more likely to sustain their engagement as adults.

The Excommunication of Early Jewish Christians and Its Interpretive Value for the So-called Temple Cleansing in the Gospel of John

Joanna Caffrey
Dr. Wayne Coppins, Religion, Franklin College of Arts & Sciences

The alleged excommunication of early Jewish Christians from the synagogue and the mention of such a phenomenon in John chapter nine most notably, as well as in other passages in the Gospel of John, has long been and continues to be an extensively debated topic in Johannine studies. Each occurrence of such a reference contains key words that are consistently connected either directly or indirectly to this expulsion when they occur in the Fourth Gospel, with the previously assumed exception of the use of the word "*ekballo*" in chapter two of the Gospel of John. This research proposes that the presence of "*ekballo*" in chapter two should not be seen as an exception, but rather as a purposeful reference to the subsequently mentioned excommunication, and therefore as an interpretive tool for the literary understanding of the so-called temple cleansing. The methodology involves examination of literary and historical aspects of the primary text in question. The significance of this research is that it will provide new information concerning the manner in which the author of the Gospel of John responded to conflicts between early Jewish Christians and Jews outside of the Christian movement.

Vocal Intonation as a Social Referencing Cue in Infants and African Grey Parrots

Rachel Callery
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

The proposed comparative study will investigate social referencing capabilities in 12- and 16-months old infants, as well as speech-using African Grey parrots. A choice

paradigm involving intonation cues and pairs of baited containers will be used. The experimenter will glance first into one container and then the other while vocalizing a high-rising (positive), low-falling (negative), or monotone (neutral) sound. The two containers will then be presented, and the preference (i.e., container first explored) recorded. We predict the 12-months age group will demonstrate no container preference, needing more experience with referential associations in order to use the cues. By 16 months, however, infants readily use caregiver affect, facial expressions, and pointing to assess novel objects. This older group should therefore explore positive intonation containers more often than negative or monotone containers. Further, we will investigate the preference patterns of speech-using African Greys, which are attentive to their caregivers' vocalizations and so may use intonation as a cue. Data collection is currently underway. This study will show for the first time whether the ability to use intonation as a social-referencing cue (1) appears in a nonhuman, and (2) develops in humans around the same time as other social referencing cues.

Classifying the Legitimacy of Malicious Domains for Safer Internet Browsing

Tiffany Cauthen
Dr. Roberto Perdisci, Computer Science, Franklin College of Arts & Sciences

In this project, we aim to detect malicious domains by leveraging search engines to collect a sense of Internet sentiment about domain names. Domain names conveniently allow Internet users to browse the Internet using easy-to-remember alphanumeric strings rather than the numeric IP addresses browsers need to connect to the right web server. Unfortunately, attackers also use domain names to steal from and infect users. These attackers transmit data, control bots, and facilitate other malevolent actions against Internet users, usually registering under false credentials. Our hypothesis is that collective Internet knowledge about a domain name will appear differently, depending on whether the domain name is used for malicious or legitimate purposes. For example, consider domain name *d* as a keyword. We collect information on which websites refer to *d* and, based on the results, perform the classification. Although current anti-malware programs have their own malicious content databases and other network-security research explores alternative ways to classify malevolent sources, our research hopes this previously unexplored method will prove probabilistically advantageous as an additional method of malicious domain name classification and provide valuable insight into how attackers create their criminal networks. We can currently classify domain names with an accuracy of about 87%. Malicious domain names are growing exponentially and continue to cause harm on unsuspecting victims. Our research hopes to create a way to accurately determine the legitimacy of domain names to impede the efforts of attackers and speed the process of warning Internet users of these malevolent domain names.

Increasing Georgian Household Participation in the Banking System

Jesse Chan, Foundation Fellow
Dr. John Campbell, J.M. Tull School of Accounting, Terry College of Business

Checking and savings accounts are conveniences many U.S. households exercise to meet their financial needs; these accounts are used to receive wages and salaries, pay utility and telephone bills, and are vehicles for saving funds for future events. A 2011 FDIC study indicated that 8.2% of all U.S. households were unbanked and 20.1% of households were underbanked. Unbanked households can least afford the pricey alternative financial services they consume, and their exclusion from the traditional banking system puts them at a severe financial disadvantage in developing savings. This

paper assessed policy alternatives to alleviate the problems and symptoms related to a high level of unbanked and underbanked households in Georgia: 1) maintaining the status quo, 2) supporting the creation of locally-focused financial literacy programs, 3) increased pricing transparency for financial services from all providers, and 4) regulating the order in which financial institutions process transactions for retail checking accounts. Each policy alternative was evaluated based on its ability to achieve three goals: 1) improve awareness of banking services, 2) improve confidence with conducting banking transactions, and 3) ultimately reducing the number of unbanked and underbanked households. After evaluation, the recommended proposed policy to help bring more unbanked and underbanked households into the mainstream banking system is support of financial literacy programs. Challenges of implementation include its relative difficulty to scale, funding challenges, and its approach to unbanked and underbanked levels through education, an indirect approach to solving the issue of unbanked and underbanked households in the United States and Georgia.

The Origin of Unusual Phosphate Deposits on the Venezuelan Island of Gran Roque, Leeward Antilles

Na Hyung Choi
Dr. James Wright, Geology, Franklin College of Arts & Sciences

The Leeward Antilles island of Gran Roque contains phosphate deposits that replaced the rinds of spheroidally weathered gabbro. The mineralogy and geochronology of the deposits were studied in order to interpret their origin. X-ray diffraction results indicate that the deposits consist principally of phosphate minerals variscite, phosphosiderite, and strengite. The island's mafic bedrock has been interpreted as an exposure of the Caribbean Plate, which formed in the Late Cretaceous when oceanic plateau magmatism thickened Pacific oceanic crust. The petrography, geochemistry, and age (87.0 ± 4.1 Ma) of the mafic complex are similar to those of other exposures of the Caribbean Plate, including the nearby islands of Aruba and Curaçao. The upper constraint for the age of the phosphates is given by the quartz diorite (65.6 ± 1.4 Ma) and pegmatite (65.3 ± 0.91 Ma) that intrude and postdate the phosphatized mafic complex. U-Pb dating of zircons from the pegmatite was carried out by laser ablation inductively coupled plasma mass spectrometry. The intrusions themselves are not phosphatized, demonstrating phosphate formation between ca 87 Ma and 65 Ma. This time period is consistent with the periods of subaerial weathering as documented for the Caribbean Plate exposures on Aruba and Curaçao. We interpret that the rinds of phosphate formed when rainwater leached guano deposits and reacted with the weathered mafic complex, resulting in the unusual suite of phosphate minerals. Similar modern processes have been observed and described from other localities, but to our knowledge this is the oldest well-documented example.

Democratic Dialogue: Comparing Presidential Debate Content and User-Generated Comments in Online News

Savannah Colbert
Dr. Bryan Reber, Grady College of Journalism & Mass Communication

Will there be common themes between the material candidates discuss in the presidential debates and the discussion about the debates by online news respondents? Using content analysis of presidential debate transcripts and online user-generated comments (UGC) about the debates, frames and themes were identified by two coders. The stratified random sample of 1,600 UGC was developed from comments following six articles about the 2012 presidential debates. To avoid skews in the data, one historically conservative newspaper (*The Wall Street Journal*, N = 1,111)

and one historically liberal paper (*The New York Times*, N = 489) were sampled for UGC following each of the three 2012 presidential debates. Based on a pretest, debate and UGC contents appear to be remarkably different. Most UGC express a strong opinion about a candidate while the debate content focuses on specific issues facing the U.S. It is further anticipated that user-generated comments about the presidential debates will be more partisan than the debates themselves, which will focus more on national issues and solutions or policies. UGC provide an important forum for citizens to voice their opinions as political participants in their democracy. Furthermore, the media is increasingly reliant on UGC to spur interest in news content. All the information used in the study was publicly posted or broadcast information, so there are no ethical issues in this content analysis study.

Exploring the Use of Comprehensive Nutrition Education Programs as a Means of Addressing Food Insecurity in Georgia

Carol Conroy
Dr. Jung Sun Lee, Foods & Nutrition, College of Family & Consumer Sciences

Food insecurity persists as one of the most pressing public health issues in Georgia. As defined by the United States Department of Agriculture (USDA), food insecurity suggests that an individual or family either consistently or periodically does not have access to enough food to lead a healthy, active life. In Georgia, approximately 16.9 percent of households experience food insecurity. The Supplemental Nutrition Assistance Program (SNAP) is the most broad federal food assistance program, benefitting approximately 45.8 million people in the United States. This program is coupled with an optional nutrition education initiative, SNAP Education Program (SNAP-Ed), which promotes the adoption of healthy eating habits and an active lifestyle as a means of preventing obesity and chronic illness. The education program is funded through the SNAP-Ed grant and can be administered to Cooperative Extension Services at any land grant university (LGU). The University of Georgia is the only LGU in Georgia and operates nutrition education programs in county offices across the state. Although the Cooperative Extension currently offers education services to all populations through the Expanded Food and Nutrition Education Program (EPNEP), it does not receive SNAP-Ed funding and therefore cannot adequately serve all SNAP beneficiaries. This paper evaluates current policy failures as well as proposes policy alternatives. By reapplying for the SNAP-Ed grant in addition to its existing grant funding, the Cooperative Extension will have an opportunity to extend services to a broader population of SNAP recipients and provide a more comprehensive nutrition education program for the state.

Second Law of Thermodynamics Efficiency Analyses of High-voltage Electricity Transmission

Kevin Cown
Dr. John Schramski, College of Engineering

The objective of this research is to determine the feasibility of conducting a second law of thermodynamics efficiency analysis of high-voltage electricity transmission. The efforts are to use exergy in conjunction with a second law efficiency. This will be done in addition to a first law of thermodynamics efficiency analysis. It is anticipated that the results of this analysis will reveal valuable insight concerning electricity transmission that is not commonly understood. The experimental model consists of an arbitrary section of high-voltage transmission cable with associated energy input and output. Quantification of this energy flow is not entirely understood at this point, and literature search for related study that may provide further knowledge is ongoing. This research is based on input-output analysis of the closed system under investigation. The goal is to reach a conclusion that could be environmentally

beneficial. Electricity transmission lines are the conveyance systems by which electrical power is distributed to the user from the generation site. Electricity generation has negative environmental consequences including coal combustion emissions, nuclear wastes, and increasing infrastructure real estate demands. Transmission losses of this environmentally expensive, high-quality energy could be further reduced with system designs based upon theoretical models derived from second law analyses.

When is a Kiss a Thimble? Sexuality in Adaptations of *Peter Pan* Over Time

Maria Cox, CURO Honors Scholar, Foundation Fellow
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

The character of Peter Pan first took the stage in 1904 and has become a symbol of eternal youth, leading Wendy Darling and her brothers to Never Land, a paradise of pirates, Indians, and adventurous Lost Boys. In Barrie's treatise on childhood, Wendy learns through her adventures in Never Land that she must grow up, but before she even learns to fly, she tries to give her new friend Peter a kiss. Yet Peter, the boy who has no parents, does not know what a "kiss" is. Thinking a kiss is an object, he holds out his hand, leading Wendy to give him a thimble instead. With this gesture Barrie addresses childhood romance, Wendy's transition to adolescent sexuality, and the importance of love. A kiss can represent the rewards of maturity, and when it is eliminated, so too are the positive aspects of adulthood. Barrie expanded on these themes in his novelization of the tale, *Peter and Wendy* in 1911. This novel by Barrie is the most fully realized version of *Peter Pan*. How this scene is cut, changed, or reproduced in over a century of film adaptations shows a growing interest in these themes of love and romance. How the adaptations address them allows the viewer to think about the original in a new way. My research shows that the live-action *Peter Pan* (2003) is the most faithful adaptation of the novel, encompassing the thematic elements of "The Kiss" most effectively. This project uses materials from the University of Georgia Libraries' Peabody Collection.

Proteomic Analysis of the Tomato/ *Botrytis cineria* Interaction

Dervin Cunningham, CURO Honors Scholar, CURO Summer Fellow
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Botrytis cinerea attributes to the post-harvest rot of more than 200 species of fruits and vegetables. As these produce ripen, their cellular wall drastically degrades, making them more susceptible to pathogens. Significant protein-protein interactions occur between the necrotrophic fungal pathogen, *Botrytis cinerea*, and the tomato fruit. By describing host and pathogen proteomes simultaneously in infected tissues, the plant proteins that provide resistance and allow susceptibility and the pathogen proteins that promote colonization and facilitate quiescence can be identified. This study is aimed to characterize the fruit and fungal proteins occurring in the tomato/*B. cinerea* interaction using shotgun proteomics. Mature green, red ripe, wild type and *rin* and *nor* mutant tomato fruit were infected with *B. cinerea* B05.10. After 5 days the infected tomatoes were gently agitated in a 1.5M NaCl solution followed by a SDS and heat treatment to collect solubilized proteins. The collected proteins were separated on a one dimensional SDS-PAGE gel, followed by in-gel digestion. Peptides were then analyzed by LC-MS/MS on a linear ion trap mass spectrometer. Data was searched using Mascot algorithm. Proteins were identified by combining the *B. cinerea* BO5.10 (Broad Institute, MA), and T4 databases (Genoscope, France) with a tomato protein database (SOL Genomics Network, Cornell University, NY). A decoy database was constructed by

reversing the sequences in this target database. Statistically significant proteins were determined at a 1% protein FDR. The composition of the collected proteins populations and their putative functions allow for a better understanding of the plant-pathogen interaction mechanism.

A Therapeutic Nanoparticle Platform for Ischemic Brain Injury

Kasey Darley
Dr. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Stroke is the number one cause of long-term disability and the third leading cause of death in the United States. Despite a concerted effort by medical and research communities to develop therapeutics, there are few treatments and no cure. Neuro-protectants such as mitochondria acting antioxidants that shield the brain from cytotoxic effects caused by stroke have shown significant promise in rodent stroke models, but by themselves have not translated to a viable treatment in human patients. One limitation of antioxidant treatments is that they offer little in the way of tissue regeneration, which would lead to the re-growth of lost neural networks and recovery of cognitive, sensory and motor function. This has led to significant increase in the development of regenerative neural stem cell therapies that would be able to differentiate and form new networks leading to improved recovery. Neural injury often leads to a toxic environment not conducive to tissue regeneration including the expression of reactive oxygen species (ROS) and inflammatory cytokines. Advances in regenerative medicine focusing on the development of multifunctional nanoparticles (NPs) for delivery of synergistic antioxidants and anti-inflammatory agents to the mitochondria of cells followed by treatment with embryonic and induced pluripotent stem cells capable of differentiating into function neural progenitors can provide a platform technology to create a robust neural regenerative therapeutic system. In this presentation, we will demonstrate a novel combination treatment of mitochondrial targeted NP mediated delivery of synergistic antioxidant and anti-inflammatory agents and induced pluripotent stem cell derived neural stem cell therapy.

Trinucleotide Insertion and Deletion in TgTPC1 cDNA

Jay Dasigi
Dr. Silvia Moreno, Cellular Biology, Franklin College of Arts & Sciences

Toxoplasma gondii is an apicomplexan parasite, which can be grown in the laboratory in large quantities and is readily amenable to genetic manipulation. In an effort to better understand calcium homeostasis in this parasite, the two-pore channel TgTPC1 was studied. Two-pore channels are receptor complexes that have been recently discovered to release Ca2+ in response to NAADP. While trying to clone the gene coding for TgTPC1 in *T. gondii*, the results suggested that one TgTPC1 gene may be able to produce three different mRNAs (+3 nucleotides, wild type, and -3 nucleotides) by trinucleotide insertion and deletion. To further characterize this phenomenon, *in vitro* methods were used to exclude the possibility of an *in vitro* amplification artifact, and to confirm that there are 3 different populations of mRNAs. The different populations of the cDNAs were studied by direct cloning/sequencing, with a sequenced cDNA construct containing three extra nucleotides and the cloned genomic DNA used as controls. It is expected that there will be only one population of TOPO clones from the two controls, and that a different population of cDNA can be identified by direct sequencing the cloned RT-PCR products. This work suggests that *T. gondii* can produce 3 different proteins from one gene. There are more than a dozen neurological dysfunction diseases caused by trinucleotide expansion. Although DNA replication slippage has been widely accepted,

this is the first evidence that there is also transcription slippage. This work will shed new light on the molecular mechanisms of these neurological diseases.

Topology of the Ras Converting Enzyme
Dillon Davis
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The Ras converting enzyme (Rce1p) is a membrane-associated endoprotease of undefined mechanism that is involved in post-translational modification of the Ras GTPases and other isoprenylated proteins. Its role in Ras biosynthesis marks Rce1p as an anti-cancer target. By assessing the chemical accessibility of cysteine residues occurring naturally or substituted throughout the yeast Rce1p sequence, evidence is presented that Rce1p has eight inaccessible regions. Our evidence indicates that the natural cysteine residues of Rce1p lie within several of these inaccessible regions. Furthermore, we report that the natural cysteine residues are fully dispensable for enzyme activity, formally eliminating a previously proposed cysteine-based enzymatic mechanism for Rce1p. Our findings are most consistent with Rce1p having a single transmembrane domain near the NH2-terminus and seven additional segments that are either monotopic or tightly folded domains. At least one monotopic domain is expected based on the observation that Rce1p lacking the NH2-terminal transmembrane segment remains tightly membrane associated. The topological arrangement that we propose places the NH2-terminus within the endoplasmic reticulum (ER) lumen and all remaining segments on the cytosolic side of the ER, possibly within the cytosolic leaflet of the ER membrane itself. This arrangement allows for relative proximity of the three residues that are essential for yeast Rce1p function (E156, H194 and H248), consistent with their proposed role in forming an active site that lies at or within the cytosolic face of the ER membrane bilayer.

The Ordinance of 1669 in Application on the Grande Maîtrise de Toulouse as Documented by Louis de Froidour
Sara De La Torre Berón, Foundation Fellow
Dr. Ted Gragson, Anthropology, Franklin College of Arts & Sciences

Louis de Froidour was a forest surveyor appointed by Jean Baptiste Colbert during the reign of Louis XIV in 17th century France. Froidour was commissioned to document and represent the tracts of land owned by the inhabitants of the grande maîtrise de Toulouse, encompassing the southwest region of France. During his acclaimed tenure as surveyor, Froidour earned the title of France's "Grand Master of Waters and Forests." Using Froidour's personal records, archived in the Archives départementales de la Haute-Garonne and the Bibliothèque d'étude et du patrimoine de Périgord in Toulouse, as well as secondary literature, I evaluated the state of the land in the region Froidour surveyed before the implementation of the Ordinance of 1669. Using this information, I evaluated the lack of uniform land management policies across the grande maîtrise de Toulouse and particularly in the Pyrenees Mountains. The so-called "disrepair" in the land provided an impetus for comprehensive forest reform for the region Froidour surveyed, as well the entire kingdom. Finally, I also evaluated Froidour's methods of documentation and his personal impact on the surveying of land during his tenure, as well as his influence on later surveyors. This research contributes to the knowledge of land management practices in the area where Froidour conducted his surveys as well as the influence of economic governance on how local farmers determined the use of their lands.

The Relationship between Communication and Satisfaction with Change Management with Supervisor Trust as a Moderator

Shelby Devine, Kelsey Hardy, Katelyn Briggs
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

Every organization will experience change in one form or another, and it is how that change is managed that can facilitate successful employee attitudes regarding that change. Studies show communication and trust with one's superior are vital factors in employees' satisfaction towards change. We expect to find that supervisor communication strength will be positively related to employee satisfaction with organizational change. We also predict supervisor trust will moderate the relationship between supervisor communication strength and employee satisfaction with change management in that when trust is high the relationship will be stronger, but when trust is low, the relationship will be weaker. The data was gathered through self-reported surveys from a large Fortune 50 company. After analyzing the data using ordinary least squares regression techniques in SPSS, we found evidence that supervisor communication strength was positively related with employee satisfaction of change management. Additionally, we found support for supervisor trust moderating satisfaction with change management; however, the relationship was in the opposite direction from what we had predicted. Our results indicated that when supervisor trust was high, the relationship between supervisor communication strength and employee satisfaction with change was low. When trust is low, we found the relationship to be weaker. Our data shows that communication and supervisor trust impact how employees feel about change management. These findings can be utilized by organizations to facilitate change more effectively. This will contribute to the satisfaction of employees with organizational change and their company as a whole, ultimately resulting in greater organizational success.

Effects of Electrical Stimulation Intensity on the Non-invasive Evaluation of Mitochondrial Function Using Near-infrared Spectroscopy

Parveen Dhillon, Kanan Talati
Dr. Kevin McCully, Kinesiology, College of Education

Near infrared spectroscopy (NIRS) can be used to measure muscle oxygen consumption (mVO2). Repeated arterial occlusions after exercise provide an index of skeletal muscle mitochondrial function. The purpose of this study was to examine the effects of electrical stimulation (ES) intensity (i.e. current amplitude) on mVO2 and the recovery rate of mVO2 after exercise. Ten healthy subjects (age = 21.2 ± 1.4 years) were tested at three levels of ES current. Twitch ES (4 Hz) of the medial gastrocnemius/soleus muscles was used to increase mVO2. Repeated measures of mVO2 were fit to a monoexponential curve and rate constants were calculated. A force transducer was used to measure the time-tension integral (TTI) of ES exercises. Average currents used in this study were 45 ± 11, 61 ± 12, and 82 ± 14 mA for the low, medium, and high currents. Normalized TTI for low, medium, and high current trials were 54 ± 11, 82 ± 7, and 100 ± 0 % ($p < 0.001$). The initial (end-exercise) mVO2 were 2.56 ± 1.44, 3.64 ± 0.85, and 3.79 ± 0.60 %sec-1 for low, medium, and high current trials. NIRS rate constants were not different between trials (2.02 ± 0.54, 1.95 ± 0.44, 2.02 ± 0.46 min-1 for low, medium, and high current trials; $F(2,9) = 0.264$, $p = 0.771$, $\eta 2 = 0.028$). In summary, changes in ES intensity influence measurements of mVO2, but the recovery of mVO2 represents only the activated tissue and was independent of the ES intensity.

Analyzing Linkages between Economic Development Models and Food Security: Comparative Case Study of Thailand, Vietnam, and the Philippines

Colin Dungu
Dr. Jack Houston, Jr., Agriculture & Applied Economics, College of Agricultural & Environmental Sciences

This study seeks to answer the following question: What are the linkages between a country's development model and its food security? To answer that question, I compare the relationship between economic reforms and food security levels for Thailand, Vietnam, and the Philippines. This thesis emphasizes the economic rationale of liberalizing economic reforms and examines the reasons why those countries that adopt market reforms attract more foreign investment, which is the key to overall economic growth, and consequently food security. This study first investigates what is food security, and what are the causes of food insecurity. It then examines the economic models pursued by three Southeast Asian states that are relatively similar in population and size. Thailand and Vietnam have spearheaded forward in their goal towards attaining food security, whereas the Philippines remains a chronic importer of rice, which is their staple crop. The adoption of liberalization, trade, and market reforms in the former two has infused foreign direct investment (FDI) into the agricultural sector and enhanced efficiency in production methods, which has helped improve food security. However, by maintaining its reliance on the Import Substitution Industrialization (ISI) model for a significantly longer time period, the Philippines fell further behind in its economic development and failed to attract outside investment, which lowered agricultural production and increased food insecurity.

Text Messaging: A Tool to Increase Physical Activity Compliance?

Alexandra Ely
Dr. Michael Schmidt, Kinesiology, College of Education

Compliance of subjects is a key issue faced when implementing exercise programs. No universal recipe for success exists when it comes to increasing subjects' compliance to a physical activity intervention. Research has shown that increased levels of self-efficacy, social support, and knowledge about the benefits of exercise lead to greater compliance to an exercise program. The purpose of this study is to use accelerometry to analyze women's compliance to a walking program on weeks they receive motivational text messages as compared to compliance on weeks the texts are not sent. Participants, women ages 25-45, comprise three groups of six. During weeks three, five, and seven of the eight week intervention, each woman in a respective group receives a text on Tuesday, Thursday, and Saturday. These texts fall into one of three categories: self-efficacy, social support, or increasing knowledge. Every group is assigned a different category during each "text week," and during those weeks receives messages exclusive to that category. Post-intervention, total minutes walked during weeks when texts were received will be compared to those walked during weeks no texts were received. Differences between walking totals comparing texts from the three categories will also be examined. The impact of motivational text messages on program compliance will be analyzed to determine if text messaging is an effective tool to increase physical activity participation, as well as whether certain types of messages better increase participation. Results will have implications for the effectiveness of increasing physical activity compliance by use of motivational text messages.

Comparison of an Embedded Effort Measure on CNS Vital Signs between Older and Younger Adults

Sarah Evans
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

Adequate effort displayed by participants and patients is an essential foundation for experimental and clinical testing. Clinicians and researchers need to be aware of potentially invalid results that may not accurately reflect optimal levels of effort from subjects. The objective of this study was to compare effort between younger and older adults within the CNS Vital Signs test, a neurocognitive computerized test battery. An embedded effort measure for a variety of clinical domains was compared across old and young participants. This indicator was determined by comparing each participant's performance to cutoff scores on multiple tests. It was hypothesized that a higher percentage of older adults would demonstrate adequate effort compared to younger adults. Examining effort in both populations is much needed given the sparse literature examining effort performance on this test. Additionally, due to the widespread tendency of college students to be used in university studies, research highlighting their degree of effort will play a critical role in determining the credibility of their results and the impact of motivation on performance. The results will serve as an indicator of the differences in effort between age groups as a further step in achieving the goal that data being used to make conclusions or diagnoses is both appropriate and dependable.

Managers vs. Employees: The Differing Effects of Communication Strength and Supervisor Support on Work Engagement

Meghan Foley, Katryna McCann
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

Employee engagement can predict critical outcomes for the bottom line of business operations; organizations want employees to feel engaged and therefore be motivated to produce significant results. Research has focused on employee engagement, but significantly less research has examined managerial engagement. The purpose of the present study is to test whether or not managers and employees derive their sense of engagement in the same manner, which could ultimately lead to ways in which businesses can most effectively build an engaged workforce of both entities. We defined engagement as our dependent variable, and used leader-member exchange to predict the positive effects of communication strength. The nature of the social exchange relationship between supervisor and employee also led us to predict a mediating role of supervisor support on communication and engagement. Using data from a Fortune 50 company, we tested the effects of communication strength and the mediation of supervisor support on engagement for samples of lower level employees and managers. Results showed that for both employees and managers, communication strength had a significant impact on their feelings of engagement. However, when testing for mediation, supervisor support was not a mediator for employees but was a significant partial mediator for managers' engagement. These results imply that there may be differences in the way employees and managers become motivated and engaged in their work roles, and points to the need for more research on how to best engage managers.

Identification of GABA-responsive Neurons in the Zebrafish Brain

Hope Foskey, CURO Summer Fellow
Dr. James Lauderdale, Cellular Biology, Franklin College of Arts & Sciences

Over 2 million people in the United States have experienced unprovoked seizure activity or been diagnosed with epilepsy. While medication has been developed that can help some people control their seizures, the mechanism by which seizures occur is not well understood, and the neural circuits by which seizure activity is propagated are unknown. The purpose of my experiments was to identify the neurons likely to be involved in generating seizure activity by using zebrafish (*Danio rerio*), an emerging vertebrate model in the study of seizure disorders. To do this, an adult zebrafish brain was cryosectioned transversely, and GABA-responsive neurons were identified by immunolabeling for GAD65/67, GABA, and GABAAR. GAD is the enzyme that catalyzes the decarboxylation of glutamate to GABA, a major inhibitory neurotransmitter in the brain. These experiments identified for the first time the neural pathways in the zebrafish brain that are affected by seizure activity and provided insight into the pathways that normally are affected in human seizures.

A Testosterone Tale: Do Females Really Have Higher Levels Than Males?

Melanie Fratto, CURO Summer Fellow
Dr. Vanessa Ezenwa, Odum School of Ecology

Testosterone is the principal male sex hormone in mammals. Males typically have testosterone levels 2-7 times higher than females, and testosterone affects reproductive behavior and aggression. Recent studies in hyenas and hyrax suggest that in some mammals, females can show testosterone levels equivalent to males, with important consequences for female behavior. Data from a long-term study on Grant's gazelle (*Nanger granti*) in Kenya showed that testosterone levels of some females reached concentrations 10-fold greater than male concentrations. Variation in female testosterone was associated with reproductive status and aggression. Since this study quantified testosterone levels from fecal samples, and sex differences in fecal metabolite concentrations may not reflect actual differences in circulating testosterone, our objective was to investigate whether fecal testosterone differences reflect true differences in circulating testosterone between male and female gazelle. First, we tested whether serum concentrations showed the same differences between sexes as fecal concentrations. We found that the female fecal average was 2 times higher than the male average, but the male serum average was 3 times higher than the female average. Next, we collaborated with the UGA Complex Carbohydrate Research Center to isolate specific testosterone-like metabolites present in fecal samples that may explain the differences between the fecal and serum samples. We will test the metabolites for binding to the testosterone ELISA assay. This study will improve current understanding of biochemical controls on behavior.

Water Loss Rates of Two Terrestrial Salamanders, *Plethodon shermani* and *Plethodon teyahalee*, and Their Hybrids

Samantha Frigerio, Elijah White
Dr. Jeff Hepinstall-Cymerman, Warnell School of Forestry & Natural Resources

In the Southern Appalachian Mountains, two salamander species, *Plethodon teyahalee* and *Plethodon shermani*, hybridize across an elevational gradient. Studies show the upper bounds of this hybrid zone are expanding. We hypothesized that this upward movement is affected by differing water loss rates between species which, in turn, may affect their responses to climate change; specifically that *P. teyahalee*—located at lower elevations—has lower water loss rates than *P. shermani*—

located at higher elevations. We conducted a reciprocal transplant field experiment in which salamander water loss was measured in natural environmental conditions. Using linear mixed-effects models, we found that an interaction between body size and hybrid level most accurately predicted salamander water loss. A lab experiment was also conducted in which we measured water loss of individuals from the ends of the hybrid zone under controlled conditions. Using a repeated-measures ANOVA, we found a significant difference in water loss rates between the two species ($F_{30,930} = 2.325$, $P < 0.001$). Water loss is likely one factor contributing to the hybrid zone's upward movement. Future studies may determine how water loss affects behavior and project future zone dynamics in the context of climate change.

Landscapes of the Interior: Ethnobotany and Sense of Place among Karen Refugees
Terese Gagnon, CURO Summer Fellow
Dr. Virginia Nazarea, Anthropology, Franklin College of Arts & Sciences

Forced by ongoing government persecution to leave their homeland in Burma, Karen refugees residing in Georgia continue each day the process of remembering and reaffirming their cultural traditions while seeking meaning and belonging in their new environment. Through engaging in interviews and gardening practices with the Karen people this project examines the anthropological phenomenon of the 'landscape of the interior,' particularly as experienced from a transnational perspective. Recognizing the value of preserving genetic biodiversity alongside culturally situated knowledge, it aims to record—through the process of memory banking—ethnobotanical traditions of the Karen and their cultural relationship to the natural environment. One important product of this research is a compendium of plant species grown by Karen gardeners in Georgia. This compendium includes plant characteristics, methods of cultivation, uses, religious/cultural significance and photo documentation. Additionally, this project explores the role of 'interior landscapes' in shaping relationships with a new inhabited environment. This investigation seeks to benefit the Karen people and the community at large by encouraging the continuation of traditions — creating senses of 'rootedness' and preserving ethnobotanical knowledge and biodiversity. This research is approached with the belief that practices of remembrance and resilience are often the strongest means of combating forces of hegemony and oppression.

On Memory's Tidewater: Sapelo Island Documentary Project
Terese Gagnon, CURO Summer Fellow
Dr. Virginia Nazarea, Anthropology, Franklin College of Arts & Sciences

The Geechee Gullah people, descendents of enslaved individuals brought from the western coast of Africa, have inhabited Sapelo Island, Georgia for four centuries. Through closely knit community and a strong sense of place, their culture has maintained a distinct life way that includes knowledge and practices passed down from their African forbearers. Local traditions include unique forms of art, music, agricultural practice and the Gullah language. Though there were once many such communities, today the Hog Hammock community is the last intact Geechee Gullah community on Sapelo, and one of the last surviving in the world. The residents of Hog Hammock have clung to their deeply storied land for generations, despite numerous adversities. However, a drastic tax imposition now threatens to push them from their island home, potentially fracturing their community once and for all. Drawing on both anthropological and journalistic perspectives, this documentary aims to capture a glimpse of the history and feel of the Hog Hammock community, while exploring the ramifications of the recent tax legislation. It draws on interviews with Hog Hammock residents,

research on the history of the Island, discussions with prominent local figures, and footage of the Island community. Ultimately this cross-disciplinary project seeks to call us to our senses, appealing to our sense of beauty as well as our sense of injustice, hoping to stir within us the waters of place and memory.

Access Care

Smitha Ganeshan, Foundation Fellow
Dr. Monica Gaughan, Health Policy & Management, College of Public Health

In Athens-Clarke County (ACC), 20% of the population is uninsured and 38% of the population receives Medicaid assistance. This 58% of the population faces severe financial and structural barriers in accessing primary care services. Most of the uninsured and Medicaid patients are seen in Athens Regional Medical Center and Mercy Health Center's emergency departments, where the cost of care is mostly uncompensated and approximately three times higher than it would be in a primary care setting. Additionally, poor longitudinal care for chronic diseases results in repeated preventable hospitalizations. A thorough literature review was conducted to develop a policy proposal to make Athens-Clarke County more competitive for federal money and assistance through the Patient Protection and Affordable Care Act. After evaluating various policy alternatives based on a cost-benefit analysis, a proposal that calls for Athens to apply for a Health Professional Shortage Area (HPSA) designation was chosen. A comprehensive survey of all primary care providers in ACC was conducted, and the data shows that less than a handful of practitioners in ACC accept Medicaid insurance. This data supports the anecdotal evidence that describes the primary care provider shortage for low-income patients. This designation will ultimately enhance Athens-Clarke County's applications for having a Federally Qualified Health Center (FQHC) and improve low-income patients' access to primary care services in Athens. An integrated health system that provides adequate access to primary care services for low-income patients in Athens-Clarke County would improve community health, reduce health disparities, and reduce health costs.

"Pretty What?"— An Exploration of Society and Gender through Movement

Allison Gantz
Prof. Rebecca Enghauser, Dance, Franklin College of Arts & Sciences

"Pretty What?" is a choreographic work created to question societal norms. Specifically focusing on gender roles and beauty, this dance explores the heightened expectations present in our American culture. Representation is the central idea, and the tension between people's definitions of image and media-defined beauty are the resulting concepts. The intention was to begin the piece with the accepted, stereotypical images of men and women in society. Leaning towards nostalgia, I presented the highly stereotypical figures of glowing, elegant women and strong, domineering men. Then, a film of compiled images of women in magazine photographs and advertisements played to demonstrate the relevance of this work in the current society. After setting up a dichotomy of men and women, pretty and not so pretty, I blended the two definitions together through movement. The awkward deconstruction of gender and sexuality was the result. Research of advertisements and movement generated through conversation with the cast of my dance helped me create unexpected movement combinations and relationships. As a culmination of my research on image identity, I ended the dance in the middle, between hyper-sexualized gender extremes and irreverent gender role reversal. The idea of middle ground leaves someone being completely honest with who he or she is. How do people feel when they are alone with their thoughts? How do people

feel about their personal beauty and personal worth? I left the piece open ended in hopes that a viewer could consider these questions for him or herself, and question the magnitude of influence the media has on creating accepted roles in society.

The Death of the Death Penalty
Richard Gardiner
Dr. James Monogan III, Political Science, School of Public & International Affairs

The death penalty is a major topic in the realm of criminal justice policy. Past research has clearly shown that the death penalty is in decline across the nation. This paper researches why states differ in their capital punishment policies. I, however, propose that there are multiple factors all leading to the decline: the rise of the innocence frame, differing reactions due to error, economic feasibility, and changing public opinion. My research method is unique from other works in that I am studying public opinion at the state level combined with a coding system that assigns the level of restriction for each state's laws pertaining to the death penalty. I expect to find that public opinion is the single most important factor with economic factors being secondary. How death penalty policy is made in the U.S. depends on what the states are doing. Also, this study can be used in other areas of public policy to help examine future debates empirically. Because there is no actual contact with individuals and those defined as vulnerable, there are not any ethical implications hindering my study.

Compensatory Exercise and Thinness Expectancies
Ashton Garner
Dr. Sarah Fischer Nowaczyk, Psychology, Franklin College of Arts & Sciences

Women with eating pathology tend to report higher weight and shape concerns and more frequently list shape and weight as motivation for exercise than healthy women. Compensatory exercise (exercise performed in an effort to control weight/shape or in response to caloric intake) is considered a maintenance factor in eating disorders. Thinness expectancies (beliefs that thinness will improve the overall quality of life) are also strongly linked to eating disorder symptoms. There is little literature, however, examining the relationship between compensatory exercise and thinness expectancies. The present study was designed to examine the predictive relationship between thinness expectancies and endorsement of compensatory exercise using the TREI, EDE-Q, and exercise Timeline Followback calendars. Additionally, the study examined the specific types of exercise (e.g., walking, running, elliptical, etc.) that individuals who report compensatory exercise choose. Our data was obtained through self-report questionnaires completed by a sample of undergraduate women at a large southeastern university. Logistic regression will be used to identify participants as compensatory exercisers based on their endorsement of thinness expectancies. Additionally, in the sample of women who endorse compensatory exercise, we expect to find a significant positive correlation between the frequency of compensatory exercise and level of thinness expectancies. We further expect to find individuals who report higher thinness expectancies to engage in high-intensity cardiovascular exercises such as running. These findings will be a valuable addition to the current literature concerning factors of eating pathology and will have implications for both treatment and prevention programs.

Teacher Cheating Scandals in Georgia and Possible Policy Solutions
Eilidh Geddes, Foundation Fellow
Dr. Sylvia Hutchinson, Emeriti Scholar, College of Education

A major problem facing Georgia's education system is teacher manipulation of test score data, which was brought to the forefront of

public attention by the recent Atlanta Public Schools cheating scandal. Cheating scandals hurt the educational outcomes for children and erode the credibility of our schools. Current incentives align to push teachers towards cheating, and current testing practices make it possible for this cheating to occur. Possible policy solutions to address this issue include using an algorithm to better detect cheating, having outside monitors administer tests, changing legislation that creates bad incentives, and implementing a comprehensive testing policy. These four alternatives were evaluated based on their ability to reduce teacher cheating, improve educational outcomes, and be passed and implemented successfully. Of these four alternatives, a comprehensive testing policy would best meet these policy goals. This alternative would involve use of an algorithm to better detect teacher cheating, would provide guidelines for improved testing security, would mandate investigations by the state, and would increase legal education for teachers over the consequences of cheating.

Assessing the Role of Soluble TNF Receptors I and II in Placental Malaria

Mina Ghobrial
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Malaria is an infectious disease from the parasite genus *Plasmodium,* which kills approximately 2.7 million people each year. *Plasmodium falciparum* causes a vast amount of malarial infections. Where *Plasmodium falciparum* is present, malarial infections in pregnant women is correlated with both maternal and neonatal morbidity, low birth weight, and a reduced chance that the offspring will survive their first year. In placental malaria, infected erythrocytes (IEs) gather in the intervillous space of the placenta. Sequestration of IEs in the intervillous space leads to changes in cytokine balance, namely an increase in TNF- α (Tumor Necrosis Factor). Low levels of TNF- α result in an enhancement of phagocytic activity, which works to control parasite densities; high levels can inhibit endocrine function and initiate extracellular matrix degradation, resulting in poor pregnancy outcomes. Activity of TNF- α can be modulated by its soluble receptors, soluble TNF receptors I and II. Understanding the role of soluble TNF receptors I and II can help to accurately diagnose placental malaria, be predictive of negative outcomes, and assess the role of oxidative stress in disease and role of Caspase 3 (CASP 3) for apoptosis. In these experiments, approximately three groups of mice are used: infected not pregrant (INP), infected pregnant (IP) and uninfected pregnant (UP). INP and UP mice are controls for parasitemia and weight, respectively. Furthermore, these mice are genetically modified to express 1) both TNF receptors I and II, 2) neither of the receptors, or 3) only one (soluble TNF receptor I or II). Approximately 15 mice are used per experiment. On gestation days 0 and 6-14, clinicals are performed on these mice. Clinicals include examining weight, hematocrit and parasitemia. Trends in these categories are then evaluated. On gestation day 14, mice are euthanized, and their placental tissue is further assessed. Placental tissues are analyzed using immunostaining for CASP 3, a protein associated with apoptotic cells. The expectation is that mice lacking soluble TNF receptors I or II will have less expression of CASP 3. Immunohistochemistry is used to further analyze mouse tissues. Additional examinations are considered to evaluate the role of oxidative stress in TNF knockout mice versus wild type. Understanding the role of soluble TNF receptors I and II has a plethora of benefits, ultimately leading to better understanding pathogenesis of placental malaria and being able to predict and control its associated outcomes.

Science Lecture Classrooms: Extending the Bounds of Creative Teaching and Learning

Olivia Gorbatkin
Prof. Tracie Costantino, Lamar Dodd School of Art, Franklin College of Arts & Sciences

How do we enhance the learning of science students in large lecture classrooms? Based on research of synergistic learning and creativity, students can benefit significantly in their ability to problem solve by increasing their creative thinking due to various pedagogical styles and curricular innovations. In this study science students at the University of Georgia will be surveyed about the most effective and ineffective teaching strategies in primarily lecture classes. I will also explore tactics in non-science classes that could be incorporated into large lecture classes, all for the purpose of enhancing the engagement of students with their professors and course material. I will additionally review existing research on synergistic learning, pedagogy, and attention span. Permission will be sought from the UGA Institutional Review Board before data collection will commence.

Cell Cycle Gating of the Mammalian Sonic Hedgehog Signaling Pathway

Philip Grayeski, Foundation Fellow
Dr. Jonathan Eggenschwiler, Genetics, Franklin College of Arts & Sciences

The Sonic Hedgehog (SHH) signaling pathway regulates cell fate specification, differentiation and growth within the tissues such as the central nervous system during metazoan development. While the regulation of cell cycle progression by SHH signaling has been extensively studied, it remains unclear whether the cell cycle controls response to SHH signals such that individual phases can be conducive or refractory for signaling. One reason to suspect this is the fact that primary cilia are required for SHH signaling in mammals, yet in cultured cells the primary cilium is present only in G1 (or G0) phases. A method in our lab was devised to assay the unspliced (intron-containing) mRNA signal of targets induced by a SHH pathway agonist to provide a real-time assay for pathway activity. Using this method, we analyzed the cell's response to the SHH agonist under different culture conditions and measured the half-life of the unspliced messages. The real-time responses will be determined with respect to each phase of the cell cycle, and data will be compared to the ciliogenesis profile in each cell cycle phase. These experiments will test the hypothesis that progression though the cell cycle gates Hedgehog pathway activity and that assembly and disassembly of the primary cilium may be responsible.

Examination of the Link between Glycosaminoglycans and Pectins

Elizabeth Guarisco
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Glycosaminoglycans (GAGs) are polyanionic macromolecules localized in the extracellular matrix with roles in structures and cell function. Chondroitins, a class of GAGs, may also serve as biomarkers for disease diagnosis and progression (Rye et al., 2002). Furthermore, the application of chondroitins, and thus chondroitin degrading enzymes, extends to proliferation, cell communication, wound healing, tissue growth, and angiogenesis in abolishing tumors (Fikri et al., 2007). The corresponding plant matrix polysaccharides are the pectin polysaccharides, partially esterified macromolecular polygalacturonic acids (Gemeiner, 2012). Glycosaminoglycans and pectins provide, in separate species, similar functions. The similarity between the functions of pectins and GAGs suggests possible insights into the mechanism by which pectins impact human health. The three dimensional structures between bacterial enzymes which degrade chondroitins and fungal pectin degrading enzymes (PDEs)

show striking similarity. Pectin degrading enzymes could alter cell processes moderated by GAGs, opening up utilization of these molecules in treatment of conditions such as spinal cord injury, where improper deposition of chondroitins leads to inhibition of axon growth. Previous studies in our lab revealed that pectins are able to alter the glycosidic activity GAG degrading enzymes and conversely chondroitins are able to bind PDEs and alter their activity. The thermodynamics of binding of pectins to chondroitinases and chondroitins to PDEs is required to validate the appropriateness of these interactions *in vivo*. Such data is obtained using Surface Plasmon Resonance (SPR). We will present the results of our SPR studies of combinations of the pectins, chondroitins, PDEs, and chondroitinases.

Reliability and Validity Study of an Accelerometer-based Approach to Estimate Free-living Energy Expenditure

Ryan Guilbault
Dr. Michael Schmidt, Kinesiology, College of Education

Actigraph accelerometers track acceleration in three planes of movement, which provides an objective measure of exercise intensity during physical activity. Accelerometer data can be paired with an individual's oxygen consumption (VO_2) during exercise to generate a personalized prediction equation for energy expenditure (EE) at varying exercise intensities. The purpose of this research study is to evaluate the reliability and validity of free-living, EE estimates derived from individually calibrated accelerometers. Participants completed a walking bout of exercise at sub-maximal speeds, while wearing two accelerometers, on two different days. Participants also had their VO_2 recorded on both days using a COSMED $K4b^2$ (portable metabolic unit) to generate personalized EE prediction equations. Participants then completed bouts of brisk walking, outside the laboratory setting, with an accelerometer and a COSMED unit. Reliability of the accelerometer-based EE prediction equations was evaluated by comparing the prediction equations formulated on separate days. To test the validity of accelerometer estimates of EE, accelerometer predicted values of EE were compared to accepted COSMED measures of EE. If personalized EE prediction equations, formulated using accelerometers, prove to accurately reflect EE during free-living exercise, then accelerometers may be used to evaluate EE in a multitude of energy balance studies.

Anoxic Transition within the Smoky Hill Chalk Member of the Niobrara Formation and Its Effect on Organic and Inorganic C-N Assemblages

John Harper
Dr. Paul Schroeder, Geology, Franklin College of Arts & Sciences

World fossil fuel supplies continue to be constricted by the ever-increasing need for energy. Traditionally, this energy has been supplied by conventional oil deposits, but geoscientists are now searching for less conventional hydrocarbon deposits to satisfy global demand. Understanding the provenance and depositional history of the organic material in these deposits can greatly benefit exploration and recovery. Oceanic Anoxic Events (OAEs) may influence the quality and type of organic/inorganic sediments deposited. OAEs are interpreted as rapid, global depositions and concentrations of organic-rich marine facies. The Smoky Hill Chalk Member of the Niobrara Formation was deposited in the Western Interior Seaway during the Cretaceous (Coniacian–Santonian), which has been hypothesized as an OAE event. X-ray diffraction (XRD) and stable Carbon (C) and Nitrogen (N) isotopes were used to determine the concentrations of C and N in the inorganic/organic pools. Carbon pools identified include carbonates and organic matter (OM) with sub-pools of C-OM located as particulates and in interlayer sites of

the expandable part of mixed layered clay minerals (i.e., smectite). Nitrogen pools identified include N-OM particulate, N-fixed in clay minerals, and N-OM in interlayer sites of smectite. The mineralogical and isotopic data support oxic to anoxic conditions progressed upsection. An increase in the total percent carbon and nitrogen available within the organic assemblages was found, including an increase in lamination and inclusions of sulfide minerals. Understanding the accumulations of organic material and the progression of anoxia can assist scientists to pursue similar formations in the exploitation of unconventional hydrocarbon deposits.

Epigenetic Pathways and Glutamate Transporters in Neuropathic Pain

Hannah Harrison
Dr. Han-rong Weng, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The mechanisms underlying neuropathic pain are not well understood. This presents difficulties for the development of an effective treatment. It is known that the major excitatory neurotransmitter glutamate holds a significant role in the development of neuropathic pain. There are many glutamate transporters that reuptake glutamate into the neuron and astrocytes from the synapse. One of such transporters that participate in neuropathic pain is the glutamate transporter amino acid transporter-1 (GLT-1). Additional molecular epigenetic pathways are known to be involved in neuropathy, particularly those of the pro-inflammatory cytokines interleukin-1β, TNfα, and interleukin 6. The purpose of this research is to investigate how epigenetic mechanisms are involved in the interaction of the cytokines and GLT-1. If neuropathic pain is created and sustained, then epigenetic mechanisms are involved in the maintenance of the neuropathy. In order to examine possible epigenetic mechanisms a partial sciatic nerve ligation (pSNL) neuropathic pain model was first developed using male Sprague-Dawley rats. Behavior tests were conducted to verify pain development in the model. The lumbar 4-5 spinal dorsal horn tissue from these animal models was then collected via laminectomy surgery for histone methylation analysis. Methylation modification mark at the histone H3-K27 is involved in cell proliferation and differentiation of glial cells. The results of this study demonstrated hypermethylation in the pSNL animal models. This evidence leads to the conclusion that epigenetic pathways are involved in the maintenance of neuropathic pain. The hypermethylation result suggests a possibility of more progenitor cell proliferation and less differentiated cells occurring at the molecular level of neuropathic pain.

Target Training: Is It an Effective Method for Enriching the Lives of Captive Capuchin Monkeys?

Amanda Heaton, Amy Cohen
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

We set out to evaluate "Target Training" for immediate food reinforcement as a form of enrichment to promote psychological wellbeing for five captive capuchin monkeys. The activity allows researchers to attract monkeys to a specific area, permitting, for example, modification of the cage or examination of the monkeys. Support for psychological wellbeing may result from positive interaction with humans and the learning challenge that the activity offers. Four of the five monkeys are housed in pairs; the fifth is housed individually. In each pair, one monkey is dominant, as evidenced by displacement of the other and unfettered access to offered resources. In training, the monkeys were reinforced for holding a plastic ball bolted to the end of a stick for an arbitrary length of time. Two to three days a week from November 14, 2012 to February 4, 2013, the subjects performed three trials of 5, 10, and 15 seconds each (9 trials total). All the monkeys mastered the task quickly, suggesting

that the task is not particularly demanding cognitively or motorically. Unexpectedly, subordinate monkeys had high rates of failure after mastery due to distraction and interference by the dominant monkey. We conclude that effective enrichment strategies cannot promote direct competition between pairmates in confined spaces. Target training fails on this measure, although it retains practical value for management. Offering challenging, attractive activities simultaneously to both monkeys may have better enrichment outcomes.

The Role of Lipid Fluidity in the Assembly of Trypanosome Lytic Factor

Matthew Hess
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosome Lytic Factor (TLF) is a minor subspecies (< 1 %) of high-density lipoproteins (HDL) that protects higher primates from the majority of African trypanosomes and contains haptoglobin-related protein (Hpr) and apolipoprotein L-1 (apoL-1). Although Hpr and apoL-1 assemble into the same HDL particle, no protein-protein interaction between the two has been reported. Here we have investigated a potential mechanism of HDL sub-speciation, and we propose that lipid fluidity plays a significant role in the assembly of TLF. It has been shown that the lipid component of HDL is sufficient for Hpr binding and that higher lipid fluidity confers faster association kinetics of Hpr. Utilizing a model liposome system and dye release assays, we show that apoL-1, like Hpr, interacts more rapidly with liposomes composed of phosphatidylcholines with short or unsaturated acyl chains. Additionally, we report that the incorporation of both cholesterol and ergosterol reduces the rate of apoL-1 interaction with lipid membranes. To study how apoL-1 affects the fluidity of the model liposomes, we utilized anisotropic dyes corresponding to different lipid bilayer regions. We show that apoL-1 decreases the rigidity of the interfacial region of the phospholipids and hypothesize that this prepares the HDL for interaction with Hpr. Our results suggest a potential mechanism of HDL assembly and sub-speciation that relies on sensitivity to lipid fluidity rather than protein-protein interactions. Understanding this mechanism not only impacts TLF-mediated killing of trypanosomes, but also cardiovascular disease and metabolic syndrome, in which the level and composition of HDLs is affected.

How the White Protestant Church Should Respond to Issues Affecting Lesbian, Gay, Bisexual, and Transgender People

Charles Hicks, CURO Graduation Distinction
Prof. Cynthia Tucker, College of Journalism & Mass Communication

The white Protestant church should expand upon Jim Wallis's notion that religion is "personal, but never private" to resolve its multiple positions on issues affecting lesbian, gay, bisexual, and transgender people. In my thesis, I discuss how the white Protestant church in the United States has shied away from public life since the Scopes Monkey Trial of 1925 and stopped offering institutional responses to public issues, as it did with the Prohibition movement and for women's liberation in the early 20th century. However, there has been a recent occurrence of a white Protestant-driven institutional response to the public issue of human trafficking via the End It Movement, which echoes Wallis's notion that a person's personal faith should affect his or her response to public life. The white Protestant church could use the End It Movement as a model for addressing the church's muddled stance on other social issues, including those affecting LGBT people, without compromising denominationally determined theology about LGBT issues. It is important for the church to address issues affecting LGBT people, because one-third of U.S.

Americans in 2010, according to the Public Religion Research Institute, said the messages from religious bodies are contributing "a lot" to higher suicide rates among lesbian and gay youth. Another third, according to the same study, said these messages contribute "a little."

Development of an Immunohistochemical Technique to Detect *Burkholderia mallei* in Horse Tissues

Yun Ho
Dr. Elizabeth Howerth, Pathology, College of Veterinary Medicine

Burkholderia mallei is a gram negative organism that is responsible for the disease glanders in horses. Infection can result in the formation of lesions in the lungs, ulcers in the mucosal membrane of the upper respiratory tract, skin lesions, and lymphangitis. *B. mallei* can also be transmitted to humans, resulting in pneumonia and skin lesions. This bacterium is difficult to visualize in tissue lesions even with the help of histochemical stains. Therefore, the goal of this research was to develop an immunohistochemical technique to facilitate identification of the organism in formalin fixed tissues from experimentally infected horses to study *B. mallei* pathogenesis. In developing this technique, we initially used tissue from mice infected with *B. mallei*, a variety of antigen retrieval methods, serum from both mouse and horse infected with *B. mallei* as the primary antibody at various dilutions, and a variety of detection systems. Once standardized for mouse tissues, we converted and optimized the technique for use in horse tissues. Our optimized protocol includes proteinase K as the antigen retrieval agent, mouse *B. mallei* antiserum at a 1:850 dilution, a commercial polymer detection system linked to horse radish peroxidase (Mach 3; Biocare), and DAB as the chromagen. This technique has allowed us to visualize bacteria in lesions within epithelium and extracellularly in exudate in tissues of experimentally infected horses. This technique will help us track the bacterium and better understand lesion development in glanders.

Top-down Control by Bonnethead Sharks in Oyster Reef Communities through Consumptive and Non-consumptive Effects

Zachary Holmes
Dr. James Byers, Odum School of Ecology

The eastern oysters (*Crassostrea virginica)* along the Atlantic coast are an important foundational species upon which many estuarine species are dependent for food and structure. Bonnethead sharks (*Sphyrna tiburo*) are the most abundant fish by biomass within some southeastern estuaries and likely play a vital role in maintaining healthy reef ecosystems. Our focus was to determine how bonnetheads exhibit top-down trophic control in oyster reefs through consumptive and non-consumptive effects. Bonnetheads are known to be voracious predators of blue crabs (*Callinectes spp.*) and therefore contribute greatly to estuarine trophic dynamics. In order to illuminate the methods by which bonnethead sharks control trophic dynamics, we conducted a replicated mesocosm experiment to examine how bonnethead sharks influence crab mortality and foraging behavior and how these effects on the crabs trickled down to affect species lower on the food chain, especially juvenile oysters. Our mesocosm study showed that sharks significantly impact juvenile oyster survival by reducing blue crab abundance and foraging. Bonnetheads, however, had little effect on mud crab (*Panopeus herbstii*) predation of oysters, with substantial quantities of oysters eaten even in the presence of sharks. We also quantified predation rates of crabs in field settings both on and away from oyster reefs. Our results indicate that crab loss is extremely high away from oyster reefs, often approaching 100% in a 12 hour period. These results indicate that bonnethead presence in oyster reef communities is a significant driver of blue crab behavior, but may have little

trickle-down effect on juvenile oyster mortality.

Converting Culture: Relating 19th Century Women's Dress to a 1960s Society

Emily Hoskins, Dakota Nesbitt
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

Historical clothing designs change when translated to a stage or film environment to help the audience engage with the show and allow the actors more freedom with character and movement. Freddy Wittop's costumes for *Hello, Dolly* employed brighter colors, lighter fabrics, and embellishment to minimize weight and maximize movement. Using Wittop's designs and the costume itself in the Hargrett Library, we explored how that costume won the Tony Award.
The 1900s is one of the most fascinating eras of women's clothing. It is defined by its complexity, working its way from corsetry and crinolines to shirtwaists and bustles. Yards of fabric were tailor-draped onto corset-bound figures to create a pleasing silhouette. Innovations allowed for printed fabrics, but overall the colors remained drab and unexciting, at least to an audience living in the 1960s. The 1960s formed a sharp contrast with the 1900s as it pertains to women's clothing. Bright colors and prints, short skirts, and shift dresses that hid curves were very popular. The problem remains: how do you take such conservative dress necessary for *Hello, Dolly*, set at the turn of the century, and re-work it for a late twentieth-century audience? You hire Freddy Wittop. As a dancer for most of his life, Wittop knew how clothing moved. His costume choices for the musical *Hello, Dolly* were easy to wear and gorgeous to behold. He used every color of the rainbow and toyed with shapes and embellishments to create the illusion of a corseted silhouette without the restrictions.

Affordable Housing in a Poverty-Stricken Community

Kirstie Hostetter, Foundation Fellow
Dr. Meghan Skira, Economics, Terry College of Business

Students attending the University of Georgia inflate local rental property rates, reducing the amount of affordable housing available to the 34.6% of the population living below the Federal Poverty Line in Athens-Clarke County. A literature review was conducted to evaluate mandatory and incentivized affordable housing programs as well as the status quo based on three main criteria: increased efficiency of existing housing options, improved low-income household stability, and political feasibility. The analysis revealed that Athens-Clarke County should offer incentives to property owners equal to the market rates of participating units in exchange for designation as affordable housing. This policy would utilize the 23,277 rental rooms currently vacant, provide stable mixed-income living environments, and be implemented through the use of the $1,272,476 in federal funding received by the county for programs addressing issues of human development. An incentives program provides a realistic, timely solution to the pressing issue of affordable housing. Property owners are justly compensated for participation in the program, receiving money for units that would otherwise provide no source of revenue considering the 19% rental vacancy rate. Lower-income families experience the many benefits associated with mixed-income housing, including better school performance and a home environment conducive to a healthy family and financial life. Both participating and surrounding properties are not affected by the stigmas attached to traditional, concentrated affordable housing structures.

Relationship between Approximate Entropy and Dynamic Postural Stability in Ankle Instability

Katherine Hsieh
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Chronic ankle instability (CAI) is a condition of repeated episodes of the ankle "giving way" that develops after repeated ankle sprains. Approximate entropy (ApEn) measures the randomness of biological signals, while dynamic postural stability indices (DPSI) measure the ability to maintain balance transitioning from a dynamic to static position. Seventy-nine participants (21.04 ± 2.4; mass 70.31±13.70; height 169.70±9.85) completed three 10-second single leg balance tests and three vertical jump landings onto a force platform. Ground reaction forces were collected and exported. DPSI composite scores were calculated for the dynamic trials while ApEn was calculated in the anterior-posterior and medial-lateral directions during static balance trials. ApEn was correlated with DPSI to determine if a curvilinear relationship existed. Pearson bivariate correlations were performed, and no correlations were significantly significant ($r = -0.009$-0.077, $p>0.05$). Static and dynamic balance appears to measure different constructs, and ApEn and DPSI also seem to measure different components of those constructs. ApEn as a non-linear measure does not vary with the linear DPSI. Dynamic stability and variability may influence CAI, and ApEn and DPSI measures should be considered separately when trying to measure balance ability.

The Prevalence of *Salmonella* Infection in Various Southeastern Wild Aquatic Turtles and Captive Painted Turtles (*Chrysemys picta*)

Joyce Huang
Dr. Sonia Hernandez, Warnell School of Forestry & Natural Resources

There are very few studies of *Salmonella* infection in wild turtles. Although the prevalence of infection of aquatic turtles for the pet trade has been well established, the rate of *Salmonella* carriage by wild turtles is still largely unexplored. We had two objectives with this study: 1) to describe the prevalence of *Salmonella* infection of various species of Southeastern wild aquatic turtles; 2) to determine whether the infection status changes after placed in captivity and presumably stressful conditions. For the first objective, we sampled wild turtles. Using baited hoop traps, a total of 134 turtles were captured from seven sites in Athens-Clarke County, Georgia. Each turtle was kept in an individual, clean plastic container filled with roughly 1 cm water depth for approximately 12 hours until they defecated. Feces were collected with sterile disposable 1mL pipettes and immediately placed in 10 mL of dulcitol selenite broth media. The samples were submitted to Athens Diagnostic Laboratory within a 24-hour period from collection. Of the turtles previously captured, 21 were selected to investigate the second objective. They were housed individually in 10-gallon tanks at the Whitehall Herpetology Lab. Turtles were part of a concurrent study and underwent a minor surgical procedure during the first week, which is considered a stressful event. For a period of 45 days, weekly feces samples were collected from each captive turtle. In a second captive trial, 10 turtles were kept in the same conditions as the first captive trial. For this trial of 90 days, three feces samples were collected: one at the beginning, in the mid-period, and at the conclusion of the study. The feces were also submitted to

the Athens Diagnostic Laboratory for testing. The results of the studies are still pending.

In Vivo and _In Vitro_ Analyses of the Human Insulin-degrading Enzyme Reveal That the Yeast A-Factor Mating Pheromone Can Serve as a Universal Substrate for M16A Family Proteases

Kaitlin Hufstetler
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Though the exact cause of Alzheimer's Disease (AD) is not fully understood, it is believed that its development is due to the accumulation of neurotoxic Aβ peptides. The M16A protease human insulin-degrading enzyme (hIDE) cleaves many small peptides, including Aβ. Thus, hIDE is of biomedical relevance because it is proposed to forestall the onset of AD by promoting clearance of these Aβ peptides. To better understand the function of hIDE, this study focuses on *in vivo* and *in vitro* analyses of hIDE. Using yeast as a genetically tractable model system, a yeast expression plasmid encoding hIDE was created and *in vivo* functional tests based on a-factor production were performed. Previously, it was determined that the roles of the yeast M16A proteases Axl1p and Ste23p in the production of the a-factor mating pheromone could be substituted by other non-yeast M16A proteases. It was expected and subsequently confirmed through a yeast mating test and an a-factor halo assay that hIDE can mediate a-factor production. Thus, it appears that a range of M16A proteases can be expressed and evaluated using the yeast system. This study was largely prompted by a recent *in vitro* study that demonstrated an inability of hIDE to recognize a synthetic substrate based on a-factor. The different outcomes of the *in vivo* and *in vitro* assays suggest that substrate differences underlie the differential outcomes. Nevertheless, our results demonstrate that hIDE can indeed recognize a-factor *in vivo* and supports that hIDE has enzymatic properties consistent with those of other M16A enzymes.

Resolving Species Relationships When Reproductive Barriers Are Incomplete: A Case Study in Drosophila

Devon Humphreys, CURO Summer Fellow, CURO Graduation Distinction
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

Reproductive isolation is not an instantaneous process. Over time, geographic or ecological barriers can facilitate independent genetic changes such that populations may accumulate differences that prevent successful reproduction when they come back together. When populations have been separated for a long time, but are still reproductively compatible in the laboratory, we wonder whether they can be considered distinct species. Incomplete reproductive barriers correlate strongly with variable levels of genetic divergence, and understanding how many genetic differences are required for speciation is of key interest. Here, I use phylogenetic methods to reconstruct the evolutionary history of three closely related species with incomplete reproductive barriers: *Drosophila recens, Drosophila subquinaria,* and *Drosophila transversa*. I complement this with behavioral assays with classical genetic crosses to investigate how genetic divergence is associated with reproductive isolation. *Drosophila transversa* is found in Europe and Asia, whereas the other two species co-occur in North America. I find some genetic divergence between *D. subquinaria* and *D. transversa*, consistent with their strong geographical isolation, but I find no evidence of reproductive isolation between these species at either the premating or postmating levels. In contrast, I find that *D. recens* is strongly genetically distinguished from both *D. transversa* and *D. subquinaria*, and that unidirectional behavioral isolation as well as hybrid male sterility and cytoplasmic

incompatibility operate to keep these species separate.

Higher Education and Future Planning

Lindsay Ives
Dr. Leonard Martin, Psychology, Franklin College of Arts & Sciences

Higher education allows individuals to specialize their knowledge in a specific area of study. But what happens after they obtain degrees? Past studies have shown that changes in the labor market have affected the young adult's ability to achieve self-sufficiency. It has also been previously shown that the roles of social support and optimism in adaptability are important in making this transition. The current study focuses on how different guides regarding a person's future can affect psychological well-being. Participants completed surveys measuring different psychological traits while in the presence of a degree checklist (laptop condition), a career plan and notebook with questions about the relationship between college and career (notebook condition), or a blank desk (control condition). Data indicated that participants in the Laptop and Notebook conditions viewed the world as more hostile. Those in the Notebook condition also exhibited a higher search for meaning in their lives and lower life satisfaction. These findings suggest that current approaches to planning life after college may have negative effects on students. Checklists and plans regarding life after college may cause students to adopt a negative worldview and experience discontentment. Recommendations for approaching this school to work transition are included in this article.

Targeting the *Mycobacterium smegmatis cobU* Gene to Study Vitamin B12 Biosynthesis

Elena James, CURO Honors Scholar, CURO Summer Fellow
Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Mycobacterium tuberculosis (*Mtb*), the causative agent of tuberculosis, latently infects 1/3 of the human population and kills approximately 1.4 million people annually. The success of *Mtb* relies on its ability to obtain and utilize nutrients from the host. Vitamin B12 (B12) is a cofactor of various metabolic enzymes. *Mtb* appears to have a complete set of B12 biosynthetic genes. When assayed using a *Salmonella typhimurium* auxotroph, B12 is not made under standard culture conditions by *Mtb*, but is made by the nonpathogenic soil saprophyte *Mycobacterium smegmatis*. This might be due to tightly-regulated B12 biosynthesis in *Mtb* or perhaps *Mtb* produces a form of B12 that cannot be utilized by the salmonella auxotroph. My project investigates B12 synthesis in mycobacteria. Of the B12 biosynthesis genes, *cobU* encodes an enzyme that functions late in the assembly process and is less conserved between *Mtb* and *M. smegmatis* homologs than other genes in the pathway. The goal is to create a *cobU* knockout mutant in *M. smegmatis* and determine if B12 production can be restored by introducing the *cobU* gene from *Mtb*. Vitamin production will be examined using auxotrophic salmonella strains and by mass spectroscopy. A plasmid designed for use in knocking out *cobU* by homologous recombination will have the following features: ~1000-bp *cobU* flanking regions, an origin for replication in *E. coli*, a hygromycin resistance gene, and a sucrose counter-selection marker. Progress toward the completion of this plasmid and of the overall project will be presented.

Abstracts

Effect of Different Pheromones on the Transcriptional Activator LuxR in *Vibrio fischeri*

Dabin Ji
Dr. Eric Stabb, Microbiology, Franklin College of Arts & Sciences

In the marine bacterium *Vibrio fischeri*, bioluminescence is regulated in part by the pheromones *N*-3-oxo-hexanoyl-L-homoserine lactone (C6) and *N*-octanoyl-homoserine lactone (C8). These pheromones bind to and activate LuxR, resulting in induction of the *lux* genes responsible for luminescence. In this study we compared the response of four LuxR variants to different concentrations of C6 and C8. Bioreporter strains were constructed with luminescence controlled by one of four different LuxR's. We used two artificially evolved LuxR derivatives (LuxRA and LuxRB), and the wild-type LuxR's from *V. fischeri* strains ES114 and MJ11. ES114 and MJ11 have different luminescence and pheromone outputs in culture, and we hypothesized that they had evolved LuxR's with different responsiveness to C6 and C8. Using the Bioreporters, luminescence was compared with the addition of different concentrations of C6 and C8, alone and in mixes. With both LuxRES114 and LuxRMJ11, increased concentrations of C8 inhibited the stimulation by C6. In addition, lower concentrations of C6 elicited a luminescence response with LuxRES114 compared to LuxRMJ11. The differences in the two artificial LuxR derivatives were also compared. LuxRA responded similarly to C6 and C8. LuxRB responded to C8 but not to C6, and high concentrations of C6 could inhibit the stimulatory effect of C8. Our results raise exciting questions regarding the evolution of LuxR and its relationship with two distinct pheromones in *V. fischeri*.

Drug and Mental Health Courts in Georgia's Criminal Justice System

Melinda Johnson
Prof. Todd Krohn, Sociology, Franklin College of Arts & Sciences

Georgia's incarceration rates and annual budget have doubled over the past two decades. Without change, these trends are expected to continue in the years to come. One suggested solution is to increase the number of accountability courts, or courts that address a specific population while adhering to standard operating principles. These courts focus on the mentally ill and drug offenders that make up a significant portion of the prison and parole populations in the state. The purpose of this research was to compare the effectiveness of expanding the accountability court system with other alternatives that may address the same problem. Data included recidivism rates, cost estimates, current legislation, and past success rates of each alternative. An impact and goals analysis on feasibility, cost, and effectiveness was used to compare the options. The data supported the conclusion that accountability courts will be effective in lowering recidivism rates in addition to being cost effective and feasible to implement. This result has important implications for Georgia's criminal justice system, including increased promotion of humanitarian values and an estimated savings of $264 million over the next five years. Recommendations for implementing this policy and the challenges that it may bring are provided.

Autophagic Responses in the Murine Model of Placental Malaria

Mathew Joseph
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Plasmodium falciparum is the deadliest malaria-causing parasite in humans. Malaria during pregnancy is associated with the accumulation of parasitized red blood cells and infiltration

of leukocytes in the placenta. This is known as placental malaria (PM). Autophagy is a vital catabolic process which involves cells degrading and recycling cytosolic contents because of nutritional deprivation and stress. We hypothesized that PM's symptoms will induce excessive autophagic activity in the placenta which contributes to poor birth outcomes. We have initiated studies on PM using *Plasmodium chabaudi* AS to infect C57BL/6J and A/J mice as models for understanding the immunopathogenesis of PM. On day zero of pregnancy, mice are infected with *P. Chabaudi* inoculum. Throughout gestation, secreted cytokines and chemokines are assayed by ELISA. At sacrifice, spleens and fetoplacental tissues are homogenized for proteins and RNA isolation. RNA is made into cDNA and real-time PCR is performed to assess levels of autophagy-related genes. Immunohistochemistry is performed to histologically view markers for autophagy-related proteins. Autophagy marker (LC3a, LC3b, BEC-1, and Atg5) levels are compared between infected pregnant A/J and B6 mice and their respective uninfected counterparts. Preliminary data indicate that *Plasmodium chabaudi* induces local and systemic profinflammatory responses, and autophagic response data will be analyzed to assess correlation with pregnancy outcome. In conclusion, our research analyzes the mechanistic basis for malaria-induced compromise of pregnancy, especially midgestation, when high parasitic density is coincidental with pregnancy loss in our model. Continued study promises to reveal common and critical mechanisms which contribute universally to malaria compromised pregnancies.

Academic Steroids: The Need to Control Adderall Abuse on University Campuses

Mugdha Joshi, Alex Edquist
Dr. Christopher Cornwell, Economics, Terry College of Business

Adderall is an amphetamine drug that is prescribed to treat symptoms in patients diagnosed with ADHD. While it treats excessive hyperactivity, impulsivity, and inattention, it can be highly addictive and has serious side effects including insomnia, anxiety, dizziness, and cardiovascular or psychiatric problems. Modern trends show that university students are abusing prescription Adderall when they do not have ADHD because it provides "laser-like" focus and enhances academic performance. Surveys show that 25 percent of college students admit to using Adderall to help prepare for and take exams. The increased abuse of Adderall has caused health problems in students; the number of 18-25 year-olds going to the ER because of ADHD stimulant medications has risen from 2,131 in 2005 to 8,148 in 2010, and half of those visits involved nonmedical uses of those medications. Though literature indicates that this is a growing problem in America, very little has been attempted from a policy standpoint to prevent it. Following an extensive literature review and after conducting interviews with administrators and health professionals at the University of Georgia, a policy has been developed in order to best address this growing concern for university students. The most feasible approach to solving this problem is to include Adderall awareness education in required student drug and alcohol education in order to combat students' lack of understanding of the dangers of Adderall abuse and its nature as a violation of student academic honesty code.

The Influence of Muscle Heme Concentration on Optical Measurements of Mitochondrial Capacity

Jane Jurma, Stephanie Tan, Graham Mercier
Dr. Kevin McCully, Kinesiology, College of Education

Near infrared spectroscopy (NIRS) has been used to measure muscle mitochondrial capacity in healthy and diseased humans. The NIRS technique uses changes in heme oxygen levels to measure mitochondrial capacity; however, patients with diseases could have reduced heme concentrations. The purpose of this study is to test whether changing muscle concentrations of blood alter the measured mitochondrial capacity. We first learned how to perform muscle mitochondrial capacity measurements using NIRS. Then measurements were made to select the muscle of interest (either vastus lateralis or medial gastrocnemius), and the type of exercise to perform (voluntary or electrical stimulation). Muscle heme oxygen levels were made with a commercial NIRS device (Portamon, Artinis LTD). After metabolic rate was increased with exercise, the rate of recovery of oxygen consumption was measured. A series of short duration ischemic periods produced by rapidly inflating a blood pressure cuff was used to measure oxygen consumption during recovery. The individual oxygen consumption measurements were fit to an exponential curve and a rate constant determined. The experiment will measure mitochondrial capacity in healthy college aged students before and after five minutes of venous occlusion (60 mmHg) to fill the muscle with blood. Voluntary exercise of the medial gastrocnemius will be used. Six subjects will be tested as prior studies suggest a medium effect size can be detected with this sample size. We predict that while venous occlusion will increase blood volume in the muscle, it will not change the rate constant related to mitochondrial capacity. NIRS studies of muscle are either ongoing or planned for people with SCI, ALS, COPD, PAD, and heart failure. This study will be very important in helping us interpret the results of the clinical testing.

Developing a Sustainability Policy for the University System of Georgia

Ian Karra
Dr. Laurie Fowler, Odum School of Ecology

With more built space than any Georgia state agency, the University System of Georgia has a significant impact on the energy budget of the state. But with student enrollment and square footage expanding every year, the system remains one of the largest university systems nationwide not to have a comprehensive sustainability policy to address associated growth, operations, and emissions. Additionally, this policy gap creates varying levels of funding and administrative commitment to sustainability and sustainability planning among the 35 individual institutions. Mechanisms in said sustainability policy should create new funding for sustainability initiatives, facilitate renewable energy purchasing and production, institutionalize sustainability planning, and involve students in the research/implementation process. The alternative that maximizes these qualities at lowest cost and ease of implementation is to standardize the green fee process, the self-imposed mandatory student fee. By reducing administrative barriers and promoting self-determination, the fee provides flexible funding for projects ranging from energy efficiency to green power purchasing. Clear allocation guidelines, such as those in policies from Tennessee and California, ensure that the funds are not used onerously on administrative costs and ensure student participation in administering the funds. As fuel costs and energy demand rise and state education funds take uncertain trends, controlling operations costs in a sustainable and inclusive manner is an essential part of the university system modeling responsible

investment, application of research, and student engagement.

Pervasiveness of Science News in First-world Countries vs. in Emerging Economic Powerhouses

Jeanette Kazmierczak
Dr. Leara Rhodes, Journalism, College of Journalism & Mass Communication

Many industrialized nations believe their leading national newspapers present accurate and adequate coverage of health and science news. However, financial hardships have caused many major print media to eliminate dedicated science sections. Therefore, the goal of this study is to assess science coverage in media within five countries – two industrialized countries, the US and the UK, and emerging economic powerhouses Brazil, South Africa, and India. I intend to gauge the pervasiveness and depth of science coverage in these countries using methodology similar to that employed by Veneu, Amorim & Massarani (2008) in a study on science coverage in Latin American countries. Using online versions of daily newspapers, I will choose two media sources from each country – one with a dedicated science section and one without – and will collect all science articles on the website for the same one-month period. Dailies without a dedicated science section will be searched for articles using key terms selected from science news aggregating websites like *Futurity* and from science articles in the selected papers with science sections. I expect most newspapers with a science desk will have fairly consistent coverage of science news, but daily papers without one will show stronger coverage in the U.K. and the U.S. than in Brazil, South Africa, and India.

Mitochondria Targeted Delivery of Cisplatin Prodrugs

Samuel Kennedy
Dr. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Targeted delivery of therapeutics to tumor cell mitochondria could potentially be a powerful approach to selective cancer treatment. Cisplatin is one of the most widely used anticancer therapeutics, most notably for the treatment of ovarian and testicular cancer. Research focuses on minimizing cisplatin's toxicity and overcoming the resistance of the drug. Only 5-10% of the Pt(II) compound cisplatin that enters cells binds to its targeted nuclear DNA. We speculated that by re-routing the cisplatin in the form of a pro-drug and by using a mitochondria-targeted nanoparticle-based delivery vehicle to the mitochondria of cancer cells, thereby attacking the mitochondrial DNA, we would be able to provide a new therapeutic target for the age-old drug cisplatin. A promising strategy for achieving this goal will be discussed.

The Birth of Metrosexuality in South Korea

Gloria Kim
Dr. Katalin Medvedev, Textiles, Merchandising & Interior, College of Family & Consumer Sciences

In a rapidly modernizing world, clothing styles are expected to change according to the cultural standards of each generation. Despite this, the sudden eruption of the phenomenon of metrosexuality—characterized by individualistic and aesthetic male dress styles among young men (Yung, 2011)—in a conservative and collectivist society like South Korea is a paradox that symbolizes a lot more than just a change in fashion trends.
To explore the reasons for the cultural and social metamorphosis that underlies the emergence of South Korean metrosexuality, I have examined numerous academic sources

that discuss the country's shifting definition of masculinity and the transformation of its gender ideals. I found that in South Korea's patriarchal society masculinity is equated with mandatory military service, with men's financial ability to provide for their family, and with men's continuing rejection to participate in domestic labor activities. I realized that events such as the end of the Cold War, the 1997 IMF financial crisis, and the "Korean Wave" appear to be responsible for the birth of South Korean metrosexuality and the erosion of its traditional gender ideals. I argue that because of these occurrences South Korea's concept of masculinity has become flexible, malleable, and multi-dimensional. The new concept of masculinity is not confined to a simple distinction between "metro" or "masculine." Instead, it is a hybrid masculinity. Although the average young South Korean male dresses as a metrosexual, which would suggest a soft form of masculinity, the way he treats women and acts in his daily life continues to be driven by a traditional, male chauvinist attitude.

What Differentiates Certain Salmonella Serovars from Others in Their Ability to Cause Human Illnesses?

Lily Kim
Dr. John Maurer, Population Health, College of Veterinary Medicine

Salmonella enterica causes one million cases of gastroenteritis each year in the US. While certain Salmonella serovars cause thousands of illnesses annually, others are linked to only a handful of cases. *Salmonella Mikawasima*, a serovar from the coastal waters of Georgia, contributes to substantially fewer cases of salmonellosis than serovars such as *S. Typhimurium* and *S. Enteritidis*. In the Maurer lab, additional novel serovars have recently arrived, fully sequenced. I hypothesized that this disparity in virulence was due to differences in the distribution of pathogenicity islands (PAI) between *S. Mikawasima* and other more virulent Salmonella serovars. To test this hypothesis, we performed whole genome sequencing on a previously uncharacterized *S. Mikawasima* and compared its sequence to several published Salmonella genomes. We identified several PAIs and prophage genomes shared with a referenced Salmonella genome, LT2. We also determined *S. Mikawasima*'s evolutionary relatedness to other Salmonella serovars commonly associated with outbreak by focusing our phylogenetic analyses on a series of housekeeping genes common to several annotated Salmonella genomes. After analyzing our data, we found that *S. Mikawasima* was more closely related to a subdivision of environmental Salmonella than those serovars (*S. Enteritidis*, *S. Typhimurium*, etc.) commonly associated with human illnesses. *Salmonella Mikawasima* shares the same virulence composition as other Salmonella serovars commonly encountered in foodborne outbreaks. Rare occurrence of human illnesses associated with this serovar is more likely due to its distribution in nature. My thesis will detail my findings concerning these novel strains and the degree of relatedness between them and other highly pathogenic serovars.

Fanny Kemble: A Juliet of a Different Era

Hannah Klevesahl
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

I will analyze Frances "Fanny" Kemble's interpretation of the role of Juliet in William Shakespeare's *Romeo and Juliet*. In analyzing her interpretation of the character, I will connect it to a historical point in time: the period of the American Civil War. Fanny Kemble, a British actress, married the plantation owner Pierce Butler and settled on his plantations on the Sea Islands in Georgia. Fanny was appalled by the treatment of the slaves and their working conditions, but was threatened with revocation of access to her daughters if she published anything about those experiences with slavery. Fanny Kemble

eventually separated from her husband and began touring in the United States as a notable Shakespeare reader. The Richard B. Russell Special Collections Library is fortunate enough to have Kemble's original copy of Shakespeare's "Works," in which she details many of her character analyses and her own rehearsal processes. With the help of Dr. Fran Teague, I will relate Fanny Kemble's interpretation of Juliet with her own disconnect from the slavery that she was faced with on Butler's Sea Island plantations. Juliet is forced to choose between two worlds, much like Kemble herself, who had to choose between access to her daughters or speaking out against what she thought was wrong. The actor's connection to the role of Juliet comes from a personal experience that encourages a different interpretation of the performance.

Trout Angler Awareness of the Hemlock Wooly Adelgid and Its Effect on Trout Habitat and the Available Treatment Methods

Matthew Knull
Dr. Neelam Poudyal, Warnell School of Forestry & Natural Resources

The Hemlock is a riparian tree that provides shade that keeps water temperature low in North Georgia streams and rivers. Hemlock Wooly-adelgid (HWA), an invasive insect accidentally brought from Asia, has recently become a factor in the death of Hemlock trees, resulting in high stream temperature and unsuitable habitat for trout. Brook trout, a trout native to the mountain streams of Georgia, cannot survive water temperatures above 77◦ F. This may lead to decline in the population of trout and other aquatic species. This could mean a lower catch rate and lower recreational satisfaction for Georgia trout anglers. While there are a number of treatment methods available to contain HWA, some are more harmful to the environment in general and aquatic species like trout. In addition, application of treatment methods in public lands could cost anglers in terms of increased access fee, license fee, etc., and expensive methods might not be a desirable option. The objective of this survey is to assess the trout angler's knowledge of and attitudes towards HWA and its potential impact on their fishing experience. This survey will also analyze and compare the acceptability of the different treatment methods among trout anglers. To meet these objectives, a convenient sample of trout anglers in Georgia is being sampled using a paper-based survey instrument. To increase the response rate, a variety of approaches have been taken to recruit participants in the survey. One approach is surveying trout anglers on-site at popular fishing areas. Another approach is surveying anglers at statewide trout fishing conventions and gatherings where a variety of trout fishermen will be in attendance. So far completed responses from 70 anglers have been obtained. Data is being analyzed using descriptive statistics and ANOVA tests. The majority of fishermen surveyed so far agree with the statements that Hemlocks are a valuable tree species and are being negatively affected by HWA. They also find the environmentally friendly treatment methods such as trunk injections and predator beetles to be more acceptable than soil treatments or foliar spray. The majorities are members of Trout Unlimited and, therefore, are assumed to be more specialized fishermen. This information will help researchers to understand what the majority of fishermen value, justify the protection of the hemlock trees along rivers and waterways and find treatment methods that are acceptable to fishermen who may have their values at stake in the deteriorating condition of trout habitat.

Key to Thrive as Larvae: Cross-fostering Analysis between Two Species of Burying Beetles, *Nicrophorus vespilloides* and *Nicrophorus orbicollis*

Kyungmin Ko
Dr. Allen Moore, Genetics, Franklin College of Arts & Sciences

Parental care is a specialized behavior found mainly in vertebrates. However, this evolutionary strategy exists in some insects, including burying beetle species such as *Nicrophorus vespilloides* and *Nicrophorus orbicollis*. Parental care in these two species is divided into two types of behaviors: indirect parenting, which is more commonly found in insects and direct parenting which is rarely found. Indirect parenting involves behaviors caring for the carcass, and direct parenting involves behaviors that directly interact with the larvae, including feeding the larvae mouth to mouth. Direct parental care given during the first 12 hours to *N. vespilloides* and *N. orbicollis* larvae is required for the survival of larvae. However, little is known about the amount of parental care provided by parents of each species and keys that trigger parenting for larvae of these species to thrive. Given that direct care rarely evolves, is it specialized in a species-specific manner or is the parenting of burying beetles generic? I tested this question using cross-fostering between species to measure the response of larvae to parental care given by an adult of the same or of a different species. The timing in which larvae appeared was controlled, because *N. orbicollis* required a longer time for their eggs to hatch due to their larger size. I found that parental care provided to larvae across the species is only subtly different, in that larvae survived as well if cared for by their own or a different species. Therefore, the larvae of these species need generic parenting to flourish.

A Comparison of the Effectiveness of Plant DNA Extraction Methods against Two Common Secondary Metabolites

Delaney Kolich
Dr. Marianne Shockley, Entomology, College of Agricultural & Environmental Sciences

Extraction of high quality DNA is usually required before performing downstream protocols such as PCR amplification or gene sequencing. However, extraction of DNA from plant tissue is often complicated by the presence of secondary metabolites, resulting in poor DNA quality or low yield. Success of the extraction is largely dependent upon the protocol used and the types and amounts of secondary metabolites produced by the study species. Alkaloids and terpenoids are frequently problematic secondary metabolites in DNA extractions. This study compared the quality and quantity of DNA extracted from *Asimina triloba* and *Vinca minor* (both produce high levels of alkaloids) and *Pinus strobus* and *Aloysia citriodora* (high terpenoid production) using a CTAB (cetyltrimethylammonium bromide) extraction, an SDS (sodium dodecyl sulfate) extraction, and a Qiagen DNeasy kit. Preliminary analysis of extracted DNA was performed using NanoDrop spectrophotometry and agarose gel electrophoresis. Preliminary quality and quantity measurements were then confirmed by analysis of representative samples from each species and extraction method using an Agilent Bioanalyzer. Observation of the differences, if any exist, in the effectiveness of these extraction methods against two common secondary metabolites could help guide researchers in selecting a DNA extraction method to begin work with new species of study.

Annotation of the *Sarcocystis Neurona* Genome - Challenges and Lessons Learned

Katharine Korunes
Dr. Jessica Kissinger, Genetics, Franklin College of Arts & Sciences

Sarcocystis neurona, a protist parasite of the phylum Apicomplexa, causes equine protozoan myeloencephalitis (EPM). We have undertaken the sequencing and annotation of the *S. neurona* genome. The completed sequence and annotation will hold significance for the equine industry and provide biological insights. We started with genome sequence data produced by 454 and Sanger, and transcriptome sequence data produced by 454 and Illumina. The RNA-Seq data was mapped to the genome using the reference-based TopHat/Cufflinks, and a *de novo* assembly was created with Trinity. RNA-Seq assembly data were used to generate gene predictions. However, predictors require training, and their outputs are often not consistent with each other. The process is further complicated by the fact that this is the largest genome found in the Apicomplexans, a phylum in which a large number of the genes, ~40%, are hypothetical. To approach the challenges presented by this genome, we decided to create a metric for evaluating the quality of our assemblies and improving gene-predictor training: the set of 1,000 orthologs found in the 15 other sequenced genomes in the phylum. We identified 782/1000 orthologs in *Sarcocystis*, and we annotated this set of conserved genes. Having manually analyzed the evidence and refined the annotations for this set of 782 genes, we now have a standard that is allowing us to evaluate the performance of several automated gene predictors and improve their performance in our automated annotation pipeline. This process is bringing us closer to a completed, high-quality genome annotation.

Influence of Weight Distribution on Biomechanics of Performance Horses

Simone Lalvani, Lauren Cobb
Dr. Kylee Duberstein, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Injuries to a performance horse's lower leg are common and often result in lameness causing the horse to be retired. If a horse's gait is asymmetrical, then there is a possibility that the angles of joints directly related to weight bearing will affect the pressure placed on lower leg bones and tendons. One can assess the impact of this on the longevity of the horse's career by analyzing the relationship between asymmetrical rider weight distribution and its influence on the corresponding joint angles and other stride parameters. Using synchronized high-speed cameras, eight sound horses were recorded for multiple repetitions trotting through a 24.4×1.5 meter chute to evaluate stride length, velocity, swing time, stance time, and angles of front and hind leg using the program EquineTec. Each horse was subjected to three treatments in a random order: no added weight, equal distribution of 45 kg added weight, and unequal distribution (40:60) of 45 kg added weight. Observations indicate that horses bring their limbs farther underneath their center of gravity when carrying a load. Unequal distribution of weight does result in some gait adaptations, primarily in the proximal portion of the limb compared to the distal portion. Some natural gait asymmetry is present in horses, as observed by asymmetrical effects on fetlock dorsiflexion. Research of this topic is limited due to the difficulty of creating standard conditions measuring appropriate values to determine if there is an association between rider weight distribution and degree of lameness.

Grandparenting from the Dump

Madison Lamar
Dr. Denise Lewis, Child & Family Development, College of Family & Consumer Sciences

Data from 10 Cambodian grandparents raising grandchildren around the Phnom Penh Municipal Dump were collected through in-depth interviews and were analyzed using multi-stepped coding techniques. A multitude of factors that inhibit individuals' quality of life can arise in families in grandparent-headed households. It is typical that in such settings the middle generation is missing due to deaths or because of out-migration in search for better economic opportunities. An HIV/AIDS epidemic that has claimed large numbers of reproductive-aged members of society, few options for earning a living wage, and the resultant chronic poverty from these conditions have exacerbated the resources of many of Cambodia's families. Under the family stress theory, we propose that custodial grandparenting in skipped generation families triggers new challenges for older caregivers because this role is non-normative. This shift adds financial, emotional, physical, and psychological burdens to the grandparents, most of whom are in extreme economic crisis. Many must relearn childrearing under dire conditions. The themes from the interview narratives included the following: poverty and food insecurity, health concerns, and social disengagement. The grandparents alluded to the need for better respite care but also showed a great concern for the advancements of their grandchildren through educational achievements. These findings point to the need for better community empowerment and deliberate policy and welfare planning to cater to the needs of impoverished older grandparents heading grandfamilies.

Transforming Animal Shelters in to a Service-based Economy

Torre Lavelle, Foundation Fellow
Dr. Janet Martin, Small Animal Medicine & Surgery, College of Veterinary Medicine

Big Black Dog Syndrome, the extreme under-adoption of large black dogs in shelter settings, identifies certain characteristics adopters have historically discriminated against, which include specific breed types and traits (e.g. high energy, intense focus). Costing U.S. taxpayers a total of $2 billion to impound, shelter, euthanize, and dispose of homeless animals annually, these "problem dogs" account for a significant burden of that expenditure. The current model fails to realize key indicators of these dogs as potential candidates as service dogs. A thorough review of existing literature and economic modeling was conducted to develop a policy proposal to support a standardized screening process for these dogs and their selection to the type of service that suits each canine best, such as in handicap assistance, drug and bomb detection, therapy, and PTSD support. After evaluating various policy alternatives based on a cost-benefit analysis, the selected proposal focuses on cultivating working relationships between service dog training organizations with established internal breeding programs and shelters in order to encourage consideration of shelter dogs as a resource. Specifically, the policy would provide an educational mechanism to eliminate the stigma against using shelter dogs in service work, create a centralized network to identify service dog candidates within shelter environments, and establish pathways to facilitate transfer of these dogs to service dog providers. The innovative association will reduce the costs and public health concerns related to shelter overpopulation while increasing opportunities for the successful placement of some historically less adoptable dogs as service dog candidates.

Abstracts

Rekindling the Hermit Kingdom
Kangkyu Lee
Dr. David Williams, Religion, Franklin College of Arts & Sciences

North Korea continues to threaten international security and stability in East Asia. As global attention is diverted elsewhere, North Korea will continue its pursuit of nuclear weaponry. The Kim Jong-Un regime is altering its economic policies, going as far as allowing farmers to trade their crop, relaxing tourism, and reforming education standards. The United States' reluctance to participate in diplomacy is a fatal foreign policy that does not take advantage of the unique political climate. Economic engagement is the best way to jumpstart better relations with North Korea and pave the way for a well-coordinated and peaceful East Asia. Data demonstrates an increasing number of the North Korean population warming up to private economic practices. The purpose of the research is to explore possible alternatives to established American foreign policies and how it can impact prospective long-term interests in East Asia. The research accounts for empirical economic data used by Chinese companies and historical examples as a threshold for newer, better alternatives. In addition, statistics taken from research organizations will evaluate public and international perception of such alternatives. The alternatives discussed are the following: the status quo, a peace process, the establishment of a US-Sino trade partnership, and a comprehensive Six-Party aid package. These alternatives will be evaluated using criteria in the form of effectiveness, political feasibility, and cost. With Chinese investment in North Korea also steadily increasing and the interests of its allies in East Asia in mind, the United States should take initiative to normalize relations with North Korea and globalize its development. Satellite imagery demonstrates an expansion in rocket launch sites, and there is evidence that North Korea will be preparing numerous missile tests. Neglect of North Korea is an act of appeasement and North Korea is taking the opportunity to bulwark its belligerent rhetoric. With the Kim Jong-Un regime slowly sealing its power over the nation, the United States must take action. Economic engagement will result in long-term infrastructure development and better political decency.

Pharmacological Manipulation of the Neuromuscular Junction between Stem Cell Derived C2C12 Muscle Cells and Motor Neurons
Natalie Levey
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Nerve and muscle diseases are causes of conditions like amyotrophic lateral sclerosis and muscular dystrophy. Motor neurons (MN) synapse with muscles at neuromuscular junctions (NMJ). Excitation of MNs causes depolarization and releases acetylcholine (ACh), which diffuses across NMJ and stimulates muscle contraction. Replacing diseased tissues requires functional restoration of neuromuscular units. The purpose was to investigate the functional interaction between MNs and muscle cells, derived from stem cells. C2C12 myoblasts were differentiated into myotubes and cultured with differentiated MNs. Pharmacological manipulation was performed when cells began contracting five days after co-culture. Two experimental groups were used: 1) C2C12 + MN and 2) C2C12 only. Both were observed contracting before manipulation. Glutamate (10uM to 100uM) was used as an excitatory molecule that stimulates MNs. D-Tubocurarine (50uM and 100uM), ACh receptor antagonist, was used to block neuromuscular transmission. Unexpectedly, when C2C12 + MN plate was stimulated with glutamate (100uM), contractions stopped. In C2C12 only, glutamate (20uM) terminated contraction. Therefore, motor neurons affected contraction of muscles by dampening

inhibitory effects of glutamate in co-cultures. D-Tubocurarine (100uM) inhibited muscle contraction in both groups, while (50uM) had no effect, suggesting contractions were not initiated by MN. These preliminary results will be extended to investigate pharmacological effects on NMJ in co-cultures where muscles have not progressed to the contractile state to determine if functional neuromuscular units can be regenerated from stem cell-derived MNs and muscle cells. Once contractions can be manipulated, it will be possible to create more neuron-muscle systems that mimic the actual biological system.

Parental Meta-emotion Philosophy as It Relates to Child Emotional Functioning

Graham Levitas, Isabel Cohen, Brittany Saraga
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

Parent meta-emotion philosophy (i.e., beliefs about emotion) is revealed through parental emotion coaching and communication regarding the identification, acceptance, and remediation of children's emotion experiences (Gottman, Katz & Hoovan, 1996). Emotion communication predicts child socioemotional adaptation (e.g., Gentzler, et al., 2005; Eisenberg et al., 1996), but further research is needed to examine a parent's meta-emotion beliefs as correlates of parent and child emotional functioning (Gottman, et al. 1996). We hypothesized that high parent awareness, acceptance and coaching would correlate with high child awareness and expressivity, and low child dysregulation, all of which were measured via parent and child Meta-Emotion Interviews (MEI; Gottman et al., 1996), and that parent/child MEI would correspond with measures of parent/child emotional functioning. Participants included 34 diverse mother-child (5-12 years) dyads who completed MEIs, parent self-report measures (Parental Stress Index- Short Form, Abidin, 1995; Difficulty in Emotion Regulation Scale, Gratz, 2004) and child self-report measures (Childhood Depression Inventory, Kovacs, 1992; Multidimensional Anxiety Scale for Children, March, 1997). Bivariate correlations revealed that child emotion expression was related to parent's emotional functioning: high parenting stress with less expression of sadness ($r = -.531$, $p = .013$) and anger ($r = -.485$, $p = .019$); parent emotion dysregulation with less expression of anger ($r = -.369$, $p = .064$). Children's greater comfort expressing anger was related to lower child depressive symptoms ($r = -.351$, $p = .092$). Coding of parent MEIs is underway to test other study hypotheses. Results suggest the importance of parent/child meta-emotion in child emotional functioning.

Mapping Narrative: The Structure and Composition of a Short Story Cycle

Daniel LoPilato, CURO Graduation Distinction
Prof. Reginald McKnight, English, Franklin College of Arts & Sciences

The first problem of studying the short story cycle—or the novel in stories, or the composite novel, or the novita—is one of terminology; what do we call it? This problem is resonant, however, of the broader problem of genre. When we speak of story cycles, we speak of an assemblage of stories which relate broadly in theme and characterization, even plot. Is the short story cycle, then, a novel told in stories, or is it a story collection that tells a novel? I will examine this question and another larger concern, in tandem with my ongoing composition of an original manuscript: the gesture toward myth. The story cycle, like the novel, tells a tale of breadth and scope; and, like the epics of Homer and Virgil, it tells a tale grounded in the episodic nature of the oral storytelling tradition. In light of literary theorists like Walter Benjamin, who examined the short story and its divergences from the novel, I will discuss three principle works—James Joyce's *Dubliners*, Sherwood Anderson's *Winesburg, Ohio*, and Ray Bradbury's *The Martian*

Chronicles—and their effects on the structuring and execution of my own creative thesis, the foundation of a story cycle investigating the notion of personal and cultural myth. My research will add a new voice to the narrow field of scholars studying the short story cycle and lend insight into the creative concerns of a writer at work.

Study on the Ste24p Zinc Binding Motif, Ste24p Substrate Loading Mechanism, and Archae Ste24p Homologs

Robert MacDonell, Dillon Davis, William Saunders III, Kaitlin Hufstetler, Colby Ruiz, CURO Honors Scholar
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Ste24 is a protease that is involved in the processing of prelamin A in humans, the yeast a-factor mating pheromone, and unknown targets in other species. Mutations in human Ste24 may result in progeria, a disease characterized by accelerated aging. Ste24p is highly conserved among many species, so much so that yeast Ste24p can be functionally substituted by a eukaryotic ortholog, allowing for investigations relevant to disease in the case of human Ste24. Analyses of Ste24p have largely been limited to yeast and mammalian Ste24p. In this study we have cloned and expressed Ste24p from *Pyrococcus furiosus*, a species in the archae domain, in *Saccharomyces cerevisiae*. An *in vivo* assay based on a-factor production revealed a lack of enzymatic activity in this recombinant yeast strain, suggesting that functional similarity among Ste24p enzymes may be restricted to eukaryotic species. We are also investigating the importance of residues that are involved in coordinating a catalytic zinc cofactor associated with Ste24p. We have evidence that the mutation of a Glutamate residue at position 390 in yeast Ste24p abolishes activity as measured through an a-factor production based *in vivo* assay. The potential role of other residues in the substrate loading properties of Ste24p were investigated through analysis of recent structures defined for both *S. cerevisiae* and human Ste24p with a Difference Distance Matrix program. These studies are expected to provide more information on the enzymatic properties of Ste24p, leading to a better understanding of the role of this protease in disease.

Cope's Gray Treefrog's Preference to Occupy Different Colors of Artificial Refugia

Michelle MacKenzie
Dr. John Maerz, Warnell School of Forestry & Natural Resources

Treefrogs are beneficial to biologists as ecological indicators. Polyvinyl chloride (PVC) tubes are used to sample treefrogs in pine plantations. A technique that incorporates the biological capabilities or perceptual preferences of the animal is rare and makes this study unique. Use of artificial refugia is not an effective method in the Piedmont region. However, studies on amphibian color vision have demonstrated that the color white, the color of PVC pipes, is a wavelength that is avoided by treefrogs. These studies have also demonstrated that amphibians prefer to go to blue wavelengths. In this study, we conducted a controlled lab experiment to test Cope's Gray Treefrog's preference to occupy different colored artificial refugia. Treefrogs were individually placed in nylon mesh cages. Sixty-centimeter long PVC pipes with an inside diameter of 3.81 centimeters were spray-painted either blue, brown, or white. One of each color was placed in each cage. The tubes were terminally capped and filled with 15-centimeters of water. Each day, the color tube occupied was recorded. Refugia were rinsed to remove any trace pheromones and then replaced in random orientation. Frogs were removed from the study after 10 selections. We performed a one-way ANOVA test that indicated a color preference ($p < .001$) and a Tukey HSD post-hoc test showed that blue occupancy was more common than

brown and white PVC refugia, while there was no difference between brown and white. Thus, we recommend the use of blue refugia to be used in place of white refugia.

Development of a PCR-based Marker to Identify Overwintering Sites for *Exobasidium sp.* on Blueberries in Georgia

Ridwan Mahbub
Dr. Marin Brewer, Plant Pathology, College of Agricultural & Environmental Sciences

An emerging disease in Georgia and the southeastern United States, *Exobasidium sp.* is a fungus that causes fruit and leaf spots on blueberry that significantly decreases marketable yield of berries. We are interested in understanding the disease cycle, particularly where the fungus overwinters, so that improved management strategies can be developed. Our hypothesis is that *Exobasidium sp.* overwinters in buds of blueberry plants. *Exobasidium sp.* grows very slowly and is difficult to isolate from other fungi on growth medium, so in order to detect it we have developed an *Exobasidium*-specific PCR-based marker using primers for the internal transcribed spacer (ITS). Results demonstrate that successful amplification of ITS is possible even at low *Exobasidium* cell concentrations (≈4 CFU/μL) in the presence of blueberry plant DNA, indicating that our PCR-based marker is reliable for detection of potential overwintering sites. We used our marker to detect the fungus in blueberry buds, other plant tissue, soil, and plant debris collected from highly diseased South Georgia field plots prior to disease outbreak in the spring. We compared our results with low-disease plots at the same site and a control site in Watkinsville, GA where disease was not observed. Our expectation was that there would be frequent detection of *Exobasidium* sp. with the PCR-based marker in blueberry buds from highly diseased field plots, less frequent detection in buds from low-disease plots and no detection at the control site.

From Feudalism to Democracy: Using Political Philosophy to Reframe Traditional Distinctions between the Great Ages of Europe

Dalton Mark
Dr. R. O'Brian Carter, History, Franklin College of Arts & Sciences

This paper will examine the development of political philosophy in Western Europe during the fourteenth through eighteenth centuries. It is a refutation of the traditionally held perspective that the iconic periods of history were distinct ages, arguing instead that these periods were different stages in a larger global trend. The Middle Ages, the Renaissance, and the Enlightenment were together one extended reassessment of humanity and man's place in the world. This paper will examine the writings of such notable political philosophers as Dante, Brandolini, Machiavelli, More, Bodin, Montaigne, La Boetie, Hobbes, Locke, and Rousseau to demonstrate that political trends transcended political borders. I will focus first on Italy from the fourteenth century to the seventeenth century to explain the transition from a religion-infused feudalistic structure to an anti-monarchical despotism. Then I will focus on France and England from the seventeenth century to the eighteenth century to explain the transition to a democratic notion of the social contract. These political changes are demonstrative of the change in perspective of society from the importance of strong rule over an inferior public to the justice of a symbiotic relationship between rule and people. My research will demonstrate that this change in mindset did not begin and end in one year or another – it was instead a gradual transition that took place over several centuries. This reframing of the intellectual movements is important to properly understanding the progression of history and the foundations for various political structures in place today.

The First Rule of Camorra is You Do Not Talk about Camorra: An Investigation into the Rise of the Organized Crime Syndicate in Naples, Italy

Dalton Mark
Dr. Steven Soper, History, Franklin College of Arts & Sciences

In Naples, Italy, an underground society has a hand in every aspect of civilian life. The success of this crime syndicate, and others like it, is predicated on a principle of omertà – a strict silence that demands non-compliance with authority and non-interference in rival jobs. Presumably birthed out of the desperation of impoverished citizens, the Camorra has grown over the last three centuries to become the most powerful force in southern Italy. Nonetheless, in 1911, the Camorra was brought to a mass trial, resulting in the conviction of twenty-seven leaders. Unfortunately, the Camorra, indefatigable as always, has continued to run their illicit operations through recent decades, despite any arrests that may be made. It is important to understand the roots and methods of the Camorra because it is and will probably remain the uncontested strongest force in southern Italy. Research for this paper was based in secondary sources to synthesize the various theories and perspectives on this dangerous gang. Results showed that their resilience is based on their size, their depravity, their decentralization, and perhaps most importantly, the corruption of the government attempting to supplant them.

The Use of Scheduled Combination Treatments of Etoposide and Doxorubicin to Treat Feline Injection Site Sarcoma Cells

Steven Mathew
Dr. Robert Gogal, Jr., Anatomy & Radiology, College of Veterinary Medicine

Doxorubicin and etoposide, topoisomerase inhibitors, are known chemotherapy drugs utilized to treat select cancers in humans and veterinary species. A combination of chemotherapeutic drugs at doses lower than the IC50 could improve the therapeutic index of anticancer drugs, such as etoposide and doxorubicin, whose individual success rates are deterred by adverse side effects and drug resistance. The overall objective for this study was to determine the level of cell proliferation inhibition of feline injection site sarcoma (ISS) cells with doxorubicin and etoposide in scheduled combination treatments. ISS cells in monolayer cultures were plated in 96 well plates with treatments applied to quadruplicate wells followed by the timed addition of IC50, IC25, and IC12 concentrations of etoposide and doxorubicin. One treatment protocol consisted of adding different concentration combinations of both drugs within the same period of time. The second treatment protocol involved adding different concentration combinations of the two drugs with a time period ranging from 24 hours to 48 hours separating the addition of the first and second drug. At 72 hours, Alamarblue™ dye was added to each well, and plates were read 8 hours after dye was added. The data indicated that scheduled combined treatments of the two drugs did positively reduce viable cell proliferation compared to controls. Thus, these preliminary results suggest that combination of these drug cocktails at doses lower than the IC50 are efficacious for treating feline ISS with possibly lower adverse risks to the feline host.

Comparison of Crustal Chemical Composition of the Carolina Terrane and Inner Piedmont Using Vp/Vs Ratios Obtained from Broadband Seismic Data

Abigail Maxwell
Dr. Robert Hawman, Geology, Franklin College of Arts & Sciences

Seismic data from several seismic stations in Georgia and South Carolina are collected and analyzed. The chemical compositions of the Carolina Terrane and Inner Piedmont are compared using Vp/Vs ratios to determine if

there are any differences in the crust in these two locations. The structure and thickness of the crust are determined by processing the data collected from the seismic stations and the differences in crustal thickness can therefore be compared and possible reasons for such differences such as difference in topography or orogenic events are considered. The travel times for P waves and S waves produced by earthquakes vary with chemical composition of the crust and any structural features such as faults or areas of high topography that may be present in the particular area of study. The reflection, refraction and transmission of the P waves are also considered when determining the structure of the crust.

Performance on a Saccade Task under Varying Cognitive Load

Brett McCardel
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Throughout the day we are bombarded with sensory input, and cognitive control processes help us determine what stimuli should be attended to or ignored. Eye movement tasks which require saccadic responses are excellent models for cognitive control processes in general because the stimuli can be tightly controlled and responses easily quantified. Thus, simple versus complex versions of the task can be compared. Prosaccades (rapid glances towards a visual stimulus) are more reflexive and easier to perform than antisaccades (rapid glances towards the mirror location of the stimulus). Antisaccades require the inhibition of a reflexive glance, are generally slower than prosaccades, and result in more errors. Previous research suggests that cognitive control may differ based on stimulus presentation. The current study will determine the response characteristics in a saccadic task involving manipulation of cognitive load, which will be done by varying the proportion of simple prosaccades to more difficult antisaccades on five separate runs. Participants will wear a headband with two small eyetracking cameras to record saccades. We will index the difficulty of each run based on reaction times and percent of correct trials to determine which proportion of simple and complex trials require the most cognitive control. It is hypothesized that a run with 50% prosaccades and 50% antisaccades will produce the greatest demand on cognitive control due to task switching. These results will add to our understanding of how cognitive control functions during eye movement tasks and possibly illuminate the limits of cognitive control processes within the saccadic system.

Development of Avian Infectious Bronchitis Virus-Like Particles

Julia McElreath
Dr. Mark Jackwood, Population Health, College of Veterinary Medicine

Infectious bronchitis virus (IBV) is the causative agent of infectious bronchitis, a highly infectious, globally distributed and economically significant upper respiratory tract disease in commercial chickens. IBV is an enveloped, single stranded RNA virus. The virion is composed of four structural proteins, Spike (S), Membrane (M), Envelope (E), and Nucleocapsid (N). M, E, and N compose the viral particle and package viral RNA during replication in infected cells, while S projects from the surface of the virus and is responsible for attachment and binding to host cells. We hypothesize that virus-like particles (VLPs), functional virions with no internal cargo, can be constructed using the four structural proteins individually cloned into expression vector systems. Reverse-transcriptase polymerase chain reaction (RT-PCR) will be used to amplify the four structural proteins individually, and they will then be cloned into a novel expression vector system. Plasmids containing the four structural genes will then be transfected into a mammalian cell line to produce VLPs. We expect that the expression system will

efficiently produce IBV structural proteins, and that the proteins will associate in transfected cells to produce VLPs. Currently, we have successfully cloned the four IBV structural proteins into the expression vector system and are culturing mammalian cells in preparation for transfection. Developing an efficient viral protein expression system and then producing functional IBV VLPs will be significant because they can be used as a delivery system to cells of the avian respiratory tract.

The Need for Universal Design: An Environmental Assessment of Residential Interior Spaces and the Built Environment

Brittany McGrue, CURO Honors Scholar, CURO Summer Fellow
Prof. Sarah Zenti, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The Americans with Disabilities Act became law in 1992, mandating that all facilities integrate disability accommodations with those for the general public. Before 1992, individuals with disabilities were provided with separate facilities, if they were provided with any at all. The law stipulates that people with disabilities were a part of the general public and should be treated as such. While these regulations and standards made buildings and designed spaces more accessible to those with disabilities, they also discriminated against them, highlighting their differences. To combat this, some architects and interior designers began operating under the principles of Universal Design, which "implies that well-planned [spaces] will meet the needs of every user without drawing attention to persons with disabilities." To date, incorporating Universal Design into residential space plans and architecture is seen more as an option rather than a necessity. My research intends to demonstrate the importance of Universal Design in residential spaces. I used my first-hand experience of being temporarily handicapped to observe the difficulties disabled individuals face maneuvering in standard residential spaces beyond the typically included minimum Universal Design features. I made written observation and analysis about my day-to-day activities and challenges. I then detailed my findings in a weekly blog, highlighting the difficulties I experienced and how they could have been alleviated, to be used as a resource for other interior design students as they learn how and why it is important to incorporate Universal Design into their own work.

Policy Analysis: US-Afghanistan Reconstruction Efforts

Mackenzie McRae
Dr. Michael Beck, Center for International Trade & Security, School of Public & International Affairs

Operation Enduring Freedom [Afghanistan] includes a heavy reconstruction effort for Afghanistan's social, political, and economic infrastructure, notably the completion of the Afghani Ring Road highway system. The reconstruction efforts provide short-term solutions and fail to achieve long-term growth and stability. This analysis reviews the current US policy and proposes amendments to the US policy that will better incorporate current international infrastructure projects and Afghanistan's vast geopolitical trade potential. The current US policy addresses economic growth and road infrastructure as separate entities, but does not adequately incorporate Afghanistan's key geopolitical position. Neighboring states China and India, as well as the Asian Development Bank, have independently funded transport projects in Afghanistan, as the state is a regional bottleneck stifling transcontinental trade. This policy paper will analyze each US infrastructure project and propose a revised policy which better collaborates with non-US backed infrastructure projects in Afghanistan. The policy will use data on historical trade routes, incorporate the geographical distribution of Afghanistan's natural

resources, and the market demand to establish which infrastructure projects would best serve Afghanistan's economic growth. The U.S. has invested $100billion in to reconstruction efforts since 2002. Misappropriation of these funds will leave Afghanistan economically unstable, and its new democracy unsound. It is essential that the US policy promotes long-term socioeconomic growth in order to achieve democratic stability in the state.

Components of Economic Freedom and the Institutional Approach to Economic Growth

Peter Melampy
Dr. David Mustard, Economics, Terry College of Business

Recent economics research has investigated a new series of explanations for the wide disparities in long-term economic performance across countries. This relatively new approach, contrasted with the neoclassical and geographical approaches to economic growth, uses government and economic institutions to explain differences in growth. This approach primarily employs empirical studies rather than theory, as the neoclassical growth model cannot predict the effect of institutions on growth beyond their effect on the investment rate. Since this approach is less than 30 years old, discrepancies in many areas of the research persist, and the goal of this paper is to reconcile some of these disputes. This paper reviews the literature on various areas of this institutional approach to economic growth. In addition, I use data from the World Bank, the Economic Freedom of the World Index, and Transparency International's Corruption Perceptions Index to run preliminary OLS regressions on regulation and corruption to supplement the previous research. Reviewing the literature, I find that economic freedom indexes are correlated with growth and that, within these indexes, measures of rule of law and judicial system quality are most robustly correlated with growth. In my preliminary analysis of the data, I also find that economic regulation and corruption have no discernible effect on growth. Finally, I resolve disagreements in the current debate over whether political institutions cause growth or vice versa. I argue that terminology is the primary source of discrepancy and that while economic institutions and policies affect growth, democratic government structures do not cause growth.

"Why Is There an Alligator in My Pool?" Assessing Potential Range Shifts with Sea Level Rise

Lara Mengak
Dr. Nathan Nibbelink, Warnell School of Forestry & Natural Resources

Rising sea levels precipitated by climate change threaten southeastern coasts. Models indicate a substantial loss of salt marsh habitat and a transition from current freshwater marsh to saltwater and brackish marsh habitat, which could adversely affect marsh-dependent species. We will examine the potential responses of the American Alligator *(Alligator mississippiensis)* to sea level rise along the Georgia coast. Spotlight surveys will be used to determine alligator occupancy at randomly selected locations within potential alligator habitat (defined using existing landcover maps). We will then use alligator occupancy data and current habitat features to predict where alligators will be found in the future as a result of sea level changes. Preliminary modeling indicates a slight decline in total suitable habitat area, patch size, and habitat permanence. Habitat quality, however, shows a substantial increase. The model output maps show suitable habitat moving further inland due to sea level rise. These potential range shifts may put alligators into increasing contact with humans. Alligators displaced by sea level changes may be forced into new habitats, both natural and human occupied. Additional research may allow us to determine where alligators will move, changes in habitat size due to sea level changes, and the specific

responses of people to increased contact with these predators.

Early Developement of Benzimidazole Resistant *H. contortus* within Individual Sheep

Adam Michalak
Dr. Ray Kaplan, Infectious Diseases, College of Veterinary Medicine

Haemonchus contortus is a gastrointestinal haematophagic parasite which causes significant production loss and death of ruminants worldwide. Deworming drugs are administered to sequester *H. contortus*'s detrimental effects, but increasing resistance levels are rendering the drugs ineffective. However, little about the early-stage evolution of this developing resistance is understood. We hypothesize that the dynamics of the initial resistance development are significantly impacted by parasite load size and the number of anthelmintic treatments per sheep. A multiple-resistant population of *H. contortus* in the UGA sheep flock was replaced with a fully drug-susceptible population. The sheep herd was then moved to a new, parasite free, location. Sheep were treated with anthelmintics selectively based on parasite loads, and fecal samples were collected four times during the year to measure the worm-egg counts. Analysis of the fecal egg count data from 31 sheep demonstrated that the five with the highest totals contain 64.26% of the eggs, while the five with the fewest totals contain 0.52% of the eggs. The *H. contortus* eggs were then isolated from the feces for future DNA extraction and measurement of resistance-associated mutations in the beta-tubulin gene using real time PCR. Data will be analyzed to determine the impact parasite levels, treatment numbers, and sheep age have on resistance development. Results should provide a deeper understanding of factors contributing to the early-stage evolution of drug resistance in nematode parasites.

Trade-offs: The Effects of Contiguous Rivalries on International Decision-Making

Travis Miller
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

When states face a trade-off between two salient conflicts, how do they choose to expend their scarce military resources? In this study, I argue that the existence of an interstate rivalry with one's neighbor compels a state to minimize the resources it commits to disputes outside the rivalry. A state will evaluate its distribution of capabilities and determine that the military threat and intense competition associated with contiguous rivalries requires the utmost attention for both offensive and defensive purposes. This is due to the opportunity for aggressive action that contiguity affords such adversaries and the willingness that rivalry pervades them with to fight over the issues inspiring the conflict. The leaders will then proceed to act more amicably in disputes of a non-contiguous, non-rivalrous distinction due to the relatively reduced saliency of such dyads. This allows the state to concentrate its resources on confronting the more primary, immediate threat – the rival state – thereby making its foreign policy more focused and efficient. I assess this argument by examining the behavior of major states over the period 1816-2001, both in conflict and negotiation. I also outline the implications of this study's conclusions in broad terms and in greater specifics as it relates to contemporary United States-China relations.

Civil Society Collaboration between the U.S., E.U., and Turkey

Kameel Mir, Foundation Fellow
Dr. Cas Mudde, International Affairs, School of Public & International Affairs

The U.S. faces a security concern regarding Turkey's accession to the E.U. Years of delay to Turkey's membership process are slowly beginning to evidence their effect on Turkish

politics. Turkish elites have stalled some of their progress towards meeting E.U. membership criteria, and in the realm of global politics, they have clashed with Israel and refuse to support further American sanctions on Iran. The Turkish populace has voiced a new aversion to joining the E.U., and Turkish public opinion of the U.S. ranks dismally low. In order to preserve the U.S.'s invaluable partnership with Turkey, the most powerful Middle Eastern democracy, the U.S. must strengthen Turkey's bond with the western sphere through substantially furthering its progress towards E.U. accession. Analyzing policy alternatives according to how they increased U.S. legitimacy through furthering Turkey's cause, political feasibility, and logistical success revealed a solution in the civil society arenas of Turkish, European, and American politics. Establishing and promoting collaboration between the leaders of the most influential CSO's in the three societies, specifically through a discussion on the place of religion in a democratic civil society, would target the crucial link between popular opinion and elite power. This alternative aims to address Islamophobia in the E.U. and U.S. and aversion to the West in Turkey, all the while assisting the progression of Turkey's democracy. As the Middle East writhes in chaos and as the U.S.'s ability to monitor the region dwindles, the timely implementation of this alternative becomes increasingly crucial.

Expression of Toll-Like Receptor-3 in Response to EHDV

Spencer Mitchell, CURO Graduation Distinction
Dr. Elizabeth Howerth, Pathology, College of Veterinary Medicine

Epizootic hemorrhagic disease (EHD) is a widespread disease affecting white-tailed deer and rarely cattle in North America. The disease is caused by epizootic hemorrhagic disease virus (EHDV), a double-stranded RNA virus in the orbivirus family that infects the endothelium lining the blood vascular system. Little is known about the innate response to infection with this virus. Toll-Like Receptors (TLRs) are proteins within a cell or on the cell surface that recognize and initiate a response to pathogen-associated molecular patterns (PAMPs). Toll-Like Receptor 3 (TLR3) is responsible for recognizing double stranded RNA (dsRNA) viruses. We hypothesize that TLR-3 plays a role in the susceptibility of deer to EHDV so the purpose of our project was to evaluate the response of TLR3 and the effect of such a response following inoculation of cow endothelial cells with EHDV. We performed a quantitative reverse-transcriptase polymerase chain reaction to evaluate changes in TLR-3 mRNA over time in cow pulmonary artery endothelial cells infected in vitro with various amounts of EHDV. We did not detect changes in the levels of TLR-3 mRNA in response to infection with EHDV. Next we will evaluate expression of NF-kB, a rapid response transcription factor that acts to produce an inflammation response in the body, which is up-regulated when ds-RNA binds to TLR-3 via immunohistochemistry. An increase in cellular NF-kB and a constituent level of TLR3 in the cell following infection might offer insight about the mechanism by which TLR3 is activated and potentially recycled following infection with EHDV.

Conformational Preferences of a Prototype Biomolecule in Liquid Helium Nanodroplets

Grant Moody, CURO Graduation Distinction
Dr. Gary Douberly, Chemistry, Franklin College of Arts & Sciences

We report the infrared action spectroscopy of a prototype dipeptide in low-temperature liquid helium nanodroplets. The molecule used for this experiment is Ac-Gly-NHMe (NAGMA). The NAGMA sample is vaporized, and the vapor is entrained in a beam of the helium nanodroplets. The

vibrational energy of the NAGMA molecules is quenched so rapidly (~1014 K/s) via energy transfer to the helium droplet that the conformational distribution in the vapor phase is frozen out upon helium solvation. Because the conformers of NAGMA cannot interconvert at the droplet temperature (0.4 K), the spectroscopy of the helium solvated NAGMA ensemble is representative of the conformational ensemble at the vapor temperature (~600 K) within the NAGMA pick-up cell. Possible conformations of this dipeptide were computed using *Gaussian03*, a quantum chemistry software package. Three local minima were identified using Density Functional Theory, and a molecular mechanics method was used to probe for additional minima on the potential energy surface. An infrared spectrum was obtained for helium solvated NAGMA in the range of 3200-3700 cm-1. Four distinct peaks were observed, signifying either bonded or free N-H stretches. These peaks are most likely due to two conformations of the NAGMA molecules, as the molecule has two separate secondary amines. Vibrational transition moment angles and permanent electric dipole moments were obtained experimentally for each of the peaks observed in the spectrum. The complete set of spectroscopic data is compared to the calculations of the various conformational minima in order to arrive at a definitive assignment of the conformations of NAGMA present in the vapor phase at ~600 K.

Occupational Complexity as a Predictor of Cognitive Reserve

Jake Moskowitz
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

The concept of cognitive reserve suggests that certain individuals possess built-up mechanisms that enable them to cope with the onset of degenerative neurological diseases better than others. This "reserve" of cognitive function is thought to be derived from a variety of demographic factors, including but not limited to occupational and educational attainment, race, gender, and age. The Wechsler Test of Adult Reading (WTAR) has proven to be a valid proxy for cognitive reserve in older adults, successfully predicting premorbid IQ in patients with minimal to mild Alzheimer's disease. WTAR scores have been shown to be heavily predicted by several demographic variables, including education, occupation, age, gender, race, and region of residence. The relative importance of occupational data to predicting WTAR scores, however, remains a point of some disagreement among researchers. This study seeks to determine the significance of occupational complexity toward predicting the WTAR values of a local older-adult population. Demographic data containing educational and occupational attainment, age, and gender were compared against participants' WTAR scores. When analyzed using a hierarchical regression model, occupational complexity was found to significantly predict WTAR scores, even when education, gender, and age were controlled for. This finding supports the notion that long-term occupational complexity contributes to cognitive reserve throughout one's life. While further research is needed, this link between occupation and cognitive reserve could contain valuable implications for the public health struggle against the rising global epidemic of neurological degenerative disorders such as Alzheimer's disease.

Stepping into Masculinity: The Dress and Body Modification of African American Fraternities

Amy Moulton
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The cultural and sartorial practices of National Pan-Hellenic Council (NPHC) fraternity members play a key role in constructing the desired masculinity of the

fraternity men. The most obvious of these practices are the members' emphasis on particular sartorial styles during step performances and the body modifications—especially brandings—they routinely adorn their bodies with. Through my research and personal communication with NPHC members I have discovered that large-size brands are most coveted among Black Greek step performers because they require proportionally large arms that can be attained only through a grueling physical exercise regimen. Large brands that showcase strength and represent pain endurance are rights of passages for NPHC members to enter into manhood and gain acceptance into their close-knit subcultural group. Through the analysis of the dress, body modifications, and culture of the NPHC fraternities, one can discover how NPHC fraternities foster their members' perception of ideal masculinity. NPHC fraternities' step performances aid in mapping out and constructing the desired masculinity of African American men through the use of erotic costumes, suggestive chants, and sexualized dance moves that create an aura of heightened sexuality. The steppers' muscular and branded bodies suggest a relationship between physical strength, pain tolerance, machismo, and African American Greek life.

Story-gathering and Community Performance

William Murdock, Jr.
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

As the 20th Anniversary playwright for *Swamp Gravy*, Georgia's official folk-life play, I collected stories from the community of Colquitt, GA, and used them to create a new community performance piece. Focusing specifically on one woman's story, I will detail the research process behind one scene, "Mail-Order Murderer." "Mail-Order Murderer" tells a story of intrigue, arranged marriage, false identity, premeditated murder, and criminal entrapment—all taking place within a few short days in 1961 on a sleepy, rural cattle farm in Southwest Georgia. Using findings from the Georgia Newspaper Project, I was able to reconcile the "officially reported" version of Levi L. Henter's arrest with the familial recollections of the victim's great-niece. This story offers historical significance as the rediscovery of an almost forgotten story in Georgia's history. Forensic pathologist John Coe, who worked on inquests into the assassinations of John F. Kennedy and Martin Luther King, Jr., called the Levi Henter case one of the most fascinating of his career. This information, coupled with research into Depression-era Circuses was used to create a scene for Georgia's official folk-life play.

Investigating the Indirect Effects of Guppy Introduction on Populations of a Shredding Caddisfly in Trinidadian Streams

Kelly Murray
Dr. Catherine Pringle, Odum School of Ecology

In Trinidadian streams, guppies (*Poecilia reticulata*) have naturally colonized or were introduced to regions where previously only one other fish species, the killifish *Anablepsoides hartii*, existed. A survey of macroinvertebrates in eight streams, each with paired reaches with and without guppies shows that guppy presence is associated with higher abundances of the leaf-shredding caddisfly *Phylloicus hansoni*, an important decomposer in these stream ecosystems. Reaches with long-term guppy presence exhibit the greatest differences when compared to their killifish-only reaches. Our aim is to tease apart mechanisms for these observed differences. Benthic macroinvertebrates are important resources for both fish species. We hypothesize that interference competition between introduced and native fishes will result in niche partitioning within the community. To

determine this, we are analyzing gut contents of killifish from killifish-only reaches as well as guppy+killifish reaches, which are at different time points of guppy introduction: 2-3 years, 35 years, and 100+ years. This experimental design will allow us to assess any differences in how killifish forage in response to guppy presence through time. Relative amounts of defined food categories in gut contents will be quantified and compared between reaches, especially concerning amounts of terrestrial versus aquatic insects present. We predict that guppies' benthic foraging behavior causes killifish to feed preferentially on terrestrial insects fall-in compared to benthic invertebrates, including *Phylloicus*. Because *Phylloicus* is such a prominent decomposer of allochthonous material, differential predation by killifish on this aquatic insect would be an important factor affecting rates of leaf breakdown in these streams.

Three Dimensional Cell Based Assay Standard for Pharmaceutical Testing

Rebekah Myrick
Dr. William Kisaalita, College of Engineering

Present 3-D cell cultures for pre-clinical screening of pharmaceuticals lack a standard to validate their emulation of cells *in vivo*. Therefore, 3-D cultures reduce the use of humans and animals in the pharmaceutical industry, but the challenge to optimize the cultures make this innovation less cost efficient. This research investigates complex physiological relevance (CPR). CPR will confirm the formation of cell cultures that mimic corporeal arrangement and performance. In these experiments, the cell densities that yield optimal CPR in HEP-G2 hanging drop experiments were determined. Next, the materialization of cell cultivations resembling liver hepatocellular carcinoma cells (HEP-G2) will be validated by measuring albumin production (performance) and visualizing canaliculi formation (arrangement) with transmission electron microscopy and confocal microscopy. The resulting procedures will substantiate CPR of 3-D cell cultures and reduce costs in the pharmaceutical industry.

Characterizing a Novel Intragenic RpoN-dependent Promoter in Salmonella

Kiana Nezafat
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

Transcription initiation in bacteria is mediated by RNA polymerase in the presence of a sigma factor. There are two main families of sigma factors, sigma 54 (RpoN) and sigma 70 (RpoD). The mechanism by which RpoN directs the initiation of transcription by RNA polymerase is different from the RpoD-related sigma factors. *Salmonella enterica* subspecies *enterica serovar Typhimurium* (*S. Typhimurium*) has been a model organism for studies of bacterial gene regulation and is an excellent system in which to characterize the RpoN-dependent regulon. Our lab has identified several potential RpoN-dependent promoters in *S.* Typhimurium strains LT2 and 14028 in the presence of a universal activator of RpoN-dependent transcription, DctD AAA+, using microarrays and chromatin immunoprecipitation coupled to DNA microarray (ChIP-chip). A point mutation in the start codon of a secondary sigma factor in LT2 results in a less complex pool of sigma factors as compared to 14028s. One hypothetical RpoN-dependent promoter that was identified in LT2 is a potential intragenic promoter controlling the expression of a *cas1*-like gene in a CRISPR-CAS System. Although there are no differences in the hypothetical promoter sequences between the two *Salmonella* strains, we did not see strong activation from this promoter in the microarrays with 14028s, despite strong ChIP-chip evidence of RpoN binding in both strains. The work presented in this poster seeks to characterize this hypothetical RpoN-dependent promoter and its activation in 14028s using 5' RACE to map the

transcription start site for the RpoN-dependent *cas1* transcript and qRT-PCR to assess the transcription activity.

Vietnamese Language Attitudes, Use, and Identity: Determining a "Fobby" Vowel Quality

Minh Ngoc Nguyen
Dr. Chad Howe, Romance Languages, Franklin College of Arts & Sciences

In the United States, 2nd generation Vietnamese-Americans have varying levels of language proficiency and are often heritage speakers, usually never having learned Vietnamese formally. For this reason, we often see a varied array of how younger Vietnamese define their ethnic identity along the lines of language. This study will explore language attitudes, language use, and language and identity of 2nd generation Vietnamese-Americans in the Athens, GA area, particularly those attending the University of Georgia. The study will also analyze internalized racism among 2nd generation Vietnamese-Americans, examining the push towards a bi-cultural middle between "fobby" and "whitewashed" – "fresh off the boat" foreign and completely assimilated to American culture respectively. Participants will first be interviewed about their personal experiences, language fluency, and what it means to be Vietnamese. Then, participants will read sentences in English containing target vowels. After reading sentences in English, participants will engage in a picture identification activity, where they will be shown pictures of common concepts whose words contain Vietnamese target vowels. The two sets of target vowel frequencies, or formants, will be compared in order to determine if participants demonstrate any cross-linguistic influence from one language to the other. Participants will finally answer questions about what it means to be or sound foreign, or "fobby." The results of the study will provide insight on societal pressures Vietnamese-Americans may feel concerning their language proficiency and their ethnic identity while determining if there is a quantifiable foreign, or "fobby," vowel quality in certain speech patterns.

Structural Evolution of the Ca_2^+/Calmodulin Dependent Protein Kinase

Tuan Nguyen, CURO Honors Scholar, Ramsey Scholar, CURO Summer Fellow
Dr. Natarajan Kannan, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The Ca_2^+/Calmodulin Dependent Protein Kinase (CAMK) of the eukaryotic protein kinase (EPK) superfamily forms a large group of homologous protein kinase implicated in diverse cellular functions. Although past studies have provided extensive insights on the CAMKs' diverse modes of regulations, substrates, and functions, the evolutionary basis of the CAMKs' structural divergence has not been well understood. Here, we identify selective sequence constraints unique to the CAMKs and its family members via a Bayesian approach. Our analysis of CAMK specific constraints reveal a contiguous network of co-conserved residues that physically link the EPK specific hydrophobic network to distal sites along G-H-I domain (CAMK Network) and a distinctive H-helix N-terminal capping motif. We found a conserved insert segment unique to many of the CAMKs that are structurally coupled to the EPK core via layers of co-conserved residues. Many family-specific constraints and variations reveal features building upon the CAMK Network. Further analysis points to convergent mode of CAMK-like structural motif across sparse families across the kinome. We thus propose that the CAMK core form an allosteric module that can mold the dynamics of the C-lobe to exert control of catalytic activity. Our analysis provides avenues to elucidate allosteric regulatory mechanism unique to the CAMKs, aiding the drug discovery efforts and building a

framework to study other cell signaling systems.

Dormant: A Photographic Series

Michelle Norris
Prof. Marni Shindelman, Lamar Dodd School of Art, Franklin College of Arts& Sciences

Dormant is a series of images that investigate the action of watching the television. Each image portrays a human that is vacant, in addition to the pixelated image of that which they are watching. This concept grew out of my interest in television culture, the uncommonly seen state of its viewing, and the film *Evidence* by Godfrey Reggio, in which children are filmed while viewing TV. My subjects would watch their favorite television show or movie as they were photographed. The photos were produced with a digital camera combining the glowing light from laptops, televisions, and colored light bulbs. The series reveals an alien and submissive human state that is evoked when these subjects mentally check out and live vicariously through programming. This work is important for continuing the research of other artists who are interested in investigating the physiological aspects of this common activity, as well as the consequences to follow.

Removing Barriers to Vision Services for School Children

John-Jordan Nunnery
Dr. Neale Chumbler, Health Policy & Management, College of Public Health

Barriers between students and vision services have a negative impact on student performance both inside and outside of the classroom. An estimated one in every five US school children has an undiagnosed vision problem, a burden that disproportionately affects low-income and minority students. Elementary school students with uncorrected hyperopia earned perceptibly lower achievement scores in one British study, while another study conducted in New York found correlation between students' performance on vision tests and percentile of grades earned. While these findings do not imply direct causation, the role that poor vision plays in a student's sub-par performance cannot be denied. The social impact of poor vision has also been documented. One Baltimore study found that a vast majority of juvenile delinquents screened failed vision tests. School implemented vision screenings are not improving eyesight in the classroom. In one study, roughly only a quarter of at-risk students received follow-up care after failing school vision exams. Barriers to follow-up care are logistical (difficulty scheduling appointments), financial (no insurance), and social (parents with disabilities) in nature. A thorough literature review was conducted to develop three policy alternatives. The policy proposals were evaluated by a cost-benefit analysis, the degree to which the policy would increase access to vision services, and feasibility. From this analysis, the policy alternative that calls for state funding for a mobile vision clinic program was chosen. This program would be managed by a non-profit organization, similar to the mobile vision clinics found in Florida and California.

Classification of Protein-ligand Interactions of P-glycoprotein

Phillip Ogea, CURO Summer Fellow
Dr. Arthur Roberts, Pharmaceutical & Biomedical Science, College of Pharmacy

P-glycoprotein (P-gp) is a transport protein found in the membrane of mammalian cells that plays an active role in the efflux of drugs and toxins. While P-gp protects cells from natural toxins, it also hinders metabolism of modern pharmaceuticals by preventing them from entering target cells. P-glycoprotein is well documented for its wide substrate promiscuity; it transports a wide variety of drugs with varying structure and function, contributing to what is known as multiple-drug resistance. P-glycoprotein was

discovered in 1976, yet scientists still do not fully understand the nature of its protein-ligand interactions. A clear knowledge of these interactions is vital to classifying the activity of P-glycoprotein. This project has used various methods, mainly nuclear magnetic resonance (NMR) spectroscopy, to collect data on P-gp's interactions with several ligands. This data can be matched with computer-simulated models of binding to create testable hypotheses on the location of binding sites. Additionally, activity assays can be paired with spectroscopic data to examine the rates and kinetics of drug transport. A collection of data on protein-ligand interactions, based on a variety of substrates, should establish trends that can better define the activity of P-glycoprotein. If the binding interactions of P-glycoprotein were elucidated, its contribution to multiple-drug resistance could potentially be circumvented. With this knowledge, drug developers will be able to produce more effective medicine for patients.

An Assessment of Neutrophil Enrichment by Single Step Differential Density Separation

Batare Okivie
Dr. David Hurley, Large Animal Medicine, College of Veterinary Medicine

Neutrophils are used as an indicator of innate immune function. A simple method is used to enrich the neutrophil population from blood. The purpose of a study in our lab is to assess the function of an oral immunestimulant, using neutrophil function as a monitor of innate immunity. During these studies, the purity of the enriched neutrophil population was questioned. My study assesses the enriched neutrophil population using microscopic differential leukocyte counting and compares these finding with the differential leukocyte distribution of these cells by flow cytometry. Our hypothesis was that the enrichment of leukocytes collected from blood using a single step density gradient of 1.077 gm/ml would yield at least 70% of neutrophils. The neutrophil fraction was collected, and slides were prepared using a cytocentrifuge. The slides were stained with a commercial Wright's stain kit. A classical differential count (neutrophils monocytes, and lymphocytes) was done using a compound microscope by counting at least 200 cells per slide. These results were compared to the "leukogram" generated from a forward angle and side scatter assessment of the cells using a cytometer and analysis software. A comparison of the correlation between the microscopic distribution of leukocytes and that from flow cytometry will be assessed. To date, it appears that samples taken 30 and 60 days pre-delivery and those taken 30 days after delivery were consistently enriched in neutrophils. Samples collected 1, 7 and 14 days after delivery contained a smaller fraction of neutrophils.

Transmission Strategies of *Trypanosoma cruzi* in Wild Reservoir Hosts

Ronke Olowojesiku, CURO Summer Fellow
Dr. Nicole Gottdenker, Pathology, College of Veterinary Medicine

Trypanosoma cruzi is the cause of Chagas disease, a zoonotic vector-borne protozoan parasite affecting approximately 10 million people worldwide. Better understanding the means through which *T. cruzi* is transmitted to animal hosts will contribute to strategies aimed at reducing the number of *T.cruzi* infections in humans. The objective of this study is to describe factors influencing T. cruzi infection in the common opossum (*Didelphis marsupialis*), a key reservoir for Chagas disease in Panama. Based on previous studies, it was expected that *T. cruzi* would be detected at higher levels in the scent glands than in the blood of the opossum. Samples were collected from the blood and scent glands of opossums trapped around the Panama Canal. PCR tests showed a higher detection of *T. cruzi* in the scent glands (6 positive/15 tested) as compared to the blood (1 positive/15 tested). Additionally, ecological

factors affecting transmission were evaluated. Because the palm *Attalea butyracea* is a known habitat for the Chagas disease vector, we hypothesized that there would be more *T. cruzi* infection in the opossums from a densely populated *A. butyracea* region. The study results supported the hypothesis, but more data is needed. I discuss findings from this preliminary study in relation to their significance for *T. cruzi* infection dynamics.

Analysis of P1 Function in *Mycoplasma pneumoniae* Adherence and Gliding

Babajide Oluwadare, CURO Honors Scholar, CURO Summer Fellow
Dr. Duncan Krause, Microbiology, Franklin College of Arts & Sciences

Mycoplasmas are small bacteria having a minimal genome and no cell wall. This study focuses on *Mycoplasma pneumoniae*, a human pathogen causing bronchitis and primary atypical "walking" pneumonia. Despite its small genome *M. pneumoniae* has a complex, differentiated polar structure called the terminal organelle. The terminal organelle initiates mycoplasma binding to receptors on respiratory epithelium and is the motor for gliding motility. Located on the terminal organelle surface is the P1 protein, which functions directly in both cell adherence and motility. There is evidence from recent studies to indicate that P1 repeatedly catches and releases sialic acids, present on animal cell surfaces, to thrust the mycoplasma cell forward. Furthermore, P1 is believed to exist in conformationally distinct subpopulations that shift when mycoplasma cells glide. Little is known about the specific mechanism by which the bacterium exhibits motility through the P1 protein. Learning about this unique form of movement can lead to new strategies for treatment of infections and a greater understanding of bacterial motility. By means of immunofluorescence microscopy with monoclonal antibodies specific for P1, mAB1 and mAB2, we sought to define quantitatively the location and relative amounts of P1 subpopulations. The antibodies mAB1 and mAB2 consistently yielded distinct labeling patterns which were not the result of background or "noise." Furthermore, mAB1 appeared to bind only to a subset of P1 proteins and only at specific times, as opposed to mAB2, which appeared to bind to all P1 at all times.

Finite-difference Time-domain Investigations of Metamaterials

Elliot Outland, CURO Honors Scholar, CURO Summer Fellow
Dr. William Dennis, Physics and Astronomy, Franklin College of Arts & Sciences

Metamaterials, artificially engineered materials possessing properties not normally found in nature, have a variety of applications in a number of fields. In order to put these materials to their best uses, it is necessary to understand how and why they work as they do. The finite-difference time-domain (FDTD) method is one way of achieving such understanding; by solving electromagnetic equations at different time-steps, one can gain information about the way that waves interact with the material in question at a future time-step. This new information can then be used to understand the interactions at a third time-step, and so on. Our research uses the MIT Electromagnetic Equation Program (MEEP) to perform FDTD analysis on the behavior of electromagnetic waves as they propagate through various materials in different configurations. After we specify the parameters of and run the simulation, MEEP produces an output file from which we can obtain numerical and quantitative data about the light-material interaction. Through this analysis, we can gain a better understanding of what properties produce what results; this will aid in the designing of metamaterials to better fulfill specific functions.

Abstracts

Characterization of the Light Signaling System in Fireflies

Jennifer Pallansch
Dr. David Hall, Genetics, Franklin College of Arts & Sciences

The universal nature of communication systems makes an understanding of their evolution a central question in biology. In the vast majority of species, the molecules underlying signal production and reception are usually unknown or complex, which makes an understanding of their evolution essentially intractable. In fireflies, however, light signal production is controlled by a single enzyme, luciferase, which acts by oxidizing its substrate, luciferin. My project fills in two gaps in our knowledge of firefly light production. First, the nature of the variation in luciferase genes between and among species was elucidated by recording emission spectra from fireflies in the *Photinus* genus using a portable spectrometer. These individuals were collected, and their identity was confirmed both molecularly and morphologically. This data was coupled with recorded activity times and background vegetation to compare two factors cited as possible influences on the evolution of light production, and this information will be supplemented by additional collections this summer. The second part of my project investigates the hypothesis that the luciferase enzyme is the sole determinant of light color variation. Luciferase genes will be sequenced across species to be cloned into a vector and expressed in *E. coli*. In this way, emission spectra that are the product of the luciferase gene alone can be measured with a portable spectrometer. By combining the *in vivo* and *in vitro* spectrum comparisons and field data, my work will contribute to a complete understanding of the evolution of a signal in a communication system.

Leading from Behind: A Progressive Outlook on U.S.-North Korean Relations

Jinny Park
Dr. Brock Tessman, International Affairs, School of Public & International Affairs

The Democratic People's Republic of Korea (DPRK) is notorious for its opaque foreign policy process and fickle approach to international diplomacy. For its part, the United States and its allies have focused on hard power tools such as economic sanctions and military posturing in their attempt to force the DPRK to abandon its nuclear weapons program. But there are important considerations that are being missed with the current foreign policy strategy employed by the United States. This paper addresses U.S. foreign policy towards the DPRK from a perspective other than that of scrutiny and disdain, and aims to outline what steps the United States should take to alleviate the current strained relationship. Numerous U.S. policy briefs, agency reports, and case studies of intervention from the late 1990s to the current era are used in support of my argument that using soft power and engagement policies will provide better policy results for the United States. In particular, I suggest that the United States has recently adopted a more supportive (rather than leadership) role with respect to international policy regarding Iran and Libya. Using a similar diplomatic approach, the United States can play a supporting role to China, which enjoys much greater leverage over the DPRK. Proposed alternatives are measured in the criteria of political feasibility, social equity, and effectiveness. Ultimately, the United States will have a better chance at building a working relationship not only with the DPRK but also with China, and spread its national interests of global peace, stability, and non-proliferation.

Understanding the "Gap" Effect in the Generation of Express Saccades

David Parker, CURO Summer Fellow
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

A saccade is a rapid re-fixation of gaze that can be elicited in experimental settings by having an individual fixate on a center point and then introducing a peripheral target. Previous studies have shown that when a brief "gap" period is introduced following the disappearance of a fixation point before the appearance of the peripheral target, it produces a significant portion of "express saccades" that are 40-50% faster than normal saccades. The highest proportion occur when the "gap" period is 200 ms. This experiment examines why a 200 ms "gap" period produces the highest proportion of express saccades, which will give key insights into how saccades are generated. In order to investigate this question, two groups of 15 subjects were formed; one consisted of a blocked interval group and one interleaved interval group. The blocked group performed 5 sets of 300 saccade trials, with each set having the same "gap" interval (0, 100, 200, 300, and 400 ms). The interleaved group performed 5 sets of 300 saccade trials with random "gap" intervals. Behavioral data indicated that only for the blocked group did a 200 ms "gap" period elicit the highest proportion of express saccades. This suggests that top-down cognitive processes involving expectation influence the production of express saccades. Future analysis of distribution statistics of the psychophysiological data will attempt to shed light on why the 200 ms "gap" period effect is only observed during the blocked condition. By investigating the mechanisms of saccade generation this experiment can give vital insights into the ocular motor system and top-down cognitive control processes.

Children's Emotional Awareness: Relations to Emotion Regulation and Coping in Middle Childhood

Heather Patterson
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

Emotion regulation includes the processes involved in coordinating the intensity, frequency, and expression of emotions (Morris, Silk, Steinberg, Myers & Robinson, 2007). Children's ability to effectively regulate their emotions has important implications throughout their lifetime. In clinical populations, individuals with psychological disorders tend to modulate their emotions relatively poorly and children who do not develop early emotion regulation skills may have an increased risk for later psychopathology (Cole, Michel & Teti, 1994). The current study examines how children's awareness of their emotions relates to child emotion regulation. A racially diverse sample of 27 children (ages 6-12) was recruited as part of an intervention pilot study. Children completed the Meta-Emotion Interview (Katz & Gottman, 1986), a semi-structured interview including dimensions of the child's emotional awareness and dysregulation, as well as remediation strategies used to cope with emotions, specifically anger and sadness. It was hypothesized that children scoring higher on awareness would have lower dysregulation and higher remediation scores. Results supported hypotheses with moderate effects sizes, although the small sample size prevented correlations from reaching statistical significance. For sadness, awareness was associated with lower dysregulation (r = -.32) and higher remediation (r = .36). Similar relations were found for anger awareness with lower dysregulation (r = -.26) and higher remediation (r = .21). Interestingly, there was a significant positive correlation between dysregulation and remediation for anger (r = .39), but not sadness. Future analyses will incorporate other reports of children's

emotion dysregulation and behavior as they relate to children's own emotional awareness.

Lipid Association Improves Hemoglobin-binding Capacity by Haptoglobin Related Protein

Savannah Pena
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Haptoglobin related protein (Hpr) is a component of a minor subclass of human high density lipoproteins (HDLs) called trypanosome lytic factors that function in innate immunity against *Trypanosoma brucei brucei*. Hpr is >90% identical to the soluble serum protein haptoglobin (Hp); the major difference being the presence of a hydrophobic signal peptide in Hpr. This signal peptide mediates association of Hpr with HDL. Because purified Hpr does not bind Hb, it was hypothesized that the delipidated signal peptide interferes with Hb-binding. This hypothesis was tested using fluorescence spectroscopy. Hpr contains tryptophan residues that fluoresce, and as Hb binds to Hpr, the tryptophan residues are quenched and the relative fluorescence decreases. This change in the relative fluorescence was measured for Hb titrated into native Hpr alone, a recombinant form of Hpr which lacks the signal peptide, and native Hpr in a lipid environment. The lipid environments tested included high-density lipoproteins (HDLs) and 1-Palmitoyl-2-oleoylphosphatidylcholine (POPC) liposomes at two different concentrations. Recombinant Hpr and lipid-associated native Hpr showed Hb-binding capacity, and Hb-binding increases with higher concentration of lipids. This suggests that when the signal peptide on the native Hpr protein is delipidated, Hb-binding is inhibited and Hb-binding capacity is rescued in a lipid environment. These results have important implications for understanding the trypanosome lytic factors, which contain Hpr and require the binding of Hb for uptake into the trypanosome and killing of the parasite.

Increasing Access to Specialty Services in Community Health Centers: Policy Alternatives and Implications for Minority Communities

Emily Peng, Ramsey Scholar
Dr. Toni Miles, Gerontology, College of Public Health

Community health centers (CHCs) are federally-funded clinics that provide primary outpatient care to the country's most vulnerable communities. Because a significant portion of their patients are uninsured, insured by Medicaid, or from a racial or ethnic minority, CHCs play an important role in reducing health disparities. Despite their success in providing comprehensive preventive and primary services, CHCs are limited in their provision of specialty care. In a survey conducted by the Commonwealth Fund in 2008, 71% of 800 surveyed CHCs struggled to provide specialty services for patients insured by Medicaid, and 91% of the same centers reported difficulty in arranging specialty services for their uninsured patients. Barred access to necessary specialty services for a large segment of the population already suffering from health disparities holds drastic socioeconomic consequences. These include decreased workforce productivity and the overcrowding of emergency rooms. The current method of specialty care coordination where CHC providers use personal networks to solicit charity services is unsustainable. These informal referral networks require labor-intensive coordination and are extremely sensitive to economic recessions. Through extensive literature review and policy analysis, this paper proposes a two-pronged alternative to increasing access to specialty care in CHCs. CHCs located in remote areas without access to public hospitals should hire specialists on site, and those located in communities with public health infrastructure should engage in partnership contracts to

share resources. By increasing access to specialty care, CHCs can not only improve patient outcomes but also reduce the socioeconomic consequences of health disparities in the United States.

The Fever for Progress: Yellow Fever in 19th and 20th Century Havana and Savannah

Rachel Pérez, CURO Honors Scholar, CURO Graduation Distinction
Dr. Reinaldo Román, History, Franklin College of Arts & Sciences

Yellow fever outbreaks in late 19th century Havana, Cuba and Savannah, Georgia provide effective backdrops for examining the divergence of folk and professional healing. The epidemics both affected and reflected the demotion of certain religious and folk institutions to the status of outdated entities and concurrent elevation of biomedical science as a more modern and, therefore, superior mode of interpretation. These shifting attitudes are seen in the standardization of medicine, refinement of biomedical rhetoric, and labeling of religious folk healing practices as archaic superstitions. Besides yellow fever outbreaks, Havana and Savannah both experienced costly independence wars, reliance on the shipping industry, and considerable Catholic influence. The U.S. Federal Government did little to rectify the situation in post-epidemic Savannah, but seized on the Havana outbreaks as a means of demonstrating U.S. superiority and proving the necessity of intervention in order to bring modernity to the island. In both cases, civic institutions like the Catholic Church, the Savannah Benevolent Association, and *clínicas mutualistas* played significant roles in addressing the epidemics, particularly when governmental response was inadequate. These institutions faced the challenge of maintaining certain principles without appearing obsolete impediments to progress. This project deploys primary sources drawn from the archives of the Savannah Benevolent Association, the Catholic Church, 19th century medical literature, and military and government reports to offer a comparative account of the American "sanitation empire" from the 1870s to 1900s. The analysis reveals the role of religious and other non-state actors in modernization campaigns that are usually credited to the state.

Embodied Energy Requirements for Meat Calorie Versus Non-meat Calorie Production: A Comparative Study of Nine Countries

Miriam Perryman
Dr. John Schramski, College of Engineering

Energy return on energy investment (EROI) analyses have been performed on various societal and biological processes since the 1970s to evaluate energy efficiencies. If the system requires more energy to build or operate than it eventually returns, it is either inefficient or will soon cease to exist. This emerging method of analysis has been particularly useful in evaluating the efficiency of human food systems (e.g., energy invested versus dietary calories (Calories) produced). Given that upstream energy inputs (i.e., embodied energy) for meat and non-meat food products are very different (meat typically requires significantly more energy to produce), we propose a modified ratio of the embodied energies required to produce a society's meat versus non-meat food products. This would serve as a modern metric with expanded capabilities of quantifying a society's energetic efficiencies, its potential affluence, and overall nutritional quality of its diet. We either calculated the EROI of food systems or used existing EROI studies, along with additional data, to calculate meat to non-meat embodied energy investment ratios in nine countries. This value was plotted against each country's physiologic density (arable land per person), percent meat in diet, and annual Gross Domestic Product (GDP), thus providing quantified geographic,

social, and economic measures of that country's food supply system. We reveal that there is a notable correlation between this new metric and the other three measures studied. This may be significant as an additional application for EROI studies of food systems as a gauge of the overall status of a country.

Traditional and Environmental DNA Detection of a Rare Amphibian

Todd Pierson, Foundation Fellow
Dr. John Maerz, School of Forestry & Natural Resources

Much conservation attention has been directed towards the amphibian declines of the last several decades, but biologists wishing to study these amphibians are often faced with the difficulty of low detection rates. The Patch-nosed Salamander (*Urspelerpes brucei*) was discovered in Georgia in 2007 and is still found in just a dozen streams across a 7 km2 area. In order to develop a plan for the management of this species, we used leaf-litter traps to quantify the detect rate and understand fine-scale occupancy of *Urspelerpes* across its small range and additionally recorded data on all sympatric salamander species. *Urspelerpes* was found to have a stream-level detection rate of just .0476; when compared with the detection rates of sympatric salamanders (e.g. *Desmognathus quadramaculatus* at .9524), it is evident that *Urspelerpes* has a relatively low detection rate which is capable of hindering monitoring efforts. Motivated by these findings, we pursued an alternative means and developed an 'environmental DNA' assay—a relatively new method which allows for the detection of an animal indirectly through the detection of its DNA in the environment—to attempt to more effectively detect *Urspelerpes*. Here, we present the results of the leaf-litter trapping experiment and preliminary results of the environmental DNA sampling, and we compare and contrast the efficacy of these two methods. The results of this study have implications beyond the conservation of *Urspelerpes* and will be used for the further development of environmental DNA studies with other aquatic Appalachian salamanders.

Examining the Rates of Development of Manipulation and Nut Cracking Skills in Juvenile Bearded Capuchin Monkeys

Anakela Popp, CURO Summer Fellow
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Bearded capuchins, *Sapajus libidinosus*, crack nuts using stone tools. Juveniles are not taught to crack. Instead, they observe adults cracking and practice manipulation and percussion of nuts and other objects for several years. We were interested in whether the rates at which young monkeys manipulated nuts changed as they got older. We collected data on a wild group of bearded capuchins (N = 20) in Piauí, Brazil. For 10 juveniles, we cataloged the behavior of each juvenile and its neighbors for multiple 20 minute observation periods during June – July in 2011 and 2012. In this report, we focused on three behaviors: manipulation of nuts and shells, all percussive activity, and striking a nut with a stone. We analyzed the difference in rates from 2011-2012 for these behaviors when one or more of the focal monkey's neighbors were cracking nuts, and when no neighbor was cracking. We found no consistent directional change for these variables, but large changes across years for the four older monkeys (from 3.5 to 4.5 years or older) for all manipulation, and large increases in percussion for the 3 youngest monkeys (from .5 to 1.5 years), especially when no others were active. Overall, these results show no significant change in rates of percussive and striking behavior from 2011 to 2012 except for the youngest monkeys, and group activity did not alter the pattern. It appears that social context does not consistently affect the magnitude of the change in the component behaviors.

The Few. The Proud. The Marines.

Alexandra Prather
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

This paper explores the history, meaning, cultural significance, and material properties of the Marine Corps dress uniform. My research was conducted through academic books and journals, miscellaneous references, and an interview with a Marine Corps officer. My research demonstrates the importance of understanding each part of the Marine Corps uniform as well as explaining the culture and historically rich meanings that each detail represents. My study also shows what type of person is qualified to wear the Marine Corps uniform. I discuss the rigor of the process and competition required to become part of the highly selective Marine Corps. From my research I have concluded the true meaning and significance of being a Marine soldier and how wearing the uniform influences their personal and professional lives. Each detail of the uniform represents a part of the Corps' 237-year-old history. The United States Marines not only proudly fight and work for worldwide freedom, but also make a strong effort to honor all fallen Marines that came before them. An example of this is the 'blood stripe' down the pant leg of officers' uniforms, which represents the Marines before them. A better understanding of the Marine Corps culture as well as their perfectly tailored uniforms is a way, especially for American citizens, to have a greater sense of respect and pride for all that the uniform symbolizes and represents and what these service members do for the country.

"Is Black So Base a Hue?" An Examination of Aaron and Racial Dynamics in *Titus Andronicus*

William Prigge
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

Since the seventeenth century, critics have denigrated Shakespeare's *Titus Andronicus* for its excessive violence, both physical and linguistic, so much so that in 1687 Edward Ravenscroft decided to adapt the play into a much tamer version that superseded Shakespeare's in performance for over a century. Amid critics' ever-present discussion of the atrocities of the play, however, the more important issue of race is often overlooked; in the character of Aaron the Moor, the play's main antagonist, Shakespeare presents a racial Other who revels in his Other-ness, allowing for a variety of interpretations in performance. As such, Aaron serves as the focal point of my research, an instrument and exemplar of racial relations. After searching the play's production history, I narrowed my scope to three stagings of special interest: Ira Aldridge's 1849 rewrite, Dieter Reible's 1970 Cape Town production (in which a white actor plays the role of Aaron), and Gregory Doran's 1995 *Titus Andronicus* in Johannesburg. Examining first-person accounts of specific performances and production notes from people involved in the creative process—particularly in regards to the portrayal of Aaron and his race as compared to others around him—revealed three radically different interpretations. These interpretations range from Aaron as protagonist to a focus on absolute segregation to a somewhat unclear reflection on the arbitrary nature of race. Nonetheless, all three hold a message for the societies in which they were performed, ultimately pointing to the artifice of racial division and questioning such social constructs in three separate cultures.

Discover Life Mothing Project

Cameron Prybol, CURO Summer Fellow
Dr. John Pickering, Odum School of Ecology

Weather patterns and seasonal cycles are known to play major roles in insect development and regulation, although there is little data to understand how various climate shifts may affect species populations. Lepidoptera are an incredibly diverse taxon, with 165,000 known species and an estimated 100,000 species yet to be described. They are also easy to work with, as they are harmless, attracted to lights, and readily identifiable from photographs. Study sites have been established in Athens, GA and Monteverde de San Luis, Costa Rica to sample Lepidoptera populations on a nightly basis. The Athens site, established in Spring 2010, has collected 87,404 data points to date, 66,650 of which have been identified to 856 species. The Costa Rica site, established in May 2012, has collected 49,858 data points to date, 20,822 of which have been identified to 606 species. Nightly data is collected by photographically documenting each specimen present at each study site. Photos are uploaded to the DiscoverLife database and identified to species, providing safe, efficient, and reliable data storage and analysis. Data is compared to local weather station readings and evaluated across years to show species distribution, relative abundance, phenology, and voltinism. These sites are providing insight into how weather patterns affect species in both temperate 4-season climates and tropical dry/rainy-season climates. Understanding the intricate behavior of insect life cycles holds tremendous implications for agriculture (pest insects), public health (disease vectors), and conservation (population health).

Extending Genetic Methods to Members of the Genus *Caldicellulosiruptor*: Use for Metabolic Engineering Biofuel Production from Biomass

Alyse Ragauskas
Dr. Janet Westpheling, Genetics, Franklin College of Arts & Sciences

Members of the bacterial genus *Caldicellulosirptor* are thermophilic anaerobes that grow optimally at 78°C and are the most thermophilc cellulolytic organisms known. Members of this genus vary in their ability to use different types of unpretreated lignocellulosic biomass and have the potential to produce biofuels and chemicals directly from plants like switchgrass and populus. Our lab recently reported the first methods for genetic manipulation of *C. bescii* and here we report methods for extending those genetic methods to other members of the genus. We have isolated a spontaneous deletion of the *pyrF* gene in *C. hydrothermalis* allowing genetic selection of transformants and engineering of this strain. We generated the mutant by growth at four different temperatures 55°C, 60°C, 68°C, and 75°C and after growing the cells to the same density, the cells were plated on uracil (required for a *pyrF* deletion) + 5-FOA that selects against the wild type copy of *pyrF*. The mutants are 5-FOA resistant and uracil auxotrophs allowing selection and counter selection of the wild type *pyrF* gene. PCR was used to screen mutant colonies for deletions and we identified one with a 100bp deletion. We will use a plasmid vector containing the wild-type *C.bescii pyrF* gene to establish transformation protocols for *C. hydrothermalis*. This strain has some advantages for metabolic engineering for ethanol production and our ability to genetically manipulate this strain will allow us to investigate its use for biofuel production.

Democratic Peace Theory-An Accurate View or Team Alliance

Nicholas Ramos-Franklin
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

Democratic Peace Theory is a prominent aspect of International Relations claiming that democratic states do not engage in interstate warfare. The theory is furthered by scholars such as Francis Fukuyama and Immanuel Kant who state that democracy is the highest level of political development, that eventually states will converge on this government type, and that world peace will be extant. This paper will attempt to determine if this theory is relevant only with democracies, or if there is empirical evidence supporting a Communist or Socialist Peace Theory. The paper also attempts to test the Democratic Peace Theory by focusing on alliance politics and more specifically the idea that democratic governments face a common ideological enemy in communist and socialist states. The paper will explore this topic by case study analysis of interstate warfare in the last 80 years. The paper also will compare and contrast warfare between states with the same government type and create a statistical analysis of the occurrence of war between states with the same form of government. This paper is important because it introduces the viability of peace theories in various government forms and poses the possibility that democratic peace depends on the alliance against competing forms of government. Finally, the paper raises the question that, if all states were democratic, would conflict arise for other reasons because there is no longer a common enemy in government types?

Algae Biomass Production Using Compost Leachate Water and Evaluation of Biomass Harvesting Techniques

Nicholas Richwagen, CURO Summer Fellow
Dr. K.C. Das, College of Engineering

Algae-derived biofuels, possible alternatives to fossil fuels, are presently too costly for widespread use. Costs associated with algae production and harvesting have to be minimized for algae biofuels to be economically viable. Waste-water sources can be rich in nutrients and easy to obtain, and are therefore a desirable alternative to constructed media for algae growth. Additionally, filtering collection methods could potentially lower the costs of harvesting. A local leachate-pond provided sufficient nutrients for algal growth, and indigenous algae strains were explored for growth potential. Pond growth was monitored by daily optical density and total suspended solids (TSS) tests. The leachate water and its algal community only provided substantial biomass when regularly supplemented with conventional green algae species. Prepared filtration collection systems showed mixed benefits over the centrifuge. Incidental herbivorous organisms (rotifers*, chironomid larvae*) had a detrimental effect on growth. The leachate water and its indigenous alga community could not provide the desired biomass on its own. Further work with filter harvesting could support using filter systems at certain production scales. Problems with microherbivores reflect problems faced in algeaculture worldwide with antagonistic organisms.

Identifying Possible Roles for Structural Proteins in Thymus Morphogenesis

Krista Ritchie
Dr. Nancy Manley, Genetics, Franklin College of Arts & Sciences

Foxn1 positive thymus and Gcm2 positive parathyroid originate from third pouch endoderm. While it is known that this endoderm first resembles columnar epithelium, tissue structure changes as the thymus and parathyroid undergo morphogenesis, and little is known about how structural proteins are involved in these changes. My preliminary work shows that Z0-2 and Integrin beta-2 are present in the thymus. By observing changes in these

proteins, possible roles have been identified throughout thymus development. My results show that Integrin beta-2, a cell-surface protein, may have specific functions in TECs at later stages, which suggests that the protein could be required for cell adhesion during T-cell differentiation and/or thymocyte migration. Z0-2 is a structural protein found in epithelial cell junctions. By co-staining Z0-2 with a variety of cell markers, it can be concluded that the prenatal structure changes from cell clusters to a postnatal vasculature-type structure. In the present study, data has been collected to determine the presence of both Integrin beta-2 and Z0-2 in TECs, thymocytes, vasculature, or cell subpopulations of the thymus in order to support the working hypothesis that these structural proteins have specific roles during thymus development.

Melt Inclusion Study of the East Fork Rhyolite Member of the Valles Caldera, New Mexico

Abigail Saenger
Dr. Michael Roden, Geology, Franklin College of Arts & Sciences

Volcanic eruptions are a major societal threat in the western US, as well as around the world. The study of magmatic melt inclusions trapped in igneous crystals can record the events that trigger explosive eruptions, such as mixing of mafic and felsic magmas. Valles Caldera, NM was the site of a catastrophic eruption at 1.14 Ma, followed by eruption of the East Fork Rhyolite (EFR) lava domes and pumices between 55 and 40 Ka; these relatively younger eruptions may be precursors for a more catastrophic eruption. In order to determine whether magma mixing occurred in the EFR magma chamber, I analyzed the chemical composition of melt inclusions within plagioclase grains in samples taken from lavas and pumices of the EFR. Melt inclusions represent melt trapped at the time of the host grain crystallization, and evidence of two melt compositions should be preserved if magma mixing occurred. I analyzed the inclusions using the electron microprobe in the UGA Department of Geology. Melt inclusion concentrations of FeO, Al2O3, MgO, CaO, Na2O, and K2O were plotted against SiO2 and compared to the plagioclase compositions in order to preclude contamination from the host grain. Textures such as hornblende-rimmed orthopyroxene and sieve-textured feldspars are evidence of chemical disequilibrium, which can be an indicator of magma mixing. However, oxide variation diagrams for the melt inclusions do not show a clear bimodal grouping expected from the presence of two melt compositions. These geochemical data suggest that simple magma mixing was not a significant process within the EFR.

The Epistle of James: Discovering its Conception of Faith and Works and its Call for Social Justice

Adam Samples
Dr. Wayne Coppins, Religion, Franklin College of Arts & Sciences

The Epistle of James is one of the seven Catholic Epistles in the New Testament, traditionally attributed to James the Just, the brother of Jesus. The epistle's teachings on faith and works have been among the most debated theological issues in Church history. In my research, I will look to the historical and literary context to understand the distinctive voice of James regarding faith and works, and I will also investigate his call for social justice. James' ideas regarding faith and works, his egalitarian, communistic worldview, and his idea of the "true religion" (James 1:27), I will argue, express a universal call for a reversal of traditional social constructs. It becomes clear that when one truly assesses the importance of James, it has a broader and more significant role in defining the Christian life than has often been credited to it; moreover, rather than being confined to the religious sphere, the epistle can be seen as

a valuable resource for the broader task of addressing social justice in today's world.

Chinese Foreign Direct Investment in the United States: A New Game

Aveek Sarker, CURO Honors Scholar
Dr. William Keller, Center for International Trade & Security, School of Public & International Affairs

In the past, foreign direct investments flowed predominantly from the "developed world" to the "developing world." Those flows are continuing, but China is now taking a lead role in seeking to invest in ventures around the world through mergers, acquisitions, and greenfield investments. Current trends indicate more than 1 trillion dollars in direct Chinese investment will flow worldwide by 2020, a significant share of which will be destined for advanced markets such as the United States. Chinese firms have already established operations in 35 states and across dozens of industries including energy, telecommunications, and industrial machinery, creating approximately 30,000 jobs. How the United States responds to this new reality will have enormous consequences for its own economic future and for both its business and political relationship with China in this new era of global finance. In undertaking this study, my purpose is to better understand the broader implications of increasing amounts of Chinese FDI in the United States and across the world to determine how they will affect the geopolitical balance of power in the near future. My methodology includes compiling time series data to analyze the distribution of investments by region, sector, and industry in addition to examining specific case studies and business deals to evaluate the various benefits and security risks that such incoming investments pose. By doing so, I will have contextualized the many implications of this emergent trend- one that will work to define the socio-political relationship of the world's two largest economies in the coming decades.

The Future of Lyme Disease: Virulence Determined by Climate

Scott Saunders
Dr. Andrew Park, Odum School of Ecology

How will vector-borne diseases change in the future under different climate change scenarios? Lyme borreliosis is the most prevalent vector-borne disease in North America and is caused by the bacteria *B. Burgdorferi*. The bacteria is spread and maintained in hosts by a vector, the black-legged tick, *I. Scapularis*. There are many different strains of *B. Burgdorferi* that generally employ either a 'rapidly clearing' or 'persistent' strategy when infecting hosts, and there is an existing model that simulates competition between these two phenotypes in a host population. The outcome of this competition depends on the difference in activity between the larval and nymph stages of *I. Scapularis* in a given season. This time delay is best predicted by the amplitude of the annual temperature cycle of a given region. Although previous studies have examined future distribution of ticks and host species, none have examined the future distributions of the different bacterial strains. Using climate predictions for the Southeast for the year 2050, this project connects these components and creates a map of predictions for the strain of *B. Burgdorferi* for each county. This data will be useful because only the persistent strains of bacteria are commonly associated with human Lyme disease cases. Early results show that most of the Southeast should favor bacteria with 'persistent' phenotypes, yet currently this region reports few incidences of Lyme borreliosis in humans.

Non-canonical CaaX Motifs Can Drive Protein Isoprenylation

William Saunders III, Colby Ruiz, CURO Honors Scholar
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

This study explores the possibility of longer non-canonical CaaX motifs. Based on the findings of Kho, et al. it was hypothesized that longer CaaX motifs may be biologically relevant. A thorough understanding of CaaX proteins and how they are post-translational modified is important because CaaX proteins are of significant biomedical relevance. For example, mutated Ras proteins, members of the CaaX family, are associated with 90% of pancreatic cancer, 50% of lung cancer, and 30% of all cancers in humans. This study was conducted using yeast as a model organism and the production of a-factor as a reporter to investigate the functional potential of extended CaaaX motifs. Over the course of the study, nearly 40,000 recombinant colonies were screened and 24 of those colonies tested positive for production of a-factor. Upon retesting to validate the positive hits, only eight retested positive. Based on the collected data, it appears that the longer CaaaX motifs may be biologically relevant.

Using Next Generation Sequencing to Identify Unique Sequence Types Associated with Gravidity-based Immunity in Placental Malaria

Stephen Scott
Dr. David Peterson, Infectious Diseases, College of Veterinary Medicine

Even with a global effort to eliminate malaria, the disease caused primarily by the parasite *Plasmodium falciparum* continues to threaten entire regions of the world, particularly pregnant women and newborns living in sub-Saharan Africa. In 2010 alone there were 215 million clinical cases and 655,000 reported deaths due to malaria. In pregnant women, *P. falciparum*-infected red blood cells accumulate in the placenta by adhering to receptors on fetal cells called synthiotrophoblasts. The parasite ligands and host receptors that mediate cytoadherence have been extensively investigated, resulting in the discovery of a protein encoded by a single member of the highly polymorphic *var* gene family called *var2csa*. During placental malaria (PM), *var2csa* mediates binding of infected red blood cells to synthiotrophoblasts in the placenta. We have recently completed a project assessing the *var2csa* diversity in Kenyan placental samples, which has important implications for the development of immunity to PM. We used nested PCR and applied high-throughput DNA sequencing and bioinformatics analysis to these samples for which clinical information including placental pathological state are known. As a result, we were able to identify gravidity associated immunity and unique sequence types. This information will be critical for the development of a PM vaccine.

***Pseudo-nitzschia* in the Diet of *Paraprionospio pinnata*, a Polychaete in the Gulf of Mexico Hypoxic Zone: Potential Mechanism for Toxin Bioaccumulation**

Chelsea Sexton
Dr. James Byers, Odum School of Ecology

Anthropogenically-derived riverine nutrients stimulate spring phytoplankton blooms, including the potentially toxic diatom *Pseudo-nitzschia spp.*, over the continental shelf waters in the northern Gulf of Mexico. Cells of *Pseudo-nitzschia spp.* that are not grazed in the upper water column sink to the seafloor and likely contribute to the carbon that fuels bottom-water hypoxia. Opportunistic polychaetes are essential members of the marine benthic community in areas affected by low oxygen conditions. With better survival in hypoxic bottom conditions (≤ 2 mg L-1 dissolved oxygen) than most infauna, they play a year-round role in benthic-pelagic

coupling and transfer of organic matter to upper trophic levels. We collected the polychaete, *Paraprionospio pinnata* at a station 100 km west of the mouth of the Mississippi River monthly from Aug 2003 to Oct 2004 to determine their gut contents. *Pseudo-nitzschia spp*., which are capable of producing the neurotoxin domoic acid, comprised 2.8% ± 1.0% (n=27) of the total diatoms consumed per polychaete. The presence of intact cells of *Pseudo-nitzschia spp*. on the sediments and in *P. pinnata* gut contents supports the inference of the dominant polychaete in this hypoxic area as a potential vector of domoic acid to upper trophic levels.

The Unpublished Letters of Elizabeth Bishop

Fiona Sheehan
Dr. Susan Rosenbaum, English, Franklin College of Arts & Sciences

Elizabeth Bishop was one of the most important poets of the 20th century, yet she only published 100 poems in her lifetime. Most of her biography comes from her letters. My grandmother, Rhoda Wheeler Sheehan, and Bishop were lifelong friends, and Rhoda was one of her closest friends during the last decade of Bishop's life. My research examines the biographical and literary significance of 49 unpublished letters and postcards from Bishop to my grandmother, sent between 1969 and 1979. Additionally, this collection of correspondence is one of the largest from this period in her life. I will summarize research from my directed reading through a PowerPoint with slides of Bishop, Rhoda, and several key letters. I analyzed their literary and biographical significance, researched my grandmother and Bishop's relationship, and researched scholarly opinion of letter-writing and postcards as an art. I found that at times Bishop used correspondence to generate material for her poems and to engage her correspondents in a collaborative, creative effort. Additionally, my letters are artful in their own right: many poetic descriptions and even a drawing are woven into Bishop's letters, something rare for her to include in correspondence. The letters also provide insight into events Bishop was thinking about at the time—from Indian land settlement claims to US space laboratories falling to earth. This semester I continue my research in the form of a senior thesis. This summer I will write and submit my research for publication.

Effects of the Amazon River Plume on Subsurface Waters: Measuring the Effectiveness of the Plume's Uptake of Atmospheric CO_2

Megan Sheehan
Dr. Patricia Yager, School of Marine Programs, Franklin College of Arts & Sciences

The Amazon River plume is an important biological pump for the Atlantic Ocean, acting as a sink for atmospheric CO_2, and providing an important mechanism to counteract increasing amounts of CO_2 in the Earth's atmosphere. This study is centered on the question of how effective the plume is in sequestering atmospheric CO_2. To quantify this, water samples were taken from the plume's surface and subsurface waters. Bacterial respirations were measured from this water by measuring the amount of dissolved inorganic carbon available in the water after incubation. This study is proposing that the surface plume bacterial respiration rates are affecting the subsurface plume bacterial respiration rates. If indeed there is a trend between the surface and subsurface bacterial respiration rates, this will be an indicator that the bacteria at the surface of the plume are sinking atmospheric CO_2 and the subsurface bacteria are using it. Surface respiration rates within and around the plume have already been analyzed and show a strong relationship between bacterial respiration rates and salinity of the water. Low salinity water, or freshwater, has high respiration rates, and high salinity water, or ocean water, has lower respiration rates. The remaining subsurface

bacterial respirations will be compared to the surface respiration rates, and a trend between them will be determined. If there is no trend, then other factors, such as chlorophyll and nutrient availability, will be examined with the respiration rates in order to see if another relationship is available between the surface and subsurface plume waters.

Searching for the Minimal Segment of Alpha Toxin Necessary for Binding to GPI-anchored Proteins on Cancer Cells

Collin Shumate
Dr. James Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Ovarian cancer is one of the more difficult cancers to diagnose because symptoms do not arise quickly and because tests are currently quite invasive for a simple check-up. Our research aims to contribute to diagnostics of cancer by exploiting the differences in cancer cells from healthy cells. Cancer cells over-express genes that cause the cells to produce certain GPI-anchored proteins, which anchor to the outside of cells. Because the genes are over-expressed, GPI-anchored proteins are elevated in these cancers, such as breast carcinoma and ovarian cancer. Alpha toxin is a protein of interest that binds to GPI-anchored proteins. It is structured similarly to aerolysin and they function and bind to GPI-anchored proteins much in the same way. I am using PCR amplification of the alpha toxin DNA to produce a variety of lengths of alpha toxins to perform binding assays with GPI-anchored proteins. Our research aims to find the minimal portion of alpha toxin needed to bind to GPI-anchored proteins so that diagnostic assays can be developed by taking advantage of alpha toxin without the toxic functionality being expressed.

Self-control in the Workplace: The Relationships between Self-control and Perceived Task Difficulty

Lane Siedor
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

Recent research suggests that managers delegate more tasks to people with high self-control. Furthermore, they are less likely to reward people with high self-control for high quality work. The purpose of the present work was to test the hypothesis that managers underestimate how difficult tasks are for people with high self-control. Participants (N = 120) were recruited from an undergraduate research pool. Participants were randomly assigned to either an actor role or an observer role. The actor was designed to simulate an employee and the observer to simulate a manager. Both participants completed questionnaires that provided background information and a typing task, in which they followed complicated instructions in retyping a text. The actor completed an eight-minute version of the typing task while the observer typed a brief paragraph, enough exposure with the task to assess how hard the full-length version might be for someone else. Then, the observer was given false information about the actor's self-control and asked to make predictions about how difficult the typing task was for the actor. The self-control information was randomly assigned so that half of the actors were presented as having high and half as having low self-control. Additionally, actors reported how difficult they found the task and we assessed their state self-control levels objectively using a Stroop task. Preliminary results support our hypothesis. The observers thought the task was easier for actors believed to have high (vs. low) self-control. However, actors with high and low self-control reported the task to be equally challenging.

Characterization of an RNA-protein Immune Complex Functioning in Prokaryotic Viral Defense

Cole Skinner, CURO Honors Scholar, CURO Summer Fellow
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

CRISPR-Cas (Clustered Regularly Interspaced Short Palindromic Repeats – CRISPR associated) systems provide bacterial and archaeal organisms with genetically based, heritable defense from nucleic acids of viruses or other genomic invaders. In a CRISPR-containing host, Cas proteins bind invader-derived crRNAs (CRISPR RNAs) produced from the CRISPR locus to form crRNPs (CRISPR ribonucleoproteins), which provide the primary line of defense against invaders. At least ten structurally and functionally diverse CRISPR-Cas immune systems have been discovered that each consist of specific Cas proteins and associated crRNA species. The objective of my work is to characterize the structure and function of a previously uncharacterized immune system (the *Tneap* complex) from the hyperthermophilic archaeaon, *Pyrococcus furiosus*. Our evidence indicates that the *Tneap* complex is comprised of four Cas proteins (Cas5t, Cst2, Cst1 and Cas3) and a specific crRNA form that has a functionally important sequence element (called the 5' tag). To gain a detailed understanding of the structural organization and function of the *Tneap* immune complex, we attempted to reconstitute these complexes *in vitro* from recombinant, purified *Tneap* Cas proteins and synthetic crRNAs. Using native gel electrophoresis mobility shift assays, I observed 5' tag-specific binding of the *Tneap* proteins to a crRNA to form specific crRNP complexes. Moreover, I found that the assembled crRNP stably associates with complimentary DNA targets (that mimic viral sequences). Further characterization of this CRISPR-Cas system could contribute to ongoing work to develop CRISPR-based technologies with important industrial and biomedical applications.

Multiple Marlows: Intertextuality and Irony in Conrad's Marlow Tales

Samuel Smith
Dr. Adam Parkes, English, Franklin College of Arts & Sciences

Joseph Conrad wrote four texts featuring Charles Marlow as a first-person narrator: "Youth" (1898), *Heart of Darkness* (1899), *Lord Jim* (1900), and *Chance* (1914). Conrad's redeployment of Marlow raises several questions. How does Marlow function as both a narrator and a character in each individual text? How are each of his incarnations related to those in the other three works? To what degree is it valid to read the Marlow of one text as being continuous with the Marlow of another? All of these questions deal with intertextuality, a theoretical concept that is concerned with the way in which—and the extent to which—texts depend on other texts to generate meaning. I will approach these questions by investigating Conrad's use of Marlow as an ironizing narrator and an ironized character, both in each text and in the collection of these four texts. I see Conrad's redeployment of Marlow as a conscious move to separate the Marlow texts from his other works, effectively indicating that we should read them together. However, at the same time, Conrad's decision to create four works that can stand on their own indicates that they can and should be read on their own as well. I will argue that while both ways of reading the four Marlow texts are valid, holding each reading in tension with the other produces an effect that deepens the ironic meanings of both the individual texts and the ironic project that is the collection of the four texts.

The Black Youth Vote in the 2012 Presidential Election: Disillusioned or Reenergized?
Elijah Staggers
Dr. James Bason, Vice President for Research Services, Vice President for Research Units

This research project investigates the political attitudes of the black youth vote in the 2012 Presidential Election between Barack Obama (D) and Mitt Romney (R). Research suggests that African American youth voters recorded the highest increase in voter turnout during the previous 2008 Presidential Election. I will attempt to establish a continued trend in voter political participation and optimistic political attitude of this demographic for the 2012 presidential election. I will also attempt to prove the existence of a "shared identity" between Barack Obama and the minority youth vote. This specific question will also shed light on a larger political question, whether the debated success of Barack Obama's policies during his first term in office have disillusioned a voting bloc which he strongly retained in 2008. The method of this research involves the distribution of a survey to gauge the political attitude of the black youth vote approaching the 2012 Presidential Election. The data yielded evidence to suggest a continued trend in African American youth voter support of Barack Obama, with 67% of African American youth describing their political attitude as "enthusiastic," 76% of African Americans viewing Barack Obama's first term policies as successful, and 95% of African Americans youth holding a "shared identity" with Barack Obama. This research demonstrates that despite criticism of Barack Obama's policies, the African American youth demographic still unilaterally supports him. Moreover, it reveals a trend in voting behavior, evidencing a positive correlation between that high level of support and a "shared identity" and political attitude.

Body Size and Temperature: A Report on Moth Activity in Clarke County
Victoria Staples
Dr. John Pickering, Odum School of Ecology

Because insects are ectotherms, their activity depends on temperature. We hypothesize that the flight activity of smaller moths will be more affected by temperature than the flight activity of larger moths. To test this hypothesis, a data set of 71,000 photographs of moths will be analyzed. In this study, a community of moths was attracted to a study site in Clarke County, Georgia and documented nightly, in photographs, for two years. Of these photographs, 93% of moths have been identified to more than 850 species, and most photographs contain rulers from which wing size may be measured and used as a proxy for body size. We will present an analysis of this data set and a weather data set collected by weather stations at the Ben Epps Airport and in Winterville, Georgia to correlate body size and flight activity with temperature. A natural experiment such as this may aid in the understanding of moth communities as they are affected by global climate change.

Sitcom Technology through the Ages
Jared Stepp
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

Media technology has changed drastically over the years; we've gone from hand cranks and film reels to computers and digital effects, grainy black and white to vivid high definition, and each day we build new technologies that promote innovation and bolster the creativity that we see on television from the comfort of our own homes. My project is to track these changes through the use of Russell Special Collections Library's Peabody Award winners, to create a standard for comparison. Our favorite shows like *Modern Family* use these developing technologies to enhance their storytelling. My

area of focus is the technology used at the time, and how it shaped the potential of the show—if the show was filmed in front of a live audience, the opportunities for quick camera maneuvers are lost; if the show is recorded in high definition, special considerations need to be undergone for makeup and costume design, etc. Sitcoms are one of the greatest flagships for our history; they represent the trials we face in our modern lives. The area of relevance to current events helps signify the state of technology and the limits that are held within. I recorded a digital narrative to show the progression of many features, including several scenes that best represent them. I begin with the early stages of single-shot studio audience sitcoms and progress to modern day multi-camera sitcoms, closely analyzing the range of camera, sound, directing, and acting capabilities brought forth by the developments in sitcom technology through the ages.

Developing Methods to Locate and Survey for Rare Species: a Case Study Using the Endangered Bog Turtle (*Glyptemys muhlenbergii*)

Theresa Stratmann
Dr. John Maerz, Warnell School of Forestry & Natural Resources

North America's smallest turtle, the bog turtle (*Glyptemys muhlenbergii*), is listed as threatened under the Endangered Species Act, mainly due to habitat loss and deterioration. Cryptic and rare, this species is difficult to find and consequently many states are still in the process of locating bog turtle populations. To aid this cause we are (1) developing a species distribution model (SDM) to better identify areas in the landscape suitable for bog turtles, and (2) use a mark/recapture study to determine the best trapping methodology and minimal effort required to estimate bog turtle presence/absence at a site, ultimately designing a step-by-step process for state agencies to locate and survey for bog turtle populations. A preliminary SDM, using MaxEnt, indicates that elevation, distance to wetland, slope of the landscape, and maximum temperature of warmest month are best at predicting suitable bog turtle habitat. By overlaying the model with topographical maps, satellite imagery, and known bog turtle sites, areas to survey will be located and prioritized. One season of mark/recapture data from 8 Georgia bogs, using a standard trapping density, shows that detection probabilities at the bog level, as calculated in Program MARK, ranged from 0.05 to 0.01. This detection probability will then be used to determine trapping effort required for each site. Combining these parts, this project gives state wildlife agencies an efficient methodology to locate and survey for bog turtles, but more generally, it is a case study that contributes to refining how biologists survey for rare and cryptic species.

For the Love of God: Damien Hirst and a Room with a Corpse

Emily Stubbs
Prof. Isabelle Wallace, Lamar Dodd School of Art, Franklin College of Arts & Sciences

In order to meaningfully reframe the issue of western religion in contemporary art, this paper explores the religious implications of Damien Hirst's work involving dead animals. Western religion and art have a long, flourishing history together. In the Age of Enlightenment, however, God became more abstract, the world became more secular, and production of religious art markedly decreased. In recent years, religion has become entirely estranged from the art world. Many artists and art historians claim that religion has no place in contemporary art. Despite such claims, there are a number of celebrated artists whose work clearly engages with religion. In *Postmodern Heretics: The Catholic Imagination in Contemporary Art*, Eleanor Heartney expounds on the relationship between postmodern art and the Catholic imagination. While there is validity to her argument, the framework Heartney lays out is

limited, not accounting for the entire picture. Although Damien Hirst's work confronts death as does Andres Serrano's *Morgue* series, Hirst's clean, scientific aesthetic, reminiscent of minimalism, seems diametrically opposed to the sense of Catholic morbidity that Heartney asserts in Serrano's work. Nonetheless, Hirst's work – in its use of dead animals, formaldehyde, and the vitrine – stages impulses that are religious. *The Physical Impossibility of Death in the Mind of Someone Living*, perhaps Hirst's most famous work, beckons viewers to reflect upon their own projections of death. Criticisms of Hirst's financialization of art notwithstanding, Damien Hirst's provocative engagement with western religion is significant of a much greater current within contemporary art that remains insufficiently examined.

The Characterization of F-actin/34kDa Binding Sites and Their Contribution to the Formation of Model Hirano Bodies

Connor Sweetnam, CURO Honors Scholar, CURO Summer Fellow
Dr. Marcus Fechheimer, Cellular Biology, Franklin College of Arts & Sciences

Hirano bodies (HBs) are paracrystalline inclusions that appear frequently in autopsied brains of those affected with neurodegenerative diseases. They have been shown to play a potentially protective role in disease pathways. HBs are composed of highly ordered actin filaments. Actin, both monomeric and filamentous, is a component of the cytoskeleton that is necessary for cell shape changes and movement. Actin filaments are regulated by actin binding proteins resulting in the dynamic organization of polymerized actin. Mutations in the 34,000-Dalton F-actin Bundling Protein (34 kDa) have been shown to induce the formation of model Hirano bodies in amoeba and mammalian cell culture models. We are interested in characterizing the sites of F-actin/34 kDa interaction in order to further analyze the biochemical basis of 34 kDa regulation of F-actin and the formation of Hirano bodies. We previously identified specific sites of interaction between the two proteins by chemical cross-linking, proteolytic digestion, and mass spectroscopy. Now, using techniques in molecular biology and protein purification, we have generated point mutations of the 34 kDa protein in three F-actin binding sites. We will study the effect of these alterations on F-actin/34 kDa binding. Further characterization of this interaction could help us understand the biochemical basis of the induction of Hirano body formation.

There's Another Side to the Story: Examining the Blacklist Resulting in the HUAC Hearings of the 1950s

Ashley Thompson
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

In the 1950s, the House Un-American Activities Committee gained wide recognition for holding hearings and questioning people as to if they were members of the Communist Party. The media portrays this committee in a post-Cold War culture as heartless, due to their extreme measures for extracting information on affiliation with the Communist Party. However, every story has two sides, and I wanted to know how Americans could have participated in the 1950s witch hunts that destroyed so many lives. To answer my question, I conducted research in the Richard B. Russell Library for Political Research and Studies to learn what Senator Russell and his constituents thought of the Red Scare. Evidence demonstrates that Russell, as well as many other American citizens, had a genuine fear of warfare occurring between the United States and the Soviet Union. The measures now considered so extreme were actually a way for government officials to provide a protective barrier against Communist ideals. Materials examined include correspondence between Senator Richard Russell and his constituents

as well as submitted materials to the Senator. These materials include such items as comic books, newspapers, tracts, and sermons detailing the dangers of Communism. Results from this research provide evidence that no event in history is simple, and sometimes methods that may seem extreme after the fact were not only accepted, but encouraged at the time they originally occurred.

The Anti-Inflammatory Effects of Lipoic Acid on Inflammatory Cytokines

Lauren Titus, CURO Graduation Distinction
Dr. Nick Filipov, Physiology & Pharmacology, College of Veterinary Medicine

Dopaminergic cell death in the substantia nigra produces most symptoms of Parkinson's Disease (PD). While the cause(s) of this cell death is still largely unknown, numerous studies have demonstrated that reactive oxygen species and inflammatory cytokines, produced in activated microglial cells, damage neighboring dopaminergic neurons, possibly by triggering apoptosis. Microglia are activated by multiple factors, one of them being LPS, an endotoxin from gram(-) bacteria. My research focuses on the anti-inflammatory effects of lipoic acid (LA), an anti-oxidative fatty acid capable of passing through the blood-brain barrier. Because certain antioxidants also exhibit anti-inflammatory properties, I hypothesized that LA would decrease inflammatory cytokines produced by microglia. If neuroinflammation of microglia can be reduced by LA, then potentially the severity of PD could be lessened. In previous research, I pre-treated microglial cells with LA and then activated them with LPS. Using ELISAs and qRT-PCRS, I found that LA pre-treatment corresponds with significantly decreased transcription and expression of the cytokines TNF-α and IL-6, especially TNF- α. Western blots demonstrated that LA inhibited the activation of NF-ϰB, a key inflammatory transcription factor. My current research involves the surface molecule F4/80, which is upregulated upon microglial activation. Data from qRT-PCRs revealed that LPS significantly increases F4/80 transcription. LA (both alone and in conjunction with LPS) decreases F4/80 transcription by 15-30%, but this effect did not reach significance ($p \geq 0.10$). These results demonstrate that LA has effective anti-inflammatory properties, but its main mechanism of action occurs within the cell, not by upregulation of cell surface molecules associated with microglial cell activation.

The Women of *Richard III* Re-visited

Margaret Touchton
Dr. Lisa Bolding, English, Franklin College of Arts & Sciences

Based upon the War of the Roses, Shakespeare's historical tragedy *Richard III* is a play about the formation of the Tudor dynasty and the villain who nearly ruined it all. Many of the studies done on this play focus on the antihero, but few have focused on the women whose lineage gave birth to the female monarch, Elizabeth I. While some are quick to brush away the significance of the women in *Richard III,* there are echoes of Elizabeth's life and rhetoric in the roles Shakespeare created for her foremothers. Through analysis of the text, historical documents, Elizabeth I's speeches, and literary criticism, this study examines how various stages in her life are reflected in Shakespeare's portrayal of her foremothers' story. The play paralleled their transition from being powerless, to political tools, and finally gaining their own agency, like Elizabeth during her life. This correlation is unusual since during Shakespeare's time women had a subservient role to men. Even though England was ruled by a woman, there were few changes in the cultural attitude towards women. Thus the parallel between these women and a powerful queen not only suggests their importance in the play but also challenges societal norms by featuring strong women. The agency these women gain throughout the play has been overlooked by

existing scholarship and this study seeks to amend this problem.

Determining a Method for Pharmacologic Rescue of Mutations that Affect Tissue-specific Glycan Expression in *Drosophila melanogaster*

Brittany Truitt, CURO Summer Fellow
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Protein glycosylation is essential for cell-cell signaling, cellular differentiation, and tissue formation, yet its regulatory mechanisms are highly unknown. While examples of cell and tissue specific glycosylation are abundant among all animal species, the fruit fly, *Drosophila melanogaster*, provides an excellent tool for discovering genes that might regulate this process. In a screen for mutations that disrupt neural-specific glycosylation, we identified a gene called sugar-free frosting (sff) that affects the expression of a particular class of glycans in the embryonic nervous system. Based on genetic interactions between sff and a gene involved in the biosynthesis of biogenic amine neurotransmitters, we hypothesized that pharmacologic treatment of sff mutant embryos with anti-depressant drugs might rescue neural glycan expression. Therefore, we undertook the development of a method for delivering drugs into the embryo. Such treatment is difficult because of the numerous layers that surround and protect the embryo. The waxy layer surrounding the vitelline membrane has proven to be an especially problematic layer because it is impermeable to small molecules. Our current approach involves the use of a previously identified embryo permeabilization solvent (EPS) containing limonene, alcohol, and a cocamide mixture which may dissolve the waxy layer. Using this technique, we have succeeded in allowing a small fluorescent dye to gain access to the embryo without affecting viability. The current goal of this research is to optimize a reproducible method to allow an assessment of the pharmacologic effects on tissue glycosylation.

The Role of Cognitive Tasks in the Conceptualization and Assessment of ADHD

Kelly Tucker
Dr. Janet Frick, Psychology, Franklin College of Arts & Sciences

Attention Deficit Hyperactivity Disorder (ADHD) is defined by the DSM-IV-TR as a behavioral disorder with an onset of hyperactive or inattentive symptoms that must be present prior to age seven. The DSM-IV-TR specifies that these symptoms must be present in two settings and, therefore, most children are diagnosed based on parent and teacher behavioral ratings. There is a need for objective cognitive-based tasks that clinicians could utilize to substantiate their diagnosis of ADHD in children. This literature review discusses the ways in which cognitive tasks may help to narrow the conceptualization of ADHD, as well as provide a more objective way of assessing the disorder in children. We reviewed literature that examined two models of conceptualizing the etiology of ADHD as due to deficiencies in working memory or inhibition. This literature review utilized these models as a framework to investigate laboratory-based tasks that are currently being researched as possible ADHD assessment techniques. We found recent evidence that supports the idea that ADHD is caused by deficiencies in working memory, as well as some evidence that speaks to the validity of tasks that test children's ability to delay gratification in detecting ADHD. This literature review integrates theoretical and empirical findings that may inform future research, and more specifically serve as background for the study of whether the inattentive and hyperactive subtypes of ADHD may be caused by two separate cognitive deficiencies.

Differential Expression of RGS Proteins During Neural Differentiation

Katie Tuggle, CURO Graduation Distinction
Dr. Shelley Hooks, Pharmaceutical & Biomedical Sciences, College of Pharmacy

G-protein coupled receptors are ubiquitous cell surface molecules that control an abundance of physiological functions. These include but are not limited to immune response, neurotransmission, muscle contraction, and cell proliferation. Regulators of G-protein signaling (RGS) proteins halt the G-protein signaling cascade by acting as GTPase-accelerating proteins and turning the G-protein back into its GDP-bound, inactive state. The goal of this study was to determine if RGS expression changes during neural differentiation. qRT-PCR analysis revealed the expression of RGS proteins is dynamically regulated as cells transition from a neural progenitor into a neuron, thus changing the signaling capabilities of their respective GPCRs. Characterizing the expression changes of RGS proteins and understanding how the cell alters the expression of these proteins is paramount in developing a comprehensive understanding of cellular function. Many genes of RGS proteins have high levels of CpG sites in their promoter region, which indicates the possibility of epigenetic regulation by DNA methylation. DNA methylation involves the activity of DNA methyltransferases (DNMTs) and results in the silencing of the gene. After treatment of neuroblastoma cells with a DNMT inhibitor, qRT-PCR revealed the upregulation of mRNA transcripts of many RGS proteins, suggesting DNA methylation plays a role in the regulation of these proteins. The study of the regulatory mechanism of RGS proteins provides insight into how RGS proteins can be targeted in the treatment of various diseases.

Major Clarity in a Minor Paradox: The Role of Mark 9:24 in Illuminating the Markan Conception of Faith in the Context of Discipleship

Lindsay Ullrich
Dr. Wayne Coppins, Religion, Franklin College of Arts & Sciences

"I believe; help my unbelief!" is the cry of a minor character in Mark's gospel, a father seeking Jesus' help in healing his possessed son. Scholars often interpret this verse, Mark 9:24, and the surrounding passage as evidence that the father is a substandard model of discipleship and faith. This paper argues that biblical criticism, specifically narrative criticism, reveals that it is better to interpret the father as a positive model that furthers Mark's development of what faith should look like in the context of discipleship. Examination of this verse consisted of studying the interplay of the characters presented and looking at the passage in the context of the larger narrative. Contemporary theories concerning minor character function and the Markan definition of faith informed the analysis. Findings indicated that Mark 9:24 functions to add a depth dimension to the flat portrayal of Mark's ideal discipleship presented in a later character. Markan faith has an allowance for struggle, and examination shows that the father not only helps reveal this but also functions as a positive model of Mark's ideal proper response to it, namely reliance on Jesus and, ultimately, God. This finding not only redirects current views of this passage in Markan scholarship but also puts a sharper focus on the depth Mark presents in his realistic portrayal of faith. This portrayal, in turn, contributes to the dialogue in religious circles and beyond concerning what faith and doubt mean as part of the human experience and how the tension between them should be handled.

Mechanism of Gap Junction Inhibitor Carbenoxolene (CBX) in Regulating Gap Junction Proteins in ECC-1 Cells

Michelle Uzor
Dr. Xiaoqin Ye, Physiology & Pharmacology, College of Veterinary Medicine

Embryo implantation is a prerequisite process for successful pregnancy in mammals. It requires a competent embryo, a receptive uterus, and synchronized communication between them. How a uterus becomes transiently receptive for an embryo to implant is still largely unknown. Our *in vivo* study shows that carbenoxolene (CBX, a gap junction blocker) prevents the upregulation of gap junction proteins alpha1 (*Gja1*) and beta 2 (*Gjb2*) mRNA levels in the uterus, and disrupts uterine preparation for embryo implantation in mice. The mechanism by which CBX blocks uterine transformation for implantation is unknown. We hypothesize that CBX inhibits the transcription of *Gja1* and *Gjb2*, the two prominent gap junction proteins in the uterus upon implantation, and prevents the cellular and morphological changes associated with the establishment of uterine receptivity. To test the hypothesis, human endometrial cancer cell line ECC-1 cells are cultured and treated with different concentrations of CBX (0, 1 μM, 10 μM, 100 μM, and 500 μM). The end points include *Gja1* and *Gjb2* mRNA levels determined using realtime RT-PCR, cell morphology determined by F-actin staining, and cell proliferation/death determined by Trypan blue staining and cell number counting. Data collected so far indicate that 500 μM CBX decreases the number of live cells, most likely due to increased cell death. I have mastered all the needed techniques, and the data from the other two end points are being collected.

Purification of Periostin for Future Protein Screening Assays

Tram Van
Dr. James Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Periostin (POSTN) is a secreted extracellular matrix protein that contains an EMI and four Fasciclin (FAS1) domains. The protein promotes cell adhesion, cell attachment, and spreading of osteoblasts. Previous studies indicate that tumor-specific glycosylation changes on periostin are potential biomarkers for breast and ovarian cancer. As periostin has an *N*-linked glycosylation site at the amino acid numbered 599, we applied the program named Clustal Omega to examine how conserved sequences of periostin excreted from humans, mice, and frogs are at the *N*-linked site in the fourth FAS1 of the C-terminus. The result showed that the *N*-linked glycosylation site of periostin is highly conserved from humans to frogs. The conservation of the *N*-linked site in periostin suggests structural and functional importance. We would like to purify periostin with tumor-specific glycosylation for future functional studies and for use in the development of diagnostic cancer detection assays. We are adding a His-tag into the C-terminal end of periostin using a PCR strategy. Success in doing so will yield a massive amount of purified proteins for future experimental purposes. Although we are still in the process of completing the expression of periostin, the results we have gotten so far have supported our hypothesis, and moving forward should yield positive results with a His-tag put on periostin.

Abstracts

A Critical Examination of Anglicanism in the Life of Laurence Sterne and its Implications within *Tristram Shandy*

Jacqueline Van De Velde, Foundation Fellow
Dr. Elizabeth Kraft, English, Franklin College of Arts & Sciences

It is no surprise that *The Life and Opinions of Tristram Shandy, Gentleman* by Laurence Sterne was once dubbed the "dirtiest novel in English." Sexual innuendo and scatological humor pervade the pages of the novel – and, unhappily by extension, the minds of the reader – from the very first pages of the book, as Walter Shandy mourns the moment of Tristram's untimely conception. From then onwards, a slew of jokes, wisecracks, and sly comments, each with highly-charged sexual undertones, sustain the narrative. However, Sterne's authorial indecency is made all the more shocking when viewed in the context of his profession: an ordained minister of the Anglican Church. For a clergyman to engage in such bawdy writing seems strange, if not altogether blasphemous, and critics have sought to make sense of Sterne's unseemly mixture of professions since *Tristram Shandy*'s publication. Despite extensive literary scholarship on the text, several bibliographical and textual questions remain unanswered. Does Sterne's work within *Tristram Shandy* build upon the work of his pre-literary career as a clergyman? Despite its bawdy nature, does it purvey a Christian, specifically Anglican, ethic? Through an exhaustive study of Sterne's biography, examination of the reception of *Tristram Shandy* and Sterne's *Sermons*; and close readings of the elements of Anglican theology that were promoted – or misinterpreted – within *Tristram Shandy,* I will answer these questions, yielding clarity to Sterne's own life and opinions, which then will serve a reader as a guidepost within the otherwise often confounding narrative present in *Tristram Shandy*.

Crossing the Threshold: British Integration Policy through Haifa Zangana's *Women on a Journey Between Baghdad and London*

Jacqueline Van De Velde, Foundation Fellow
Dr. Esra Santesso, English, Franklin College of Arts & Sciences

Over the past fifty years, the Muslim population in Europe has grown from tens of thousands to 16 or 17 million – or approximately one out of every twenty-five Western Europeans – in 2010. Projections show continued demographic growth before leveling off at 25-30 million people (or 7-8%) in 2030, and the increasing tactical importance of the Middle East and North Africa solidifies the West's need to successfully engage Muslim populations in order to strengthen its own peace, security, diplomatic missions, and economic interests. Western European governments have no choice but to examine and engage with their current Muslim population as a force both permanent and enduring. Governments around the world are desperately seeking the answer to this Muslim question: what factors encourage integration, and what should the state's role be within the integration process? In my paper, I will provide an answer to this question through exploring literature as testimony: examining Kurdish-Iraqi refugee Haifa Zangana's novel *Women on a Journey Between Baghdad and London*, which documents the lives of five Iraqi immigrants to London. In my paper, I analyze the extent to which each of the five characters integrates into society, searching for common trends which either encourage or discourage the process. At the conclusion of my paper, I will present a case study, useful within European domestic policy, identifying the behaviors that encouraged integration within literature and to suggest ways by which states can utilize policy to encourage the integration process.

An Analysis of the Effect of Phytase Phosphorous Absorption and Growth in Nursery Pigs

Emily Vermillion, CURO Honors Scholar
Dr. Robert Dove, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Phytase is an enzyme that breaks inorganic phosphorous found in plants from its phytic ring into organic phosphorous that can be absorbed and utilized by the animal. Phytase is absent from pigs' gastrointestinal tract; therefore, pigs are unable to effectively absorb the inorganic phosphorus in their plant-based diet. To meet nutritional requirements, large quantities of supplemental phosphorous must be fed, or phytase must be added to the diet. When large amounts of phosphorous are added without phytase, substantial quantities of this phosphorous are still excreted. In this study, 24 nursery pigs of mixed gender are randomly assigned to 12 pens. There are 3 feeding phases which correspond to weeks 1-3 following weaning. There are two dietary treatments in each phase, one diet with phytase and one without phytase to serve as a control. Samples of the phase I diet, and phases II and III control and phytase diets are all analyzed to determine initial nutrients available. Fecal samples are collected from each pen at the end of each dietary phase and analyzed for excreted nutrients; thus, total absorbed nutrients can be measured. Additionally, pigs are weighed weekly to measure and compare growth rates of pigs. If phytase is added to the recommended diet, then pigs should be able to absorb more available phosphorous and thus grow at a faster rate. Our data will presumably affect nutritional composition of swine diets by reduction of phosphorous supplements and addition of phytase, thus improving overall nursery pig performance.

Capuchin Monkeys and Emotional Contagion: Displaying Affiliation towards Humans Who Imitate Them

Stephanie Villarreal
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

An expansive literature details the phenomenon of emotional contagion, or the matching of another's emotions and behaviors, in humans. Synchronizing behaviors with another may facilitate group cohesion and interpersonal relationships, because we tend to like people who match us. In the long term, this phenomenon may be adaptive because we are more likely to be generous and helpful towards those who match our behavior. Recent research supports the idea that emotional contagion exists in other species as well. This study looks into whether capuchin monkeys, like humans, display affiliation towards humans who imitate them by spending more time in proximity to, looking at, or exchanging tokens with a human that they "like" rather than another human. We will test seven male capuchin monkeys individually using these conceptualizations of "liking" to answer this question. In each of several sessions, for a five-minute period, we will videotape the monkey while one human imitates the monkey's actions and another human performs contingent, yet non-matching actions. Subsequently, we will code the monkey's behavior from video in playback mode, producing quantitative data (frequencies, durations) for statistical analysis. We hypothesize that the monkeys will tend to spend more time in proximity to, looking at, and exchanging more tokens with the imitator rather than the non-imitator. If the monkeys do not exhibit these preferences, this may suggest that capuchin monkeys do not prefer humans who imitate them, and thus that the phenomenon of emotional contagion is not present in this species.

Effective Organization of Complex Visual Information

Kylie Wagner
Prof. Julie Spivey, Lamar Dodd School of Art, Franklin College of Arts & Sciences

The conference poster is a popular medium used to display research results. An effective poster conveys the essence of its message in a compact, comprehensible format, with the integrity of its information as its top priority. However, creating such a poster can be difficult for the non-designer, and as a result many posters suffer from a severe lack of information organization, utilizing graphic gimmicks (e.g. drop shadows, text boxes, garish color schemes), that hinder the transfer of content to viewer. The consequence is a diminished impact of the presenter's work, and by extension, their own professional credibility. Using the conference poster as a case study, I will investigate visual and typographic devices that improve readability and legibility, such as line length, font choice and size, layout principles, and data arrangement. I will study contemporary research in the fields of visual communication, marketing, eye tracking and reading comprehension, and then synthesize these findings into a set of basic guidelines useful to non-designers. Once this process is complete, I will take pre-existing posters and re-design them, then conduct comparative tests such as survey and eye-tracking analyses to assess their effectiveness. The criteria for a poster's success will be based on the level of comprehension by its audience, as opposed to mere aesthetics. Visual communication has the potential to inform, educate, and persuade its audience. By determining what visual formula maximizes readability for intended viewers, we discover the most effective way to transmit complex content in a concise manner.

Navigating Sickle Cell Disease in Africa

Amelia Watson
Dr. Anne Marie Zimeri, Environmental Health Science, College of Public Health

Sickle cell disease (SCD) is caused by abnormal hemoglobin structure, causing deformed, sickled red blood cells that can clot easily. Globally, 7% of humans carry an SCD variant. Africa has high estimates of SCD-related mortality, particularly in children, but lacks reliable data to address the issue. Without relevant epidemiological data, providing medical aid to areas of greatest need is impossible. Systematic data collection allows countries to intensify efforts on areas that need most help; it successfully decreased incidence of other African diseases, including HIV/AIDS. Because SCD lacks relevant data, it continues to have high incidence and mortality rates. The research question is: what policy option will be best suited for this problem? Several different approaches were examined to determine this problem: status quo, premarital screening, and newborn screening. These were examined for cost effectiveness, decreasing SCD incidence, decreasing childhood mortality for SCD, and increasing SCD data collection. The best way found to decrease the high incidence of SCD-related deaths and collect the most data is to develop newborn screening in urban hospitals and rural clinics. Screening, paired with education, impacted childhood mortality in many other countries. US newborn screening resulted in a 68% reduction in SCD-related mortality (ages 0-3). Once diagnosed, caretakers can plan their families and raise them accordingly with education from health care providers and genetic counselors. Data, paired with education, is key to this process, as it allows states to allocate resources for preventative measures.

Associations between BMI and Folate Status of Normal Weight and Obese Women of Childbearing Age

Arielle Weekley
Dr. Dorothy Hausman, Foods & Nutrition, College of Family & Consumer Sciences
Dr. Lynn Bailey, Foods & Nutrition, College of Family & Consumer Sciences

Folate is a water-soluble B vitamin required for cell division and especially critical during periods of rapid growth. Sufficient folate status is important prior to conception to reduce the risk of neural tube defects (NTD) during early embryonic development. NTDs result from incomplete closure and exposure of the central nervous system and currently affect approximately 300,000 pregnancies worldwide. The prevalence of NTDs has decreased in the US since 1998, when the FDA set folate fortification requirements in enriched cereal-grain products; nonetheless, the risk of having a NTD-affected pregnancy is up to threefold higher for obese mothers than for normal weight mothers. To examine associations between folate biomarkers and obesity status, we performed a secondary analysis of baseline folate concentrations and body composition parameters from a recent study conducted on normal weight and obese women of childbearing age. While accounting for each participant's total folate consumption, overall calorie intake, and age, we determined a significant inverse relationship between body mass index (BMI) and serum folate and a direct relationship between BMI and red blood cell folate. This evidence suggests that the current RDA for non-pregnant women (400μg DFE [dietary folate equivalents]) should be revised and adjusted based on BMI measurements to support NTD risk reduction.

Where Chemistry Meets the Classics: First-ever Modern Scientific Analysis of Pompeiian Polychrome Sculptures

Richard Weimar III
Dr. Tina Salguero, Chemistry, Franklin College of Arts & Sciences
Dr. Mark Abbe, Lamar Dodd School of Art, Franklin College of Arts & Sciences

The white marble of ancient Greek and Roman sculpture and architecture was originally vividly colored. This polychromy was first demonstrated with the 'Treu Head' in 1889; since then, archaeologists' and historians' view of the ancient West has become much more colorful. However, until the development of modern scientific technologies, the analysis of these masterpieces was limited largely to stylistic and historical approaches. Despite the huge wealth of information and insight that becomes available with state-of-the-art analytical chemistry techniques, their application to archaeological artifacts has not been refined or widely applied. The highly multidisciplinary studies described in this work–The Oplontis Project and The Orpheus Relief Project–seek to establish scientific analyses as integral to further advances in the fields of archaeology and art history. In doing so, we seek to set a new, high standard for future contributions and to robustly establish a fruitful intersection between the physical sciences and the humanities. This particular work encompasses our technical findings on the first-ever scientific analysis of polychrome statues in the Gulf of Naples, along with findings on an ancient polychrome Roman relief currently on loan at the Georgia Museum of Art. The techniques used include micro-Raman spectroscopy, near infrared luminescence spectroscopy and polarized light microscopy. Through our results, we can accurately appraise the sculptures' authenticity, sociopolitical significance, and historical context. Additionally, we can inform conservation methods and generate virtual replicas that are faithful to the cultural

heritage of one of the most influential civilizations ever known.

Justice for All: The Vitality of Addressing Judicial Structures during Reconstruction Period

Patrick Wheat
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

After an ethnic conflict, a state undergoes a reconstruction period that can be characterized by either a general increase or decrease in hostilities between different factions. If the increase in hostilities is not addressed, it is likely that war can break out again in the state. To ensure that there is not an increase in hostilities, the role of the government during this period should be focused on the reestablishment of an unbiased judicial system and law enforcement agencies. The reason for this is because during the first few months of reconstruction, ethnic factions will likely be hostile and unwilling to accept opposing ethnic factions. Through the judicial system, the government will be able to establish a "rule of law" that is fair to all ethnic groups. By doing this, the government should be able to act as a mediator by addressing individuals, not ethnic groups, who committed crimes against each other. This will allow for a better chance of reconciliation between ethnic groups during this period as a result. To demonstrate this possibility while also discussing potential obstacles within both the government and society to effectively reconcile ethnic factions, I will be discussing the situations in several nations, including Bosnia and Herzegovina, Rwanda, and Kyrgyzstan.

Investigation of the Mechanism of Bile Acid-induced Prostate Cancer Cell Death

Stephanie Wilding, CURO Summer Fellow
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Bile acids mediate the digestion and absorption of fats and fat-soluble vitamins; however, pathological increases are associated with choleostasis and cell death. Recent studies show that high concentrations of bile acids can induce apoptosis in several cells, including cancer cells, by mechanisms that are not fully understood. The goal of this study was to determine the mechanism of toxicity of three different bile acids (chenodeoxycholic acid, deoxycholic acid, and lithocholic acid) in prostate cancer cell lines (PC-3, LNCaP, and DU-145). Based on reports that bile acids increase the expression of inflammatory enzymes called secretory phospholipase A2 (sPLA2), we tested the hypothesis that these enzymes regulate the mechanisms of bile acid-induced cell death. Analysis of sPLA2 expression using quantitative PCR showed that several sPLA2 isoforms were expressed in PC-3, LNCaP and DU-145 cells, including Group IB, IIA, V and X sPLA2. Nevertheless, treatment of cells with the sPLA2 inhibitor LY311727, prior to exposure to bile acids, did not alter MTT staining compared to cells exposed to bile acids alone. Similar results were seen with the calcium-independent PLA2 (iPLA2) inhibitor bromenol lactone. Other reports suggested that bile acids had a role in oxidative stress, so the antioxidants glutathione, N-acetyl cysteine, and ascorbic acid were tested. Dosing the cells with these antioxidants prior to bile acid exposure did not alter MTT staining. Collectively, these data show the novel finding that bile acids can induce toxicity to prostate cancer cells and suggest that neither sPLA2, iPLA2, nor oxidative stress mediates the mechanisms of cytotoxicity.

Comparison of Two Biocatalysts for Ethanol Production from Pectin-rich Biomass with Varying Levels of Industrial Processing

Travis Williams, Jr.
Dr. Joy Doran Peterson, Microbiology, Franklin College of Arts & Sciences

Pectin-rich biomass is an overlooked alternative energy source in the USA. Pectin-rich biomass includes spoiled or rotten fruits, like cull peaches, and waste products from juice and sugar production, like citrus waste (CW) and sugar beet pulp (SBP). This set of experiments examined how varying levels of industrial processing influenced the carbohydrate composition and ethanol production of pectin-rich biomass through the use of two biocatalysts. The biocatalysts used were the yeast, *Saccharomyces cerevisiae* XR122N and the engineered bacterium, *Escherichia coli* LY40A. First, the composition of each biomass was analyzed. The biomass with the least amount of industrial processing, cull peaches, contained a higher concentration of monomeric sugars. The biomass with the most industrial processing, SBP, contained the least amount of free sugars and the intermediately processed CW fell somewhere in between. The amount of available monomeric sugars decreased and the concentration of polymeric biomass increased significantly as the amount of industrial processing of the biomass increased. Next, fermentations with *S. cerevisiae* XR122N were compared to fermentations with *E. coli* LY40A. The industrially processed biomasses, SBP and CW, were best fermented by *E. coli* LY40A. The unprocessed peach biomass was best fermented by *S. cerevisiae* XR122N. Finally, the optimal enzyme loading for fermentation of cull peaches was studied using 15% w/v peach pomace and varying amounts of commercial enzymes. The lowest enzyme loading which still produced the maximum amount of ethanol was 1.88 FPU of cellulase/g dw, 7.50 PGU of pectinase/g dw, and 6.25 CBU of cellobiase/g dw.

The Role of Technology in Early North American Pacific Colonialism

William Willoughby IV
Dr. Claudio Saunt, History, Franklin College of Arts & Sciences

This paper asks one central question: What was the role of technology in early colonialism on the West Coast? Within this context, a series of secondary questions arise: Was it particularly influential? Did it provide a significant advantage to imperialists in conquering new territory? Research methods focused on independent reading, with an emphasis on primary source documents. A common presumption in the historiography of imperialism is that sophisticated European technologies were superior to native technologies, and that this superiority ensured domination. However, in the case of the eighteenth century in the North American Pacific, this reasoning is problematic for two reasons. First, the conflation of sophistication and superiority is presumptuous and often incorrect. Second, given the remoteness of this region, Europeans often found themselves limited not necessarily by technological capacity but by what was available or affordable. The limited availability of European goods increased the importance and use of native technologies, which were adapted to the local environment and made use of locally available materials. Consequently, Europeans relied on native technologies despite preference for their own. In some cases they discovered native technologies to be more useful. In short, European technologies were far less important than we have understood.

Stories of Roswell, Georgia: A Sociolinguistic Study of Narrative Structure

Anna Wilson, CURO Summer Fellow, CURO Graduation Distinction
Dr. Bill Kretzschmar, English, Franklin College of Arts & Sciences

Labov & Waletzky in 1967 established a framework for understanding spoken narrative from a sociolinguistics perspective, which breaks down a story into seven different parts according to function: abstract, orientation, evaluation, temporal juncture, complicating action, resolution, and coda. They established that these structures are employed predictably in spoken narrative, and appear in the above order. In 2010, Hettel & Bounds combined this methodology with corpus linguistics and complexity theory for fresh insights into how speakers tell stories. They found Labov & Waletzky's proposed sequence of structures was preserved as a generalization across speakers, but was highly variable at the individual level. In my own research, I have used Hettel & Bounds' methodology to further investigate the variable nature of narrative structure in English, as well as to address Spanish. Since fall 2011, I have been researching with the Roswell Voices Project, a civic-academic partnership between the Convention & Visitors Bureau of Roswell, Georgia, a northern edge city of Atlanta, and the University of Georgia. Its purpose is to describe the Roswell community culturally and linguistically. As a part of this objective, I have endeavored to extend the scope of the Project to encompass Roswell's Latino community, which now comprises a quarter of the city's overall population of 100,000. I interviewed 26 Latino community members, from which I selected a sampling plan of eight to transcribe and annotate for narrative structure. Each phrase of each speaker's narrative, subdivided by word, is labeled as fulfilling one of the narrative functions delineated by Labov & Waletzky (1967). Results indicate that narrative structure is more variable than originally supposed, and that the paradigm functions differently in Spanish than in English.

Serum Free Cortisol Fraction and Insulin Concentration in Normal Horses, Obese Horses and Horses with Pituitary Pars Intermedia Dysfunction

Devon Wochele
Dr. Kelsey Hart, Large Animal Medicine, College of Veterinary Medicine

Cortisol has been theorized to play a role in the development of endocrinopathic laminitis and insulin resistance, important complications of Pituitary Pars Intermedia Dysfunction (PPID) in horses. Measurement of total serum cortisol concentration, which is not typically increased in affected horses, quantifies both protein-bound and free cortisol, though only free cortisol is biologically active. The objectives of this study were to compare free cortisol fraction (FCF) between horses with PPID and age-, sex- and season-matched healthy horses, and to determine if FCF and hyperinsulinemia are correlated in PPID and obese horses. Body condition scores (BCS) were determined and blood was collected in October, January, April, and July from 57 healthy adult horses. Archived frozen serum samples were obtained from 20 horses diagnosed with PPID and from 19 obese horses. Serum insulin and total cortisol concentrations and FCF were measured with previously validated radioimmunoassay, chemiluminescent immunoassay, and ultrafiltration/ligand-binding assay respectively. In healthy horses, there was a significant association of increasing BCS with increasing insulin concentration and increasing FCF ($P < 0.0001$). Total cortisol concentration was not significantly different between PPID and healthy horses, but both insulin concentration and FCF were significantly higher ($P=0.011$ and $P=0.0004$) in PPID horses than healthy horses. In obese horses, FCF was significantly

higher in hyperinsulinemic horses than normoinsulinemic horses (P = 0.037); there was no difference in PPID horses (P = 0.6341). These data suggest that cortisol binding dynamics may be altered in horses with obesity and PPID, resulting in increased free cortisol.

Clarification of the Mechanism of *Aliivibrio fischeri* HutW, a class C Radical SAM Methyltransferase Enzyme

Addison Wright, Foundation Fellow
Dr. William Lanzilotta, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Aliivibrio fischeri is capable of utilizing external heme as an iron source. In iron-limiting conditions, the bacterium expresses a heme utilization (hut) operon that codes for three proteins, HutW, HutX, and HutZ, homologs of which are necessary for the growth of *Vibrio cholerae* with heme as the sole iron source. The precise roles of these proteins in heme utilization in *A. fischeri* are unclear. HutW contains a core domain characteristic of radical SAM enzymes, with a specialized [4Fe-4S] cluster coordinated by three cysteine residues in a conserved CxxxCxxC motif, as well as a distinct C-terminal domain. Recent work suggests that HutW is a member of the Class C radical SAM methyltransferase (RSMT) family, a group of enzymes with an unknown mechanism. RSMTs are involved in a range of reactions that utilize SAM as the source of a radical, generated by reductive cleavage of S-adenosyl methionine, and either another SAM molecule or methylcobalamin as a methyl donor. Class A RSMTs use two SAM molecules and proceed via a methylthioether intermediate, while class B enzymes are cobalamin-dependent. HutW has methyltransferase activity in the presence of SAM, heme, and a reductant. This study proposes to clarify the mechanism of HutW through site-directed mutagenesis. Substitutions of the cluster-coordinating cysteines will confirm the importance of the cluster while substitutions of other cysteines will clarify whether the reaction proceeds by a class A-like mechanism. A greater understanding of HutW's mechanism could reveal a novel methyltransferase reaction and potentially allow for the development of enteric pathogen-specific drugs.

The Effect of Thiamine Supplementation on Transketolase Activity in Cancer Cells

Star Ye, CURO Summer Fellow, CURO Graduation Distinction
Dr. Jason Zastre, Pharmaceutical & Biomedical Sciences, College of Pharmacy

The increased glucose uptake observed in cancer cells parallels rapid tumor growth. Cancer cells preferentially undergo fermentative glycolysis in the presence of oxygen, a phenomenon termed the Warburg effect. Alterations in the activity and regulation of glycolytic enzymes cause the accumulation of intermediate metabolites, such as fructose-6-phosphate (F6P) and glyceraldehyde-3-phosphate (G3P). Excess F6P and G3P are shunted into the non-oxidative pentose phosphate pathway (PPP) for the production of nucleic acids essential to cancer cell proliferation. Non-oxidative PPP substrate flux is regulated by transketolase (TKT), a thiamine-dependent enzyme. Compared to normal cells, cancer cells are more dependent on the non-oxidative PPP. Previous studies have shown that the non-oxidative PPP provides at least 85% of nucleic acids for malignant cells. Because transketolase is a thiamine-dependent enzyme, we hypothesize that thiamine regulates glucose consumption, non-oxidative PPP substrate flux, and transketolase expression in cancer cells. Results from glucose assays demonstrate that thiamine supplementation stimulates glucose utilization. Preliminary radioactive glucose labeling experiments reveal that thiamine increases non-oxidative PPP substrate flux. Evidently, thiamine supplementation enhances transketolase

activity, which may promote cancer cell growth and proliferation.

Relationship between Number of Years in Animal Health Practice and Recognizing Pain

Courtni Young, CURO Honors Scholar
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

The gold standard for diagnosing pain in people is by self-report. Unfortunately for veterinarians, their patients are incapable of communicating with them. Several scales have been constructed to help aid veterinarians in their analysis of determining the level of pain their patients are in. The hypothesis of this study was that sophomore veterinary students would be more able to detect painful patients than freshmen veterinary students. Volunteer first and second-year undergraduates at the University of Georgia were shown short clips of dogs recovering from surgery and asked to rate how much pain, if any, the dogs were in. After collecting the data, the agreement between participants was tested using the Fleiss-Kappa and the Bland-Altman plot. Results from our data show there is low agreeability among the participants. The highest agreement score between freshmen was 0.113939 while the highest agreement score among sophomores was 0.078086. Volunteers owning several pets prior to the research also showed little agreeability, as did those volunteers who owned at most one pet. There was also little agreeability between the Visual Analogue Scale and the Numerical Rating Scale, with the average correlation between the two scales being 0.2594. Agreeability between the Numerical Rating Scale and the Glasgow Scale was very low, with the average correlation between the two scales being 0.0494. Based on these findings, we can conclude that there is little, if any, reliability of the VAS, the NRS, and the Glasgow scales between each other and little agreeability between the different undergraduate levels.

Mikhail Bulgakov's Mysteries: The Personas, Metaphors, and Names of the Novel *The Master and Margarita* Analyzed in a Historical Context

Alisa Zezetko
Dr. Elena Krasnostchekova, Germanic & Slavic Studies, Franklin College of Arts & Sciences

Brilliant Russian writer Mikhail Afanasyevich Bulgakov started writing *The Master and Margarita*, his greatest masterpiece, in 1928 and continued revising it until 1940, the year of his death. *The Master and Margarita* intertwines three stories: one about Pontius Pilate and Yeshua in Jerusalem, one about the chaos and disorder that ensues when the devil Voland and his entourage visit atheistic Moscow, and one about the romance between Master and Margarita. This paper analyzes the two revolutions in Bulgakov's novel: the revolution struggling to create the Christian faith in Jerusalem and the revolution striving to destroy that same faith in 1930s Soviet Russia. Bulgakov skillfully interweaves his anti-Soviet ideas under metaphors revealing the degraded sociopolitical morale and insanity behind the facade of a nation. Simultaneously, he deepens the complexity and interrelatedness of the plot by choosing suggestive personas and names. This research provides some new perspectives about the meaning of Bulgakov's chosen personas, metaphors, and names and explores the fears and daily tragedies of Soviet life. These interpretations come from the scrutiny of *The Master and Margarita*, Bulgakov's life, and the culture of the Soviet Union.

Understanding Ecological Networks: A Mathematical Approach to Ecosystem Balancing and Analysis

Brent Zurcher
Dr. Caner Kazanci, Mathematics, Franklin College of Arts & Sciences

New methods of mathematical network analysis have brought vast new potential to

the exploration of ecosystems. In order to perform such analysis, however, data collected by ecologists from the field must be converted into a useful mathematical form. The purpose of this study was twofold: to explore the mathematical definition of "distance" between two ecological networks and to develop a minimal-change balancing method that would account for error in field-collected data. Based on the flux decomposition of a network, the distance metric was defined to be the magnitude of a vector between two flux coefficient vectors representing two unique steady states of the same network. Based on application of this distance metric to several steady states across three different networks, the study showed that this distance metric exhibits unique geometry determined by network structure, potentially leading to further understanding of ecosystem dynamics. The network balancing method is based on the desire to generate a steady-state network from field-collected data that suggest an impossible unsteady-state network. Utilizing the stoichiometric matrix of the network and a flow value vector quantifying the network, it was shown that a constrained minimization problem yields a steady-state network with the minimal possible change to the collected data. Based on testing in MATLAB using three different networks, the amount of change required to achieve a steady state is less than any other known existing method. This new method shows promise as a data correction agent for all ecologists to more effectively analyze their ecosystem of interest.

March 31, 2014

Dear Students, Faculty, and Guests,

Welcome to the 14th annual CURO Symposium, UGA's celebration of undergraduate research across the disciplines. Many individuals—administrators, faculty members, staff, graduate students, and, of course, undergraduate students—have collaborated to make the CURO Symposium the premier undergraduate academic event at UGA.

Each year, the Symposium has grown larger, and the 2014 Symposium is the largest to date, with 258 undergraduate researchers communicating their substantial accomplishments to their peers, mentors, and the public at large.

From its inception, the CURO Symposium has showcased research and scholarship in all disciplines. The 2014 Symposium continues that commitment, featuring presenters from 50 departments in 13 colleges/schools. Thus, this two-day event displays UGA's broad and substantial support of research and the invaluable commitment of UGA's administration and faculty to mentoring and providing exceptional learning opportunities for our undergraduates.

Thank you for your continued support of undergraduate research and CURO.

Sincerely,

Dr. David S. Williams, '79, '82

CURO Research Mentoring Awards

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the CURO Research Mentoring Awards, formerly the EURM awards, in 2001.

These awards recognize outstanding faculty who consistently engage undergraduate researchers through CURO Programming (courses, the symposium, summer fellows, JURO, theses, et al.) and enhance the learning experience of undergraduate researchers at the University of Georgia. Award recipients have provided superior research opportunities and mentoring and have collaborated with undergraduate researchers on publications and presentations at professional conferences.

Before 2014, awards were designated as "Early Career" and "Master Level" and were granted to corresponding faculty ranks.

2014

Dr. Carl Bergmann, Associate Vice President for Research-Facilities; Associate Director, Complex Carbohydrate Research Center; Executive Director, Animal Health Research Center; Senior Research Scientist

Dr. Andrew Owsiak, Department of International Affairs, School of Public & International Affairs

2013

Master Level Faculty Award
Dr. Jennifer McDowell, Department of Psychology, Franklin College of Arts & Sciences

Early Career Faculty Award
Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

2012

Master Level Faculty Award
Dr. Lawrence Shimkets, Department of Microbiology, Franklin College of Arts & Sciences

Early Career Faculty Award
Dr. Michael Yabsley, Warnell School of Forestry & Natural Resources

2011

Master Level Faculty Award
Dr. Eric Stabb, Department of Microbiology

Early Career Faculty Award
Dr. John Drake, Odum School of Ecology

Program Award
Savannah River Ecology Laboratory
Dr. Kenneth McLeod, Interim Director

2010

Early Career Faculty Award
Dr. John C. Maerz, Warnell School of Forestry & Natural Resources

CURO Research Mentoring Awards

2009

Early Career Faculty Award
Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences
Dr. Anna C. Karls, Department of Microbiology
Dr. Dawn T. Robinson, Department of Sociology

2008

Master Level Faculty Award
Dr. John J. Maurer, College of Veterinary Medicine

Early Career Faculty Award
Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology

Program Award
Biomedical and Health Sciences Institute
Dr. Harry S. Dailey, Director

2007

Master Level Faculty Award
Dr. Timothy Hoover, Department of Microbiology
Early Career Faculty Award
Dr. Steven Stice, Department of Animal & Dairy Science

2006

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Department of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Department of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD candidate in Plant Biology

2005

Faculty Award
Dr. Gary Barrett, Odum School of Ecology
Dr. Sidney Kushner, Department of Genetics
Department Award
Department of Cellular Biology

2004

Faculty Award
Dr. William S. Kisaalita, Department of Biological & Agricultural Engineering

CURO Research Mentoring Awards

2003

Faculty Award

Dr. Jody Clay-Warner, Department of Sociology

Department Award

Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator

Program Award

The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Department of Plant Biology
Dr. Marie-Michèle Cordonnier-Pratt, Department of Plant Biology

2002

Faculty Award

Professor William D. Paul, Jr., Lamar Dodd School of Art
Dr. Katherine Kipp, Department of Psychology

Faculty Recognition

Dr. Susan Sanchez, College of Veterinary Medicine

Department Award

Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head

Program Award

"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Department of Physics & Astronomy
Dr. Heinz-Bernd Schuttler, Department Head, Department of Physics & Astronomy
Dr. Jonathan Arnold, Department of Genetics
Dr. Susmita Datta, Georgia State University
Dr. David Logan, Clark Atlanta University
Dr. William Steffans, Clark Atlanta University

2001

Faculty Award

Dr. Marcus Fechheimer, Department of Cellular Biology

Faculty Recognition

Dr. David MacIntosh, Department of Environmental Health Sciences
Dr. Dean Rojek, Department of Sociology

Department Award

Department of Genetics
Dr. John MacDonald, Department Head

Program Award

Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

CURO Symposium Best Paper Awards

Since 2001, CURO Symposium Best Paper Awards have recognized excellence in papers developed from work being presented at that year's Symposium.

Applicants may submit in one or more of the following categories: Arts, Humanities and Media; Business; Life Sciences; Physical and Environmental Sciences; Public and International Affairs; Social Sciences; and Technology, Engineering and Math.

Each recipient is recognized at the Symposium's Award and Keynote Session, and each award carries $100 in financial support, generously provided by the UGA Alumni Association. Winners from the 2014 CURO Symposium are listed below.

Arts, Humanities and Media:

Greyson Clark	Power Dynamics in Georgia's Poultry Industry, 1950-1965

Life Sciences:

Katherine Hsieh	The Effect of a Patellar Tendon Strap on Knee Power during a Drop-Jump

Physical and Environmental Sciences:

Carmen Kraus	Density Dependent Regulation of Survival and Reproduction in Dogbane Beetles and Underlying Host-Plant Interactions

Public and International Affairs:

Anne Chen	Sex-Ratio Imbalances and Risky Behavior in College

Social Sciences:

Lindsay DeFrancesco	Students' Perceptions of the Police – An Analysis of Greek and Non-Greek Affiliated Students

Program: Monday, March, 31, 2014

Oral Session I: 1:25-2:15 p.m.
Athena Breakout Rooms A, B, C, D

Room A	**Julia Carpenter**	A Storyworld with Incalculable Authors: Defining, Finding and Committing Narrative in the World of Social Media
	Connor Hamm	The Digital Future – Investing and Investigating
	Noah Boswell	Marketing an Online Based Education Platform
Room B	**Stephanie Wilding**	The Expression of the Bile Acid Receptor TGR5 in Prostate Cancer Cells and its Role in Bile Acid-Induced Cell Death
	Anjali Kumar	Glycoproteomic Approaches for Pancreatic Cancer Biomarker Discovery
	Taylor Chishom	Polyadenylation in Stationary Phase *Escherichia coli:* Analysis of the Role of RNA Polymerase
Room C	**Carmen Kraus**	Density Dependent Regulation of Survival and Reproduction in Dogbane Beetles and Underlying Host-Plant Interactions
	Lara Mengak	Why is There an Alligator in My Pool? Assessing Potential Range Shifts with Sea Level Rise
	Chelsea Sexton	Parasite Selective-Pressure Alters Reproductive Strategy in *Littorina saxatilis*, an Intertidal Snail
Room D	**Leslie Stapley**	The Influence of Neuroticism, Openness, and Conscientiousness on Executive Functioning in Older Adults
	Kirstie Chu	Predicting Functional Independence with Impulsivity
	Savannah Boyd	What Predicts Willingness to Support a Partner's Smoking Cessation Attempt?

Oral Session II: 2:30-3:20 p.m.
Athena Breakout Rooms A, B, C, D

Room A	**Brian Underwood**	Against All Reason: Rousseau and the Counter-Enlightenment
	Ryan Slauer	The Lines are Drawn: Christian Apologies in Late Antiquity
	Joseph Hopkins	Norse Mythology in Modern Popular Culture: Sixty Interviews Conducted in Athens, Georgia and Copenhagen, Denmark during the Summer of 2013

Program: Monday, March, 31, 2014

Room B	**Lucas Wachsmuth**	Ectopic Endodermal Expression of Foxn1 in a Murine Model
	Francine Katz	The Role of tRNA Nucleotidyl Transferase in tRNA Processing in *Escherichia coli*
	Aparna Philip	Transferrin-Crosslinked Liposomes for Targeted Drug Delivery to *Trypanosoma brucei*
Room C	**Minhnguyen Cao**	Parenting Stress, Emotion Dysregulation, and Emotion Coaching as Predictors of Child Behavior Problems in the Context of SES and Race
	Charlotte Goldman, Amy Davis, Kelsie Flanigan	Parent and Child Perceptions of Health-Related Quality of Life and Psychological Functioning in Children with Tourette Syndrome
	Hania Bisat	Embodiment and Altruism
Room D	**Patrick Wheat**	The Justification for Ethnic War
	Anne Pellegrino, Jonah Driggers, Elijah Scott, Meili Swanson, Luke Thompson, Patrick Wheat	New Aid for Africa
	Melanie Kent	Nationalism vs. Global Jihad: Al-Qaeda and Precursors in Algeria, Somalia and Yemen

Awards and Keynote Session: 4:00-5:00 p.m.
Athena Room E

Welcome and Introductions	Dr. David S. Williams, Associate Provost and Director of Honors and CURO
Remarks	UGA President Jere W. Morehead
Introduction to Awards	Dr. Martin Rogers, Associate Director of CURO and Honors
CURO Research Mentoring Awards	Dr. David C. Lee, Vice President for Research
2014 Symposium Best Paper Awards	Dr. Laura Jolly, Vice President for Instruction

Program: Monday, March, 31, 2014

UGA Libraries' Research Awards	Ms. Elizabeth White, Librarian, UGA Libraries
Introduction of Keynote Speaker	Ms. Smitha Ganeshan, Foundation Fellow '14, Biology
Keynote Address	Dr. Phaedra Corso, Professor of Health Policy and Management, "Health Policy and the Promise of Research"
Closing Comments	Dr. David S. Williams, Associate Provost and Director of Honors and CURO

Poster Session: 5:00-6:00pm
Sponsored by the Office of the President
Grand Hall South (downstairs – use the escalator in the lobby)

Poster #1	**Justin Dumrongkulraksa**	Bridging the Gap: The History of British Science Examined through Literature
Poster #2	**Moriah Jackson**	*Mycoplasma gallisepticum* Infection and Shed in Commercial and Wild Turkeys
Poster #3	**Rachel Jude**	The Pathogenicity of *Mycoplasma gallopavonis* in Wild and Commercial Turkeys
Poster #4	**George Grant**	Impacts of Organic Soil Amendments on Micro-Nutrient and Carbon Sequestration under Natural Rainfall Conditions, 2010-2013
Poster #5	**Keelan Lawrence**	Wavefront Sensorless Adaptive Optics with Differential Interference Contrast Microscopy
Poster #6	**Billie Hardigree**	Viscosity-Dependent Behavior of Cyclopenta[b]naphthalene Fluorophores
Poster #7	**Victoria DeLeo**	Intron Loss in the ABCB1 Gene
Poster #8	**Rachel Rotz**	An Integrated Approach for Verification of Rapid Focused Recharge Zones in the Arabian Peninsula Using Thermal and VNIR Remote Sensing
Poster #9	**Adam Jones**	Stable Isotope and Crystallinity Variations in Kaolin Deposits of Georgia in Up Dip to Down Dip Occurrences
Poster #10	**Philippe Bauchau**	Clinoptilolite Formation in the Lower Floridan Aquifer
Poster #11	**Hayden Field**	Hemlock Embryo Rescue Project

Poster #12	**Carmen Kraus**	Density Dependent Regulation of Survival and Reproduction in Dogbane Beetles and Underlying Host-Plant Interactions
Poster #13	**Kyungmin Ko**	The Trade-Off between Mating and Fighting in *Nicrophorus vespilloides*
Poster #14	**Lara Mengak**	Why is There an Alligator in My Pool? Assessing Potential Range Shifts with Sea Level Rise
Poster #15	**Timothy Montgomery**	Balancing Carbon and Phosphorus for Consumers: Does Nutrient Enrichment Tip the Scale?
Poster #16	**Blake Edwards**	Enzymatic Assay of DHPS Degradation in Abundant Marine Alphaproteobacteria
Poster #17	**Jasmin Melara**	Carbon Flux in the Amundsen Sea Polynya
Poster #18	**Dylan Goetz**	Data Analysis of Seawater Samples Collected Off the Coast of Barrow, Alaska
Poster #19	**Shannon Burns**	Riverwater and Seawater Dissolved Inorganic Carbon Endmembers for the Amazon River Plume
Poster #20	**Laurence Black**	Response of Microbial Nitrification and Denitrification to Redox Shifts in Beach Sand
Poster #21	**Amala Malladi**	Development of an In-Frame Deletion System for *Ruegeria pomeroyi*
Poster #22	**Laura Alexander**	Identification of a Novel O-Antigen and its Role in the Virulence of *Aeromonas hydrophila* Isolated from Diseased Catfish
Poster #23	**Anquilla Deleveaux**	Determining the Role of FhlA in Transcriptional Activation of Newly Identified RpoN Dependent Promoters
Poster #24	**Cameron Story**	Characterization of the *rsr-rtcBA* operon in *Salmonella typhimurium*
Poster #25	**Leah Williams**	Sigma-54 Promoter Activity and Gene Regulation in *Salmonella*
Poster #26	**Alison McWhorter Anderson**	Examination of the Pathogenic Nature of *Mycoplasma pneumoniae*

Poster #27	**Babajide Oluwadare**	Analysis of P1 Function in *Mycoplasma pneumoniae* Adherence and Gliding
Poster #28	**Chetan Hebbale**	A Targeted and an Unbiased Screen for Genetic Suppressors of the *Legionella pneumophila* Effector Protein LegC7
Poster #29	**Jacob Kumro**	Mapping of the oriT Region of the Virulence Plasmid of *Rhodococcus equi*
Poster #30	**Breanna Crowell**	The Evolution and Tradeoffs of Physical and Chemical Leaf Defenses in *Helianthus*
Poster #31	**Chinyere Uzoigwe**	Nitrogen Resorption in *Helianthus* Species
Poster #32	**Kaleigh Davis**	Evolution of Flowering Time and Disc Color across the Genus *Helianthus*
Poster #33	**Vanessa Gutierrez**	Investigating the Role of HAN Transcription Factors during Plant Development
Poster #34	**Janefrances Egbosiuba**	The Preliminary Investigation of Whether Switchgrass SND1 Orthologs Can Activate the Secondary Wall Biosynthesis
Poster #35	**Austin Garner**	The Genetics of Early Hybrid Lethality between Two Species of *Mimulus*
Poster #36	**Shreya Patel**	Role of Salicylic Acid in Oxidative Stress Responses in *Arabidopsis thaliana*
Poster #37	**Ishwarya Soundappan**	Genetic Analysis of the Role of *SMAX7* in Regulating Shoot Architecture
Poster #38	**Nikhil Kamath**	Identifying Interacting Proteins in the Karrikin and Strigolactone Signaling System
Poster #39	**John Brunson**	Sphingolipid Metabolism and the Biological Clock in *Neurospora crassa*
Poster #40	**Sarah Cunningham**	Modeling the Biological Clock in *Neurospora crassa*
Poster #41	**Solomon Walker**	The Effect of the Protein Ras2 on the Biological Clock of the Fungus *Neurospora crassa*
Poster #42	**Akshey Walia**	Cell Cycle Regulation of BMP Signal Transduction

Poster #43	**Philip Grayeski**	Cell Cycle Gating of the Mammalian Sonic Hedgehog Signaling Pathway
Poster #44	**Amy Webster**	Breaking Mendel's Laws: How Abnormal Chromosome 10 Causes Meiotic Drive
Poster #45	**Brianna Stadsvold**	The Effect of Telomere Dysfunction on Non-Allelic Recombination in the Subtelomere of *Kluyveromyces lactis*
Poster #46	**Briana Bennett**	Differential Expression of Genes Involved in the Insulin Growth Factor Pathway in Breast Cancer
Poster #47	**DeJuana Ford**	Healthcare, Genetics, Society and the Black-White Breast Cancer Survival Disparity
Poster #48	**Krupa Merchant**	Clicking on Platinum: Copper(I)-Catalyzed Azide-Alkyne Cycloaddition Chemistry for Axial Functionalization of Pt(IV) Prodrugs
Poster #49	**Trenton Berding**	The Creation of an Anticancer Prodrug – Combining Aspirin with Cisplatin
Poster #50	**Laura McLean**	Effect of Metformin Treatment on Feline Sarcoma Cancer Cell Cycle and Apoptosis
Poster #51	**Sheela Sheth**	Characterization of Proteoglycans in Prostate Cancer Cell Growth
Poster #52	**Christopher Watkins**	Mimicking the EGFR Dimerization Arm Using Triazolyl-Bridged Peptides: An Alternative Approach to EGFR Inhibition
Poster #53	**Anish Narayanan**	Analysis of Cancer Mutations in Protein Kinases Using Semantic Web Technologies
Poster #54	**Caitlin Gilbert**	The Role of O-Linked β-N-Acetylglucosamine in the Epigenetic Regulation of Colon Cancer Stem Cells
Poster #55	**Joshua Chang**	Proteomic Identification and Analysis of Potential Biomarkers for Pancreatic Adenocarcinoma
Poster #56	**Sindhu Prabakaran**	Investigating Missense Mutations in O-GlcNAc Transferase that Lead to Human X-Linked Intellectual Disability
Poster #57	**Niraj Patel**	Recombinant Protein Therapy: Generation and Purification of Various Fukutins

Poster #58	**Jill Modi**	Fiber Isotype Post-Injury in Secondary Dystroglycanopathies
Poster #59	**Vedika Rajasekaran**	Validating *In Vitro* Cell Culture Models for Molecular Pathogenesis Studies in *Fktn*-deficient Muscular Dystrophy
Poster #60	**Karishma Sriram**	Bone Fracture Putty: A Combined Stem Cell and Lentiviral Approach
Poster #61	**Joshika Money**	VacSIM, a New Vaccine Delivery Method, Improves Cellular Recruitment to Local Draining Lymph Nodes
Poster #62	**Matthew Winn**	Interactions between Neutrophils and *Pseudomonas aeruginosa* Flagellum
Poster #63	**Chelsea Fitzhugh**	Examination of the Function of *cobU* in Vitamin B12 Synthesis in Mycobacteria
Poster #64	**Mathew Joseph**	Immunopathogenesis of Placental Malaria in Mice Lacking Tumor Necrosis Factor and its Receptors
Poster #65	**Omar Martinez-Uribe**	Signaling Through TNF Receptors during Placental Malaria
Poster #66	**Tiffany Jenkinson**	Investigating the Relationship between the Complement and Coagulation Cascades in Placental Malaria
Poster #67	**Kristen Bascombe**	Light-Dependent Protein Degradation in *Plasmodium falciparum*
Poster #68	**Nina Paletta**	Use of Synthetic AKAP Peptides to Assess the Importance of the Protein Kinase A Signaling in the African Trypanosome
Poster #69	**Zachary Whitt**	The Utilization of Genetic Manipulation to Better Understand Kinative Function of CK1.2 in *Trypanosoma brucei*
Poster #70	**Melissa Jennings**	Biosynthesis of Base J by JBP1 and JBP2
Poster #71	**Allison Becker**	Plasmonemes: A Novel Cell-Cell Interacting Structure in *Trypanosoma brucei*
Poster #72	**Hayes Patrick**	The Double Knockout of the Haptoglobin-Hemoglobin Receptor in Bloodstream-Form *Trypanasoma brucei brucei* Lister 427-Single Marker Clone

Poster #73	**Lauren Dennison**	Mechanism of Mammalian Resistance to Trypanosome Lytic Factor
Poster #74	**Christopher Witt**	TLF2 Synthesis from Oxidized Lipids in TLF1
Poster #75	**Michael Cheng**	*Saccharomyces cerevisiae* as a Model System of Aβ Peptides Using a Copper Resistance Reporter
Poster #76	**William Saunders**	Investigations of a Protease (Ste24p) Associated with Progeroid Disease
Poster #77	**Elijah Mehlferber**	Effect of Differing Larval Diet on Adult Fitness Measured through Body Size, and Novel Methods for Body Size Quantification in *Drosophila suzukii*
Poster #78	**Melissa Masserant**	The Role of Dopamine in the Perception of Olfactory Inputs in Drosophila Larvae
Poster #79	**Caroline Blatcher**	*Pax6* Expression in the Adult Sey and Wildtype Brain
Poster #80	**Ojaswa Prasad, Dennis Dwan**	A Yeast-Based Screen for Drugs That Can Inhibit Human *Cdc6*
Poster #81	**Elizabeth Guarisco**	Examination of the Link between Glycosaminoglycans and Pectins
Poster #82	**Jerin Varghese**	A Proteomic Study of the *Botrytis cinerea*-Tomato Interaction
Poster #83	**Lucas Wachsmuth**	Mutations Impacting Copy Number Control and Host Cofactor Involvement in Retrotransposition of Ty1
Poster #84	**Stanislav Bushik**	Purification and Characterization of APAP1-Like Proteoglycans from Rice Suspension Culture Media
Poster #85	**Swayamdipto Misra**	Generation of Transgenic Plants Carrying Promoter: Reporter-Gene Constructs to Investigate Transcriptional Expression of GAUT Genes in Arabidopsis
Poster #86	**Lisa Ishii**	Molecular and Functional Characterization of FUCOSYLTRANSFERASE 10 in *Arabidopsis thaliana*
Poster #87	**Korry Tauber**	Examining the Function of O-GlcNAc in Regulating Inter- and Intracellular Signaling Pathways during Drosophila Development

Poster #88	**Leah Caplan**	Pigmentation and Protein Glycosylation in the Drosophila Embryo
Poster #89	**Ramon Reddick**	Purification of Xyloglucan-Specific Endo-β-1, 4 - Glucanase after Expression in *Escherichia coli*
Poster #90	**Sarah Premji**	Suboptimal Time in Therapeutic Range (TTR) for International Normalized Ratio (INR) Measurements Observed in an Outpatient Cardiology Clinic: Impact of Gender, Ethnicity, Disease Etiology, CHADSVasc score, Physicians and Clinic Site
Poster #91	**Mary Elizabeth Nuttall**	Economic Transition and Psychological Distress as it Relates to Risk Factors for Cardiovascular Disease in St. Lucia
Poster #92	**Christina Nguyen**	Work-Sites with Physical Exercise Facilities and Their Effect on Employee BMI and Waist Circumference
Poster #93	**Natalie Taylor**	Differences in Children's Physical Fitness by Rural or Urban Location
Poster #94	**Tracy Phan**	Football Facemask Mass Influences Head Impact Location
Poster #95	**Brice Hsu**	Mitochondrial Up-Regulation after Moderate Exercise in Able-Bodied Individuals with Near-Infrared Spectroscopy
Poster #96	**Hannah Bossie, Miller Singleton**	Evaluation of Mitochondria on Persons with Mitochondrial Myopathies Using Near-Infrared Spectroscopy
Poster #97	**Stephanie Tan, Hannah Bossie, John Hann**	Assessing Mitochondrial Function and Fatigue in the Human Gastrocnemius with Near Infrared Spectroscopy (NIRS)
Poster #98	**Hannah Cornelia**	Effect of Drying on Pulp Characteristics
Poster #99	**Meagan Patterson**	Association between Body Composition and Serum Folate Concentrations in Women Of Childbearing Age: Secondary Analysis across Three Studies
Poster #100	**Courtney Alvis**	Effect of Folate on Lipid Accumulation and Proliferation in Human Primary Adipocytes
Poster #101	**Kathleen Norris**	Proteomic Analysis of Erythrocyte Ghosts: The Effects of Zinc Supplementation

Poster #102	**Andrea Lobene**	The Relationships between Zinc and Bone Strength in Healthy Children
Poster #103	**Megan Ernst**	Addressing Inequality in Early Childhood Executive Function Development
Poster #104	**Brett McCardel, Breanna Ernst, Meghana R. Nathan, Victoria Smith**	The Effect of Order and Condition on Assessments of Executive Function
Poster #105	**Allison Fialkowski**	Single-Case Research Designs to Evaluate Social Behavior Development of Children with Autism Spectrum Disorders
Poster #106	**Amy Davis, Kelsie Flanigan**	Social Skills as Protective Factors against Poor Attitudes Towards Having Tourette Syndrome in Children
Poster #107	**Thomas Greco**	Neural White Matter Integrity Differs between Patients with Schizophrenia and Healthy Controls
Poster #108	**Ian Anderson**	Personal Distress and Response to Ambiguous Emotions
Poster #109	**Lauren Head**	Differences between Cohabiting and Non-Cohabiting Couples Who Participated in Premarital Education
Poster #110	**Yuri Kim**	Marital Security, Depression, and Sleep Quality: Assessing Bidirectional Associations with Actor-Partner Interdependence Model
Poster #111	**Courtland Hyatt**	Effects of Music on Male Aggression: Do Lyrics Matter?
Poster #112	**Jake Moskowitz, Amanda Heaton, Joshua Lukemire, Stephanie Villarreal**	Investigation of Hand-Tool Mastery in Tufted Capuchins Using a Multiple-Jointed Tool
Poster #113	**Kristen Smith, Rhianna Baldree**	Nut-Cracking Skill in Wild Capuchin Monkeys
Poster #114	**Natalie Schwob**	Vocal Repertoire of Red and Green Macaws

Poster #115	**Katherine Partrick**	Exploring the Variable Weaning Strategies of Female Rhesus Macaques through Stable Isotope Biochemistry
Poster #116	**Amber Davidson, Seyi Amosu, Brennen Clift, Sam Craig, Kyle Ledesma**	The Effects of Centralization on Performance When Moderated by Diversity
Poster #117	**Aaron Conley**	The Politicization of Soccer and the Effects of the 2014 World Cup on Brazilian Politics
Poster #118	**Alexa DeAntonio**	Perceptions about Global Development
Poster #119	**Jessie Lian, Alex Ballasiotes**	The Emergence of Sustainability as the New Dominant Logic in Business

Oral Session III: 9:30-10:45 a.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Richard Gardiner**	The Death of the Death Penalty
	Cecilia Moore, Holly Boggs	Analysis of International Media Coverage of Key North Korean Military Events
	James Barrow	Game Theory and Literature
Room B	**Amelia Watson**	Polio Eradication: What's Still Needed?
	Hannah Reiss	Neonatal Mortality in Uttar Pradesh, India and Possible Policy Solutions
	Smitha Ganeshan	Positive Psychology in Teen Mothers
	Max Tarica	Oxidative Stress within the Placenta during Malaria Infection
Room C	**Minh Ngoc Nguyen**	Metaphors of Color: The Linguistics of Internalized Racism
	McKinley Alden	Age and Formality in German Inalienable Possession Constructions
	Jonathan Dickens	Towards a Dynamical Model of Language Processing
	Ashleigh Starnes	The Linguistics of Artistic Language: Poetry, Complexity, and Mass-Market Novels
Room D	**Katherine Partrick**	Exploring the Variable Weaning Strategies of Female Rhesus Macaques through Stable Isotope Biochemistry
	Natalie Schwob	Vocal Repertoire of Red and Green Macaws
	Leigh Anna Young	Swath Size in Boa Vista's Bearded Capuchin Monkeys
	Thomas Johnston	Influence of Maternal Presence, Age, and Sex on Social Learning
Room G	**Anne Fernandes**	The Evolution of the Little Black Dress
	Lindsay Nation	The DIY Phenomenon: Why We "Do It Ourselves"
	Nancy Satola	Lesbian Dress: Recognizing and Being Recognized
	Devon Sprague	Native American Traditional Dress: Drawing the Line between Celebrating a Culture and Making a Mockery of It
Room H	**Hannah Bossie, Miller Singleton**	Evaluation of Mitochondria in Persons with Mitochondrial Myopathies Using Near-Infrared Spectroscopy

	Sudeepti Kuppa	The Dynamics of MglA in *Myxococcus xanthus* Motility Systems
	Kristen Farley	*Salmonella enterica* and *Escherichia coli* Can Exploit Diverse Pathways to Form Vitamin B1 in the Cell
	Megan Chesne	Applying CRISPR-Cas Interference for Genomic Manipulation in *Streptococcus thermophilus*
Room I	**Lindsay DeFrancesco**	Students' Perceptions of the Police – An Analysis of Greek and Non-Greek Affiliated Students
	Mitra Kumareswaran	A Tax-Deferred Trust: Reducing the Financial Burden of Families with Special Needs Children
	Walker Marlatt	A Change in the Winds: How the 'Dawgs Can Be Proud of More than Just Sports
Room J	**Giovanni Righi**	Addressing Droughts and Water Overuse in the Flint River
	Kirstie Hostetter	The Negative Side Effects of Organophosphate Pesticide Usage in Thailand
	Jasmin Melara	Carbon Flux in the Amundsen Sea Polynya

Oral Session IV: 11:00 a.m.-12:15 p.m.
Athena Breakout Rooms A, B, C, D

Room A	**Mallory Cox**	Ta-Tas or Not: The Needs of Female Breast Cancer Survivors Will Not Be Forgotten
	Lisa Ye Suh	Solution to Allworthy: The Magisterial Roles of Henry Fielding and Allworthy in *Tom Jones*
	Justin Dumrongkulraksa	Bridging the Gap: The History of British Science Examined through Literature
Room B	**Piyush Joshi**	Integrating of Human Neural Progenitor Cells into a Developing Chicken Embryo for a Toxicology Model
	Moriah Jackson	*Mycoplasma gallisepticum* Infection and Shed in Commercial and Wild Turkeys
	Julia McElreath	Arkansas Vaccine Virus Transmitted to SPF Chickens from Vaccinated Broilers Does Not Provide Protection from Challenge
	Hannah Reiss	Creating a Chimeric Chicken Resistant to Newcastle's Disease Virus

Room C	**Meili Swanson**	Improving Access to Screening for Post-Traumatic Stress Disorder in Operation Enduring Freedom and Operation Iraqi Freedom Veterans
	Karishma Sriram	Increasing Physical Education in American High Schools
	Christina Nguyen	Work-Sites with Physical Exercise Facilities and their Effect on Employee BMI and Waist Circumference
	Carver Goodhue	Applying International Strategies to Domestic Issues of Micronutrient Deficiency
Room D	**Pete Nkengasong**	Effects of Patellar Tendon Strapping on Lower-Extremity Kinematics
	Tyler Daugherty	On a Lack of Identifying Obstructive Sleep Apnea
	Jonathan Brown	Comparison of Peak Vertical Ground Reaction Forces between Individuals with Patellar Tendinopathy and Asymptomatic Individuals

Oral Session V: 12:30-1:45 p.m.
Athena Breakout Rooms A, B, C, D, G

Room A	**Sara Black**	And Justice for All: Scale, Solidarity, and Integrational Organizing in the Climate and Immigrant Justice Movements in Georgia
	Manisha Banga	A Mythological Chain of Oppression
	Kinsey Pebley	Issues in the Therapy Experience for the LGBT Community and Their Implications
	Tiffany Brown	The Importance of Local Grassroots Organizations in the Reshaping of Afro-Argentine Consciousness
Room B	**Emily Vermillion**	An Investigation of the Metabolic Changes Associated with Feeding a High-Fat/High-Sugar Diet in Swine
	Amanda Seamon	Incidence of Anesthesia-Related Fatality in Birds
	Elizabeth Wilkins	The Role of Notch Signaling in Astrocyte and Oligodendrocyte Derivation
	Kayla Hargrove	Necessity of Universal Pre-Operative Blood Work Testing in Healthy Dogs

Room C	**Shaun Kleber**	Decreasing Summer Learning Loss among Low-Income Students in Athens-Clarke County
	Shalin Jyotishi	The Executive Science Network: Variations between Public and Private Trustee Networks
	Megan Ernst	Addressing Inequality in Early Childhood Executive Function Development
	Paul Kirschenbauer	Closing the Income Gap – Education and Technology in the United States
Room D	**Mary Douthit**	Octopaminergic Gene Expression and Flexible Social Behavior in the Subsocial Burying Beetle *Nicrophorus vespilloides*
	Tuan Nguyen	Mitogen Activated Protein Kinase Flanking C-Terminal Tail: Structure and Function
	Matthew Hess	Nanoparticle-Delivered Therapeutics for African Trypanosomiasis
	Travis Williams	Fermentation of Cull Peaches Using a Pectinase Producing *Saccharomyces cerevisiae* Strain
Room G	**Megan Griffin**	Do Knee Straps Decrease Self-Reported Patellar Tendon Pain after Jump Landings?
	Katherine Hsieh	The Effect of a Patellar Tendon Strap on Knee Power during a Drop-Jump
	Edmund Afful	The Association between High Intensity Athletic Participation and Chronic Ankle Instability

Oral Session VI: 2:00-3:15 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Patrick Wheat**	The Rationality of Peacekeeping
	Cody Knapp	Building a Record: Requesting Roll Call Votes under Changing Institutions
	Mitchell (Trey) Flynn	Modifying Appointments to the FISA Court
	Marco Roca	1970s Czechoslovakia: A Foundation for the Study of International Human Rights Law

Room B	**Amy Webster**	Breaking Mendel's Laws: How Abnormal Chromosome 10 Causes Meiotic Drive
	Jennifer Pallansch	Bioluminescent Color Shifts in North American Fireflies
	Emily Fawcett	Investigating Female Remating Rates in Wild *Drosophila neotestacea* and Their Association with Sex-Ratio Drive
	Philip Grayeski	Cell Cycle Gating of the Mammalian Sonic Hedgehog Signaling Pathway
Room C	**Aaron Conley**	The Politicization of Soccer and the Effects of the 2014 World Cup on Brazilian Politics
	Molly Malone	Job Training to Combat Poverty among Unemployed Coal Miners
	Thomas Oliver	Max Contracts: Savings or Reallocation?
Room D	**Jerica Bornstein**	Keeping Good Company: Creating Social Environments that Promote Goal Pursuit
	Joseph Coppiano	Individual Differences in Cognitive Control: Antisaccade Performance in Those with Schizophrenia and Low Cognitive Control
	Alan Gerlich	Neural Abnormalities in Ocular-Motor Inhibition in Schizophrenia, Bipolar Disorder, and First-Degree Relatives
Room G	**Anne Chen**	Sex-Ratio Imbalances and Risky Behavior in College
	Alexandra Edquist	Capital-Intensive Punishment: Reducing the High Costs of Federal Drug Incarceration
	Tiffany Toteno	Variables Affecting Attitudes toward Police
	Anthony Reyna	College Credit Experience and Financial Literacy
Room H	**Tiffany Washington**	Concussions from the Past Continue to Predict Present Symptomology Above and Beyond Mood Symptoms
	Victoria Moreira	EnVISIONeD: Examining VISion among Inpatients with Diabetes
	Brett McCardel	Neural Activation Changes Associated with Antisaccade Task Practice
Room I	**Isaiah Norris**	Hydrothermal Synthesis and Particle Size Study of Ancient Pigments

	Samuel Kennedy, Trenton Berding	Attacking the Fire and Fuel: Nano Formulation of Platin-A for Cancer and Associated Inflammation
	Joseph Sanchez	A Unique Mechanism in *Staphylococcus aureus* Ketopantoate Reductase
Room J	**Sheela Sheth**	Reducing Vitamin D Deficiency among Individuals Aged 50 and Older in Georgia
	Torre Lavelle	How to Tackle the Bike Share Helmet Problem
	Rahul Shah	Decreasing HIV Incidence in Russia through Needle & Syringe Programs

Oral Session VII: 3:30-4:45 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Greyson Clark**	Power Dynamics in Georgia's Poultry Industry, 1950-1965
	Laura Nelson	"Please Excuse Me as I Am in Need:" Bondage and Freedom in Civil War-Era Athens
	Anthony Sadler	Lester Moody: A Man, a River, and a Quest for Industry in the Twentieth Century South
	Seth Euster	Uncovering the Heritage of Slavery at the Shields Ethridge Farm: Memory, Identity, and Heritage Tourism
Room B	**Matthew Winn**	Interactions between Neutrophils and *Pseudomonas aeruginosa* Flagellum
	Raja Atchutuni	Distribution of Novel Genes in *Salmonella* Isolated from the Environment
	Kapil Chandora	Role of Mir-34a in Regulation of Macrophage M2 Phenotype
Room C	**Giovanni Righi**	Searching for Noise-Induced Phase Transitions in Ecological Systems
	Kelly Murray	Evidence for Indirect Effects of a Predatory Fish on the Size Distribution and Behavior of a Larval Caddisfly Species in Trinidadian Streams
	Mariana Satterly	Issues of Economic Efficiency in the Domestic Conservation Easement System
	Scott Saunders	A Mechanistic Explanation of How Regional Winter Climate Differences Influence Lyme Disease Distribution

Room D	**Anudeep Neelam**	ChuW as a Class C Radical SAM Methyl Transferase
	Allison Becker	Plasmonemes: A Novel Cell-Cell Interacting Structure in *Trypanosoma brucei*
	Allison Doyle	Measuring Brain Tissue Factor Levels in Malaria Infection
	Chris Slade	Genetic Assessment of the Role of TNF and its Receptors (RI and RII) in Placental Malaria Pathogenesis
Room G	**Julian Traas**	The Five-Fold Division: Shadow Personalities in Beckett's Three Novels
	Molly Dodd	Grace Kelly: Femininity in Film
	Hannah Klevesahl	Henry V: Legitimacy in Kingship and Film
	Chiara Tondi Resta	Reexamining a Little-Known Aphrodite Anadyomene Statue from Ancient Stabiae
Room H	**Scarlett Sumner**	Ecology and Genetic Characteristics of Haemogregarines in Fresh Water Turtles
	Shannon Burns	Riverwater and Seawater Dissolved Inorganic Carbon Endmembers for the Amazon River Plume
	Meg Babcock-Adams	Chemistry at Sea: An Expedition to the North Pacific to Analyze Deep Ocean Refractory Carbon (DORC)
Room I	**Fred Hohman**	3D Printing Techniques in Topology
	John Stroud	The Monkey Saddle
	David Flake	Membrane Electrode Assembly Preparation Utilizing Platinum Catalysts for Use in Polymer-Electrolyte-Membrane Fuel Cells
	Mehreen Sultana	Fabrication of Hinged Nano-Motors Utilizing Metal Assisted Chemical Etching, Nano-Sphere Lithography, and Physical Vapor Deposition
Room J	**Erin Hollander**	Increasing Nutrition through Genetically Modified Organisms
	Dayna Hardgrove	An Integrative Outlook on the State of Sustainable Development in Sarawak, Malaysia
	Kristyn Nock	*In Vitro* Protease Digestion and Reduction of Tropomyosin using Shrimp and Tropomyosin-Enriched Samples

The Association between High Intensity Athletic Participation and Chronic Ankle Instability

Edmund Afful
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Ankle sprains are a common athletic injury and may develop into Chronic Ankle Instability (CAI). CAI onset, determining factors, and relationship to sport participation remain unclear. The purpose of this study was to determine whether there was a relationship between participating in high intensity physical activity and CAI status. We hypothesized because of dynamic activity involved, there would a greater association of CAI in higher intensity sporting activities. In this retrospective review, recreationally active individuals' (90 female, 98 male, 21.0±2.9years, 173.3±9.6cm, 70.9±13.7kg) self-reported questionnaires quantifying ankle function were used to determine CAI status with appropriate cut-off values. Subjects also indicated the types of physical activities in which they participated. Activities that included jumping, cutting, and multiplanar motion (basketball, volleyball, field sports, etc.) were labeled as high-risk activities. Low-risk activities were those that did not require jumping, landing, and were uniplanar (walking, running, weightlifting etc.). A chi-square analysis was completed to assess the relationship between high-risk sporting activities and CAI status. There was a significant association (X^2=8.665 $p<0.01$) between those who participated in high-risk activities and the likelihood of having CAI. It appears those who participated in less demanding activities such as walking and lifting weights were less likely to report CAI, while those who did participate in high intensity activities were more likely to have CAI. High demand sports, with muliplanar movements and larger loading forces, may exacerbate symptoms of CAI. Future research should determine if specific sport participation is a risk factor for developing CAI.

Age and Formality in German Inalienable Possession Constructions

McKinley Alden
Dr. Vera Lee-Schoenfeld, Germanic & Slavic Studies, Franklin College of Arts & Sciences

In German, possessive constructions with inalienable prepositional phrase-embedded objects wield either an accusative- or dative-marked possessor. The construction in question is defined by the seemingly random interchangeability of the accusative and dative case, for example, "Das Mädchen kneift mich/mir in den Arm" ("The girl has me *Acc./Dat.* in the arm pinched," or, less literally, "The girl pinched me *Acc./Dat.* in the arm."). Recent studies show that formality tends to influence the case used in these constructions (Lee-Schoenfeld and Diewald 2013). This analysis posits that the preferred case is dependent on the age distribution of the speaker, specifically that younger speakers prefer the dative case to the more formal accusative case. The pilot data for this study was collected via survey, in which native speakers from Germany rated minimally paired sentences on a scale of *Very Inappropriate* to *Very Appropriate* for colloquial use. These results were then stratified by age of the participants in order to observe the relationship between this feature and the use of case. These ratings were imposed onto a numerical index, 1 for *Very Inappropriate* and 5 for *Very Appropriate*, and averages of the total responses of each stratum were taken. Within the aforementioned sentence pair, speakers 21 to 30 preferred the dative case, giving the accusative an average rating of only 3.5 (*Neutral*), whereas participants over age 61 gave the accusative an average rating of 4.67 (*Appropriate)* in the same sentences. This methodology has yielded results that will, when superimposed on preordained German case laws, generate valuable sociolinguistic

information on the relationship between age and formality.

Identification of a Novel O-Antigen and its Role in the Virulence of *Aeromonas hydrophila* Isolated from Diseased Catfish

Laura Alexander
Dr. Timothy Hoover, Microbiology, Franklin College of Arts & Sciences

Affecting primarily mature, market-sized catfish, *Aeromonas hydrophila* has caused the loss of millions of pounds of the largest product in America's aquaculture industry since 2009. This gram negative, rod-shaped bacterium causes septicemia in catfish, which is quickly followed by death. In an effort to characterize the virulence factors of *A. hydrophila,* genes suspected of playing a role in causing disease in catfish are being explored, such as those involved in the synthesis of O-antigen. In order to investigate its role in the virulence of *A. hydrophila,* a mutant lacking O-antigen ligase (Δ*waal*) was constructed and found to be avirulent in an aquarium model of infection using fingerling catfish. In order to further confirm this result and to determine how it allows the bacterium to infect catfish, the ligase (*waal)* gene was complemented in the mutant *in trans*, and visualized through SDS page analysis. Motility assays comparing the abilities of wild type, ligase mutant and ligase complement to swarm were conducted in order to both confirm complementation and determine if O-antigen affects motility in *A. hydrophila*. Upon discovery that the structure of *A. hydrophila* O-antigen is unique and possibly novel, we conducted a Multi-Locus Sequence Typing analysis using multiple housekeeping genes: *dnaJ*, *dnaX*, *recA*, *gyrB*, *rpoD*, and *gyrA* in an attempt to ascertain whether virulent strains of *Aeromonas hydrophila* may be classified as a novel subspecies. The results support the high degree of genomic homogeneity among virulent *A. hydrophila* strains and their tentative classification as a novel subspecies.

Effect of Folate on Lipid Accumulation and Proliferation in Human Primary Adipocytes

Courtney Alvis
Dr. Hea-Jin Park, Foods & Nutrition, College of Family & Consumer Sciences

Folate is an essential water-soluble vitamin that is involved in multiple cellular metabolisms including DNA synthesis and epigenetic regulation. Epidemiological studies report inverse associations between serum folate concentrations and body mass index; however the potential influence of changes in folate status on adipose cell development and metabolism has only been examined in animal models or a murine cell line, which is why this research is significant. The question of this study was to determine how folate influences differentiation and proliferation of human primary subcutaneous preadipocytes. Human primary preadipocytes, derived from subcutaneous adipose tissue of normal weight female donors (ZenBio Inc.), were exposed to 0.06, 6 or 60 uM folic acid (FA, oxidized form of folate; Sigma) and 5-methyltetrahydrofolate (MTHF, reduced form of folate; Merck). The impact of treatment on differentiation and proliferation were determined by AdipoRedTM Adipogenesis assay (Lonza) and CellTiter-Blue® Cell Viability assay (Promega), respectively. Results indicate that FA and MTHF decrease lipid accumulation in mature adipocytes after adjusting for cell number. Interestingly, MTHF, reduced form of folate, exhibited a greater inhibitory effect on lipid accumulation. Proliferation data suggest that FA had no effect on proliferation, while MTHF increased proliferation in a dose-dependent manner. Taken together, these results suggest that biologically active reduced forms of folate may have a greater effect on adipocyte proliferation and differentiation in human adipocytes. This study also supports preliminary findings in murine cell lines demonstrating the importance of maintaining

folate availability during adipose cell development.

Personal Distress and Response to Ambiguous Emotions

Ian Anderson
Dr. Brian Haas, Psychology, Franklin College of Arts & Sciences

Personal Distress (PD) is a tendency towards experiencing a high level of stress in response to intense emotional situations. Prior studies have shown that higher levels of PD are associated with higher social dysfunction, anxiety, and fearfulness. It is currently unknown, however, if PD is associated with the interpretation of ambiguous emotional stimuli and/or the speed at which people make emotion-based decisions. Based on prior studies, we predicted that higher PD scores would be associated with a negative emotional bias during the interpretation of ambiguous emotional stimuli. Furthermore, we predicted that higher PD scores would be associated with faster reaction times to negative emotional stimuli. To test these predictions, participants (N=59) performed a task in which brief movies of neutral faces morphed into emotional faces. Each participant was instructed to decide whether they believed the person in the image had just received either good or bad news. The three emotions presented were happy, fearful, and surprised. The results show that PD scores were positively correlated with a greater tendency to interpret surprised faces as negative ($r=.268$, $p=0.040$) as well as negatively correlated with fear response time ($r=-0.354$, $p=0.006$) and negatively correlated with reaction time when interpreting surprised faces as good ($r=-0.295$, $p=0.023$). These findings support the hypothesis that a higher PD score is associated with a negative emotional bias during the interpretation of ambiguous emotional situations and suggests that PD affects reaction time differently for negative and positive stimuli.

Distribution of Novel Genes in *Salmonella* Isolated from the Environment

Raja Atchutuni
Dr. John Maurer, Population Health, College of Veterinary Medicine

Salmonella is responsible for 1 million gastroenteritis cases in the United States each year. In the past, most illnesses were attributed to the consumption of fecally contaminated meat, milk, and eggs. However over the past 20 years, we have seen a significant increase in foodborne outbreaks linked to produce. Water is believed to be a potential source of *Salmonella* contamination in produce production. We have recently performed whole genome sequencing on a number of non-traditional *Salmonella* serovars, some of which have been isolated from the environment. We identified several unique mobile genetic elements, pilus, and metabolic genes. We screened environment *Salmonella* isolates by southern hybridization and PCR for the presence of several of these novel genes. We identified a large molecular weight, conjugative plasmid in *S*. Mikawasima, and found that this plasmid was widely disseminated among our environmental isolates. We also identified a pilus operon homologous to the *E. coli* common pilus that was also widely distributed in our isolates. However, we also found certain lysogenic phages that were limited to a handful of *Salmonella* isolates. From screening these different environmental isolates, we observed that the water isolates had a different pattern of genes present, compared to *Salmonella* that inhabit animal isolates. The variation in the distribution of genes in the water isolates from the animal isolates explains the adaptation of these particular *Salmonella* strains to the aquatic environment.

Abstracts

Chemistry at Sea: An Expedition to the North Pacific to Analyze Deep Ocean Refractory Carbon (DORC)
Meg Babcock-Adams, CURO Summer Fellow
Dr. William Miller, Marine Sciences, Franklin College of Arts & Sciences

In the summer of 2013, I participated in a 3-week oceanographic research cruise aboard the *RV Melville* in the North Pacific. There we collected water from 33 stations, from multiple depths, and ran onboard experiments. These experiments were designed to measure several different chemical components, all working towards obtaining a comprehensive picture of the deep ocean refractory carbon (DORC) pool and the role of marine photochemistry in its removal from the ocean. The amount of dissolved organic carbon (DOC) in the entire ocean, of which a large portion is DORC, is equal to that of carbon dioxide (CO2) in the atmosphere; therefore, interconversion between DOC and CO2 is essential to understanding air-sea carbon exchange and global carbon budgets. Fueled by solar energy, photochemistry converts DOC in the ocean to CO2 and CO, which can be released to the atmosphere. This is the central idea that my project was based on. While the entire Miller lab worked together in conducting experiments, I directed most of my time to measuring CO accumulation in seawater throughout long-term exposures in a solar simulator. Using experimentally determined ratios, CO can be related to CO2 and consequently, the total mass of carbon gases that may be released into the atmosphere as a direct result of marine photochemistry can be estimated. Shipboard results look promising and follow-up experiments are underway to interpret results for contribution to new calculations of the role of DORC and photochemistry in the global ocean carbon budget.

A Mythological Chain of Oppression
Manisha Banga
Dr. Benjamin Wolkow, Classics, Franklin College of Arts & Sciences

This research examines a chain of oppression that connects the ancient Greek mythological figures of Hades, Persephone, and Adonis—ancient characters who are seldom connected in modern retellings but whose stories are surprisingly intertwined. The focus of the research will be on the following: How does Hades' oppression and objectification of Persephone lead to Persephone's oppression and objectification of Adonis? Moreover, how can these stories be related? In order to examine these relationships, the researcher will reference both primary and secondary sources, including translations of the original myths and critical essays on the myths themselves. The research will involve a primarily analytical and literary examination of the archetypes that Persephone's relationships embody, as well as the application of these archetypes in the modern world. Additionally, the research will examine the descriptions of these characters in their original myths and will place these descriptions in conversation with each other in order to further explore the characters' interconnectedness. Ultimately, classical, literary, and feminist viewpoints on the myths will be considered in order to examine the myths in ways that have not yet been explored.

Game Theory and Literature
James Barrow
Prof. Michael Lynch, Political Science, School of Public & International Affairs

William Poundstone, writes "[g]ame theory is a study of conflict between thoughtful and potentially deceitful opponents" (Poundstone, 1993). One problem with game theory is that scientists typically examine an event of the past and attempt to explain why certain results emerged but they assume one thing: that all

actors acted rational. This is not always the case; in fact most people act irrationally. It is through literature that we observe how irrational people behave and the consequences that ensue. As Walter Wangerin Jr. wrote in *The Orphean Passages*, "[i]n order to comprehend the experience one is living in, he must by imagination and by intellect be lifted out of it. He must be given to see it whole; but since he can never wholly gaze upon his own life while he lives it, he gazes upon the lift that, in symbol, comprehends his own" (Dickerson & O'Hara, 35). It is only through literature and looking at an experience that was not our own, but one we can relate to, that we are truly able to study game theory. Therefore, the point of this research is to examine literature of the ages, from the Bible to Shakespeare to Jane Austin to J.K. Rowling, and observe the game theory that occurs between characters, not rational actors.

Light-Dependent Protein Degradation in *Plasmodium falciparum*

Kristen Bascombe
Dr. Vasant Muralidharan, Cellular Biology, Franklin College of Arts & Sciences

Malaria is a deadly parasitic disease, and there is widespread resistance against anti-malarial drugs. In order to develop new therapies, the biology of malaria parasites must be further understood. Gene knockdown methods used in other organisms are not effective in *Plasmodium* species. To study parasite biology we currently use drug-dependent degradation domains that require costly and toxic chemicals. Recently, light-dependent protein degradation has been reported in yeast. The purpose of this research is to develop an optogenetic tool for protein knockdown in *Plasmodium falciparum* to determine their roles in the parasite's biology. A preliminary *in vitro* assay for light-dependent protein degradation will be developed using purified proteins and *P. falciparum* lysates. If protein degradation is successful *in vitro*, *in vivo* experiments in *P. falciparum* will follow. Expression constructs for GFP, and GFP fusion proteins (GFP-Ddd and GFP-psd) were created using PCR, restriction enzyme digestion, and ligation into the pET28a vector. The resulting constructs were analyzed using diagnostic restriction digestion and DNA sequencing. The verified constructs were transformed into BL21 *E. coli* for protein production. Proteins purified from *E. coli* via HIS-tag affinity chromatography will be incubated with *P. falciparum* lysates under protein degradation and protein stabilization conditions. Protein degradation will be assessed via visual confirmation of green fluorescence and western blot with anti-GFP antibodies. This new tool for studying *P. falciparum* will help identify proteins necessary for blood stage infection and provide targets for new antimalarial drug development.

Clinoptilolite Formation in the Lower Floridan Aquifer

Philippe Bauchau
Dr. Paul Schroeder, Geology, Franklin College of Arts & Sciences

Clinoptilolite is a natural zeolite that most commonly forms in volcanic tuffs by devitrification (i.e., the transformation of amorphous glass to crystalline phases). A mineralogical study of the Miocene Lower Floridan Formation at Cockspur Island, Georgia by Ostrowicki (2012) reveals the unusual occurrence of clinoptilolite within a quartz-bearing limestone. This limestone hosted zeolite was examined by electron microprobe analysis and results indicate the clinoptilolite bears structural Na-K-Ca-Mg, giving it an average empirical formula of (NaK2MgCa1.5Al8Si30O72*24H2O). Thermodynamic modeling using Geochemist's Workbench® shows that a Na-clinoptilolite is more stable than Ca-clinoptilolite when inputting the present day pore water chemistry as reported by the U.S.

Geological Survey (Gonthier, 2012). When comparing the non zeolite-bearing Upper Floridan Formation pore water chemistry to the Lower Flordian pore waters, thermodynamic models favor the formation of Na-clinoptilolite in the Lower Floridan. The depositional environments were likely in a tropical marine setting, however when clinoptilolite is present, it suggests a higher silica activity, perhaps sourced from more basic waters and diatomaceous blooms. The question "when during diagenesis (early versus late) did clinoptilolite originate in the aquifer?" is still being considered. The occurrence of clinoptilolite is important because clinoptilolite acts as an ion exchanger for heavy metals and ammonia. The effect of clinoptilolite on formation factors used to evaluate aquifer storage potential is important, particularly as coastal communities in the SE United States look to manage fresh water sources.

Plasmonemes: A Novel Cell-Cell Interacting Structure in *Trypanosoma brucei*

Allison Becker
Anthony Szempruch, Graduate Research Assistant
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosoma brucei is the causative agent of human African sleeping sickness and the cattle-wasting disease Nagana. During the mammalian infection the parasite is exposed to the host immune system. To subvert the adaptive immune response, trypanosomes express a single variant surface glycoprotein (VSG) that prevents antibody recognition of other cell surface components. The VSG can undergo antigenic variation allowing for immune evasion. It has been hypothesized that while in the blood stream cell-cell and cell-host interactions take place. Recent research has shown that trypanosomes produces exosomes, small lipid vesicles, possibly as a means of communication during stress. The production of exosomes is highly correlated with the presence of plasmonemes. These plasmonemes are easily observed by Differential Interference Contrast (DIC) microscopy and appear at the posterior end of the parasite. The posterior end is the location of the flagellar pocket, the only site of endocytosis and exocytosis in the cell. Our research determined physiologically relevant conditions that increase the formation of plasmonemes. The increased production of plasmonemes, mediated by biological stresses, appears to increase cell-cell interactions and may serve as another mechanism for cell communication.

Differential Expression of Genes Involved in the Insulin Growth Factor Pathway in Breast Cancer

Briana Bennett
Dr. Melissa Davis, Genetics, Franklin College of Arts & Sciences

Insulin Receptor Substrate 1 (IRS1) and Insulin-like Growth Factor Binding Protein 6 (IGFBP6) are key players in the Insulin Growth Factor (IGF) pathway, and their expression is often altered in breast cancer subtypes. IGFBP6 binds to both IGF1 and IGFII, normally with higher affinity to the latter. This interaction modulates the activity of the IGFs in the cell, and IGF1 modifies IRS1 via post-translational mechanisms. In order to determine if the levels of IGFBP6 and IRS1expression varies among normal breast epithelial cells and cancerous cells, we used qPCR to obtain quantitative transcript levels and immunofluorescence microscopy to verify the gene product levels. IGFBP6 is overexpressed in Basal-like breast cancer cells and underexpressed in ER+ cancer cells compared to normal cells. IRS1 has higher levels of expression in ER+ cancer cells compared to normal. Utilizing immunofluorescence microscopy, IGFBP6

shows higher levels of fluorescence in the Basal-like cancer cells and lower levels in the ER+ cells. The microscopy also revealed that IGFBP6 is localized to the cytoplasm and shows small areas of concentration where it is likely binding to its substrate(s). The images obtained of IRS1 show higher levels of fluorescence in ER+ cells, confirming its qPCR results. The differential expression of these genes may affect the properties of cancerous cells as the growth factor pathways are possibly linked to cancer subtype etiology. Further investigation into the expression levels of other genes in the insulin pathway will provide insight into how it could be a potential target for treatment.

The Creation of an Anticancer Prodrug – Combining Aspirin with Cisplatin

Trenton Berding
Prof. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Cisplatin is a chemotherapeutic drug which targets the DNA of cancer cells causing apoptosis. Treatment with cisplatin commonly demonstrates severe adverse side effects related to inflammation, such as nephrotoxicity and ototoxicity. Creation of a prodrug, Platin-A, from the synthesis of aspirin and cisplatin, has been found to reduce the inflammatory complications and cytotoxic effects of treatment with cisplatin alone. These findings highlight the advantages of using a prodrug to decrease inflammation associated with the delivery of a chemotherapeutic agent.

Embodiment and Altruism

Hania Bisat, CURO Graduation Distinction
Dr. Leonard Martin, Psychology, Franklin College of Arts & Sciences

Embodied cognition is the idea that physical factors in a person's environment, whether the temperature, the surface a person is sitting on, or the position of certain items in a room, subconsciously affect how people perceive their surroundings, as well as how they respond to them. One of the most controversial studies on this topic is that of Williams and Bargh (2008), in which participants who were asked to hold a warm cup of coffee were more generous and more likely to see others in a positive light than those who were asked to hold a cold cup of coffee. We sought to replicate and extend this study. We gave participants various personality tests, asked them to hold a warm or cold cup of coffee, gave them Bargh's Impression Formation task, and noted if they volunteered to help the experimenter pick up a box of dropped pencils after the experiment was officially over. We hypothesized that those who held a warm drink would be more likely to rate the person in Bargh's computer task more warmly, and would also be more likely to help the experimenter. We also hypothesized that participants who labeled themselves as conservative would be more influenced by the temperature of the drink they held than liberals. If our results mirror those of Williams and Bargh, they will serve as further proof of the subconscious effects the environment has on a human's feelings, perception, and actions.

Response of Microbial Nitrification and Denitrification to Redox Shifts in Beach Sand

Laurence Black
Dr. Samantha Joye, Marine Sciences, Franklin College of Arts & Sciences

The concentration of atmospheric nitrous oxide (N2O), one of the most important greenhouse gases, has increased by 18% (270 to 320 ppb) since the industrial revolution. Human activity, such as agriculture, has increased the amount of fixed nitrogen entering the natural nitrogen cycle, in turn increasing microbial N2O production. Oxygen availability is a key driver of N2O production rates by nitrifying and denitrifying

microorganisms, and oxygen availability in beach sands may fluctuate in response to tidal oscillation. Here we test the hypothesis that N2O concentrations in these sands will increase following sudden changes in oxygen availability. Beach sand was collected from Cabretta Island, a barrier island on the Georgia coast. Sand was enriched with either nitrification (NTR) substrates (ammonium (NH4+)) or denitrification (DNF) substrates (nitrate (NO3-) and organic carbon) and incubated in bottles under oxic or anoxic conditions. After four days, some bottles were switched from oxic to anoxic conditions and vice versa while others remained unchanged. The concentration of nitrous oxide in the headspace of each bottle was measured before and after this switch using a gas chromatograph with an electron capture detector. The data generated suggest that microorganisms have a greater tendency to produce sudden spikes and depletions of N2O due to fluctuations in nutrient and oxygen availability. Tides drive this type of redox oscillation in beach sands, potentially making them an important source of N2O to the atmosphere.

And Justice for All: Scale, Solidarity, and Integrational Organizing in the Climate and Immigrant Justice Movements in Georgia

Sara Black, Foundation Fellow
Dr. Nik Heynen, Geography, Franklin College of Arts & Sciences

Georgia enters 2014 as a state with some of the most draconian anti-immigrant laws in the U.S. and two of the most carbon-intensive coal plants in the world. The immigrant justice and climate justice movements have active front lines in Georgia, peopled by local grassroots organizations navigating issues primarily framed at the state level, albeit rich with the context of national movement strategy. In the fall of 2012, student organizers from UGA Beyond Coal and the Undocumented Student Alliance at UGA coordinated a direct action tactic that offered not just statements of solidarity, but a unified message and underlying narrative justifying collaboration between immigrant and climate justice activists. This paper documents the continuing effort to deepen the relationships of solidarity and collaboration that were started with that action, and asserts that these collaborative spaces, which are not seen as strategically efficient, nevertheless create power in the form of relationships, knowledge, and narrative. Using a participant action research methodology, I have worked with local organizers to identify justifications and avenues for collaborations spanning a gradient of strategic value. In developing an underlying narrative that supports and invigorates collaborative action, local actors resisting primarily local ordinances offer frames rooted in the politics of scale which encompass and integrate the large-scale drivers of climate change and migration. Translating these frames into local action has the potential to challenge the whiteness of the climate movement and to tie more deeply the story of climate disruption to the story of economic disruption and vulnerability.

***Pax6* Expression in the Adult Sey and Wildtype Brain**

Caroline Blatcher
Dr. James Lauderdale, Cellular Biology, Franklin College of Arts & Sciences

Pax6, a member of the Pax family of transcription factors, is expressed in distinct regions of the central nervous system, specifically the eye, forebrain, hindbrain, and spinal cord. It is critical for development of the eye as well as development and patterning of the forebrain, including establishing dorsal-ventral boundaries, neuronal migration, and axon guidance. Aniridia is a human congenital condition characterized by a semidominant mutation in *Pax6*. Although well-studied for the eye phenotypes, relatively little is known

about the effects of the *Pax6* mutation on the forebrain. The mouse model for Aniridia, *Small eye (Sey),* also has a mutation in one copy of the gene, making it a good rodent model for understanding the human condition. To date, no studies have attempted to find out if there are any differences in the forebrains of *Sey* mice at the cellular level. The attempt of this study was to determine any potential differences in the structure and expression pattern in the brain of *Small eye* mice compared to wild-type. Structural analyses were performed by hematoxylin and eosin staining (H&E) on paraffin-prepared histological sections. Differences in protein expression were tested using immunohistochemistry, also on paraffin-prepared histological sections of the brain. Expression levels in adult brains were also measured at the level of mRNA by whole mount RNA *in-situ* hybridization. The differences found in this study could lead to understanding some of the non-eye-related symptoms experienced by people with Aniridia.

Keeping Good Company: Creating Social Environments that Promote Goal Pursuit

Jerica Bornstein
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

We examined how people look for goal support, namely how others' self-control affects how much time people wanted to spend with them. Specifically, we examined how individuals' own self-control affects their feelings towards people they perceive to be (a) high versus low in self-control or (b) helpful versus unhelpful. In Study 1, participants were randomly assigned to write about someone they recently met whom they judged to have either high or low self-control. Results indicated that participants with high self-control reported wanting to spend more time with people who also had high self-control relative to people who had poor self-control. In Study 2, students in a research statistics class were invited to take part in a survey about their feelings on the course. Students reported about a friend who was helpful in their goal pursuit and a friend who interfered with their goal pursuit. Results indicated that when high self-control participants were nervous before the first exam they wanted to spend more time with their friend who would help their goal pursuit and avoid the friend who would interfere with their goal pursuit. However, when high self-control students were not nervous before the first exam they did not show a preference between their helpful and interfering friend. Trait self-control predicts preferences to spend time with others who have high trait self-control, particularly when individuals feel like they need help with their goals pursuits.

Evaluation of Mitochondria in Persons with Mitochondrial Myopathies Using Near-Infrared Spectroscopy

Hannah Bossie, Miller Singleton
Dr. Kevin McCully, Kinesiology, College of Education

The aim of this study is to measure skeletal muscle mitochondrial function in individuals with mitochondrial myopathies (MITO) and compare these results to controls. These measurements will be made utilizing near-infrared spectroscopy (NIRS). The NIRS method has been used to assess mitochondrial function in individuals with various chronic conditions, including spinal cord injury, multiple sclerosis, cystic fibrosis, and heart failure. I hypothesize that patients with mitochondrial myopathies will have impaired mitochondrial function, and this will correlate with clinical symptom severity. The study will be performed in the Exercise Muscle Physiology Laboratory in the Kinesiology Department. I am collaborating with a clinical geneticist, Dr. Fran Kendall, who works specifically with mitochondrial myopathies. Participants with and without a genetically

confirmed diagnosis of mitochondrial myopathy (n=20 each) will be tested after we get IRB approval. Several recent review papers have highlighted the need for a noninvasive method that can monitor the treatment of people with mitochondrial myopathies, including one by Dr. Kendall. Because the NIRS test that we will use is noninvasive, and takes 30 minutes or less, NIRS has the potential to fill this important need. The NIRS test can serve as an important adjunct test for diagnosis of mitochondrial myopathies. It can also lead to future studies evaluating treatments for mitochondrial myopathies with various antioxidant supplements and or pharmacological interventions.

Marketing an Online Based Education Platform

Noah Boswell, CURO Honors Scholar
Dr. Piyush Kumar, Marketing, Terry College of Business

In today's world we are in the Wild West of free online education. While there are established websites such as Khan Academy and Coursera, they are not perfect and can certainly improve. It is important that these education platforms improve too, as the rising cost of college is making it increasingly harder for people to get the knowledge they need. Our goal with Faqulty.com is to attempt to make a website where people can be the student and the teacher for free. Our website will offer a way for people to aggregate information on a subject and structure it in a course-like manner for anyone to see. People will then be able to go to this website and be able to learn about a subject from the viewpoint of multiple people. Our directive is to now make sure that Faqulty.com is marketed well enough so that we can achieve these goals of improving the free online education space. If we can achieve this, this website will be a great tool and a valuable resource for everyone who accesses it.

What Predicts Willingness to Support a Partner's Smoking Cessation Attempt?

Savannah Boyd
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

People are constantly pursuing new goals, often with the expectation of support from their significant other. In this project, we focused on the goal of smoking cessation. Compared to individuals not partnered with another smoker, dual-smoker couples are less likely to both try to quit smoking and be successful. This issue prompted us to further examine factors that predict support during an individual's quit attempt. Participants were recruited via a crowdsourcing website and were screened to ensure they were in a relationship with a partner who smoked at least ten cigarettes per week. During the survey, participants answered questions about their demographics as well as their own smoking status. Then they completed the Partner Interaction Questionnaire, which measured the intended frequency of positive and negative support the participant would provide their partner if he or she attempted to quit smoking. Lastly, participants reported their own motivation to quit smoking. Analyses show that smokers are less willing than non-smokers to provide support. Among smokers, we found that self-directed beliefs (i.e., their own motivation to quit smoking) and partner-directed beliefs (i.e., worry about their partners' smoking) increased willingness to provide support. These data show there is a differential amount of support given by smokers versus non-smokers. Furthermore, beliefs about their own and their partners' smoking affect their willingness to provide support among smokers. We hope that this study clarifies the effect of smoking status on support while stimulating research to further examine the dynamics of dual-smoker couples.

Comparison of Peak Vertical Ground Reaction Forces between Individuals with Patellar Tendinopathy and Asymptomatic Individuals

Jonathan Brown
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Patellar tendinopathy (PT) is common in jumping sports, but mechanisms causing PT are unclear. Our purpose was to compare peak vertical ground reaction forces (VGRF) between individuals with symptomatic PT and healthy control participants during a jump landing. We hypothesized the PT group would display greater peak VGRF compared to healthy participants. Forty-four individuals completed this study; 23 had self-reported PT symptoms and a Victorian Institute of Sport Assessment-Patella (VISA-P) of <80 indicating decreased knee function (14 female, 9 male, age 21.6 ± 3.5years, height 174.2 ± 8.3cm, mass 70.8 ± 10.9kg, VISA-P 64.2 ± 8.5), while 21 were healthy with no history of knee joint pain (female 12, male 9, age 22.0 ± 3.4years, height 175.2 ± 10.6cm, mass 72.6 ± 12.6kg, VISA-P 100.0 ± 0.0). Participants performed 5 trials of two-legged drop jump landings followed immediately by a 50% maximum vertical jump on a force platform. The peak VGRF of the PT participants' affected limb and controls' matched limb were averaged over 3 trials. The average peak VGRF was normalized to body mass (BM). Independent samples *t*-tests ($p<.05$) identified differences between the two groups. The PT group had significantly ($p<.001$) lower scores on the VISA-P compared to the control group. PT peak VGRF (2.06 ± 0.41xBM) was lower than controls (2.30 ± 0.56xBM), but the difference was not statistically significant ($p=.11$). Peak VGRF may actually be decreased in PT compared to control participants. Peak VGRF may not be related to PT pain and decreased function at the knee.

The Importance of Local Grassroots Organizations in the Reshaping of Afro-Argentine Consciousness

Tiffany Brown, CURO Summer Fellow
Dr. Nicolás Lucero, Romance Languages, Franklin College of Arts & Sciences

In the 19th century, Afro-Argentines made up roughly 33% of the total population of Buenos Aires. Yet within the last century, the Afro-Argentine population has been decimated so thoroughly that many do not acknowledge their existence in Argentine society. The narrative of this group consequently has been silenced and few studies exist pertaining to it. In recent years, Argentina has experienced a resurgence in "orgullo negro" or black pride. Afro-Argentine groups like *Misibamba* and *AfricaVive* have dedicated themselves to promoting awareness and reconstructing the Afro-Argentine's role in Argentine history and society through cultural events and programs. The objective of this study is to document the role of grassroots organizations and local efforts in the reconstruction of the Afro-Argentine identity. The bulk of this research centered on interviews with individuals from grassroots organizations such as *Casa de Africa* and *AfricaVive*, as well as more informal interviews with white Argentine citizens. Although I am still synthesizing data from these interviews, the common thread that I found amongst these various groups is a concerted effort in promoting recognition of their daily lived experiences and hardships as they focus on educating both the government and the general populace of Argentina. This preliminary study serves to spread awareness about the importance of self-identity and local organization in the fight to redefine and reconstruct Afro-Argentine history.

Sphingolipid Metabolism and the Biological Clock in *Neurospora crassa*

John Brunson
Dr. Jonathan Arnold, Genetics, Franklin College of Arts & Sciences

The bread mold *Neurospora crassa* is a model organism that has been used for studies of the biological clock for decades. Clock function is generally conserved across many different species, and by studying the clock in a simple model like Neurospora, we can learn more about how our own biological clock functions. This area of research is growing in importance as humans take on more and more "alternative" sleep schedules and increase their exposure to sources of artificial light at odd hours. Disorders of the biological clock, such as Sundowner's Syndrome, are also reported to affect proper sleep cycles. What's more, proper knowledge of clock function may have implications for medicine, like knowing when to administer certain medicines. In this particular research effort, we look at the effects of ceramide synthase knock outs, namely *lag-1* and *lac-1*, on the clock in Neurospora. Mutants of the *bd* gene are used in conjunction with *lag-1* and *lac-1* knockouts in order to visualize the clock phenotype on race tubes. We also use cell counting methods to determine a chronological senescence phenotype for the double mutants, *lag-1KO bd* and *lac-1KO bd*. We find that both *lag-1KO bd* and *lac-1KO bd* display a unique "double banding" phenotype when run on racetubes, and that *lac-1KO bd* has a unique senescent phenotype different from *lag-1KO bd* when run through a cell counter over a 7-day experiment on minimal media. We aim to confirm the *lac-1KO bd* results using plasmid transformation with *lac-1* under a qa-inducible promoter.

Riverwater and Seawater Dissolved Inorganic Carbon Endmembers for the Amazon River Plume

Shannon Burns
Dr. Patricia Yager, Marine Sciences, Franklin College of Arts & Sciences

As the world's largest river, the Amazon River ecosystem significantly influences the global carbon cycle. Previous research identified the Amazon River Plume as a natural sink for atmospheric carbon dioxide (CO2). However, anthropogenic-driven changes to the tropical hydrologic cycle may alter the photosynthesis-respiration balance in the river's associated waters, impacting atmospheric CO2 concentrations and feedback to climate change. Here we improve calculations of the offshore sink's size using a mixing model between the river and offshore seawater. Key variables are the dissolved inorganic carbon (DIC) endmember concentrations at the river mouth and offshore, which are used to determine the ΔDIC attributed to biology (ΔDICbio). Without precedent, in July 2012 ANACONDAS expedition scientists collected measurements at the river's mouth using a CTD (Conductivity, Temperature, Depth) recorder/Niskin bottle rosette at eight stations and an uncontaminated surface seawater pumping system while underway. Salinity (S) and DIC were measured using a SOMMA (Single Operator Multi-parameter Metabolic Analyzer) system connected to a coulometer. From this data, seawater (s) and riverwater (r) DIC endmembers were identified as µmol C/kg () and µmol C/kg (), respectively. Mixing model results using these new endmembers suggest net heterotrophy nearshore (0-20ppt) and net autotrophy farther offshore (>20ppt), differing from previous studies that suggested either reduced net heterotrophy in the inner plume or sustained net autotrophy. We suspect that light limitation due to riverine sediments influences inner plume water biology. Further analysis of factors influencing the ΔDICbio

will better determine the plume's role as a carbon sink and anthropogenic activity sensitivity.

Purification and Characterization of APAP1-Like Proteoglycans from Rice Suspension Culture Media

Stanislav Bushik, CURO Summer Fellow
Dr. Debra Mohnen, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Rice is one of the most commonly grown and cultivated plants in the world. It is primarily used as a food crop which is cheap to grow and yields high returns. The non-edible structures of the rice plant may also be used to produce biofuels. If the rice plant could be modified to decrease the recalcitrance of the biomass to deconstruction and simultaneously maintain good growth under standard or harsh environmental conditions, the result could be greater food stocks around the world and a source of biomass for the cost effective and efficient manufacture of biofuels. The objective of this research is to identify specific genes responsible for cell wall structures in the plant cell. If these genes could be modified to yield biomass with improved properties, the objectives described above could potentially be accomplished. These genes can be identified using a specific process that has been shown to identify novel proteoglycan structures in the plant cell. First, proteins, glycoproteins, and/or proteoglycans are purified from the rice suspension culture cell media using High Performance Liquid Chromatography (HPLC) and the proteins are sequenced using proteomics. Once sequenced, the genes that encode these glycoproteins are identified by examining the rice plant genome. The goal is to produce knock-down, knock-out, and over-expression rice plants that can be studied in regards to their cell wall, growth and development phenotypes, and their biomass feedstock potential. At this point, the sugar compositions of several selected samples were analyzed. Preliminary data suggest that these samples are, as expected, arabinogalactan proteins (AGPs). Two selected AGP fractions are xylosylated, possibly similar to the structure of arabinoxylan-pectin-arabinogalactan protein 1 (APAP1).

Parenting Stress, Emotion Dysregulation, and Emotion Coaching as Predictors of Child Behavior Problems in the Context of SES and Race

Minhnguyen Cao, CURO Graduation Distinction
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

The goal of this study is to examine the relationship between parenting factors (stress, emotion dysregulation, and emotion coaching) and child psychopathology, while exploring socioeconomic status (SES) and race as moderators. This research is motivated by ongoing needs to identify family-level predictors of child behavior problems, while considering the importance of social contextual factors that may lead to individual variability in these relations. The following hypotheses were tested: 1) higher parenting stress, higher parental emotion dysregulation (ED), and lower levels of parental emotion coaching will predict greater child internalizing and externalizing problems, and 2) these relations will be moderated by socioeconomic status and race. The study used data obtained from a community-based sample of 34 families from racially and economically diverse backgrounds. Bivariate correlations indicated that parenting stress was significantly related to child internalizing (r=.43, p<.05) and externalizing behaviors (r=.56, p<.01). However, ED was not significantly related to internalizing (r=.26, p=.13) or externalizing (r=−.20, p=.25) behaviors. Similarly, coaching was not significantly related to either internalizing (r=−.01, p=.97) or externalizing (r=−.15,

p=.44) behaviors, although most relationships were in the predicted direction. Regressions were performed to test the last hypothesis with parenting stress and emotion dysregulation as predictors. Results indicated a significant interaction in one instance: at high levels of stress, African American mothers reported higher levels of externalizing problems than White mothers (β=.49, *p*<.05). These findings suggest the importance of considering demographic differences, although future studies would benefit from larger sample sizes to improve statistical power, as well as using multi-informant reports of child problems.

Pigmentation and Protein Glycosylation in the Drosophila Embryo

Leah Caplan
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Glycoprotein glycans are important for cell-cell interactions and intracellular communication, but very little is understood about the genetic and biochemical pathways that influence cell- and tissue-specific glycoprotein glycosylation. We have isolated mutations in the fruit fly, *Drosophila melanogaster*, that alter glycoprotein glycosylation in the embryonic nervous system. The phenotypes of two of these mutations (designated *sff* and *ms16*) are strongly affected by mutations in the *white* gene. In Drosophila, the *white* gene plays a role in eye pigmentation, but its absence (*w-*) is also accompanied by neurological and behavioral defects, suggesting that this pigmentation gene functions in other metabolic processes. Many other genes also affect eye pigmentation in Drosophila, including *cinnabar, brown, henna*, and *vermillion*. To determine whether the pigmentation pathway itself, or some undefined autonomous function of the white gene, is more important for the tissue-specific glycosylation defects that we have detected, we screened other pigmentation mutants for possible genetic interactions with *sff*, *ms16*, and *white*. We assessed neural-specific glycosylation in pigmentation mutants and in transheterozygous combinations of pigmentation and glycosylation mutants by staining with anti-HRP antibodies, which detect the production of a specific N-linked glycan epitope on neural glycoproteins. All 4 pigmentation mutants exhibited genetic interactions with the glycosylation mutants, indicating that multiple components of pigment production pathways impact glycoprotein glycosylation. Further experiments will define the specific molecular contribution of these pigmentation genes to Golgi processing of N-linked glycoprotein glycans.

A Storyworld with Incalculable Authors: Defining, Finding and Committing Narrative in the World of Social Media

Julia Carpenter
Dr. Elizabeth Davis, English, Franklin College of Arts & Sciences

New media theorist Lev Manovich once declared database and narrative "natural enemies." But tweet by tweet and story by story, he's being proven wrong. Tools like Storify, Scoop.it, and even Twitter's own "custom timeline" function enable users to curate, select, and order data into a narrative — effectively, to narrativize the database. A narrative built over Twitter, for example, is an instantaneous reconciliation of prior with emergent knowledge, and in building from a vast database, "author" and "narrator" roles disappear as "community member" roles become more important. These expanded powers of agency and disruption in temporality create a hallmark intimacy in social media narrative. In deciding what constitutes a story and what "counts as" a narrative, literary critics and social media story analysts can learn from journalists, who take vast amounts of data and synthesize it in a

way that's understandable (and palatable) to audiences. This presentation will examine several different social media feeds as narrative, the roles their creators and community members play in the story inception, and the tools that enable this kind of storytelling, thereby analyzing story creation from beginning to end. Such an examination further provides a method for measuring reader engagement within the database itself.

Role of Mir-34a in Regulation of Macrophage M2 Phenotype

Kapil Chandora
Dr. Donald Harn, Infectious Diseases, College of Veterinary Medicine

Inflammation plays an important role in providing protection against infection as well as in the development of metabolic and cardiovascular diseases. Uncontrolled inflammation is detrimental due to tissue damage and a shift in cellular metabolism and insulin sensitivity. Macrophages play important roles in regulation of inflammation as macrophage M1 or M2 phenotypes can promote or suppress inflammation respectively. M1 (classical activation) phenotype is driven by Th1/pro-inflammatory cytokines (IFNg, IL-12, TNFa) while Th2 or anti-inflammatory cytokines (IL-4, IL-13, IL-10) drive M2 (alternative) phenotype. M2 macrophages suppress inflammation, repair tissue damage, and improve insulin sensitivity. However, little is known regarding regulation of M2 macrophages *in-vivo*. In this regard, my project focused on investigating the role of microRNAs in controlling macrophage phenotype. Using various cellular biological techniques (flow cytomtery, qRT-PCR, reporter assays, western blots) we determined that mir-34a regulates macrophage M2 phenotype *via* targeting the IL-4Ra-STAT6 pathway. Specifically, macrophages transfected with mir-34a mimics failed to undergo M2 phenotypic change, associated with reduction in the expression of STAT6 transcription factor (M2 mediator), suggesting that mir-34a controls STAT6 expression to regulate M2 polarization. Further, we have bred heterezygous (mir34a+/-) male and female mice in order to obtain homozygous mir-34a deficient mice for *in-vivo* validation of our findings. Overall, findings from this study suggest that mir-34a is a potential candidate in developing therapeutic interventions against inflammatory diseases.

Proteomic Identification and Analysis of Potential Biomarkers for Pancreatic Adenocarcinoma

Joshua Chang, Foundation Fellow
Peng (Linda) Zhao, PhD
Dr. Lance Wells, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Pancreatic adenocarcinoma is currently the fourth leading cause of cancer-related death in the United States even though it is not in the top 10 for diagnosed cancers. The lack of specific methods for its detection has kept five-year survival percentages particularly low; the identification of a pancreatic cancer biomarker would thus allow for its earlier diagnosis and an increased overall survival rate. As protein alterations are commonly observed in many cancers, proteomic analysis is often the starting point for such investigations. Pancreatic ductal fluid samples were collected from four patient groups – normal, intraductal papillary mucinous neoplasm, pancreatitis, and adenocarcinoma – and are being assessed for variations in proteins and glycans. While we have already detected preliminary changes in the proteome, we are currently optimizing proteomic methods and combining this with glycomic data being generated in the group. Also, we will be examining whether observed changes in protein expression can also be observed in serum of the same patients. If specific glycoproteins can be demonstrated to have

altered expression in precancerous and/or cancerous samples, a simple, non-invasive biomarker for pancreatic adenocarcinoma can then be readily produced and applied in clinical settings.

Sex-Ratio Imbalances and Risky Behavior in College

Anne Chen, CURO Summer Fellow
Dr. Christopher Cornwell, Economics, Terry College of Business

On today's college campuses, female students make up almost 60 percent of the undergraduate population. Once male dominated, in the past 50 years four-year universities have seen great transformations in their male to female ratio. In 1960, there were 160 male students for every 100 female students in college. By 1980, there were just as many women enrolled as men. By 2003, there were 135 female students for every 100 male students graduating from a four-year institution. My research focuses on the gender imbalance on college campuses and its effects on the dating market. I hypothesize that the gender imbalance shifts the power in relationship formation to men and encourages women to engage in riskier behaviors in an effort to secure and maintain a relationship. Using data on campus arrest records and enrollment, I examine the relationship between college sex ratios and prevalence of alcohol violations and sexual assaults. Preliminary results indicate that a shortage of men significantly increases the rate of both sexual assaults and aggravated assaults. The effect of the sex ratio on alcohol violations is imprecise. My research emphasizes how behaviors and attitudes shift in an increasingly female-dominated environment and how this may affect future policy in education, public health, and beyond.

***Saccharomyces cerevisiae* as a Model System of Aβ Peptides Using a Copper Resistance Reporter**

Michael Cheng
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Alzheimer's disease (AD) is a progressive neurodegenerative disorder primarily characterized by a decline in cognitive function caused by the damage and death of neurons and the loss of synapses in the brain. AD affects millions worldwide and currently has no cure, method of prevention, or effective treatment. The mechanism of the disease is not fully understood, but beta-amyloid (Aβ) peptides, specifically Aβ 1-42, are highly implicated as a causative agent of AD, due to their neurotoxicity and strong association with the disease. Currently, Aβ peptides are primarily studied through transgenic mice and Alzheimer's patients. The principal objective of this research is to create a cost-effective and efficient model system for the expression and evaluation of Aβ peptides using yeast (*S cerevisiae*). Because Aβ peptides are not toxic to yeast, a copper resistance reporter will be used. Aβ peptides 1-19, 1-28, 1-40, and 1-42 will be attached to an enzyme (CUP1) that mediates resistance in yeast to high concentrations of copper. The presence of Aβ 1-19 fused to CUP1 does not significantly interfere with the activity of the enzyme, and it is hypothesized that the subsequent Aβ peptide and CUP1 fusions will behave similarly. The proper function of CUP1 will serve as a marker for the presence of the Aβ peptides. If successful, this model system can be used as a tool for future studies of Aβ peptides, potentially leading to greater understanding of the mechanism of AD and the development of effective treatments for the disease.

Abstracts

Applying CRISPR-Cas Interference for Genomic Manipulation in *Streptococcus thermophilus*

Megan Chesne, CURO Honors Scholar, CURO Summer Fellow
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Prokaryotes have adapted a versatile immune system called the CRISPR (Clustered, Regularly Interspaced, Short Palindromic, Repeat) -Cas (CRISPR associated) system to defend against invading nucleic acids of viruses or plasmids. CRISPR loci are composed of identical short repeat DNA sequences separated by variable spacer sequences that are identical to those found in invaders. When a microorganism is attacked by a phage, the CRISPR system selectively incorporates a segment of the invading DNA into the CRISPR array. The foreign DNA is then used as a template to generate CRISPR RNAs (crRNAs), which guide Cas protein complexes to disrupt the original invading sequence (interference). CRISPR-Cas systems have been applied for editing genomes of a variety of organisms. Previous research of *Streptococcus pneumoniae* and *Escherichia coli* indicate that crRNA and interference machinery can be designed to select for specific mutations. To create deletions, targeting plasmids and linear PCR deletion templates are introduced into cells. By selecting for the targeting plasmids, survivors will have undergone recombination, creating chromosomal deletions. Specifically, Cas2 in the CRISPR system 3 (Cas2-3) of *Streptococcus thermophilus* will be deleted as a pilot study to verify the feasibility of this technology. An artificial CRISPR plasmid targeting Cas2-3 and a PCR deletion template have been created, and transformation procedures are being optimized. Expansion of CRISPR guided genome editing into *Streptococcus thermophilus* will establish an efficient genetic approach to study CRIPSR-Cas and other processes in this important bacterium.

Polyadenylation in Stationary Phase *Escherichia coli:* Analysis of the Role of RNA Polymerase

Taylor Chishom, CURO Honors Scholar
Dr. Sidney Kushner, Genetics, Franklin College of Arts & Sciences

During exponential growth there are two enzymes in *E. coli*, poly(A) polymerase I (PAP I) and polynucleotide phosphorylase (PNPase) that can post-transcriptionally add extensions to the 3' termini of messenger RNAs (mRNAs). PAP I adds tails, primarily after Rho-independent transcription terminators, that consist entirely of A residues. These tails can range in length from 1-60 nucleotides. In contrast, PNPase adds tails, which contain all four nucleotides, at very different locations within the mRNAs. These tails can be anywhere from 20-500 nucleotides long. Previous work has shown that if both PAP I and PNPase are inactivated there are no detectable post-transcriptionally added tails in exponentially growing cells. However, when these cells enter stationary phase, which occurs under conditions of nutrient starvation, long poly(A) reappear. Since the structural genes for both PAP I and PNPase were deleted in such a strain, efforts have been made to identify the enzyme responsible for adding the poly(A) tails in stationary phase. Recent work has suggested that RNA polymerase, the enzyme that normally synthesizes RNA in the cell, is responsible for most if not all of the poly(A) tails seen in stationary phase cells. The process by which RNA polymerase could be adding the poly(A) tails is called transcriptional slippage. We have recently obtained a mutant in the b subunit (*rpoB*) of RNA polymerase that exhibits increased transcriptional slippage in *in vitro* experiments. My project involves cloning the mutationally altered *rpoB* gene into a low copy number plasmid to use in the further analysis of stationary polyadenylation. Subsequently, I will attempt to isolate mutants of *rpoB* gene that yield reduced levels of transcriptional

slippage. The long-term goal is to determine the biological importance of stationary phase polyadenylation.

Predicting Functional Independence with Impulsivity

Kirstie Chu
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

Finding a more accurate way to track functional independence is critical for early intervention among individuals who may require assisted living. Previous studies have shown a link between inhibition and functional independence in older adults, suggesting that impulsivity may serve as a predictor of functional ability. The study evaluated this hypothesis in a sample of 65 community-dwelling older adults (65-85 years old). Functional independence was assessed using the Direct Assessment of Functional Status (DAFS) to measure instrumental activities of daily living (IADLs). Impulsivity, a multidimensional construct, was assessed using the UPPS Impulsive Behavior Scale (UPPS), a self-report inventory evaluating four distinct facets of impulsivity (Urgency, Lack of Premeditation, Sensation Seeking, and Lack of Perseverance), and the Delis-Kaplan Executive Function System (D-KEFS) Color-Word Test. More specifically, impulsivity was operationalized as facet and total score on the UPPS Impulsive Behavior score and as scores on the inhibition and the inhibition/switching condition, as well as the error rates of the conditions, of the D-KEFS. Multiple regression analyses revealed that the inhibition condition task on the D-KEFS was the strongest predictor of IADLs, though the switching condition and its error rates were also significantly strong. While total UPPS score was not found to significantly predict IADLs, all but one of the facets of the UPPS, Lack of Perseverance, were able to predict IADLs, despite the unexpected directionality of Sensation Seeking and Lack of Premeditation. These findings suggest that certain aspects of impulsivity hold potential as markers of older adults' capacity to live independently.

Power Dynamics in Georgia's Poultry Industry, 1950-1965

Greyson Clark
Dr. Shane Hamilton, History, Franklin College of Arts & Sciences

The emergence of industrial-style poultry production, poultry agribusiness, between 1950 and 1965 in Georgia was a watershed period and encompassed a wide range of actors. Among the cast are government policy makers, government agents, national companies, individual farmers, agricultural specialists, technological innovators, and furnishing merchants. This project examines the relationships among these different actors with particular attention paid to the social power dynamics between government actors, small producers, and integrators. A significant portion of the historiography covering this period describes the economic establishment of the poultry industry as an agribusiness model. This project will build on the framework developed by studies of the development of the agribusiness model by focusing directly on the power dynamics between the actors within that emerging model, giving more attention to the relationships between different groups rather than retelling an account of the rise of agribusiness. To develop sound historical results, this project makes extensive use of primary source documents produced by government officials, businessmen, small producers, and others. The agribusiness poultry production which emerged in this period had ramifications beyond business model. The results of the study elaborate upon a generalized and often impersonal economic history, revealing sharp disparities of power and self-determination across different types of actors in the industrialization of poultry production. The

preponderance of evidence illustrates that small producers were disempowered and government actors were sidelined while integrators rose in prominence, concentrated decision-making power within their hands, and led the development of the new style of poultry production.

The Politicization of Soccer and the Effects of the 2014 World Cup on Brazilian Politics

Aaron Conley, CURO Honors Scholar
Dr. Barry Hollander, Journalism,
Grady College of Journalism & Mass Communication

The summer of 2014 will be extremely significant in terms of political and social issues in Brazil. Those actions will focus on a range of topics including public health and education, high tax rates, corruption, multi-billion dollar projects for the World Cup and Olympics, and social injustice for the poor in the *favelas* in major cities such as Sao Paulo and Rio de Janeiro. The catalyst for all of this comes in the form of the 2014 World Cup, hosted by Brazil, and played out in twelve major cities around the country. This research analyzes the political revolts that occurred during the 2013 Confederations Cup through media reports and public opinion polling. The uprisings staged during the tournament set a precedent that is all but assured to be upheld at the 2014 World Cup. The immediate future of Brazil will be entirely determined by the events that will unfold this year. The way that the World Cup changes the political nature of Brazil will have major ramifications on the 2014 presidential election, the 2016 Rio Olympics, and ultimately determine if Brazil will become the global power that some believe that it is capable of becoming. Politics and soccer are being combined in ways that have not been seen before, and this unique mixture will unfold on the world stage this summer. Held in this balance of politics and sport are the future of a nation, a continent, and ultimately the world.

Individual Differences in Cognitive Control: Antisaccade Performance in Those with Schizophrenia and Low Cognitive Control

Joseph Coppiano
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Cognitive control is the ability to filter irrelevant information to make task-related responses. This can be measured with antisaccade tasks, where subjects fixate on a central target and are instructed to look at the mirror image location (opposite direction, same distance) when it jumps to the side. Performance is compared with prosaccade tasks, where subjects must look *toward* the target. Compared with healthy controls, those with schizophrenia (SZ) (a psychiatric disorder) make more errors and have slower reaction times (RTs) during antisaccades, but relatively preserved prosaccade performance, except for increases in express saccades (premature saccades made in 90-135ms). Neuroimaging studies based on these tasks using fMRI are abundant, but most compare SZ to those with high cognitive control (HCC), which could lead to discrepancies in brain activation due to differences in behavior rather than SZ-specific circuitry. We suggest using low cognitive control (LCC) individuals for comparison, given our hypothesis that their behavioral performance is more similar to SZ. Subjects (HCC=17, LCC=34, SZ=12) performed both pro- and anti-saccades while eyes were tracked and behavioral measures recorded. For antisaccades, the LCC group exhibited similar error rate and RTs as SZ, while HCC individuals exhibited lower error rate and faster RTs. Express saccades were more frequent in SZ and LCC than HCC. Results support our hypothesis that LCC individuals perform more similar behaviorally to SZ in

saccade tasks. This recruitment strategy is useful for neuroimaging studies, as it identifies a more comparable control group for SZ and may better inform fMRI study design.

Effect of Drying on Pulp Characteristics

Hannah Cornelia
Dr. José Reyes De Corcuera, Food Science & Technology, College of Agricultural & Environmental Sciences

Incorporation of more nutraceuticals such as phytosterols into the average US diet can have a positive impact in the overall health of our country. One of the main issues in incorporating phytosterols into foods is that they are water insoluble and poorly-to-moderately soluble in vegetable oils. The microstructure and hydrophobic nature of citrus pulp (juice vesicles) allows for absorption of compounds that are water insoluble. In addition, citrus pulp is one of the by-products of the citrus juice industry with greatest market increase as it can be used to impart to beverages a mouth-feel and flavor that is perceived by consumers as "natural" and "fresh". Processing citrus pulp requires separation from the pulpy juice, pasteurization, and usually storage frozen. Pulp can also be dried. However, drying affects the microstructure of the pulp. We hypothesize that the method of drying impacts the oil-holding capacity of dried citrus pulp. The overall objective of this research project was to maximize the amount of oil that can be absorbed by citrus pulp, thus maximizing the amount of oil-soluble nutraceuticals that can be incorporated into a pulpy fruit beverage. Three drying methods were examined in this research project–drum drying, tray drying, and freeze drying–to determine the best way to process the pulp to maximize the amount of phytosterol-rich oils absorbed by the pulp. Our preliminary results indicate the drum dried pulp is able to absorb more oil compared to the freeze dried pulp. After three trials, I found that the drum dried pulp on average was able to absorb 24.49 % soybean oil (grams oil/ gram pulp) and the freeze dried pulp was able to absorb on average 19.66 % of oil.

Ta-Tas or Not: The Needs of Female Breast Cancer Survivors Will Not Be Forgotten

Mallory Cox
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

After battling breast cancer, many women undergo a mastectomy procedure in which one or two of their breasts are removed to get rid of the cancerous tumor. After their operations, breast cancer survivors have difficulty finding clothing that fits their new body comfortably and allows them to feel "normal" again. Because of this, a niche market has developed to accommodate the physical changes female breast cancer survivors have endured. Several department stores and specialty boutiques are catering to breast cancer survivors by supplying garments that meet the specific needs of these consumers. *Nordstrom* has a prosthesis program offering post-mastectomy bras with pockets for the prosthesis, while specialty boutiques such as *Wear Ease* and the *Alloro Collection* offer garments such as post-surgical camisoles with fiber-filled breast forms to imitate real breasts, compression garments that help with swelling caused by lymphedema, and dolman sleeves that make it easy to put on and take off a garment. Through my research, I found that specialty garments significantly increase the quality of life of cancer survivors because they allow them to find a renewed sense of identity. The clothing items created for breast cancer survivors provide a number of functional benefits; they allow for comfort and ease. However, the positive psychological impact that these clothes have on female breast cancer survivors surpasses the functional benefits because they help them accept their

new body, complete the healing process, and get on with their lives.

The Evolution and Tradeoffs of Physical and Chemical Leaf Defenses in *Helianthus*

Breanna Crowell
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

Plant defenses are a result of adaptations to biotic and abiotic factors. Plant defenses can be either physical or chemical and act in a number of ways to prevent herbivory. Because organisms are ultimately limited by resource availability, plants have been seen to balance resource allocation to defenses, growth, reproduction, and other functions in response to their particular environment. These strategies vary across species and populations and are described by the concept of the worldwide leaf economics spectrum. In part, this concept hypothesizes that plants with short leaf lifespans and high leaf nutrient concentrations will invest less in defense while plants with long leaf lifespans and low leaf nutrient concentrations will invest more in defense. Studies have been done to investigate if tradeoffs between chemical and physical defenses and growth exist across multiple taxonomies and geographies. While no evidence was found for syndromes of defense or latitudinal gradients in defense across broad collections of plant families, it has been proposed that these tradeoffs could exist at lower levels of organization like the genus level. This study uses a phylogenetic comparative study of leaf defenses across wild sunflowers (the genus *Helianthus*) to investigate evolutionary tradeoffs between physical and chemical defenses, latitudinal gradients in defenses, and the relationship between leaf defenses and the leaf economics spectrum. Traits under study include trichome density, tannin activity, leaf lipid content, and leaf ash content. Preliminary trichome and tannin data has shown variance in levels of these defenses across 84 populations of 28 species across *Helianthus*.

Modeling the Biological Clock in *Neurospora crassa*

Sarah Cunningham
Dr. Jonathan Arnold, Genetics, Franklin College of Arts & Sciences

The genome of *Neurospora crassa* contains several genes that create a closed loop network describing the function of the biological clock. The dynamic concentrations of the genes *white collar-1*, *white collar-2*, *frequency*, *vivid*, and *clock controlled genes* and their RNA and protein products in this network regulate cell growth. Several models of the clock have been suggested that include more interactions and differentiate between reactions of proteins that occur in the cytoplasm versus the nucleus. Using computer simulations and ensemble runs to test for fit to available data, the fit of each network is determined. The best network was identified and the effectiveness of other networks (previously published and otherwise) was compared. The network identified as having the best fit can now be used to gain insight into mechanisms underlying circadian rhythms in Neurospora, such as aging and metabolism, and the structure of genetic networks in general.

On a Lack of Identifying Obstructive Sleep Apnea

Tyler Daugherty
Dr. Tho Nguyen, Physics & Astronomy, Franklin College of Arts & Sciences

Obstructive Sleep Apnea (OSA) is a disorder "in which the flow of air pauses or decreases during breathing" while an individual is asleep "because the airway has become narrowed, blocked, or floppy." It afflicts a large percentage of the adult population but is most associated with the obese. OSA's mistaken exclusive association with obesity leads to a

paucity of diagnosis—only 10% of those affected are diagnosed. Undiagnosed sleep apnea is a major risk factor for Alzheimer's disease, stroke, high blood pressure, hypertension, insomnia, diabetes, cardiovascular disease, and many others. It also doubles an individual's likelihood of being involved in an automotive accident. Recognizing that approximately 56.5 million people in the U.S., 18% of the population, are undiagnosed sleep apneics, a substantial portion of society has a considerably increased likelihood of being burdened with the personal health *and* monetary costs of contracting these disorders. Additionally, societal costs to under-diagnosing this disorder are manifold and include loss of productivity and increased healthcare costs. But, through the use of a national awareness campaign and health care procedural reform, the effects and even the presence of this detrimental affliction can be significantly reduced, improving the quality of life of a large section of the population.

The Effects of Centralization on Performance When Moderated by Diversity

Amber Davidson, Seyi Amosu, Brennen Clift, Sam Craig, Kyle Ledesma
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

We were interested in using network analysis to study centralization's impact on performance when moderated by diversity. In order to explore such team dynamics, data was collected from the National Basketball Association. 800 total games played by 30 different teams were recorded from the website www.basketball-reference.com. Our diversity variable was the relationship between tenure (time with that particular team) and centrality of the team. We believe social identity theory will decrease any of the negative effects of diversity on performance because people will be associating less with their individual diversity and be focusing more on their identity as an organizational team. We hypothesize that centralization will have a significant impact on performance, specifically when moderated by diversity. Centralization measures were calculated by assembling matrices for each of the 800 games and calculating overall centralization, indegree centralization, and outdegree centralization using the assist link patterns. Finally, our dependent variable of team performance is measured by "true shooting percentage," a measure of shooting efficiency that takes into account field goals, 3-point field goals, and free throws. The main effect model results indicate a nonsignificant model fit ($F(1,798)= 1.589$, NS) and nonsignificant beta weights for Centralization as a predictor of Performance ($\beta= .045$, NS); thus, the main effect was not supported. The interaction effect was examined by comparing the R2 between the two models and testing whether the change in R2 value was significant. Results of the comparison indicate that $\Delta R2 = .011$, which was significant ($p<.05$). Further, beta weights for the interaction term ($\beta= -.024$, $p <.05$) were also significant. Thus, our interaction hypothesis was supported. Overall, our results provide support for the idea that diversity of tenure can moderate the effect of team centralization on team performance.

Social Skills as Protective Factors against Poor Attitudes towards Having Tourette Syndrome in Children

Amy Davis, Kelsie Flanigan
Dr. Ronald Blount, Psychology, Franklin College of Arts & Sciences

Children with Tourette syndrome (TS) are more likely to have poor social relationships than healthy peers. Social skills deficits may be related to children's attitudes towards living with TS. The current study aimed to examine social skills as potential protective factors that may support better attitudes toward living with TS. This study is important because the

relationship between social skills and attitudes has not been investigated and may be a target of intervention to support better attitudes towards having TS. Participants included 28 parents and 32 children with TS who completed questionnaires before attending a camp for children with TS. Children reported attitudes regarding their diagnosis with TS on the Child Attitude Toward Illness Scale (CATIS). Child self-reports and parent-proxy reports were obtained from the Social Skills scale of a camp growth measure, which included the following subscales: Making Friends, Insecurity, and Peer Relationships. Bivariate correlations showed statistically significant relationships between the CATIS and child self-reports on the Social Skills subscales, with medium to large effect sizes. There was a statistically significant relationship between the CATIS and parent report on the Insecurity and Peer Relationships subscales with large effect sizes; the Making Friends subscale was not significant. Results indicated that higher social skills might be protective factors against developing poor attitudes toward living with TS. Social skills interventions could benefit this population by supporting social competence, and therefore improve children's adjustment to having TS.

Evolution of Flowering Time and Disc Color across the Genus *Helianthus*

Kaleigh Davis
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

This research explores the effects of various environmental factors on flowering time evolution across the genus *Helianthus*, as well as the role flowering time and disc color might play as an evolutionary mechanism for sympatric speciation. Previous research in *Helianthus* has proposed two potential paths for the evolution of dark discs from light, and demonstrated a positive correlation between flowering time and latitude. Since this research, a second common garden including additional *Helianthus* species has generated a data set of multiple populations for 28 species. This has allowed for robust phylogenetic analysis of both flowering time and disc color evolution that will be used to test relationships between flowering time and temperature seasonality, frost and drought risk, soil fertility, and life history. Species and populations from more seasonal habitats and habitats with high risk of drought and frost are hypothesized to flower earlier, while species and populations from more fertile habitats are hypothesized to flower later. It is hypothesized that annuals will flower earlier than perennials due to the evolutionary risks involved in monocarpy. Furthermore, it is hypothesized that sympatric sister species will exhibit larger differences in flowering time than allopatric sister species, due to the process of reinforcement. This research expands our understanding of the ecological and evolutionary responses of flowering time, which will allow for improved prediction of species persistence and displacement under global climate change.

Perceptions about Global Development

Alexa DeAntonio
Dr. Maria Navarro, Agricultural Leadership, Education & Communication, College of Agricultural & Environmental Sciences

The conflict in the Democratic Republic of Congo is the deadliest conflict since World War II, and it is ongoing. Why, then, does the general public seem not to know or care much about this issue? This research analyzes the public's awareness, knowledge, and attitudes about the developing world, and the role that the media has (or has not) played in shaping these perceptions. A content analysis of online news articles assesses the coverage of the developing world with a focus on Africa and the Americas. Interviews will provide insight into individuals' knowledge and opinions about development in these regions.

The interviews will also be used to determine from where research participants receive their information and how their perceptions about development have been shaped. Thus far, results indicate that in the time frame analyzed, the media presents an ongoing theme of violence as it relates to the developing world, but news on development, itself, is extremely limited. Overall, the research will examine the differences between participants in levels of awareness, knowledge, and attitudes about global development and the developing world, and the reasons behind these differences, with a special focus on the sources of information and news coverage.

Students' Perceptions of the Police – An Analysis of Greek and Non-Greek Affiliated Students

Lindsay DeFrancesco
Dr. Natasha Ganem, Sociology, Franklin College of Arts & Sciences

This study investigates students' perceptions of the police in college towns. A survey was taken of 214 University of Georgia students who answered a series of statements intended to reflect their attitudes towards police in the area. This study is unique in that it broke down the sample of responses between students who are members of the University's Greek system and students who are not. The analysis also measured alcohol consumption amongst respondents to determine if drinking habits were correlated with Greek and non-Greek students' attitudes towards the police. It was found that Greek perceptions of the police were overwhelmingly negative and also significantly worse than students who were not members of a Greek organization. Frequent drinking habits did not have an effect on Greek perceptions of the police but did have a negative effect on non-Greek members' attitudes towards the police in that weekly drinkers' perceptions were worse than monthly drinkers.

Intron Loss in the ABCB1 Gene

Victoria DeLeo, Ramsey Scholar
Prof. Katrien Devos, Crop & Soil Sciences, College of Agricultural & Environmental Sciences

The *ABCB1* gene encodes an auxin transporter protein, knockouts of which cause an economically important dwarfing phenotype. The gene shows remarkable intron number variance, particularly among the *Poaceae*, from the ancestral state of nine introns, found in dicots, to as few as two, found in rice and millet. The mechanism by which intron loss occurs is not well understood, so we sought to identify patterns of loss and characteristics of this particular gene that may explain the frequency of the intron loss. Previously, we acquired and aligned sequences for *ABCB1* homologs in plant species for which sequence data was available. For non-sequenced species, we designed primers near intron/ exon boundaries to amplify across introns and determine, based on fragment size, intron presence. Based on this data, introns 1, 2, 5, and 6 were lost independently in various lineages, and introns 1, 3, 4, 8, and 9 were lost together after the divergence of grasses. To validate the results of our PCR analyses, the entire *ABCB1* gene from representative species has been cloned into *E. coli* for sequencing. In addition to tracking intron loss events, we are investigating whether the most widely conserved intron, 7, was retained for functional reasons. We are transforming an *ABCB1*/*ABCB19* Arabidopsis mutant which lacks both *ABCB1* and its functionally redundant homolog *ABCB19* with a copy of *ABCB1* from which intron 7 has been removed to see whether and how phenotype restoration is affected. Finally, we compare *ABCB1* to other genes showing high frequencies of recurrent intron loss.

Determining the Role of FhlA in Transcriptional Activation of Newly Identified RpoN Dependent Promoters

Anquilla Deleveaux
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

In our characterization of the RpoN regulon of *Salmonella* Typhimurium, 278 RpoN binding sites were identified. One of the sites is located in the 5' untranslated region of a hydrogenase two operon where it overlaps a RpoD promoter. When the RpoD promoter is activated, genes *hybC, hybB* and *hypO* are transcribed. With the activation of the RpoN promoter, its orientation is antisense of the RpoD promoter; therefore, it activates genes in the opposite direction while blocking the RpoD promoter from transcribing the *hypO* operon. Characterizing the RpoN regulon involves analyzing active bacterial enhancer binding proteins required to activate transcription at RpoN dependent promoters. A constitutive activator, DctD250, initially was used to activate the RpoN promoter; however, distinct bEBP's and environmental factors will be examined to investigate what cells use naturally to activate this promoter. A specific activator known as FhlA may serve as the activator to bind near this promoter to activate its genes. FhlA controls transcription of operons that include hydrogenase maturation genes, formate hydrogen lyase, and formate dehydrogenase which are similar to the hydrogenase operon. Our hypothesis is that FhlA will bind near the RpoN promoter in the presence of the right environmental stimulus. FhlA will be cloned into a high copy plasmid, pTrcHisC, which contains a His-tag for protein purification for the isolation of FhlA. DNA binding assays will test if protein FhlA will bind upstream of the promoter. This will be the first indicator of whether FhlA is the correct activator.

Mechanism of Mammalian Resistance to Trypanosome Lytic Factor

Lauren Dennison, Foundation Fellow
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

African sleeping sickness is a vector-borne parasitic disease that is the result of infection by certain subspecies of African Trypanosomes. One subspecies, *Trypanosoma brucei brucei*, is non-lethal to humans due to the innate immune molecule Trypanosome Lytic Factor (TLF). TLF contains the apolipoproteins characteristic of HDL (Apolipoprotein A-1) but also contains two additional proteins unique to higher primates, haptoglobin related protein (Hpr) and apolipoprotein L-I (APOL1). Upon binding of free hemoglobin to Hpr, TLF is able to bind to an HpHb receptor expressed exclusively in trypanosomes. Once bound to the receptor, TLF is endocytosed and trafficked to the lysosome where it initiates lysosomal breakdown, resulting in cell lysis. After observing the interactions of TLF and African trypanosomes, we were led to question what mechanisms are in place to protect the mammalian system from the toxic effects of TLF. Here we confirm HEK resistance to TLF using concentrations of TLF thousands of times greater than that required to kills trypanosomes. Using imaging flow-cytometry, we found that TLF was indeed taken up by mammalian cells and localized to lysosomes. Contrary to trypanosomes however, the mechanism of uptake in mammalian cells is not dependent on hemoglobin. Additional studies to address the possibility that physiological concentrations of TLF-1 (around 10μg/ml) are simply insufficient to produce the phenotype found in *T. b. brucei* will be carried out. Once the mechanism of resistance is better understood, it is possible that certain cells, such as tumor cells, may be made susceptible to this natural toxin.

Towards a Dynamical Model of Language Processing

Jonathan Dickens
Dr. Bill Kretzschmar, English, Franklin College of Arts & Sciences

A central assumption in contemporary linguistics is that language is a cognitive system, or a structured object seated in the brain that consists of rule-governed units. The result of this view has been the instantiation of grammar as a biological object in linguistic theory, and linguistics now faces the challenge of being reconciled with cognitive neuroscience. Evidence from linguistic surveys and corpora shows that rather than being a hierarchical system of fixed relations, language is a dynamical system, or an emergent phenomenon that arises from the continuous interactions between speakers and their environment. In this paper, I examine generative and cognitive approaches to linguistics in conjunction with Edelman's (1987) selectional model of brain function and Pulvermüller's (2002) neuronal grammar in order to motivate the rejection of grammar as a neurocognitive object. Specifically, I argue that the reification of linguistic structure fails to take into account the dynamical and embodied nature of language such that it precludes the development of a model that integrates language behavior and cognitive neuroscience. Furthermore, evaluation of symbolic and connectionist models of information processing against neuroscientific considerations demonstrates that the computational and modular theories of mind as espoused by Fodor (1983) and generative models fail as modes for characterizing the language-brain interface. I propose that dynamical modeling and neuronal group selection should instead serve as the basis for a neurocognitive theory of language processing. Adopting a dynamical framework grounded in neuroscience has significant implications regarding how models conceive mental representation and grammar.

Grace Kelly: Femininity in Film

Molly Dodd
Dr. Patricia Hunt-Hurst, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

Females have always faced the stigma of adhering to evolving ideas of femininity, or characteristics of "acting feminine." American feminist Susan Brownmiller defines femininity as "a romantic sentiment, a nostalgic tradition imposed of limitations" (1984, p. 14). She continues to delineate that women instinctively act upon these societal constraints to avoid the risk of losing one's sexual identification as a woman. Ideas towards femininity continually alter to meet social demand. In this paper, I present ideas of femininity and how Grace Kelly's costumes, in conjunction with her character's actions, expressed femininity in two of Alfred Hitchcock's films: *Rear Window*, 1954 and *To Catch a Thief,* 1955. Additionally, I will compare silhouettes as seen in Grace Kelly's films to popular fashions of her contemporary time, including variations of Dior's New Look, correlating her representations of femininity through the work of costume designer Edith Head. Grace Kelly was considered one of the leading actresses of her time, known for her beauty and analytical mind. The 1950s is generally regarded as a time period of conservative dress and attitude. A definition of femininity evolved that centered on domesticity and dress (Dunar, 2006, p. 590). How dress is reflected in the movies gives 21st century viewers an understanding of historical evolution of how women dressed and how dress represents the zeitgeist of a time period.

Octopaminergic Gene Expression and Flexible Social Behavior in the Subsocial Burying Beetle *Nicrophorus vespilloides*

Mary Douthit, CURO Summer Fellow
Dr. Allen Moore, Genetics, Franklin College of Arts & Sciences

Flexible behavior allows organisms to respond appropriately to changing resources and social conditions. Behavioral flexibility plays a major role in successful breeding for the beetle, *Nicrophorus vespilloides*, which exhibits highly developed parental care. Adults are socially tolerant when mating, express aggression when defending reproductive resources, and return to social tolerance when parenting. Previous works link octopamine, a molecule that acts as a neurotransmitter and neurohormone, to aggression in insects. Based on this association, we hypothesized that genes directly involved in the octopaminergic system would be differentially expressed across different social and reproductive environments important to *N. vespilloides'* life history. Following PCR verification of eight genes in the octopaminergic system, we used qRT-PCR to compare relative expression of the eight genes from virgin females, mated females, mated females on a resource required for reproduction, and mated females on a resource with a male. Contrary to our predictions, we found neither enzyme gene changed expression levels, while many of the receptor genes did. The expression of octβr1 and octβr2 was relatively higher in mated females. octαr and tyrr1 gene expression was relatively lower in mated females with a reproductive resource and a male. Considering these results along with studies on other insects, we suggest each receptor might uniquely influence *N. vespilloides*' social behaviors. We also suggest that in *N. vespilloides* the octopaminergic system is associated with resource defense, alternative mating tactics, social tolerance, and indirect parental care.

Measuring Brain Tissue Factor Levels in Malaria Infection

Allison Doyle, CURO Summer Fellow
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Malaria remains a highly prevalent disease in many regions and accounts for at least 1 million deaths every year. While several theories exist to explain the disease in humans, the mechanisms of malaria pathogenesis remain incompletely understood. Infection by *Plasmodium falciparum* has been shown to be associated with increased levels of markers of coagulation and fibrinolysis in placental malaria and cerebral malaria patients, suggesting that increased blood coagulation activation occurs in malaria pathogenesis. Although coagulation activation is known to occur in malaria, its precise role in pathogenesis is still being elucidated. In coagulation-based models of pathogenesis, the protein tissue factor (TF) is of great interest, as it is an important interface between a host's immune response and coagulation processes. Assays were performed utilizing a hemostasis analyzer to measure TF activity levels in organs of mice infected separately with *P. chabaudi* and *P. berghei*. Results demonstrate increased levels of TF activation in the lung tissue of infected mice relative to uninfected controls, as expected. However, in the brain, an unexplained trend in TF activity levels was observed: uninfected samples and samples from *P. chabaudi*-infected mice showed approximately equal levels of TF activity, but samples from *P. berghei*-infected mice showed substantially less activity. Determining whether these variations in TF levels resulted from the assay or underlying physiological mechanisms is the objective of this study. Several aspects of the assay will be altered and tested: (1) the amount of brain tissue in each sample; (2) if utilizing different regions of the brain in samples affects observed TF activity levels; (3) if lipid separation in tissue samples

after homogenization affects the observed TF levels.

Bridging the Gap: The History of British Science Examined through Literature
Justin Dumrongkulraksa, CURO Honors Scholar
Dr. Elizabeth Kraft, English, Franklin College of Arts & Sciences

Science and technology have evolved considerably since the Restoration of Charles II, and these changes have been etched in the literary history of the United Kingdom. This paper will be tracing the general shifts in British public perception toward science and technology from the Restoration era to the present with focus on the mid-nineteenth-century clash between science and religion concerning Charles Darwin's *On the Origin of Species*. With the advent of the Royal Society in 1660, prominent scholars such as Isaac Newton and Joseph Priestly engaged in scientific discourse with public support throughout the eighteenth century. It was not until Romanticism in conjunction with Industrialization that public opinion began to turn to the negatives of technology, pondering the costs of recklessly pursuing scientific inquiry without regard for nature or the common man. Technology such as the camera also incorporated the public into war, exposing people to the horrors science can bring to the human body on the battlefield such as in Crimea. To this day, the popular topic of discourse concerns the future of science and society and how the two will eventually integrate given the rate of discoveries. Questions such as the future of culture, nationhood, and human interaction are widespread, with people divided as to whether technology will be our transcendence or damnation. Understanding the form technology has assumed in the past will help bridge the gap between scientist and public that has been fueled with over three centuries of distrust and exploitation.

Capital-Intensive Punishment: Reducing the High Costs of Federal Drug Incarceration
Alexandra Edquist, Foundation Fellow
Dr. David Mustard, Economics, Terry College of Business

The federal government spent roughly $3.7 billion in 2013 incarcerating drug offenders, but the government reaped little in benefit from this extraordinary expense. The massive increase in drug incarceration from 1980 until today has only slightly decreased the crime rate, and at current levels of incarceration, incarcerating additional drug offenders actually increases the crime rate because they crowd out violent and property offenders, who must be released early to make room in prisons for drug offenders with mandatory minimum sentences, and those violent and property offenders are more likely to re-offend. Furthermore, current policy does little to address high recidivism rates and therefore future crime. This research did cost-benefit analyses on different ideas proposed to reform drug incarceration to find which would be the most effective way of closing the current cost-benefit gap. The research found that adding proven rehabilitation programs, such as vocational training and drug treatment, would increase the overall costs of incarceration but make incarceration more cost-efficient by reducing future crime. Removing mandatory minimums was the second-most effective of the methods studied at making drug incarceration more cost-efficient.

Enzymatic Assay of DHPS Degradation in Abundant Marine Alphaproteobacteria
Blake Edwards
Dr. Mary Ann Moran, Marine Sciences, Franklin College of Arts & Sciences

Patterns of gene expression in members of a bacterial-diatom model system between *Ruegeria pomeroyi* DSS-3, a member of the

alphaproteobacterial Roseobacter clade, and *Thalassiosira pseudonana*, a cosmopolitan diatom, indicate that the novel sulfonate compound 2,3-dihydroxypropane-1-sulfoante (DHPS) serves as a key carbon and sulfur source for bacteria when in co-culture with diatoms. This compound has never been described in ocean organosulfur cycling and may represent gaps in our reconstruction of marine carbon and sulfur models. With enzymatic data for homologous dehydrogenases found in *R. pomeroyi* DSS-3, a "calibration curve" can be created to help identify which other marine bacterial taxa harbor dehydrogenases that are active in DHPS degradation. Specifically, the orthologous proteins in the alphaproteobacterial clades SAR116 and SAR11 will be examined since these are two very abundant and ecologically important groups of marine bacteria, like the Roseobacter clade. With purified protein extracts from *R. pomeroyi* DSS-3 of the verified DHPS dehydrogenase, HpsN, and the paralog histidinol dehydrogenase, HisD, as positive and negative controls, respectively, enzyme activity for other "HpsN-like" dehydrogenases will be photometrically tested with DHPS through the production of NADH+. Taxonomic identification of HpsN activity across important marine alphaproteobacterial taxa will lend valuable insight into which members of the bacterioplankton community drive sulfonate cycling in the ocean and ultimately determine the fate of sulfonate-derived carbon and sulfur. Characterization of DHPS degradation will further help to determine its role in primary and secondary production and its impact on major biochemical transformations in the ocean.

The Preliminary Investigation of Whether Switchgrass SND1 Orthologs Can Activate the Secondary Wall Biosynthesis

Janefrances Egbosiuba, CURO Summer Fellow
Dr. Zheng-Hua Ye, Plant Biology, Franklin College of Arts & Sciences

In plants, there are two types of cell walls that are formed: primary and secondary cell walls. Primary cell walls provide mechanical strength for the cell as it grows and divides. Secondary cell walls are produced once the cell has ceased to grow. For plants secondary cell walls help produce strong xylem, which is used to transport water and minerals from the roots to the remaining parts of the plant. The secondary cell walls also offer strong rigid structure, which allows trees and other woody plants to stand tall for many years. Secondary cell walls serve a very important role for human life because they are huge components for woods and other products such as paper, musical instruments and many others (Zhong and Ye, 2009). Secondary cell walls in wood and fibers are also important renewable source of biofuels; therefore, this could reduce our dependency on other resources such as petroleum. My research focuses on the transcriptional regulation of secondary cell wall production in biofuel crop plants. Transcription factors control the activation of genes in the genome. The transcription factor binds to DNA and other proteins, in order to turn genes off or on. Transcription factors work by recognizing certain nucleotide sequences in the promoter region of the gene on the chromosome. The transcription factor that this research will be focusing on is SND1. This particular transcription factor is known to activate the biosynthesis of the secondary wall and particularly the secondary wall biosynthesis of Arabidopsis. We will be investigating whether switchgrass SND1 orthologs can activate the secondary wall biosynthetic program, as does Arabidopsis SND1. Switchgrass, also known

as *Panicum virgatum*, is a warm-season tall grass found in North America. It is very versatile and adaptable. Today, it is mostly used to control erosion. Switchgrass is also known to provide excellent habitat for wildlife. Research has proven that switchgrass is a good renewable bioenergy crop because of its ability to produce high yields on marginal farmlands. Benefits such as stand longevity, drought and flooding resistance, and relatively low herbicide and fertilizer input requirements are some of the many advantages of producing switchgrass. Using various scientific techniques, we investigated whether switchgrass SND1 orthologs play a role in the biosynthesis of secondary wall biosynthesis. This research project involved the use of the GenBank database to identify switchgrass transcription factor genes that show close sequence homology to the Arabidopsis SND1 gene. The PCR was used to amplify the swtichgrass transcription factor cDNA, which was engineered between the CaMV 35S promoter and a terminator in an expression vector. The engineered genes were transferred into Arabidopsis protoplasts to test their ability for activation of secondary wall biosynthesis genes. Our results showed that switchgrass SND1 genes were able to activate secondary wall biosynthetic genes, indicating that they might function as transcriptional switches controlling biomass (secondary walls) production in switchgrass.

Addressing Inequality in Early Childhood Executive Function Development

Megan Ernst, Foundation Fellow
Dr. Janna Dresden, Elementary & Social Studies Education, College of Education

This paper will demonstrate how addressing executive function in early childhood for low-income students can positively affect the achievement gap in Athens-Clarke County, Georgia. This gap is evident by the time a child enters school and only grows as children progress, indicating that school readiness is a primary factor in the sustained disadvantage of low-income students. While this reflects delays in the acquisition of academic knowledge, it also reflects delays in cognitive development, primarily executive function, the cognitive skills that support academic success. Executive function develops rapidly between birth and age six, and continues to significantly develop throughout the elementary years as well. Proper executive function plays a central role in early academic and social-behavior readiness. Through the analysis of current research and community need, and after evaluating three alternatives and the status quo against measures of equality, cost-effectiveness, and feasibility, this paper recommends an expansion of elementary school teacher education in cognitive development and its role in the connection between the classroom and home life. This paper suggests modifying the county's Comprehensive School Improvement Plan to require that 50 percent of professional training required for recertification consist of curriculum in executive function and family engagement. Long-term, this paper suggests a collaborative partnership between the local government, the school district, the state department of education, the University of Georgia, and local nonprofits to provide a home-visit program to all families below 133 percent of the federal poverty level with children through first grade.

Uncovering the Heritage of Slavery at the Shields Ethridge Farm: Memory, Identity, and Heritage Tourism

Seth Euster, Foundation Fellow, CURO Summer Fellow
Dr. Christopher Lawton, History, Franklin College of Arts & Sciences

On the morning of November 20th 1799, Joseph Roberts Shields rode towards the slave market in Lewisville, Georgia. There, he purchased two slaves, Leah and her infant

child Sophia, from the slave trader Willis Gunnels. For Shields this was a morning that marked his first investment in human chattel, a step towards agricultural success in the Georgia upcountry. For Leah and Sophia it was a morning that shaped the courses of their lives and the lives of their descendants into the 21st century. Shields's farm prospered and he and his descendants became some of the wealthiest and most powerful men in Jackson County. The number of people enslaved by the family continued to grow, as well. Yet, at the end of the Civil War, some 66 years after she and her mother were purchased, when she was the eldest of nearly 20 slaves on the place, Sophia marked an "X" by her name on a contract defining the terms of her emancipation. She and generations of her decedents lived and worked on and nearby the farm into the 1960s. Building on recent historiography, this project is an attempt to understand slavery through the lens of those who were enslaved. Drawing on a rich archive of primary documents, most still held at the Shields-Ethridge Farm, this project both reconstructs the biographies of the slaves who served the Shields family and conducts a historiographical analysis of their community. The content has been incorporated into a digital documentary for the Georgia Virtual History Project, which, when viewed on-site, can better help visitors understand the farm's rich, complex, and truly multicultural past.

Salmonella enterica and *Escherichia coli* Can Exploit Diverse Pathways to Form Vitamin B1 in the Cell

Kristen Farley
Dr. Diana Downs, Microbiology, Franklin College of Arts & Sciences

Phosphoribosyl amine (PRA) is an essential intermediate for both thiamine (vitamin B1) and purine biosynthesis in *Salmonella enterica*. PRA is synthesized by the enzyme phosphoribosylpyrophosphate amidotransferase (PurF). A null mutation in the gene encoding PurF causes the cell to have both a purine auxotrophy and a conditional thiamine auxotrophy. It has been shown that increased flux through the oxidative pentose phosphate pathway can allow PRA formation that is sufficient for thiamine-independent growth in a *purF* mutant. In a *purF gnd* mutant, flux through the oxidative pentose phosphate pathway is disturbed and thiamine-independent growth is eliminated. Suppressor mutation analysis of a *Salmonella purF gnd* strain has uncovered suppressor mutations in various genes which restore PRA formation and growth without thiamine. Due to the vast genetic similarity between *S. enterica* and *E. coli*, this study will probe the alternative PRA forming pathways in *Escherichia coli* to test the hypothesis that PurF-independent thiamine synthesis (PRA formation) is conserved in these two model systems. Preliminary data has shown that in *E. coli* i) a *purF* mutant is a thiamine prototroph, ii) a *purF gnd* mutant maintains modest thiamine-independent growth (i.e. PRA formation), and iii) at least three alternative PRA forming pathways are conserved. An in-depth suppressor mutation analysis of *S. enterica* and *E. coli purF gnd* mutants will identify the similarities and differences in their metabolic networks surrounding thiamine biosynthesis.

Investigating Female Remating Rates in Wild *Drosophila neotestacea* and Their Association with Sex-Ratio Drive

Emily Fawcett, CURO Summer Fellow, CURO Graduation Distinction
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

Selfish genetic elements (SGEs) are portions of DNA that increase rates of their own transmission even if harmful to the host. Sex ratio (SR) drive is a specific type of SGE found on the X chromosome that acts in males to destroy Y-bearing sperm and can

ultimately have grave effects on populations. The frequency of SR in wild populations of *Drosophila neotestacea* varies from 0 to 30%, although the exact cause for this variation is unknown. One proposed method for the maintenance of SR in wild populations is polyandry, or multiple mating by females, because it allows for increased sperm competition, which may affect SR males more than non-SR males because of their reduced sperm count. In this study, I explore the levels of female mating rates in wild *Drosophila neotestacea* to determine if a relationship exists between mating rates and SR levels in the wild using flies collected from two time points in the Great Smoky Mountains. I also examine number of offspring produced by wild-collected males to determine if SR males actually produce fewer offspring than do normal males. I found no evidence for a relationship between levels of polyandry and SR prevalence in the wild, nor for decreased numbers of offspring sired by SR males compared to normal males. However, we plan to update our methods to test these hypotheses once more.

The Evolution of the Little Black Dress

Anne Fernandes
Dr. Patricia Hunt-Hurst, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The little black dress is an iconic piece of women's clothing with a long history. Its everlasting popularity has come from the fact that it is a "cultural lexicon" (Smith 5). People know what you are referring to when you say little black dress: effortlessly chic, while still showing that a woman has style and taste. It is versatile, sophisticated, practical, and even sexy. To prove just how timeless the little black dress is, I researched books and *New York Times* articles dating back from 1921 to 2009. First in 1921, the *New York Times* reported that women had adopted "all-black costumes with lilac chapeaux," which Paul Poiret, a famous designer at the time, called the women's uniform ("Paris Women Wear Black," Jun 11, 1921, p. 7). Later in 1984, Paula Deitz wrote about an exhibit of little black dresses from the past. She said what was "immediately striking about the display of 21 dresses from the English and French couture is that any one of them could walk out to a real cocktail party today and look as fresh and classic as the day it was designed" (Deitz, Mar 4, 1984, p. 188). Through newspaper articles, I found a great deal of information about how the little black dress has transformed over time and why it has remained a staple in women's wardrobes. Despite the many changes the little black dress has gone through, it has always remained a classic and important piece of women's clothing.

Single-Case Research Designs to Evaluate Social Behavior Development of Children with Autism Spectrum Disorders

Allison Fialkowski, CURO Honors Scholar
Dr. David Gast, Communication Sciences & Special Education, College of Education

The autism spectrum disorder (ASD) affects an estimated one in eighty-eight children, and the numbers of diagnoses have been rising drastically since autism was first added to the third edition of Diagnostic and Statistical Manual of Mental Disorders in 1980. Characterized by an impairment in the nature and quality of social and communicative development, those with autism spectrum disorders often fail to naturally build social relationships. In a thorough literature review of autism spectrum disorders, theories such as blindness to context in situations, a tendency to systemize rather than empathize, and a cycle of negative peer interaction and social anxiety were analyzed as sources of this disordered social development. In education, an evidence-based intervention approach to promote social interaction and behavioral change is applied behavioral analysis. This systematic use of positive reinforcement

procedures when matched with data collection allows the interventionist to determine the effectiveness of certain motivators in promoting behavioral change. In promotion of intervention methods that are conducive to the classroom environment and each individual, this literature review investigates the effectiveness of applied behavioral analysis, and use of single-case research methodology, to evaluate positive social behavior change in children with autism spectrum disorders.

Hemlock Embryo Rescue Project

Hayden Field
Dr. Scott Merkle, Warnell School of Forestry & Natural Resources

The hemlock woolly adelgid (*Adelges tsugae*), an exotic insect pest, is currently causing widespread devastation of two species of hemlock: eastern (*Tsuga canadensis*) and Carolina (*Tsuga caroliniana*) in the eastern United States. Before all of the surviving examples of these two coniferous tree species are destroyed by this pest, we must attempt to save them. Working with cooperators from Camcore at North Carolina State University, we have used seeds (some up to 10 years old) collected by them from surviving hemlocks from throughout the ranges of these trees to conduct an embryo rescue experiment. We are testing embryo rescue techniques because the longer the seeds have been cold-stored, the less likely it is that they will have high percentages of germination. Our embryo rescue experiment explores alternative methods to encourage seeds from various seed lots of different ages to germinate, using three different seed pre-treatments (intact seed, megagametophyte, and embryo) and two different germination environments (moist germination paper and *in vitro* culture on a conifer germination medium). The end result, which will be measured as the percentage of germination for each seed lot on each treatment, will aid us in determining which treatments are the most promising for producing trees from the stored seeds to aid in restoration of these threatened trees.

Examination of the Function of *cobU* in Vitamin B12 Synthesis in Mycobacteria

Chelsea Fitzhugh
Samantha Tucker, Graduate Researcher
Dr. Frederick Quinn & Dr. Russell Karls, Infectious Diseases, College of Veterinary Medicine

Tuberculosis, caused by Mycobacterium *tuberculosis (Mtb),* is a disease that presents major public health issues across the world claiming over a million lives each year. Although *Mtb* uses cobalamin (vitamin B12) in some metabolic processes, it is unknown if this bacterium synthesizes cobalamin. The *Mtb* genome contains homologs of B12 synthesis genes, including *cobU*, which encodes an enzyme that functions in a late stage of B12 synthesis in other bacteria. The study of B12 synthesis by the slow-growing pathogen *Mtb* is being accelerated by examining the function of homologous genes in the nonpathogenic fast-growing species *Mycobacterium smegmatis*. The overall purpose of my project is to develop and use a suicide plasmid system to generate a *cobU* knockout in *M. smegmatis*. After the mutant has been obtained, it will be complemented separately with *cobU* from *M. smegmatis* and *Mtb*. It is predicted that vitamin B12 production will be blocked in the *cobU* mutant, but restored when complemented with *M. smegmatis cobU*. If the *Mtb cobU* homolog has the same function, it too should restore B12 production. Progress toward this study will be reported.

Membrane Electrode Assembly Preparation Utilizing Platinum Catalysts for Use in Polymer-Electrolyte-Membrane Fuel Cells

David Flake
Dr. Ramaraja Ramasamy, College of Engineering

Clean energy has been a major focus in almost every industry and development of fuel cells is becoming increasingly more prominent in recent years. Fuel cells directly convert chemical energy into electrical energy. Hydrogen gas and oxygen gas are passed through the anode and cathode respectively to produce a difference in chemical potential between the two electrodes. The chemical potential results in an electrical voltage when connected in a circuit. A polymer-electrolyte-membrane fuel cell functions through the separation of oxidation and reduction reactions by use of a semi-permeable polymer electrolyte. In this research, a Nafion membrane, a perfluorinated ion-conducting and electrically insulating membrane, is used as the electrolyte. Within the fuel cell, hydrogen is oxidized into positive hydrogen ions at the anode catalyst and diffuses through the electrolyte. During this oxidation, free electrons are produced and collected with a conductive plate and pass through the circuit. At the cathode, oxygen is reduced at the catalyst layer which results in the production of water vapor. In this research, pre-prepared platinum nanowire catalysts are applied using an air gun to a gas diffusion layer (GDL). A Nafion membrane is placed between two GDLs and then is heated and pressed to form a membrane electrode assembly (MEA). Different parameters of preparation such as the press operating pressure and temperature will be optimized. The power density is maximized by varying gas flow rates, cathode and anode backpressure, operating temperature, and plate pressure. Gas flow rates, cathode and anode backpressure, operating temperature, and plate pressure are varied to achieve the maximum power density possible and compared to commercial products.

Modifying Appointments to the FISA Court

Mitchell (Trey) Flynn
Dr. John Maltese, Political Science, School of Public & International Affairs

With the Foreign Intelligence Surveillance Act of 1978, Congress created the Foreign Intelligence Surveillance Court to hear surveillance warrant requests from executive agencies. Appointment power to the Court was vested in the Chief Justice. My research explores the following questions: Does the current appointment structure enable the Court to review warrant requests with proper scrutiny and jurisprudence? And if not, what appointment structure would be more effective? Drawing from news articles, law reviews, and declassified Court rulings, research suggests that the concentration of appointment power in the office of Chief Justice fails to insulate the Court from political imbalance. Shifting to a Court-based appointment structure that requires Senatorial consent, I propose, would restore the Court to political balance and foster greater scrutiny of surveillance activity.

Healthcare, Genetics, Society and the Black-White Breast Cancer Survival Disparity

DeJuana Ford
Dr. Susan Tanner, Anthropology, Franklin College of Arts & Sciences

Black and African-American (BaAA) women have lower breast cancer incidence than European-American women, but suffer greater breast cancer mortality. This disparity is discussed widely in diverse fields, and the degree to which genetic factors are implicated in the disparity may vary significantly across disciplines. It is important to compare

researchers' assertions about the role of genetics in the disparity with the degree to which BaAA women attribute their relatively lower breast cancer survival rates to genetic versus environmental factors. In this study, I review literature on breast cancer disparities in the U.S. to explore whether researchers in social science, public health, and clinical medicine perceive the disparity as arising more from genetic or environmental factors, and I compare these perceptions to data from literature on BaAA women's perspectives on factors underlying the disparity. Using keywords "breast cancer AND (African-Americans OR black) AND disparity" to search the NCBI PubMed database, I located 140 articles and studied those focusing on factors driving the Black-White breast cancer survival disparity. I categorized articles as "genetic," "behavioral," "healthcare system," or "societal" based on their explanations for the disparity. Preliminary data suggest that differences in tumor type and healthcare system disparities are commonly implicated across fields in driving the survival disparity. Future data will elucidate connections between factors BaAA women perceive as underlying the disparity and statements made by researchers. Understanding these connections is crucial for more informed discussions on the breast cancer disparity and for improved communication between the medical community and minority patients.

Positive Psychology in Teen Mothers

Smitha Ganeshan, Foundation Fellow
Dr. Neale Chumbler, Health Policy and Management, College of Public Health

While the rates of teen pregnancy have been on the decline, the United States continues to have one of the highest rates among developed nations. Teen pregnancy and parenting is associated with societal stigma resulting from a perceived shortcoming of the individual's moral character. Most studies focus exclusively on the negative consequences of stigma on health, social, and behavioral outcomes. An emic perspective on teen pregnancy and parenting mothers is crucial to elucidate the complex and convoluted role of stigma and stereotypes in these women's lives. Pregnant and parenting teen mothers in Indiana were recruited to participate in a journaling study in Lake County, India through a community partner, Empowering Teens As Parents (ETAP) that allowed the mothers to keep daily journals. The journal content of twenty unique individuals were coded and analyzed by NVivo software. Analysis of the data demonstrated that negative stereotypes and stigma do serve as stressors, but that parenting and overcoming these stereotypes generate positive affect that can mitigate or counteract this stress. Parenting's contribution to positive psychology results in positive self-image and augmented motivation. All of the women, regardless of the degree of social support experienced, indicated that their role as a mother was the best part of their life. Further, the desire to provide a good life for their children and the ability to teach their children new things lead to positive self-image and an emphasis on goal-setting, optimism, and happiness.

The Death of the Death Penalty

Richard Gardiner
Dr. James Monogan, Political Science, School of Public & International Affairs

This paper researches why states differ in their capital punishment policies and in the total number of executions. To explore the issue, this research identifies variables that likely shape death penalty policy and practice. The variables that I have identified as possible predictors are state ideology, issue opinion, political culture, unemployment, and violent crimes. The results show that state ideology is a strong predictor of both policy (measured with an original index of death penalty policy) and the number of executions in the states

(measured from 1976-2012). How death penalty policy is made in the U.S. depends on what the states are doing, and this study can help forecast which states are most likely to continue the trend of reducing or even eliminating death penalty provisions in the law.

The Genetics of Early Hybrid Lethality between Two Species of *Mimulus*

Austin Garner, CURO Summer Fellow, CURO Graduation Distinction
Dr. Andrea Sweigart, Genetics, Franklin College of Arts & Sciences

Speciation occurs when genetically diverging populations develop reproductive isolating barriers that limit interbreeding or reduce the viability and/or fertility of their hybrid offspring. The evolution of these hybrid dysfunctions riddled Darwin and his contemporaries because they knew that unfit hybrids could not be favored by natural selection. We now understand that hybrid dysfunction results from incompatible interactions between genes from divergent species; however, our understanding of the identity, number, and function of the genes involved remains insufficient. To resolve this deficiency I am investigating the genetic basis of hybrid lethality between two closely related wildflower species, *Mimulus guttatus* and *Mimulus tilingii,* by 1) Quantifying the strength of hybrid lethality as a reproductive barrier and 2) Identifying the genes involved. To date, I have shown that when these species are artificially hybridized, 99% of the offspring die during early embryonic development, confirming that hybrid lethality is a strong reproductive barrier between these species. Self-fertilizing the few viable offspring, I generated 250 second generation hybrids, F2s, each containing unique arrangements of both parental species genomes. Quantitative measurements of lethality in crosses between these F2s and parental lines indicate that multiple gene interactions underlie this incompatibility. I am now performing genome-wide sequencing on each F2 and will combine our quantitative and genomic data in order to identify our hybrid lethal genes. This project will thus expand upon the solution to Darwin's conundrum by identifying the genes causing hybrid embryonic lethality and providing a basis for understanding their function in creating and maintaining biodiversity.

Mapping the Horn, 1991-2011

Joseph Gerber, Foundation Fellow
Dr. Brock Tessman, International Affairs, School of Public & International Affairs

While the standard political maps are helpful representations of certain realities in international affairs, they are insufficient at capturing the whole picture of any region, and understanding actors' interactions in and among North and South Sudan, Ethiopia, Eritrea, Djibouti, and Somalia requires more than an understanding of those government's actions. It requires helpful representations of the interests and the interactions among many different kinds of actors in this complex, multifaceted and unstable region. This research project's aim is to answer the question of how the Horn of Africa as a region has changed over time with regards to questions most pertinent to the study of international relations. To answer this question, four different aspects of this region are mapped over time in four different sets of depictions spaced along sensible time intervals: 1) each Westphalian state's relative material capabilities; 2) the presence of various significant non-state armed actors; 3) behavior among various ethnic groups, including migration flow and ethnic tension; and 4) various great powers' economic involvement in the region. These maps are constructed from data gathered from 1991 to 2011 and those actors whose interactions in that area have generated sufficient data, either in set or in map form, are represented visually

in the four maps listed above. This data is compiled in spreadsheet format. Specific methods of representing this data are determined sensibly according to what data is available with the guidance of the research mentor.

Neural Abnormalities in Ocular-Motor Inhibition in Schizophrenia, Bipolar Disorder, and First-Degree Relatives

Alan Gerlich
Dr. Brett Clementz, Psychology, Franklin College of Arts & Sciences

Schizophrenia (SZ) and bipolar disorder (BPD) are characterized by poor prefrontal cortex (PFC) mediated cognitive control. Ocular-motor saccade activity is indicative of the deficit in inhibitory control commonly found in BPD and SZ. Furthermore, biomarkers of such a lack of inhibitory control can be isolated and analyzed using high temporal resolution electroencephalography (EEG) in order to pinpoint the neural basis of the phenotypical deficits of BPD and SZ. The current study included 59 healthy control subjects, 43 with SZ, 56 with BPD, 51 relatives of those with SZ (SZrel), and 71 relatives of those with BPD (BPrel). Each subject completed an inhibition control task in which 3 checkerboard patterns were presented in a horizontal row. On prosaccade trails, the subject was asked to make a saccade toward whichever peripheral checkerboard became more luminous after initial presentation, and on antisaccade trials, the subject was asked to make a saccade toward the more-luminous checkerboard's mirror image. Analyses of the EEG data were performed to evaluate event-related potentials (ERP) resulting from presentation of the steady-state stimulus as well as presentation of the pro/anti-cue. Voltage topographies across the scalp at ERP peaks will be compared across groups. We hypothesize all patients and relative groups will show differences from healthy controls, while patients will show greater differences than relatives. Such data could be used to open new avenues of research to help delve deeper into the underlying etiologies, manifestation, and possible treatment of BPD, SZ, and similar disorders.

The Role of O-Linked β-N-Acetylglucosamine in the Epigenetic Regulation of Colon Cancer Stem Cells

Caitlin Gilbert
Dr. Michael Pierce, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Growing evidence suggests that cancer stem cell (CSC) populations have a role in the initiation and maintenance of some cancers. These populations are regulated by post-translational modifications, such as O-linked b-N-acetylglucosamine (O-GlcNAc). O-GlcNAcylation is regulated by two enzymes: O-linked β-N-acetylglucosamine transferase (OGT) and O-GlcNAcase (OGA). The transfer of the carbohydrate O-GlcNAc to cytosolic and nuclear proteins is catalyzed by OGT, and OGA regulates the process by removing the glycan. O-GlcNAcylation is analogous to phosphorylation in the sense that both modifications are notably dynamic. O-GlcNAcylation affects numerous cellular processes, so aberrant expression is hazardous and can lead to many diseases. The O-GlcNAc modification is associated with several different varieties of cancer, but its role is still unknown. OGT utilizes uridine diphosphate N-acetylglucosamine (UDP-GlcNAc), which is produced from extracelluar glucose via the hexosamine biosynthetic pathway (HBP), as the substrate for O-GlcNAc transfer. This metabolic shift from oxidative phosphorylation to the HBP is a hallmark characteristic of cancer metabolism. The transition from oxidative phosphorylation to the HBP results in the up-regulation of OGT, which further suggests its involvement in tumor onset. In current studies, the knockdown of O-GlcNAc is

accomplished in two mammary colon cancer cell lines through transfection with OGA. The following experiments will be performed using these cells lines to determine which genes are regulated by O-GlcNAc and support the idea that the down-regulation of OGT may reduce cancer metastasis. Identification of the genes that are regulated by O-GlcNAc expression could yield valuable targets for cancer therapy and treatment.

Data Analysis of Seawater Samples Collected Off the Coast of Barrow, Alaska

Dylan Goetz
Dr. Patricia Yager, Marine Sciences, Franklin College of Arts & Sciences

Seasonal patterns in the Arctic Ocean are largely affected by environmental factors, including ice cover, temperature, and sunlight. In winter, with lower light availability, there is a drop in biological productivity. During summer, with minimal ice coverage, productivity blooms. Understanding these cycles can help us predict the impact of changes in the Arctic Ocean. To better understand these strong seasonal cycles, my research examines biological and biogeochemical data collected from a series of research expeditions conducted by Yager, Frischer, and Bronk near Barrow, Alaska (71° 21'N, 156° 41'W) over two years during the months of January, April, and August. I hypothesize the nutrient data should reflect the strong seasonal patterns described above. By graphing depth profiles for limiting nutrients and determining the seasonal averages, I compared the nutrient concentrations to predicted general patterns. The samples' inorganic nitrogen concentrations showed a general trend of a large depletion in August, indicating an increase in primary productivity as phytoplankton take up these nutrients. Higher amounts are shown during the winter season when sunlight is less available and sea ice coverage is higher, limiting photosynthesis when heterotrophic bacteria and respiration prevail. These microorganisms incorporate the dissolved organic nitrogen (DON) produced by phytoplankton. By measuring rates of incorporation of radioactive leucine, heterotrophic bacterial production rates can be calculated. The full data set allows us to explore the balance between autotrophy and heterotrophy in the Arctic. Continuing to create data sets like these over time will allow us to observe and predict changes of the ocean climate in the future.

Parent and Child Perceptions of Health-Related Quality of Life and Psychological Functioning in Children with Tourette Syndrome

Charlotte Goldman, Amy Davis, Kelsie Flanigan
Dr. Ronald Blount, Psychology, Franklin College of Arts & Sciences

Tourette syndrome (TS) is a chronic neurological disorder characterized by tics, involuntary behaviors, and vocalizations. The aims of this study were (1) to evaluate the degree of agreement between child self- and parent proxy-reports of health-related quality of life (HRQOL) and psychological functioning in children with TS, and (2) to compare these ratings to normative data for healthy children. Twenty-eight children, ages 8-18, and their parents rated the child's HRQOL and psychological functioning (depression, inattention, and hyperactivity). *T*-test and intraclass correlation (ICC) analyses were used to examine study aims. Parent-child agreement was strong on all HRQOL and psychological functioning domains based on ICC analyses. However, *t*-test analyses revealed that parents reported significantly higher levels of depression than their child. In addition, children reported significantly lower levels of physical HRQOL compared to their parents. Compared to normative data, only parents reported significantly higher levels of depression, and only children reported

significantly lower levels of physical HRQOL. Overall, these results indicate that parent-proxy reports may not accurately reflect children's perceptions of all HRQOL and psychological functioning domains. This study is important because it demonstrates that parent-proxy reports should not be used exclusively, but should be collected in conjunction with child self-reports whenever possible in this population. Variations in the degree of agreement between individual parent-child dyads should be further evaluated with factors such as child age, clinical outcomes, and quality of parent-child relationships.

Applying International Strategies to Domestic Issues of Micronutrient Deficiency

Carver Goodhue, Foundation Fellow
Dr. J. Peter Brosius, Anthropology, Franklin College of Arts & Sciences

This paper provides a brief analysis of micronutrient deficiency in impoverished communities in Athens-Clarke County, its causes, effects, and the possible approaches to resolve it. Our conclusion is that the establishment of a program to fund vitamin purchases for SNAP (Supplemental Nutrition Assistance Program) eligible Athens residents would provide this sector of the population with a cheap, easily implemented method for increasing micronutrient consumption. This option stands in contrast to others which demand a greater investment of time and money on the part of poor communities least capable of supplying it.

Impacts of Organic Soil Amendments on Micro-Nutrient and Carbon Sequestration under Natural Rainfall Conditions, 2010-2013

George Grant
Dr. Mark Risse, College of Engineering

Organic soil additives also considered as amendments have become widely used throughout the agriculture industry in response to controlling soil erosion. This property as well as the sequestration of valuable micro-nutrients and organic Carbon back into the soil are important areas of study given the variety of soil amendments available in today's market. This experiment explores the following scientific questions: how do present day soil amendments affect the accumulation/sequestration of micro-nutrients, % Carbon, and pH stability under natural climate conditions and what duration of time do these effects require to be available in the soil? 5 years (currently the 3rd year) of data collection and analysis will help the agricultural community understand these available soil treatments and their benefits over time when applied to soil as ground cover or amendment. The following data analysis is based on the average % Carbon (Organic matter) and micro-nutrients found in an 18 plot experimental area located off Hog Mountain Rd. in Athens, GA. There are 24 total plots; however, only 18 out of the 24 are being tested. Each plot is 1.52 m × 4.57m set at a 10% slope and exposed to natural environmental conditions. The variable which is being tested is a specific treatment of soil amendment. The five treatments are as follows: control grass (grass seed) (CG), mulch (M), surface compost (SC), incorporated compost (IC), incorporated biochar (BC), and a control bare soil (BS). Other data such as micro-nutrient concentrations, total soil particle mass from erosion, and rain fall occurrences have also been recorded during this experiment; however, the primary area of interest is the relative increase or decrease in % Carbon and

micro-nutrients accumulation over time(annually) in response to the described soil treatment additives and natural climate conditions. The treatments correspond to the plot numbers as follows: BS: 5,9,20; BC: 6,13,21; M: 2,14,23; CG:4,11,24; SC: 3.10,19; IC: 1,12,22; Not Tested Plots: 7,8,15,16,17,18. The plots not tested are due to limited resource availability and to ensure spacing for needed maintenance and soil sampling. The soil data was taken annually starting in 2010. Soil samples were taken using a soil auger. For the BC and IC treatments only two measurements were taken, one at 4-6 inches, and one at 10-12 inches. This is due to the 0-2 inches region being incorporated into the 4-6 region during the beginning experiment (preliminary incorporation of compost and biochar). For the remainder of the treatments three measurements were taken: 0-2 inches, 4-6 inches, and 10-12 inches. (The following data was analyzed by the University of Georgia's Plant and Soil Analysis Lab.) No results are available at this time. A total micro nutrient, pH and % Carbon ANOVA analysis will be presented along with a discussion of results.

Cell Cycle Gating of the Mammalian Sonic Hedgehog Signaling Pathway

Philip Grayeski, Foundation Fellow
Dr. Jonathan Eggenschwiler, Genetics, Franklin College of Arts & Sciences

The Sonic Hedgehog (SHH) signaling pathway regulates cell fate specification, differentiation, and growth within the tissues, such as the central nervous system during metazoan development. While the regulation of cell cycle progression by SHH signaling has been extensively studied, it remains unclear whether the cell cycle controls response to SHH signals such that individual phases can be conducive or refractory for signaling. One reason to suspect this is the fact that primary cilia are required for SHH signaling in mammals, yet in cultured cells the primary cilium is present only in G1 (or G0) phases. A method in our lab was devised to assay the unspliced (intron-containing) mRNA signal of targets induced by a SHH pathway agonist to provide a real-time assay for pathway activity. Using this method, we analyzed the cell's response to the SHH agonist under different culture conditions and measured the half-life of the unspliced messages. The real-time responses will determined with respect to each phase of the cell cycle and these data will be compared to the ciliogenesis profile in each cell cycle phase. These experiments will test the hypothesis that progression though the cell cycle gates Hedgehog pathway activity and that assembly and disassembly of the primary cilium may be responsible.

Neural White Matter Integrity Differs between Patients with Schizophrenia and Healthy Controls

Thomas Greco
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Patients with schizophrenia show alterations in brain structure compared to healthy subjects, and, differences in major frontal white matter (WM) tracts are related to deficits in cognition. Some healthy subjects from the general population, however, also show low levels of cognitive control. The present study sought to examine differences in WM structural integrity between patients with schizophrenia and healthy controls with low cognitive control (LCC). WM integrity was assessed in 15 individuals with schizophrenia and 15 LCC healthy controls using a magnetic resonance imaging (MRI) scanner. Specifically, diffusion tensor imaging, an MRI method which measures the diffusion of water to index the organization of WM, was used to characterize WM structural integrity. In highly organized, densely myelinated WM tissue water, diffuses primarily along the length of axons, as opposed to diffusing randomly in less

organized tissue. Fractional anisotropy (FA) values occur on a scale of zero (total isotropic diffusion) to one (diffusion only along one axis) and are a commonly used index of the extent of directional diffusion, and thus WM integrity. Whole-brain FA values were calculated using TBSS, and 20 major WM fiber tracts were isolated using a standardized WM tract atlas. The preliminary results demonstrate a statistically significant decrease in the mean FA values for multiple frontal tracts in patients with schizophrenia when compared to healthy subjects with LCC. The present study provides evidence to suggest that structural deficits in schizophrenia may be specific to the disease itself, rather than a function of LCC more generally.

Do Knee Straps Decrease Self-Reported Patellar Tendon Pain after Jump Landings?

Megan Griffin
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Patellar tendinopathy is a common condition in physically active populations, often treated using knee straps to reduce pain, though there is little quantitative evidence supporting this. The purpose of this study was to determine if self-reported pain was lower in those with symptomatic patellar tendinopathy after performing two jump landing techniques with a patellar tendon strap (PTS), compared to a no-strap, control condition (Con). Twenty-nine individuals (female 14, male 15, age 21.3±3.3years, mass 73.2±12.4kg, height 174.7±9.5cm) with patellar tendon pain who scored <80 out of 100 on the Victorian Institute of Sport Assessment Patella (64.8±8.4) indicating decreased knee function, were consented. Participants performed 5 trials of two-legged drop jump landings followed immediately by a 50% maximum vertical jump (DJ) and 5 single leg landings (SL) in both conditions in a counterbalanced order. After completing each set of 5 landings, participants were asked to mark a 100mm Visual Analog Scale (VAS) to indicate their knee pain; participants were blinded to previous VASs. A single rater measured each VAS once and a repeated measures analysis of variance ($p<.05$) was used to determine differences in the VASs between the strapping conditions. There was significantly lower pain reported during the PTS condition than the Con condition for both DJ (Con= 26.28±3.8mm, PTS= 19.24±3.1mm, $p=.003$) and SL landings (Con= 36.28±4.1mm, PTS= 26.9±3.3mm, $p=.001$). The results indicated PTS may decrease acute knee pain symptoms during jump landings as measured by VAS. Future research should elicit the mechanism by which this occurs.

Examination of the Link between Glycosaminoglycans and Pectins

Elizabeth Guarisco, CURO Summer Fellow
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Glycosaminoglycans (GAGs) are polyanionic macromolecules localized in the extracellular matrix that have important structural roles and are involved in diverse cellular processes including differentiation, communication, proliferation, adhesion, and migration. Thus the impacts of glycosaminoglycans and their degrading enzymes warrant understanding. One way to approach this is the use of non-native GAGs or GAG-like polysaccharides. The corresponding plant matrix polysaccharides are the pectin polysaccharides, partially esterified macromolecular polygalacturonic acids. Glycosaminoglycans and pectins provide, in separate species, similar functions. The similarity between the functions of pectins and GAGs suggests possible insights into the mechanism by which pectins impact human health. Studies in our lab revealed that pectins are able to bind certain glycosaminoglycan degrading enzymes and alter their glycosidic

activity. Likewise, chondroitins, a class of GAGs, are able to bind pectin degrading enzymes and alter activity. Pectin degrading enzymes could alter GAG-moderated cell processes GAGs and chondroitin performance. Testing the effects of non-native GAGs *in vivo* is our next step. Hyaluronic acid (HA) functions in joint connectivity, water transport, receptor-interacting roles in tumor metastasis, and stimulates extracellular matrix production. HA fragment injections into Drosophila cells will allow us to see any functionally relevant effects of the polymer, as HA is not naturally present. The first step in this process is growth and insulation optimization of Drosophila neuronal cells. This *in vivo* approach is likely to reveal new functions for GAGs and new ways to manipulate the availability of these important molecules.

Investigating the Role of HAN Transcription Factors during Plant Development

Vanessa Gutierrez
Dr. Wolfgang Lukowitz, Plant Biology, Franklin College of Arts & Sciences

The development of *Arabidopsis* embryos relies on a sub-family of GATA transcription factors. These genes, which are called HANABA TARANU (HAN), HAN-LIKE 1 and HAN-LIKE 2, are essential for the maintenance of embryonic coordinates, and without them embryogenesis arrests. It is my hypothesis that embryogenesis arrests because HAN mutants do not continue to produce stem cells. To investigate the role of these HAN genes during later stages of plant development in seedlings, I have adopted the approach of using a method called RNA interference (RNAi) to "knock down" HAN expression in normal looking seedlings. This entailed constructing a HAN RNAi vector, a plasmid containing a small fragment of HAN transcript in inverted repeats to form a hairpin. This plasmid is under the control of a promoter that is expressed only in the presence of a hormone, dexamethasone (DEX). I introduced this HAN RNAi construct into the *Arabidopsis* genome using an Agrobacterium and I have conducted experiments to show that the HAN hairpin is indeed expressed in response to DEX treatment. I am currently extending the study to analyze the effects of 'knocking down' HAN gene expression in roots, where I can easily visualize any effects on their development. This will provide me with key information about the ability of HAN genes to regulate plant stem cells, specialized cell-types which play a key role in all aspects of plant tissue formation and plant growth.

The Digital Future – Investing and Investigating

Connor Hamm
Prof. Mark Callahan, Lamar Dodd School of Art

In October 2013 the auction house Phillips partnered with the micro-blogging site Tumblr to create the first ever digital art auction, *Paddles On!*. The auction featured only internet-based and digital art, including webcam recordings, screenshots from video games, and even an entire website, with some works valued over at $10,000. *Paddles On!* epitomizes the artistic, technological, economic, and social implications of positioning digital technology as a dominant and necessary facet of life. But what are these implications? I incorporate arts-based research methods with traditional examination of scholarship in order to investigate the impacts of this auction and of related developments within the art world, such as the Eyebeam Emoji Art+Design Show and the increasing presence of webcam art. I apply my research through creating digital art (including my own Emoji and webcam pieces), and by keeping an evolving critical commentary, all of which are posted on a Tumblr blog. This synthesis of research and application is uniquely

illuminating and has provided innovative and engaged analysis of the real world impacts of digital technology, especially on such issues as the changing nature of the art market, the global reach of Emoji and digital communication, and the power of the digitally-mediated self-image ("selfie"). This combination of objective research and personal application incorporates the very technology that I am studying, and is particularly beneficial in understanding our increasingly networked shared future.

An Integrative Outlook on the State of Sustainable Development in Sarawak, Malaysia

Dayna Hardgrove
Dr. J. Peter Brosius, Anthropology, Franklin College of Arts & Sciences

The palm oil industry is growing rapidly all over the world and is threatening both the rainforests and the indigenous communities that inhabit them. In the Malaysian state of Sarawak, the state government has initiated a major effort to expand oil palm production as part of the state's development program. While the palm oil industry has great economic potential, its rapid expansion is currently displacing indigenous communities from their ancestral lands and causing rapid deforestation. The detrimental effects of this growing industry need to be addressed more effectively by acknowledging the trade-offs between conservation and development and seeking a more sustainable development strategy that is supported by multiple actors: the state government, indigenous communities, and the palm oil industry. This paper applies an integrative framework for analyzing trade-offs from multiple conceptual lenses: values and valuation, process and governance, and power and inequality. Such an approach provides a more comprehensive foundation for addressing the state's development priorities while also supporting conservation and indigenous rights.

Viscosity-Dependent Behavior of Cyclopenta[b]naphthalene Fluorophores

Billie Hardigree
Dr. Mark Haidekker, College Of Engineering

Environment-sensitive fluorescent molecules play a significant role in the biological sciences and biological engineering. Recently, a new polarity-sensitive family of fluorophores was introduced (Kocsis et al., Org. Lett 2012; 14: 4430-33). These cyclopenta[b]naphthalene compounds showed intriguing structural similarity with viscosity-sensitive molecular rotors that we recently examined. Our research goal was to explore potential viscosity-sensitivity of the new cyclopenta[b]naphthalene compounds. Measurements were performed in a Fluoromax-3 fluorospectrometer. Polarity sensitivity was examined in Dimethyl sulfoxide (DMSO), methanol, toluene, and water and methanol mixture, and the exact fluorescence spectrum was obtained by performing matrix scans, that is, emission intensity as a function of both excitation and emission wavelength. Viscosity sensitivity was determined in a mixture of methanol, ethylene glycol, and glycerol at different ratios to afford solutions ranging from 4 mPa s to 167 mPas. Peak emission intensity was recorded as a function of viscosity. Two of three cyclopenta[b]naphthalene compounds exhibited dual emission in the viscosity gradient. Depending on the intramolecular distance of the elements of the fluorescent dipole, the second emission peak showed increasing intensity with increasing viscosity. This was an indication of molecular rotor-like behavior. The polarity tests, however, were more inconclusive, but a general trend was observed that more polar solvents lowered the emission intensity and shifted the emission peak toward shorter wavelengths. We concluded that cyclopenta[b]naphthalene-derived fluorophores, which were originally motivated by the polarity probe Prodan, gain viscosity-sensitive behavior and act as

molecular rotors. However, the viscosity sensitivity strongly depends on the spatial structure of the fluorescent dipole.

Necessity of Universal Pre-Operative Blood Work Testing in Healthy Dogs

Kayla Hargrove
Dr. Erik Hofmeister, Small Animal Surgery, College of Veterinary Medicine

The objective of this research study is to determine if performing pre-operative blood work in otherwise healthy dogs sheds light on enough previously unknown and undiagnosed diseases to warrant screening in all patients. This information would be helpful for pet owners because it could potentially cut the costs of surgery by eliminating blood work from their expenses. This would also benefit veterinarians who want to get their patients into surgery as quickly as possible and don't have time to wait for results from blood work. Cases were identified by the anesthesia records and blood work results of 100 dogs that underwent elective orthopedic surgeries. Data collected includes: name, age, weight, breed, diagnosis/problem, ASA status, reason for anesthesia, date of procedure, and abnormalities found in blood work. Results include 40 cases, 7 of which had abnormalities that would have resulted in a more conservative anesthesia protocol.

Differences between Cohabiting and Non-Cohabiting Couples Who Participated in Premarital Education

Lauren Head
Dr. Ted Futris, Child & Family Development, College of Family & Consumer Sciences

Research on cohabitation - the practice of couples living together prior to marriage - has raised concerns regarding the quality and stability of the future unions of these couples. Premarital relationship education programs have been found to promote healthy relationship behaviors that foster healthy and stable marriages. However, less is known about the effects of these programs on cohabiting couples who subsequently marry. The current study examines couples (n = 83) who completed the PREPARE (PREmarital Personal and Relationship Evaluation) program and compares those who cohabited before marriage (59%; n = 49) to those who did not (41%; n = 34). Data were collected by means of surveys taken prior to the program, two weeks post, six months post, and two years post. Mean scores were examined to explore differences and similarities in marital interactions (e.g., time spent together in shared activities, frequency of disagreements, conflict management), marital quality (e.g., positivity, negativity satisfaction), and marital stability (e.g., dedication, thoughts of divorce, confidence) over time. Preliminary analyses show that, following the premarital education program, male and female cohabiting participants tended to exhibit similar or *more positive* relationship interactions when compared to non-cohabiting participants. Thus, contrary to prior research the risks associated with premarital cohabitation were not found with the present sample. By identifying challenges unique to cohabiting couples, premarital education programs can be adapted to focus on specific needs in an effort to better help couples sustain positive interactions, effectively manage differences, and enhance marital satisfaction and stability.

A Targeted and an Unbiased Screen for Genetic Suppressors of the *Legionella pneumophila* Effector Protein LegC7

Chetan Hebbale
Dr. Vincent Starai, Microbiology, Franklin College of Arts & Sciences

Legionella pneumophila is a Gram-negative bacterium that causes a severe form of pneumonia known as Legionnaires' disease. During infection, *L. pneumophila* secretes nearly 300 effector proteins into host cells in order to evade lysosomal degradation by

modulating vesicle trafficking pathways. One of these effector proteins, LegC7, has been shown to be toxic upon expression in the budding yeast, *Saccharomyces cerevisiae*. Upon LegC7 expression, *S. cerevisiae* accumulates membranous structures reminiscent of so called "class E" compartments, which result from defects in multivesicular body function. The proteins which comprise the Class E VPS family are members of the endosomal sorting complex required for transport proteins (ESCRT) which are responsible for recognizing, sequestering and packaging membrane proteins into vesicles for vacuolar degradation. Because the Class E phenotype was produced in yeast during LegC7 expression, we hypothesize that LegC7 interacts with one or more of the yeast Class E gene products. We therefore continued a targeted screen of the yeast Class E genes by transforming a plasmid encoding LegC7 into yeast strains with deletions of *vps23, vps28, snf7*, or *bro1* and found that deletion of these genes did not suppress LegC7 toxicity. We then performed an unbiased screen in an attempt to find genetic suppressors of LegC7 toxicity using ethyl methanesulfonate (EMS) mutagenesis to isolate a strain that exhibits a toxicity reversal due to a genomic mutation. We will sequence the genome from this strain to identify the gene products that LegC7 might require for toxicity.

Nanoparticle-Delivered Therapeutics for African Trypanosomiasis

Matthew Hess
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosoma brucei causes both Nagana, a wasting disease in cattle, and human African trypanosomiasis, also known as sleeping sickness. In sub-Saharan Africa, an estimated sixty million people are at risk with no available vaccine, and hundreds of millions of dollars are lost in the form of diseased cattle. Our lab previously reported the trypanocidal activity of small, hydrophobic peptides (SHP) that specifically kill blood stream form (BSF) *T. brucei*. Here we package SHP into silica gel, mesoporous nanoparticles (SHP-np) for delivery to *T. brucei*. By measuring the growth of BSF trypanosomes overnight post-treatment, we report 50% survival with SHP-np concentrations of 1mg/mL and 0% survival with concentrations of 5mg/mL. Short-term killing assays indicate that SHP-np concentrations of 10mg/mL completely kill parasites within one hour. A comparison of killing kinetics between SHP and SHP-np shows that free SHP kills rapidly while SHP-np exhibit slower kinetics likely due to controlled release of the peptide. Blocking endocytosis by low temperature demonstrates that uptake of the particles is not necessary for killing. To investigate the specificity of SHP-np, we performed growth and short-term killing assays with human embryonic kidney (HEK) cells. Our results indicate that SHP-np are nontoxic to HEK cells at concentrations sufficient to kill parasites. Furthermore, we show that SHP-np are stable during storage in harsh conditions (37°C for one week). All together, the data suggest that SHP-np represent a potential therapeutic to combat human and animal African trypanosomiasis.

3D Printing Techniques in Topology

Fred Hohman
Dr. David Gay, Mathematics, Franklin College of Arts & Sciences

During the Spring 2014 semester, Dr. Gay and I plan to explore 3D printing in topology by observing the physical geometry of shapes that are particularly tough to visualize. This research will allow us to learn how 3D printers function, test the limits of current 3D printers, and generate mathematical objects that have not been easily explored. To start, we first worked out the mathematical theory behind the creation of the knots, imploring

various concepts such as stereographic projection. For example, one shape to be printed is generated by two cords coming together to form a trefoil knot at the center of the object. Once we had the knot constructed, we began to add other surfaces to the shape to observe the changes in the knot's structure. After finalizing the theory, I generated high resolution 3D models of the desired objects to prepare to print in Mathematica: a symbolic mathematic computer programming environment. With the aid of other modeling software and a MakerBot Replicator 3D printer, I was able to print prototypes of the basic trefoil knot with appropriate supports and code documentation. I successfully published this basic version of the trefoil knot on Thingiverse.com: the official website dedicated to sharing user-created digital design files. I am currently manipulating complex versions of the knot and digitally cutting the surface additions to print separately. Once the components are split in the appropriate way, I plan to print all the pieces in multiple colors so that an observer could pick up the shape and remove surface pieces to reveal the underlying knot at the core.

Increasing Nutrition through Genetically Modified Organisms

Erin Hollander, Ramsey Scholar
Dr. Wayne Parrott, Crop & Soil Sciences, College of Agricultural & Environmental Sciences

Genetically modified foods are organisms meant for consumption in which the genetic code has been changed through human biotechnology. These organisms can be modified for increased yield, nutritional value, or pesticide resistance, and as such have great potential for resolution of the global food crisis. This potential must be tempered by the safety concerns of the long-term effects of GM foods on human and environmental health. Some GM foods such as Golden Rice, however, are modified only for increased nutritional content. This allows impoverished families to obtain necessary nutrients without extra expense. Yet the regulatory obstacles for these crops, despite their safety, are nearly insurmountable. This project analyzes the current regulatory standards for GM foods and assesses policy alternatives: 1) increased government support for public goods research institutions; 2) regulation of GM foods through the same standards as traditional foods; and 3) creation of an international ranking system for GM regulation. After evaluation of the benefits of each option, the third option was selected due to its flexibility and feasibility on an international scale. One major boundary to GM foods such as Golden Rice is the duplication of documentation between countries, as each country has its own rules and requirements that a GM food must pass before it can be planted. The cost and time it takes to pass each standard greatly decreases what a non-profit institution can afford. Standardized ranking would decrease duplication while allowing each country to control the safety level of the GM crops gaining entrance.

Norse Mythology in Modern Popular Culture: Sixty Interviews Conducted in Athens, Georgia and Copenhagen, Denmark during the Summer of 2013

Joseph Hopkins, CURO Summer Fellow
Dr. Alexander Sager, Germanic & Slavic Studies, Franklin College of Arts & Sciences

When we use the phrase Norse mythology, we are referring to a body of texts and images that ultimately stem from the pre-Christian narratives of the North Germanic peoples; tales of gods, beings, and even historic people. This corpus is unique and enigmatic; no other branch of Germanic language-speaking people preserved their traditional pre-Christian narratives to such an extent. Upon the eventual translation and subsequent

reintroduction of these texts into the modern languages of Europe, Norse mythology gained new influence and positions in the now Christianized world, particularly in the cultural spheres of other Germanic language-speaking peoples (such as in England and Germany). The study of the ancient Germanic peoples inspired influential works of art and literature, resulted in a mountain range of scholarship, and became an element of national and ethnic pride and ideology. The latter extension came to a head under the Third Reich, and its defeat led to a lull in popular attention for things 'Germanic'. However, by way of media representations, literature, and, to a lesser extent, new religious movements, Norse mythology is again well represented in the popular culture of modern Germanic language-speaking peoples. Yet how is all this represented in the minds of these modern linguistic descendants? By way of sixty interviews conducted during the summer of 2013 in the southeastern United States (Athens, Georgia) and Scandinavia (Copenhagen, Denmark), this project examines the influence of Norse mythology on individuals between the ages of 18 and 30.

The Negative Side Effects of Organophosphate Pesticide Usage in Thailand

Kirstie Hostetter, Foundation Fellow
Dr. Nicholas Magnan, Agricultural & Applied Economics, College of Agricultural & Environmental Sciences

During the past decade, Thailand's pesticide usage has increased by approximately four-fold as the country has established itself as one of the world's major agricultural producers. This increase in pesticide usage has made organophosphates the most abundantly used insecticide group. However, organophosphate pesticides have detrimental health, economic, and environmental effects. In Thailand, 39% of the population is involved in the agricultural sector and about 12,000 cases of acute pesticide poisoning are reported annually. This statistic is a gross underestimate of actual incidences due to lack of education about poisoning symptoms, lack of proper medical facilities, and a lack of initiative to seek medical help. A literature review and cost-benefit analysis of various policy alternatives was conducted. The criteria used to evaluate the four policy alternatives, which included the status quo, an organic farming initiative, an agricultural worker education program, and bureaucratic streamlining, were cost-effectiveness, overall effectiveness, and political feasibility. Based on this analysis, Thailand's Department of Agricultural Extension should implement a mandatory, nation-wide agricultural worker education program to inform those within the agricultural sector about the negative side effects of organophosphate pesticide use.

The Effect of a Patellar Tendon Strap on Knee Power during a Drop-Jump

Katherine Hsieh
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Patellar tendinopathy is defined as anterior knee pain with patellar tendon tenderness and is common in jumping sports. Patellar tendon straps are applied as a simple and affordable wearable technology designed to reduce knee pain. There is limited biomechanical evidence supporting straps, but they may alter landing kinetics. The purpose of this study was to determine if a Universal Matt Strap™ increases knee power in a symptomatic population during a drop-jump. Twenty-three recreational athletes (14 females, 9 males, age=21.6 ± 3.5 years, height=174.2 ± 8.3 cm, mass=70.8 ± 10.9 kg) with a history of patellar tendinopathy stepped off a 40cm box, landed on two force plates, and immediately jumped 50% of their measured maximum vertical jump. Five trials were performed with and without the strap in counterbalanced

order. Sagittal plane knee power was calculated, scaled to body mass, and averaged. Peak (greatest positive) and minimum (greatest negative) knee power were compared among strapping and control conditions using paired t-tests ($p<0.05$). No significant differences were found in the peak ($p=0.617$) or minimum ($p=0.613$) values between strapping and control conditions. The Matt strap does not appear to modify concentric or eccentric knee power in patellar tendinopathy subjects compared to a no-strap control condition. Future research should determine if the Matt-strap creates any other kinematic or kinetic changes during jump landing. Alternations in movement pattern may help explain why some symptomatic wearers report improvement in symptoms.

Mitochondrial Up-Regulation after Moderate Exercise in Able-Bodied Individuals with Near-Infrared Spectroscopy

Brice Hsu
Dr. Kevin McCully, Kinesiology, College of Education

The theory of mitochondrial up-regulation after moderate exercise via calcium loading has been suggested, but requires confirmation. By using Near Infrared Spectroscopy (NIRS), mitochondrial up-regulation after moderate exercise can be assessed *in vivo* in healthy-bodied individuals. Understanding mitochondrial function would benefit treatment of mitochondrial-deficient diseases, such as peripheral arterial disease. Mitochondrial recovery testing and analysis were performed on 9 participants (78% male, 23.6 ± 3.1 years old). Changes in the oxygenation of hemoglobin during a series of 15 arterial occlusions were measured in each individual's right medial gastrocnemius before and 5 min after a 6 min bout of plantar flexion targeting 70% max effort. Data on the recovery of mitochondrial oxygen consumption was then used to determine a time constant (Tc) which can be used as an index of mitochondrial function. To better represent mitochondrial recovery, the time constants were converted into rate constants (Vmax/min). The average pre-exercise rate constant was 1.73 ± 2.00 and the average post-exercise rate constant was 2.00 ± 0.42. The average Δrate constant after exercise was -3.8 ± 4.4 ($p=0.008$), showing mitochondrial up-regulation of 15%. Mitochondrial recovery testing using NIRS supported the hypothesis of mitochondrial up-regulation after moderate exercise in the medial gastrocnemius muscle. These findings suggest that there is a possible mechanism towards mitochondrial up-regulation.

Effects of Music on Male Aggression: Do Lyrics Matter?

Courtland Hyatt, CURO Summer Fellow
Dr. Amos Zeichner, Psychology, Franklin College of Arts & Sciences

The purpose of this study was to investigate misogynistic aggression and the factors that inform this behavior. Past research has identified traits that serve as possible predictors of male aggression toward women, such as endorsements of sexist attitudes, high levels of masculinity, and rape myth acceptance. Additionally, past research has found evidence that exposure to media displays of violence increases attendant cognitions regarding violence, and aggressive behavior. This research informs a likely link between sexist attitudes, proximate exposure to violent media, and aggression in a laboratory setting. To examine this relationship, male participants first completed questionnaires designed to gather information about relevant personality and attitudinal traits. In a separate laboratory session, participants were exposed to a piece of music with either aggressive lyrical content detailing a violent act directed toward a woman, or neutral lyrical content. A subsequent laboratory aggression paradigm, in which

participants could either choose to administer electric shocks to an ostensible female confederate or refrain from doing so, was used to operationalize aggressive behavior. It is hoped that this study will elucidate the relationship among ideological attitudes, violent media, and contingent aggression. Furthermore, this research bears clinical significance in its potential for shaping intervention and prevention efforts aimed at reducing aggression and increasing awareness of the effects misogynous media and sexist attitudes have on gender inequality and violence toward women.

Molecular and Functional Characterization of FUCOSYLTRANSFERASE 10 in *Arabidopsis thaliana*

Lisa Ishii, CURO Graduation Distinction
Dr. Michael Hahn, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The *FUCOSYLTRANSFERASE (FUT)* gene family of *Arabidopsis thaliana* is known to be involved in cell wall biosynthesis. Fucosyltransferases attach fucose to cell wall components, primarily polysaccharides; arabinogalactans, pectins and xyloglucans are known to contain fucosyl residues as part of their structures. *FUT10* has been identified as a member of this *FUT* gene family. In order to functionally characterize the *FUT10* gene, localization of the gene product by expression of a GFP-tagged transgene in tobacco leaves was used. By visualizing the tagged FUT10 protein using confocal microscopy and comparing the pattern of expression with a known Golgi marker, ST-CFP, my preliminary data show that FUT10 is localized to the Golgi apparatus, which is where most polysaccharides destined for the plant cell wall are made. Further confirmation of these results is under way. Additionally, *Arabidopsis* plant lines carrying T-DNA insertions in the *FUT10* gene were characterized using polymerase chain reaction (PCR) amplification of the *FUT10* genic region to determine whether the plant lines were homozygous or heterozygous. Interestingly, I found that all plant lines failed to produce homozygous offspring, allowing me to explore the possibility of homozygous lethality. The *FUT* gene family encompasses ten genes, most of which, with the exception of *FUT1*, *FUT4*, and *FUT6*, have not been functionally characterized. Thus, detailed characterization of the *FUT10* gene is instrumental for a full understanding of the fucosylation of cell wall polysaccharides.

***Mycoplasma gallisepticum* Infection and Shed in Commercial and Wild Turkeys**

Moriah Jackson
Dr. Naola Ferguson-Noel, Population Health, College of Veterinary Medicine

Avian mycoplasmas are pathogens that affect poultry worldwide. The commercial poultry industry has significantly reduced the prevalence of pathogenic avian mycoplasma, although the rate of infection in non-commercial poultry and wild poultry can be relatively high. Domestic turkeys are highly susceptible to *Mycoplasma gallisepticum* (MG) infection, but it is unknown whether wild turkeys are similarly affected. In this study, we compared the infectivity and shed of a virulent MG strain in commercial and wild turkeys. Twenty wild turkey poults were split into 5 groups (n=5) each and housed in Horsfall-type units. At 2 weeks of age, each group was inoculated via intraocular, intranasal and intratracheal routes with a serial dilution of MG culture. Twenty domestic turkeys were similarly split into groups, housed, and inoculated with the dilutions of MG culture. The doses ranged from 1.9 to 4.9 color changing units (CCU) per 100uL. The birds were euthanized at 9 days post inoculation and evaluated by air sac lesion scoring, air sac cultures, histopathology of tracheal sections and quantitative PCR. MG infection was detected in the wild poults at a

lower inoculation dose than the commercial poults. This indicates that the wild turkeys may be more susceptible to MG infection than commercial poults. Wild turkeys and other non-commercial poultry may be significant sources of infection for commercial flocks. Further research is necessary to investigate whether domestic turkeys are more resistant to other infectious diseases and identify the underlying causes.

Investigating the Relationship between the Complement and Coagulation Cascades in Placental Malaria

Tiffany Jenkinson
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

High rates of maternal morbidity, as well as low birth weight and fetal loss, are attributed to placental malaria (PM), the accumulation of malaria infected erythrocytes in the intervillous space of the placenta, the invasion of inflammatory cells, and the release of pro-inflammatory mediators. The over-activation of markers of the coagulation cascade and the accompanying expression of C5a in complement activation have been shown to cause impairment of the surrounding placental tissues. Although coagulation and complement are generally viewed separately, they are activated together in an overlapping manner in response to pathophysiological damage. We believe that thrombin, an abundant serine protease involved in the coagulation pathway, could be a key interaction between these proteolytic activated systems. Our previous studies showed that levels of C5a, crucial in mediating innate host immunity, were significantly elevated in the peripheral and placental blood space of women with PM. Therefore, we hypothesize that thrombin is able to cleave C5 into C5a. To test the fundamentals of this hypothesis we will first determine the presence of C5a in cultures of *P. falciparum* (or uninfected red blood cells, as a control). Cultures will either include or lack the anticoagulant, acid citrate dextrose, and be allowed to incubate. By including or lacking the anticoagulant, we will be able to measure the impact of thrombin generation on the formation of C5a in culture. From this experiment we hope to better understand the mechanisms behind the increased cleavage of C5 into C5a and its relationship to the coagulation cascade.

Biosynthesis of Base J by JBP1 and JBP2

Melissa Jennings, CURO Honors Scholar
Dr. Robert Sabatini, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Leishmania major (*L. major*) is a protozoan parasite that causes leishmaniasis, which affects people in parts of Africa, Asia, South America, and Central America. The Leishmania protozoa are part of a larger class called kinetoplastids which are responsible for deadly human diseases such African sleeping sickness in Africa and Chagas' disease in South America. Research is focused on a novel modified DNA base, called base J, present in kinetoplastid protozoa and shown to regulate RNA polymerase II transcription and gene expression. By understanding base J synthesis and function, researchers may one day be able to develop a specific treatment that will manipulate base J and kill these protozoa. The initial step of J synthesis is catalyzed by two thymidine hydroxylases, JBP1 and JBP2. Somehow these enzymes recognize specific regions of the parasite genome and modify a thymidine base. Our hypothesis is that additional proteins are associated with JBP during base J synthesis. To identify these proteins, we will isolate JBP1 and JBP2 in *L. major* cell extracts followed by mass spectrometry. In order to isolate JBP from the cell, we are creating JBP fused PTP-tag constructs that will be inserted back into the *L. major* genome via homologous recombination and deleting the remaining wild type allele. The appropriate

constructs have been generated and parasite transfections are underway. We will present current data resulting from recombinant *L. major* parasite cell lines and the search for JBP associated proteins involved in J biosynthesis.

Influence of Maternal Presence, Age, and Sex on Social Learning

Thomas Johnston, Ramsey Scholar
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Some nonhuman animals learn skills socially; i.e., they have traditions. I am interested in how animals maintain traditions. A previous study showed that capuchin monkeys in captivity developed a traditional technical skill (to get juice from a vending device). Using data from this study, we examined the effects of age, sex, and maternal presence (or absence) on the proximity of monkeys to the device, to begin to understand how young monkeys learned the skill. The data were collected in twelve 30-minute sessions with each of four different groups of tufted capuchin monkeys. All trials were videotaped. The monkeys' interactions with the vending device were coded in playback using one-zero sampling in ten second intervals. Behavioral frequencies were tabulated per individual and visually represented in boxplots. The results presented here are from Group B (3 infants (0 to 2 years of age), 1 juvenile (3 to 4 years of age), 6 adult females, and 1 adult male), the group with the most infants. In this sample, infants stayed in proximity to, contacted, and solved the device more than adults. The lone juvenile was in proximity and contacted the device less than half the amount of the infants but solved almost twice as often. Maternal presence was associated with more frequent proximity, contact, and solving compared to maternal absence. Ultimately we want to determine how social partners affect activity with the device, such as whether joint proximity with others is associated with getting juice. We are exploring this challenging analytical problem now.

Stable Isotope and Crystallinity Variations in Kaolin Deposits of Georgia in Up Dip to Down Dip Occurrences

Adam Jones
Dr. Paul Schroeder, Geology, Franklin College of Arts & Sciences

Kaolin is a one billion dollar industry for the state of Georgia, where it is used primarily in paper coating, but also in plastics, ceramics, paints, and pharmaceuticals. Recently, kaolin has been used in the production of polymer nano-composites, showing its versatility and economic importance. Economically exploited kaolin beds south of the Fall Line are formed by weathering of alumino-silicate minerals, the source being granitic rocks in the Georgia Piedmont region. Variations in the crystal structure and chemical state of kaolinite are vital to how the clays can be used in the production industry. This study examined the δ18O and δD isotopic variation in sediment-hosted kaolin deposits geologically located in up dip to down dip occurrences in the Eocene-aged Huber Formation. When isotopic results from gas-source mass-spectrometry were compared with X-ray diffraction, determinations of kaolinite abundances and crystal structure correlations appeared between isotopic values and mine locations. A general trend of δD enrichment and δ18O depletion in the kaolinite occurs up dip, suggesting that post depositional recrystallization captures exchanges with meteoric water. Kaolinite crystallinity at sequence boundaries also shows considerable variability. The amount of recrystallization undergone and kaolinite purity in a deposit determine the quality and economic worth of the clay. As reserve scarcity increases, selective mining becomes a more viable operating practice, exposing the necessity to understand kaolin deposit quality.

Immunopathogenesis of Placental Malaria in Mice Lacking Tumor Necrosis Factor and its Receptors

Mathew Joseph, CURO Summer Fellow
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Plasmodium falciparum is the deadliest malaria causing parasite in humans. Malaria during pregnancy is associated with the accumulation of parasitized red blood cells and infiltration of white cells in the placenta. This is known as placental malaria (PM). We hypothesize mice lacking TNF (TNF null mutant) and its receptors (TNFRI null mutant, TNFRII null mutant, and TNFRI/RII double null mutant) will have an altered immunopathogenesis to control mice, not exhibiting the same pathogenesis of TNF driven placental pathology. The experiment uses 330 mice, including TNF RI null mutant, TNF RII null mutant,TNFRI/RII double null mutant, TNF null mutant, control, and wild type B6 (C57BL/6) mice. Each strain is infected with Plasmodium chabaudi through IV injections of 103 infected red blood cells at day 8 to 10 of pregnancy. We will include three different groups for each strain: infected pregnant (IP), infected non-pregnant (INP), and uninfected pregnant (UP). We will sacrifice the mice on days 9, 10, 12, 14, and 18, and organs will be collected for study into TNF and its receptors' effects on PM within these mice. In particular, changes in expression of markers of apoptosis, programmed cell death, and autophagy, intracellular recycling of organelles, will be assessed. Continued study of TNF and its receptors, I and II, promises to reveal common and critical mechanisms which contribute universally to malaria compromised pregnancies.

Integrating of Human Neural Progenitor Cells into a Developing Chicken Embryo for a Toxicology Model

Piyush Joshi
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

The goal of this project is to establish a developmental toxicology model system which can be used in the field of toxicology and regenerative medicine. Human neural progenitor stem cells (hNPs) will be injected into the developing chicken embryo and then tracked with magnetic resonance imaging (MRI) and GFP fluorescent cell tracking. To accomplish this, hNPs will be labeled with iron nanoparticle MRI contrast agents and injected into the chicken embryo at stage 15 in hopes of integrating those cells into the central nervous system (CNS) of the chicken. At specific endpoints, the chicken embryo will be imaged to assess cellular integration. When successful, this will provide us with a developmental toxicology model for further studies intending to assess the impact of endocrine active compounds (EACs) and other toxins on neural development.

The Pathogenicity of *Mycoplasma gallopavonis* in Wild and Commercial Turkeys

Rachel Jude
Dr. Naola Ferguson-Noel, Population Health, College of Veterinary Medicine

Mycoplasma gallopavonis has been commonly isolated from wild turkey (*Meleagris gallopavo*) populations throughout the United States, and the prevalence of infection has been estimated to be very high. *M.gallopavonis* has also been isolated from domestic turkeys that can be readily infected with the organism by contact with wild turkeys. Although the avian *Mycoplasma spp*. that are known to be pathogenic to domestic poultry have been extensively studied, there is currently no

objective information available on whether this common *Mycoplasma* infection can impact the health and survival of turkeys. In this study the pathogenicity of an isolate of *M.gallopavonis* was investigated in commercial and wild turkey poults. Twenty domestic and twenty wild turkey poults were inoculated at 3 weeks of age with *M.gallopavonis* via intraocular, intranasal, intra airsac, intra footpad and intravenous routes. Ten commercial and ten wild turkeys were evaluated and compared to non-inoculated controls at 14 and 21 days post challenge by gross and histological examination of tissues. The primary lesion observed in infected birds was synovitis in footpads and associated lameness. The joints were swollen and contained purulent exudate. The domestic turkeys were more severely affected than the wild turkeys. This study is the first investigation into the pathogenicity of *M.gallopavonis* and its potential impact on wild and commercial turkeys in the United States.

The Executive Science Network: Variations between Public and Private Trustee Networks

Shalin Jyotishi
Dr. Sheila Slaughter, Institute Of Higher Education

The Association of American Universities (AAU) is an invite-only association comprised of 62 elite research-intensive universities. Due to their status as leaders in research, AAU universities become prime incubators for the process of technology transfer, which is characterized as the process of commercializing the research of a university scientist. Prior research has revealed the potential for conflict of interest between the individual scientist and business leaders; however, there is little to no research regarding university trustees and their relationships with business leaders. Trustees act as stewards of a university and sit at the top of the university hierarchy. They are usually highly influential leaders who may also sit on boards of external corporations. Trustees often join a broader "executive science network" because, as directors of both universities and science-based corporations, these trustees are in a position to influence discovery and innovation from the highest level of organizational authority. This study seeks to identify industry-academy relationships among AAU university trustees and independent business firms by constructing a database and using social network analysis. Specifically, a component of the research will address network variations among public and private university trustees. Research has revealed private universities contain highly concentrated networks, while public universities form less robust relationships with industry. Through this study, there lies potential to contribute to public policy concerns regarding understanding of conflict of interest issues, mapping areas of overlapping research interest between industry and the academy, and comprehending how networked universities cooperate with for-profit industry firms.

Identifying Interacting Proteins in the Karrikin and Strigolactone Signaling System

Nikhil Kamath, CURO Graduation Distinction
Dr. David Nelson, Genetics, Franklin College of Arts & Sciences

Karrikins, chemical molecules found in smoke from burning plant matter, and strigolactone, a plant hormone, both act as plant growth regulators that affect the development of plants. Both molecules act through alpha/beta-hydrolase proteins called KAI2 and D14. These receptors genetically interact with MAX2, an F-box protein that ultimately allows the molecules to elicit phenotypic responses affecting branching, height, senescence, hypocotyl elongation,

germination, and root development. F-box proteins characteristically mediate ubiquitination of proteins, targeting them for degradation by the 26S proteasome. SMAX1 and its seven homologs in Arabidopsis have recently been proposed to be candidate targets of MAX2. However, MAX2 may also form complexes with many other proteins. Additionally, downstream physical interactions with SMAX1 have not been deeply studied. We aimed to identify novel protein partners using a truncated form of MAX2 that does not have an F-box domain. Without this domain MAX2 should still bind its normal protein partners yet not be able to bind ubiquitination machinery. Without the ubiquitination machinery MAX2 should be unable to facilitate degradation of its protein partners as usual. We stabilize these preserved protein interactions with MAX2 and purify them through coimmunoprecipitation assays.

The Role of tRNA Nucleotidyl Transferase in tRNA Processing in *Escherichia coli*

Francine Katz
Dr. Sidney Kushner, Genetics, Franklin College of Arts & Sciences

The CCA-adding enzyme tRNA nucleotidyl transferase, encoded by the *cca* gene, synthesizes and repairs the 3'-terminal CCA sequence of tRNAs in both prokaryotic and eukaryotic organisms. It is a member of the superfamily of enzymes that also includes poly(A) polymerase I (PAP I), encoded by the *pcnB* gene, which is the major polyadenylating enzyme in *Escherichia coli* and acts by adding adenosine residues to the 3' ends of mRNAs and tRNAs. All the tRNA genes in *E. coli* have the CCA nucleotide triplet encoded within their DNA sequences, so it is thought that the protein functions mostly to repair tRNAs without an intact CCA sequence which may have been removed by tRNA processing ribonucleases during maturation. Our objective is to characterize the properties of various *cca* mutant strains to study the relationship between the CCA-adding enzyme, PAP I, and specific tRNA-processing enzymes (RNase PH, RNase T). Initially we have examined the growth properties of various multiple mutants. Dot blots and Northern blot analysis will be used to study poly(A) levels and the nature of 3' ends of specific tRNA transcripts respectively. RT-PCR cloning of specific tRNA transcripts will allow us to examine the exact nature of the tRNA 3' ends in *cca* mutants. Our findings are expected to provide new insights into the interactions between tRNA nucleotidyl transferase and other key enzymes involved in the processing of tRNAs in *E. coli*.

Attacking the Fire and Fuel: Nano Formulation of Platin-A for Cancer and Associated Inflammation

Samuel Kennedy, Trenton Berding
Prof. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

A strong association between chronic inflammation and cancer plays roles in prostate cancer. We recently constructed a Pt(IV) prodrug Platin-*A* with the ability to release cisplatin, a widely used chemotherapeutic, and aspirin, an anti-inflammatory agent. Platin-*A* showed enormous potential for further development. However, clinical translation of small-molecule based therapeutics requires a suitable delivery system to achieve favorable pharmacokinetic parameters and appropriate biodistribution. In this presentation, a promising strategy to entrap Platin-*A* in biodegradable polymeric nanoparticles will be discussed. Specifically, we will focus on the role of the mitochondria in coordinating signaling pathways in cancer-associated inflammation. Activation of various proteins causes mitochondrial dysfunction, resulting in mitochondrial reactive oxygen species production and downstream signaling that

promote inflammation-associated cancer. Using a mitochondria-targeted polymeric-nanoparticle as a delivery vehicle, we anticipated that Platin-*A* could be re-routed to the mitochondria of cancer cells and attack the mitochondrial DNA, thereby designing a targeted pathway for the well-established drug cisplatin. A promising strategy for achieving this goal is discussed here.

Nationalism vs. Global Jihad: Al-Qaeda and Precursors in Algeria, Somalia and Yemen

Melanie Kent
Dr. Seema Gahlaut, Center for International Trade and Security

Global jihad is inherently universalist and trans-national, and therefore opposed to Islamic nationalism. Al-Qaeda has not only rejected Islamic nationalism, but has also been able to successfully influence a number of Islamic nationalist groups to pursue global jihad and target their foreign as well as domestic enemies both within and beyond national boundaries. What explains this success? This research focuses on three terrorist organizations, now officially associated with al-Qaeda, that have nationalist goals: al-Qaeda in the Lands of the Islamic Maghreb, al-Qaeda in the Arabian Peninsula and Harakat al-Shabaab al-Mujahideen. Their choice of targets over time is used as an indicator of their evolution from nationalism to global jihadism. The research attempts to understand if this evolution is a reflection of a strategic or ideological change. If the evolution is a result of strategic change, i.e., a response to specific threats to the organizations' survival, we should see an increase in factors such as: external anti-terror operations against it, local competition from other groups and difficulty in expanding funding, recruitment or expertise. If the evolution is the result of a change in ideological beliefs, we should see changes in the character of leadership ties to al-Qaeda and in the organizations' popular support. As terrorist groups become aligned with larger movements, they gain access to additional funds, expertise, recruits and affirmation, making them more dangerous. It is in the interests of anti-terror agencies around the world to understand the rationale behind such alignments in order to better prevent and combat them.

Marital Security, Depression, and Sleep Quality: Assessing Bidirectional Associations with Actor-Partner Interdependence Model

Yuri Kim
Dr. Steven Beach, Psychology, Franklin College of Arts & Sciences

Perceptions of relationship security and self-reported depressive symptoms have been implicated as important contributors to the understanding of sleep quality (Troxel, Robles, Hall, & Buysse, 2007; Sutter, Zöllig, Allemand, & Martin, 2012). The purpose of this study is to examine an integrative model that investigates the dyadic relationship between marital security, self-reported depressive symptoms, and sleep quality. A total of 196 African American married couples were asked to participate in this study. Participants were asked to complete a battery of questionnaires measuring perceived marital security, self-reported depressive symptoms, and sleep quality. The Actor-Partner Interdependence Model (APIM) was used as a framework for statistical analyses in order to incorporate responses from both members of a dyad into a single model and control for the correlated nature of spouses' reports. There were no significant partner effects. However, there were statistically significant actor effects for husband's depression, wife's sense of security in the relationship, and wife's self-reported depressive symptoms on self-reported sleep quality. In conclusion, self-reported depressive symptoms predicted sleep quality for both partners but did not predict

partner sleep quality. For wives only, relationship security accounted for variance in sleep quality beyond the effect depressive symptoms, but again there was no partner effect. Future research and further implications are discussed.

Closing the Income Gap – Education and Technology in the United States
Paul Kirschenbauer, Foundation Fellow
Dr. Santanu Chatterjee, Economics, Terry College of Business

This paper explores the effects of technology and education on income inequality in the United States. Drawing from bodies of research pertaining to these three factors and their interactions, this thesis begins with an exploration of US income inequality, both past and present. Income inequality expansion over recent decades is largely explained by evidence of earners in the top end of the income spectrum having enjoyed income growth of a much greater magnitude than earners in the lower end of the spectrum. A great deal of this may be attributed to the increased prevalence and utilization of technology by government, businesses and consumers. Ample evidence exists to support the notion that technology increases the wages of skilled workers (typically high earners), while simultaneously decreasing those of unskilled workers (typically low earners). As a means to decrease the skill premium, and thereby decrease income inequality, I recommend an increased investment in public education through scholarships for college tuition. As this thesis elucidates, any such attempt at implementing education policy must be carefully planned and correctly executed (in this case, awarding scholarships based on both merit and financial need) to achieve the desired result of closing the income gap. Otherwise, it may actually increase the income gap in the United States.

Decreasing Summer Learning Loss among Low-Income Students in Athens-Clarke County
Shaun Kleber, Foundation Fellow
Dr. Janna Dresden, Elementary and Social Studies Education, College of Education

Summer learning loss is the phenomenon of children losing knowledge and proficiency in skills—such as reading ability—during the months-long summer vacation. Low-income students suffer most, specifically in reading achievement, because of their lack of access to enrichment opportunities and resources that higher-income students enjoy. The problem is especially severe in Athens-Clarke County given the very high poverty rate. Summer learning loss also creates an ever-expanding achievement gap between low- and higher-income students that presents a myriad of problems as students progress through their later years of school. There are a few policies already in place in Athens-Clarke County to address this issue, but each program leaves gaps unaddressed. A literature review and multi-goal analysis revealed that, through a policy aimed at increasing access to educational resources such as books, the problem of summer learning loss could be significantly reduced. This would help close the achievement gap, decrease the dropout rate, increase the graduation rate, and boost the overall success of a huge portion of the student population in Athens-Clarke County.

Henry V: Legitimacy in Kingship and Film
Hannah Klevesahl
Dr. Fran Teague, Theatre & Film Studies, Franklin College of Arts & Sciences

William Shakespeare's *Henry V* (1599?) is the fourth play in a series that showcases the decay of moral legitimacy of kingship. The tetralogy begins with the murder of Richard II and the takeover of Henry IV, which leads to civil war. When Henry V becomes king in the

fourth play, he seems to reverse this trend with the victory over France at Agincourt. Since the advent of modern cinema, however, the play's performance history has been altered dramatically, as has the character's interpretation. The two most notable film versions of *Henry V* – and the ones that are discussed in this paper – are Laurence Olivier's 1944 version and Kenneth Branagh's 1989 version. Olivier's 1944 film portrays Henry V as a national hero, while Branagh's 1989 version gives us a much darker and unglamorous view of kingship. Since these films are adaptations of the same play, I chose to research whether the radically different adaptations of the title character in Henry V – and, therefore, the tone of the film – are legitimate. I will look at critiques from both movies and attempt to validate or invalidate those criticisms by examining the actors' thoughts behind themes of *Henry V* – as well as their opinions on the role – upon which both Branagh and Olivier wrote. I will then endeavor to show evidence that evaluates their production choices, based on the actors' performance and technical production of the "Once more unto the breach" speech in Act III, scene I of *Henry V*.

Building a Record: Requesting Roll Call Votes under Changing Institutions

Cody Knapp, CURO Honors Scholar
Dr. Anthony Madonna, Political Science, School of Public & International Affairs

The roll call voting behavior of members of Congress is a frequent subject of research on congressional politics, with prior research examining the determinants of members' voting behavior and the development of statistical models to scale roll call votes. Scholars of congressional politics have given less attention to the data generating process through which roll call votes arise. Understanding who requests a roll call vote allows scholars to investigate an important question: Do legislators engage in strategic behavior when requesting that a specific vote receives a roll call? I utilize an original dataset of all amendment votes on major legislation from the 57th to the 68th Congress to examine which legislators request roll call votes. The time period of this study is advantageous because the adoption of the Seventeenth Amendment, which instituted the direct election of U.S. Senators, provides a unique opportunity to assess how institutional change influences members' propensity to request roll call votes. This study focuses on two different aspects of the roll call request process. First, I determine which legislators request a roll call vote. Of particular interest is the extent to which the characteristics of the members who request a roll call diverge from the average legislator. Second, I examine whether members are more likely to request roll call votes for issues they favor or oppose. In doing so, it is possible to discern whether members were more likely to request a public vote in order to signal support for or opposition to an amendment.

The Trade-Off between Mating and Fighting in *Nicrophorus vespilloides*

Kyungmin Ko, CURO Graduation Distinction
Dr. Allen Moore, Genetics, Franklin College of Arts & Sciences

Individuals have finite resources to allocate to three major life-history components: somatic maintenance, growth, and reproduction. When division of resources amongst these cannot ameliorate two traits simultaneously, one trait is optimized and the other weakened. This phenomenon is called trade-off. For most species, if the components are in opposition, trade-offs are likely. Male burying beetles, *Nicrophorus vespilloides*, have many traits that they must perform to be highly successful: resource finding, mating, fighting, and parental care. Among such abilities, trade-offs are likely to occur since each is highly related to fitness. I hypothesized that a trade-

off could exist between mating and fighting. I chose mating as one component of this study because, prior to my experiment, three replicated population lines had been artificially selected by high or low rate of male attempts to mate with females within the first 30 minutes of pairing. I chose fighting because, theoretically, males that invest a majority of their resources here are unlikely to attempt mating as frequently as those that invest more in mating. Individuals from differing line types were pitted against each other over possession of a reproductive resource, a mouse carcass. After conducting 240+ trials, winners were determined based on body mass rather than artificial selection of mating rate. Since body mass was not controlled for, I could not detect if different line types were affecting competitive ability in individuals. Therefore, I am unable to conclude that there is an evolutionary trade-off between mating and fighting ability in *Nicrophorus vespilloides*.

Density Dependent Regulation of Survival and Reproduction in Dogbane Beetles and Underlying Host-Plant Interactions

Carmen Kraus, Ramsey Scholar
Dr. Richard Shefferson, Odum School of Ecology

Ecologists have long debated the factors most responsible for population regulation, including the relative importance of top-down (predation) versus bottom-up (food quality) forces. This experiment examined *Chrysochus auratus*, the dogbane beetle, a specialist herbivore that consumes and sequesters toxins from *Apocynum cannabinum*, the dogbane plant. I conducted a field experiment to examine if *C. auratus* populations are regulated through density dependent survival or reproduction, and whether survival and reproduction are sensitive to bottom-up forces including host-plant quality and plant chemical defenses. I caged the beetles on stems of *A. cannabinum* at four densities with eight replicates per treatment. I tracked beetle survival, collected egg capsules, and measured plant quality traits. I found evidence for density dependence in the reproduction, but not the survival, of *C. auratus*. There was an effect of beetle density on egg mass production, which varied over time. The rapidity of the effect on reproduction indicates that an induced defensive response of the plants may be responsible. I also found strong effects of the beetles on its host plant, with significant reductions in plant growth and leaf area with increasing beetle density. The strong effects on plants likely explain the beetles' density dependent reproduction. To my knowledge, no other studies have examined how bottom-up forces regulate populations of aposematic (warning coloration) species.

Glycoproteomic Approaches for Pancreatic Cancer Biomarker Discovery

Anjali Kumar, CURO Honors Scholar
Dr. Lance Wells, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Pancreatic cancer has one of the lowest 5-year survival rates. The high mortality rate, due in large part to a lack of diagnostic tests and thus late stage detection, has created an important role for pancreatic cancer researchers to change these statistics through discovering more efficient methods for detecting pancreatic cancer early. We are studying pancreatic ductal fluid (PDF) samples which contain proteins and sugars that may aid in finding early diagnostic biomarkers. In our current studies, we are comparing PDF from healthy, chronic pancreatitis and pancreatic cancer patients. Since cancer causes inflammation, we are using the PDF from patients with chronic pancreatitis as our baseline control instead of healthy individuals. My role in this project is to isolate the proteins from PDF, release and permethylate the O-glycans, and perform mass spectrometry analyses to assign and quantify the O-glycans. The goal of this work is to find

glycan/protein biomarkers for pancreatic cancer with the hope that this would increase the survival rate of pancreatic cancer.

A Tax-Deferred Trust: Reducing the Financial Burden of Families with Special Needs Children

Mitra Kumareswaran
Dr. Scott Ardoin, Educational Psychology & Instructional Technology, College of Education

In the United States, over twenty million families have a special needs member. Many are children who need extensive healthcare support and provisions for daily living. On top of current expenses, parents must plan how to financially support their special needs children throughout adulthood. Depending on the IQ level, the lifetime expense for the disabled can reach $2.3 million. The average income of a typical middle-class family is currently decreasing, yet the number of families with a special needs child is increasing. Current federal entitlements may also not meet the demands of the future disabled population. If these trends continue, a financial strain will be placed on parents and the state. Currently, special needs trust funds can be created for a beneficiary whose disability impairs the ability to engage in any substantial gainful activity. A literature review was conducted to outline potential policy solutions to assist parents and the government in better providing for special needs individuals. Three viable policy alternatives were identified and then evaluated on the basis of three criteria: cost-effectiveness, political feasibility, and improvement in quality of life for special needs children. The proposed tax-deferred special needs trust fund follows a combined format of 401 (k) and Roth IRA plans so that money deposited into the trust and dividends are tax exempted. This trust reduces the financial strains on parents and society because by not taxing a small portion of the parents' earnings, the government ensures that more money is later available to provide for special needs individuals.

Mapping of the oriT Region of the Virulence Plasmid of *Rhodococcus equi*

Jacob Kumro
Dr. Mary Hondalus, Infectious Diseases, College of Veterinary Medicine

Rhodococcus equi, an aerobic, Gram-positive soil-derived bacterium, is a common cause of chronic granulomatous pneumonia in grazing herbivores and persons with immune deficiencies such as those infected with HIV virus. The virulence plasmid responsible for its disease-causing capacity is transferable to recipient bacteria through conjugation. The plasmid oriT region is essential to conjugation, containing both the nicking and binding sites for TraA, a protein essential for plasmid transfer. Through a series of subcloning and deletion analyses, the oriT has been localized to a 178bp region of the virulence plasmid. This region, when cloned in cis on a small, normally non-conjugating plasmid, confers transmissibility of that plasmid provided the donor *R. equi* strain also carries the virulence plasmid encoding the conjugation machinery including TraA. To identify the specific residues essential for oriT function, the 178bp region of the recombinant plasmid was subjected to timed exonuclease III cleavage. Several of the exonuclease-exposed plasmids were found to be no longer conjugable. Sequencing of the oriT regions of these conjugation defective plasmids is currently underway to identify the deletion mutations associated with loss of plasmid transmissibility. Also ongoing are efforts to express and purify recombinant TraA protein for use in electromobility shift assays (EMSAs). These assays will confirm the interaction of TraA with the wildtype oriT and loss of TraA binding to the mutated fragments associated with defective conjugation. Identifying the TraA interacting

regions of oriT is crucial to understanding the mechanism of conjugation, an important means by which genetic exchange occurs between bacterial species.

The Dynamics of MglA in *Myxococcus xanthus* Motility Systems

Sudeepti Kuppa
Dr. Lawrence Shimkets, Microbiology, Franklin College of Arts & Sciences

Myxococcus xanthus cells, when starved, coordinate with other cells in their surrounding area to form fruiting bodies in which cells differentiate into dormant spores. These bacteria glide on solid surfaces and periodically reverse their movement, the direction of which is controlled in part by motility proteins MglA and MglB. These proteins localize to opposite poles of the cell, where MglA is at the leading pole and MglB toward the lagging pole. When MglA and MglB switch poles, the direction of the cell reverses, a process which takes place every 5-10 minutes. We hypothesize that the localization of these proteins within the cytoplasm directs cell movement and aids coordination during and after development of the fruiting body. This project involves creating deletion mutants of MglA and MglB and separately tagging them with fluorescent proteins in order to observe localization of MglA and MglB as well as detecting differences between wild type and mutant movement during sporulation and fruiting body formation. Collection of cell reversal frequency data is in progress for the MglA deletion mutant. MglA and MglB have both been tagged with fluorescent proteins tdTomato and sfGFP, respectively. They will be transformed into *Myxococcus* xanthus and viewed under phase contrast microscopy to visualize their localization within the cell. We also hope to learn how MglA and MglB interact during the reversal and how this affects the directional movement in the short term.

How to Tackle the Bike Share Helmet Problem

Torre Lavelle, Foundation Fellow
Prof. Kevin Kirsche, Director of Sustainability

The reinvention of city and campus transportation is demonstrated most clearly by the popular embrace of bike share programs, short-term bicycle rentals provided at unattended stations. According to both *Annals of Emergency Medicine* and *Time* magazine, however, the discrepancy in helmet use among bike share riders as compared to personal bike users is the one impediment to bike shares' integration into communities. Because helmets are not available at rental stations, New York City's Citi Bike bicycle share program currently recommends that its participants bring a helmet from home. In addition, the company offers $10 helmet coupons for annual members and encourages helmet rentals through a rental company. Nevertheless, geographic inaccessibility is one of the most cited reasons why bike share participants do not wear helmets and any off-site spree to attain a helmet deters commuters, tourists, and quick trips. After conducting a thorough review of existing literature, a multi-goal analysis was performed on multiple policy options, and it was determined that helmet rental vending machines, currently undergoing local expansion at Boston bike share hubs, demonstrate a feasible method to gaining onsite helmet accessibility. Integrating the $2 cost of this vending machine helmet rental into Citi Bike's bike rental fee would challenge an added optional expense that would discourage bike share users from achieving a safe biking experience. A bundled fee still provides the choice to individuals of whether to use a helmet, but with it comes the opportunity to not have to decide between cost and safety.

Wavefront Sensorless Adaptive Optics with Differential Interference Contrast Microscopy

Keelan Lawrence
Dr. Peter Kner, College of Engineering

Many unstained biological specimens cannot be seen when in focus under an ordinary transmitted-light microscope because they are transparent. These transparent samples can be seen with microscopes that convert phase variations due to the refractive index variations into intensity variations by use of interference methods. Differential-interference-contrast (DIC) microscopy is an interference method commonly used for the study of transparent specimens. The DIC image is formed from the difference in phase between two light waves separated by a small lateral displacement. When imaging through tissue samples many microns thick, the light becomes aberrated traveling through the sample, resulting in a distorted, lower resolution image. We demonstrate that adaptive optics can correct distortions in the image, resulting in sharp DIC images throughout multicellular organisms. Adaptive optics improve image resolution by correcting changes to the optical wavefront caused by optical aberrations with the use of a deformable mirror. We determine the optimum correction from a sequence of trial aberrations applied to the deformable mirror. For each trial aberration, we calculate a "metric" which measures the amplitudes of a band of spatial frequencies to be maximized. Trial aberrations were applied on the deformable mirror while looking at the image of a single latex bead. We demonstrate that the maximum intensity of a bad image can be improved by over a factor of 20. We then image *C. elegans* biological samples and correct the DIC images with adaptive optics. DIC imaging with adaptive optics represents a significant improvement over conventional DIC imaging.

The Emergence of Sustainability as the New Dominant Logic in Business

Jessie Lian, Alex Ballasiotes
Dr. Richard Watson, Management Information Systems, Terry College of Business

Every firm needs to establish its dominant logic, which is the critical factor that a business must consider when it makes key decisions. Dominant logics have progressed from goods-dominant (success determined by the ability to produce the most goods with the fewest inputs) to service-dominant (success determined by the ability to retain customers and please them). Firms now face the emergence of a new dominant logic, whereby success is determined by the capacity to conserve resources and provide the most value with the least unsustainable inputs. Our research considers the issues that firms must address during this migration. Through an analysis of corporate annual reports, sustainability reports, and interviews with Chief Sustainability Officers (CSOs), we show that there has been a marked shift in the mentality of motivations for business decisions across industries. Industry leaders understand that a transition to a sustainability focus not only must take place, but will also benefit their company's success. As these findings add to the body of work supporting the transition to sustainability-driven dominant logic, there are important implications for the future of businesses. In particular, we consider the implications for information systems, as they have historically supported the needs of the current dominant logic. Looking to the future, it clearly will be important for observers of the business world, as well as those who operate within it, to understand and utilize sustainability dominant logic and build appropriate information systems.

The Relationships between Zinc and Bone Strength in Healthy Children

Andrea Lobene
Dr. Richard Lewis, Foods & Nutrition, College of Family & Consumer Sciences

Zinc is an essential micronutrient required for childhood bone growth. Zinc deficient children have impaired skeletal development, but it is unclear in healthy children if zinc nutriture is associated with bone strength. The purpose of this study was to determine relationships between dietary and serum zinc and bone measures in white girls entering puberty (11.3±1.3 years of age; n=39). Dietary zinc was assessed using three-day diet records and serum zinc by atomic absorption spectrophotometry. Peripheral quantitative computed tomography was used to measure trabecular and cortical bone geometry at the radius and tibia. Bone mineral content of the total body, lumbar spine, and hip was determined by dual energy X-ray absorptiometry. Mean zinc intakes and serum zinc values were 9.8±4.4 mg/day and 8.8±3.2 mg/dL, respectively. There were significant positive correlations between dietary zinc and several trabecular bone outcomes at the tibia, including trabecular bone strength index (BSI; $r=0.59$, $p<0.001$) and periosteal circumference ($r=0.36$, $p<0.04$). When controlling for energy intake, the correlation with BSI remained significant. There were no positive correlations observed at the radius or with tibial cortical bone, and there were no significant correlations between serum zinc and any of the bone outcomes. These results suggest a link between dietary zinc and trabecular, but not cortical bone strength at the weight-bearing tibia. Since the majority of bone mass is achieved by late adolescence, a zinc intervention trial is warranted to more adequately determine the influence of zinc on bone strength and the potential for osteoporotic fracture prevention later in life.

Development of an In-Frame Deletion System for *Ruegeria pomeroyi*

Amala Malladi
Dr. William Whitman, Microbiology, Franklin College of Arts & Sciences

Ruegeria pomeroyi DSS-3 is an alpha-proteobacteria isolated from coastal Georgia capable of metabolizing the organosulfur compound dimethylsulfoniopropionate (DMSP). DMSP contributes to the global sulfur cycle and marine microbial sulfur and carbon metabolism. To extend the few genetic manipulation tools and antibiotic resistance markers available for use in *R. pomeroyi,* an in-frame deletion system for *R. pomeroyi* is being developed using flippase (Flp)-flp recognition target (FRT) recombination techniques. First, a second antibiotic resistance marker was required. The plasmid pFLP2 carrying ampicillin resistance from *Escherichia coli* was transformed into *R. pomeroyi*. The stability of the pFLP2 plasmid was checked by passing the transformant three times and extracting the plasmid after each passage. It was found to be retained by gel electrophoresis, providing another antibiotic resistance marker in *R. pomeroyi*. Next, FRT sites were added to the tetracycline resistant (TetR) cassette for homologous recombination into the *R. pomeroyi* genome. PCR demonstrated that the TetR cassette was integrated correctly. The final step involved the amplification of regions upstream and downstream of the *katG* gene from *R. pomeroyi* to be used for homologous recombination with the TetR cassette. This attempt to amplify regions surrounding the *katG* gene has not yet been successful. These experiments increase the genetic techniques available in *R. pomeroyi*.

Job Training to Combat Poverty among Unemployed Coal Miners

Molly Malone
Dr. David Williams, Religion, Franklin College of Arts & Sciences

In recent decades significant changes have been made to reduce environmental harm by the coal industry, including more stringent regulations for coal mines which force mines unable to comply to shut down. Many towns which depend on their coal mine as a source of livelihood fall into poverty without other employment options. In some coal mining counties in Kentucky, 72% of income is from the coal industry, and in the past two years alone over 4,000 mine workers in Kentucky have lost their jobs. In Kentucky nine mines are closing, and all have cited the new EPA policies as at least part of the cause for the shutdown. Possible policy solutions include improvement of a program in West Virginia, enacting state policy, and forming a community coalition. In West Virginia, the United Mine Workers Association and WorkForce West Virginia are working together to provide job training for the growing displaced mine workers. The job training program provided by the UMWA and WorkForce West Virginia is funded by a federal grant devoted to efforts in job training. The grant provides up to $5,000 per participant in Classroom Occupational Skills Training, training for occupations expected to be in high demand, such as electrical trades, welding, mechanics, heavy equipment operating, medicine and truck driving. To address the unemployment problem in Kentucky, actions should be taken based off of the program in place by these two groups, though with various changes for improvement.

A Change in the Winds: How the 'Dawgs Can Be Proud of More than Just Sports

Walker Marlatt
Dr. Adel Amer, Religion, Franklin College of Arts & Sciences

It is well known that Athens-Clarke County is poor; by some reports it is the poorest county of its size in the nation. Not surprisingly, its education statistics fall below the state averages. In contrast, the University of Georgia, whose education and rankings have improved drastically over the last few decades, has an incredible supply of funds. This study looks into how it is possible that such a prestigious and high-functioning university exists in such an impoverished city, and what could be done to alleviate that poverty. Since the academics of the university should be its main concern, I focus less on what the university as a whole could do, and more on nonacademic departments, especially athletics. Despite the fact that it owns some of the most valuable property in the city, the university is tax exempt because it is, of course, a university. However, not all of its money goes to places naturally associated with a college education. For example, it spends almost as much (78 percent!) on athletics every year as the entire county does on education. In looking for ways to change this, I gathered information from census data, websites of the various departments of UGA, and local news articles on both UGA and the nature of poverty in Athens. Ultimately, I seek to prove and persuade that the university should pay taxes on its income that doesn't go to improving the life and education of its student body.

Signaling through TNF Receptors during Placental Malaria.

Omar Martinez-Uribe
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

The effects of malarial infection during pregnancy include maternal anemia, low birth weight (LBW), preterm delivery, and increased infant and maternal mortality. Parasites sequester in the placenta and this process is associated with poor birth outcomes, but the mechanisms are still unknown. TNF is a pro-inflammatory cytokine that has been associated with malaria pathogenesis. TNF has a unique ability to induce cell death through its surface receptors, namely TNFR1 and TNFR2. We hypothesize that TNF signaling through its surface receptors (TNFR1 and TNFR2) is required for apoptosis and inflammation followed by tissue damage and pregnancy loss. To verify this hypothesis, we used TNF null-mutant, TNF Receptor 1 Mutant, and TNF Receptor 2 Mutant, as well as wild-type C57BL/6 mice. Mice are infected with *P. chabaudi* AS on day 0 of gestation, and clinical metrics are measured until day 10, day of sacrifice. Spleen, liver, and placental tissue samples are collected and fixed in neutral formalin or fresh frozen in liquid nitrogen. Proteins are isolated and key apoptotic markers such as PARP, caspase 8, RIP1 and cleaved caspase 3 are probed by western blot. Histopathological analysis will also be performed. Preliminary data show that TNFKO and TNFR2 KO are more susceptible to *P. chabaudi* AS infection than B6 mice. Histopathological analysis shows similar features of placental malaria. Continued studies using western blot and immunohistochemistry may unveil new insight into our understanding of the molecular basis of poor pregnancy outcomes in malaria during pregnancy.

The Role of Dopamine in the Perception of Olfactory Inputs in Drosophila Larvae

Melissa Masserant
Dr. Ping Shen, Cellular Biology, Franklin College of Arts & Sciences

When presented with odor inputs, *Drosophila melanogaster* larvae will desire more palatable food; therefore, they will increase the amount they eat. This mechanism requires the neuropil (lateral horn) for higher-order olfactory processing. Higher-order olfactory centers are essential for understanding the motivational significance of the odor inputs. Using *D. melanogaster* in the third instar larval stage, we found a small subset of dopamine neurons along with four neuropeptide F (similar to neuropeptide Y)-producing neurons that project to the larval lateral horns, which mediate the translation from odor signaling to an appetite-driven response. We measure the mouth hook contractions under single odor stimulations to observe the differences in the eating behavior of genetically mutated larvae. However, we are generally subjected to a combination of different odorants; therefore, we primarily focus on how odor combinations affect this mechanism. Our methods also include targeting DA neurons using laser lesion techniques to perform functional analysis studies. Further investigation of this system could lead to a better understanding of anosmia, a major symptom in Parkinson's disease.

The Effect of Order and Condition on Assessments of Executive Function

Brett McCardel, Breanna Ernst, Meghana R. Nathan, Victoria Smith
Bijoyaa Mohapatra, Doctoral Student
Dr. Rebecca Shisler Marshall, Communication Sciences & Special Education, College of Education

Executive functioning is a higher order cognitive ability that enables us to plan, organize, and attend to the stimuli around us. Neurological disorders often present with executive function deficits. A current study in our lab examined executive function in healthy aging individuals. Sixty healthy participants (young=30, aging=30) were evaluated on cognitive tasks that isolate the four fractions of the executive function system. The following tests were administered in a pseudo-random order: Color Trails Test (CTT; set switching), Conner's Continuous Performance Test II (CPT-II; inhibition), Nonverbal N-back Task (updating) and Dual-Task (divided attention). Though these assessments are standard in the literature, ordering and within-test difficulty of these cognitive tests have not been well examined. Due to lack of information in the literature and the potential impact, it is of interest to determine how test order may impact overall executive performance in healthy individuals. It is hypothesized that beginning with a more cognitively demanding test such as the CPT-II will result in poorer performance on subsequent tests. Additionally, analyses of the Dual-Task will be presented; for this Dual-Task, participants were asked to sort cards either by shape, color, or number (three conditions) while simultaneously attending to target sounds played through a computer. It is hypothesized that different conditions may differ in cognitive demands and a less cognitively demanding condition (e.g., sorting by color) may result in better performance scores compared to other conditions. The results of these findings may contribute to a more thorough understanding of test order and presentation for these particular assessments.

Neural Activation Changes Associated with Antisaccade Task Practice

Brett McCardel
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Cognitive control allows us to manage processing of incoming stimuli, and saccade tasks provide valuable insight into how these processes work in the visual system. Prosaccades are rapid, reflexive glances towards a visual stimulus that rely on neural circuitry including visual cortex and frontal and supplementary eye fields. Antisaccades are glances to the mirror location of a stimulus, requiring inhibition of a glance towards the stimulus, thus evoking cognitive control and prefrontal cortex activation. The current study examines the effects of practice on the neural correlates of saccade production when participants perform five runs of varying cognitive load with different probabilities of an antisaccade trial versus a prosaccade trial. Participants will complete a series of eye movement tasks 1) at baseline, 2) during four daily practice sessions, and 3) at post-test. One group of participants will practice five runs with only antisaccade trials while the other group will practice the five probability runs. Functional MRI data collected during the baseline and post-test sessions will be analyzed using an ANOVA to determine the differences in neural activation between the two practice groups using a region of interest (ROI) analysis. It is hypothesized that participants in the antisaccade group will exhibit less neural activation on antisaccade trials at the post-test session compared to the baseline than those in the probability group. These results will help further our understanding of practice-induced plasticity, and how cognitive control

processes are affected by increasing cognitive load.

Arkansas Vaccine Virus Transmitted to SPF Chickens from Vaccinated Broilers Does Not Provide Protection from Challenge

Julia McElreath
Dr. Mark Jackwood, Population Health, College of Veterinary Medicine

Avian Infectious Bronchitis Virus (IBV) is a gamma Coronavirus (CoV) that causes infectious bronchitis (IB), a highly contagious and economically significant upper respiratory tract disease in poultry. All commercial chickens are vaccinated against IBV but the Arkansas-DelMarVa Poultry Industry (Ark-DPI) serotype vaccine has been shown to provide inadequate protection from challenge and persist in a flock. Previous data show that the Ark vaccine follows an atypical replication pattern in comparison to most IBV vaccines, showing late single or multiple replication peaks throughout the life of the bird. This led us to question whether replication peaks were the result of a single infection with multiple replication peaks, or if chickens are being re-infected by vaccine virus shed into the environment. To test this, we placed 200 Ark-DPI vaccinated broilers and 65 non-vaccinated specific pathogenic free (SPF) chickens together in a colony house at 1 day of age. Swabs were taken for 28 days to monitor vaccine virus replication, and on day 30, select birds were challenged with virulent Ark virus. Vaccine replication was not detected in a significant number of broilers until day 24 post-vaccination and SPF chickens until day 28 post vaccination. Following challenge, 14 of 20 SPF and 9 of 20 broiler chickens tested positive for virus by qRT-PCR. This trial again demonstrates poor protection from challenge after Ark-DPI vaccination and that the Ark-DPI vaccine will spread laterally in a flock, indicating that multiple peaks of vaccine replication may be the result of multiple infections of vaccine virus.

Effect of Metformin Treatment on Feline Sarcoma Cancer Cell Cycle and Apoptosis

Laura McLean
Dr. Robert Gogal, Anatomy and Radiology, College of Veterinary Medicine

The hallmark of a metastatic cancer is uncontrolled cellular proliferation followed by cell cluster expansion into the peripheral tissues of the body. Current therapies are designed to block proliferation by directly inducing cell death via direct DNA damage, blocking cell division or impairing cell-signaling events. Still, there is no silver bullet therapy and the typical drug dose needed to achieve cytotoxicity is associated with severe adverse side effects. Metformin is an oral anti-diabetic drug that is used as a first line of defense for human type-2 diabetes with minimal reported side effects. Recent human-based studies have suggested that this drug may also possess anti-neoplastic properties. The focus of this study is to evaluate the cytotoxic effects of Metformin, *in vitro,* using a feline vaccine associated sarcoma cell line. The assays to be performed to assess cytotoxicity include drug inhibition cell proliferation assays, cell viability and apoptosis assays, cell cycle assays and cytology. Preliminary results at this time support that the drug has an inhibitory proliferative effect on the feline sarcoma cell line, which is concentration dependent. Presently, data are being collected on cell viability and apoptosis, cell cycle and cytology under different concentrations of Metformin. Time permitting, we plan to assess the cytotoxic effects of this drug in combination with another conventional antineoplastic drug and report our findings.

Examination of the Pathogenic Nature of *Mycoplasma pneumoniae*

Alison McWhorter Anderson, CURO Honors Scholar
Dr. Duncan Krause, Microbiology, Franklin College of Arts & Sciences

Walking pneumonia is a chronic infection commonly found in young adults and children. The primary cause of this infection is a bacterium known as *Mycoplasma pneumoniae*, which generally infects the ciliated epithelium of the conducting airways. We used Normal Human Bronchial Epithelial (NHBE) cells in an *in vitro* model because they create a mucocilliary barrier comparable to the one that forms in the human airway *in vivo*. Preliminary studies have shown that over time, *M. pneumoniae* will migrate from the apical to the basolateral compartment, which may be important in its ability to cause persistent infections. We infected NHBE cells with *M. pneumoniae* and tracked the course of the infection by examining the ability of the bacteria to pass from the apical surface to the basolateral chamber. This was done in an effort to qualitatively and quantitatively characterize pathogenesis and the ability of the NHBE cells to repair damage following infection. Tests were conducted on both mutant and wild type strains of *M. pneumoniae*. We observed NHBE cell sloughing, which appears to parallel what occurs during natural infections, and conducted immuno-histochemical staining and fluorescence microscopy to localize the mycoplasmas. In addition, we measured bacterial numbers in the apical and basolateral chambers to quantify mycoplasma migration. We also assessed ciliary activity visually by videotaping the movement of fluorescently labeled microbeads of various sizes. We hypothesize that colonization of the basolateral compartment provides the bacteria with a niche for hiding from the immune system.

Effect of Differing Larval Diet on Adult Fitness Measured through Body Size, and Novel Methods for Body Size Quantification in *Drosophila suzukii*

Elijah Mehlferber
Dr. Patricia Moore, Biological Sciences, Franklin College of Arts & Sciences

Drosophila suzukii are a recently introduced invasive species and highly destructive agricultural pest. They pose a unique threat because, unlike their close relative *Drosophila melanogastor*, they do not infest rotting fruit, instead attacking fresh ripening fruit. In this project I studied the relationship between larval diet and adult body size. To investigate this I first had to establish wing length as a viable proxy measurement for mesonotum length, which is the measurement usually associated with body size. I then placed *D. suzukii* eggs on blueberries (low protein diet) and artificial media (high protein diet) and allowed them to develop to adulthood, after which I measured and compared their body sizes. Regardless of which larval diet the flies were raised on, their average adult body size was the same. This indicates that *D. suzukii* have adapted to maximize the utility from a lower protein diet, and their body size may depend more on other nutrients. The preliminary steps in this experiment have yielded a reliable and accurate means to quantify the body size of *D. suzukii*, and this information will be useful for future studies of *D. suzukii* and their various life history traits. The research also allows for a better understanding of the adaptations that *D. suzukii* have undergone in reaction to their unique larval diet, and ongoing research is helping to study other related behavioral effects.

Carbon Flux in the Amundsen Sea Polynya

Jasmin Melara
Dr. Patricia Yager, Marine Sciences, Franklin College of Arts & Sciences

As atmospheric carbon dioxide levels increase from fossil fuel combustion, so increases the importance of the ocean's role of taking up CO2 and sequestering it at depth for centuries to millennia. The Southern Ocean sequesters about 20% of the global ocean drawdown of atmospheric carbon. During the austral summer (December to January), the Amundsen Sea Polynya off of west Antarctica spans an area of 27,000 km2 and is bursting with primary production, which positively correlates with rates of carbon sequestration. The Amundsen Sea Polynya International Research Expedition (ASPIRE) went during this season in 2010-11 to better understand the Polynya and the processes controlling the amount of carbon sequestered in this important ecosystem. The following was measured and calculated from water samples obtained from various locations around the Polynya to calculate the amount of carbon drawdown: dissolved inorganic carbon (DIC), air-sea CO2 flux (GE), particulate organic carbon (POC), dissolved organic carbon (DOC), dissolved organic nitrate (DON), dissolved inorganic nitrate (DIN), and particulate organic nitrate (PON). Two different methods were used to calculate carbon drawdown: a carbon to nitrogen ratio, and this formula ΔDIC + Δgas exchange – (ΔDOC+ΔPOC) = exported carbon. The average drawdown calculated was about 80g C m-2 d -1, a large drawdown compared to the Polynya's size.

Why is There an Alligator in My Pool? Assessing Potential Range Shifts with Sea Level Rise

Lara Mengak, CURO Summer Fellow
Dr. Nathan Nibbelink, Warnell School of Forestry & Natural Resources

Rising sea levels precipitated by climate change threaten southeastern coasts. Models indicate a substantial loss of salt marsh habitat and a transition from current freshwater marsh to saltwater and brackish marsh habitat, which could adversely affect marsh-dependent species, including the American alligator (*Alligator mississipiensis*). Kayak and spotlight surveys were used to determine alligator occupancy across a gradient of saltwater to freshwater marsh sites. Using this occupancy data, we explored the relationship between habitat composition and alligator occurrence. Our results show that the amount of brackish marsh within 250m of a site best discriminated between presence and absence of alligators. Tolerance to salty environments suggests that alligators may be resilient to changing marsh conditions with sea level rise. Preliminary modeling indicates a slight decline in total suitable habitat area, patch size, and habitat permanence. Habitat quality, however, shows a substantial increase. The models suggest that suitable habitat will move further inland due to sea level rise. These potential range shifts may put alligators into increasing contact with humans. Alligators displaced by sea level changes may be forced into new habitats, both natural and human occupied. Additional research on the population status and carrying capacity of important alligator habitat may allow us to better project consequences for both alligators and human communities.

Clicking on Platinum: Copper(I)-Catalyzed Azide-Alkyne Cycloaddition Chemistry for Axial Functionalization of Pt(IV) Prodrugs

Krupa Merchant
Prof. Shanta Dhar, Chemistry, Franklin College of Arts & Sciences

Cis-diamminedichloridoplatinum(II), or cisplatin, is a platinum-based compound that is widely used as a chemotherapeutic for malignant tumors of the cervix, ovaries, testicles, bladder, and lungs. Despite its great curative success, cisplatin can induce a number of toxic side effects, and certain cancers are resistant to cisplatin treatment. Chemical reactions that can manipulate the cisplatin platform will allow researchers to attach different moieties to the drug that may reduce this toxicity and overcome resistance. Cisplatin, with all coordination sites occupied by –amine and –chloro ligands to perform its anticancer activity, does not offer any vacant site to perform such attachment. However, octahedral Pt(IV) analogues can provide an additional two axial sites for such kind of reactivity. Pt(IV) compounds are known as prodrugs because of their ability to undergo reduction by biological reducing agents to produce cisplatin, the active drug. One type of chemistry that can be very useful in introducing new functionality onto platinum is "click chemistry." These types of reactions are usually 100% efficient and leave very few by-products. In this poster, we will discuss copper(I)-catalyzed azide-alkyne cycloaddition chemistry for axial functionalization of Pt(IV) prodrugs.

Generation of Transgenic Plants Carrying Promoter: Reporter-Gene Constructs to Investigate Transcriptional Expression of GAUT Genes in Arabidopsis

Swayamdipto Misra, Ramsey Scholar
Dr. Debra Mohnen, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Pectin is a family of highly complex polysaccharides that serve as important substituents of the plant cell wall and have important functions in cell-to-cell adhesion and plant development and defense. A comprehensive understanding of how pectin is synthesized will have important potential applications in crop enhancement and in better utilization of biomass for biofuels. It is known that the GAUT gene family, with 15 members in Arabidopsis, is involved in pectin synthesis, yet the function of these genes is not yet fully understood. This project aims to investigate the transcriptional expression of individual GAUT genes in different tissues or developmental stages of Arabidopsis plants by using reporter gene constructs driven by GAUT gene promoters. Over the past two semesters, β-glucuronidase (GUS) reporter gene constructs were created for several of the GAUT genes, including GAUTs 3, 5, 9, 10, 13, and 15. The promoter regions of the GAUT genes were amplified by Polymerase Chain Reaction (PCR), inserted into cloning vector pGEM-T, and verified by DNA sequencing. These promoter sequences were subsequently moved into the plant expression vector pBI101 in front of the GUS gene. The resulting constructs were introduced into Arabidopsis plants through *Agrobacterium*-mediated transformation. The seeds from the plants were grown and screened for positively transformed plants. The second generation resulting from these plants will be analyzed and stained in order to study the expression of the respective GAUT genes. Using a similar procedure, a Green Fluorescent Protein

(GFP) reporter-gene construct was also generated for GAUT 1.

Fiber Isotype Post-Injury in Secondary Dystroglycanopathies
Jill Modi, CURO Graduation Distinction
Dr. Aaron Beedle, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Loss of α-dystroglycan (αDG) glycosylation by mutations in *Fktn* causes muscular dystrophy. As severe *Fktn* deficiency has been linked to abnormal skeletal muscle regeneration and differentiation processes, we hypothesized that differentiated skeletal muscle fiber isotypes may arise at different proportions in *Fktn*-muscular dystrophy (KO, *Fktn* knockout mice) compared to normal controls. Cardiotoxin was injected into *Fktn* KO and littermate mice to create acute muscle damage. The resulting muscle fiber differentiation was analyzed 14 days after injury by measuring the proportion of immature and mature isotypes of the myosin heavy chain protein (MyHC) using immunofluorescent microscopy. We found that KO muscles retain more immature MyHC than littermates 14 days after injury, suggesting that regeneration/differentiation is slower in *Fktn* muscular dystrophy. Additional analysis of mature fiber types is ongoing. Overall, changes in KO muscle regeneration and differentiation may provide clues about the molecular events underlying muscle pathology in *Fktn* muscular dystrophy.

VacSIM, a New Vaccine Delivery Method, Improves Cellular Recruitment to Local Draining Lymph Nodes
Joshika Money
Dr. Donald Harn, Infectious Diseases, College of Veterinary Medicine

Although vaccines are a highly effective method of disease prevention, more effective vaccines are needed to increase vaccine efficacy in immune-compromised populations, such as the elderly and very young children. The Harn Laboratory developed an improved method of vaccine delivery, VacSIM (Vaccine Self-Assembling Immune Matrix) that increases vaccine efficacy. The goal of this research project is to gain a better understanding of the method of vaccine delivery used by VacSIM. Three groups of mice were utilized in this experiment; one group was injected subcutaneously with VacSIM, one group was injected with VacSIM and CpG adjuvant, and the last group was unvaccinated. Draining and non-draining lymph nodes were analyzed 24 and 48 hours after injection. Upon analysis, it was found that with VacSIM alone, cell numbers in draining lymph nodes do not increase significantly, but with the addition of CpG adjuvant, cell numbers do increase in the draining lymph nodes. This demonstrates that VacSIM does not create an immune response, allowing the CpG to activate the immune system normally. Thus, VacSIM has been shown to be a viable method of vaccine delivery that does not activate an immune response on its own. VacSIM can therefore be used to safely administer vaccines more efficiently, especially in immune-compromised populations.

Balancing Carbon and Phosphorus for Consumers: Does Nutrient Enrichment Tip the Scale?
Timothy Montgomery
Dr. Amy Rosemond, Odum School of Ecology

Forest stream food webs are based on organisms that can photosynthesize (autotrophs) as well as those that break down terrestrially-derived detritus (heterotrophs). Heterotrophic processes dominate carbon flow in forested streams; however, autotrophic processes may become more important in response to human activities such as nutrient loading. Nutrient loading can affect growth and nutrient

content (lower carbon: nutrient ratios) of autotrophs, which can affect growth of consumers and ecosystem nutrient retention. However, few studies have quantified the effects of nitrogen (N) and phosphorus (P) in changing nutrient content of autotrophic biofilms in streams or assessed how much biofilms change on natural substrates (rocks) vs. standardized substrates (tiles). We compared biofilms on standardized and natural substrates in five headwater streams that were enriched with five concentrations and ratios of N to P for two years (N:P = 2:1, 8:1, 16:1, 32:1, and 128:1). Biofilm ash-free dry mass (AFDM) and C:N:P stoichiometry were quantified and compared. Our results suggest that nutrient enrichment increased cobble biofilm AFDM by 47%. The cobble C:P decreased by 30% respectively across all streams, possibly shifting the limiting nutrient of the streams from P. Tile biofilms were 1.5-2x higher in C:P and N:P compared to cobble biofilms, while cobble biofilms were 8x higher in terms of AFDM. Overall, these results suggest that nutrient enrichment increases biofilm AFDM and nutrient content, but the degree to which was underestimated with standardized substrates.

Analysis of International Media Coverage of Key North Korean Military Events

Cecilia Moore, Holly Boggs
Dr. Brock Tessman, International Affairs, School of Public & International Affairs

Ultimately, the foreign policy behavior of a state is based on its subjective judgments about the intentions and behavior of another state. Often, media coverage can drive these subjective judgments. In this paper, we analyze international media coverage of key military events in the Democratic People's Republic of Korea (DPRK) in order to better understand the impact of media outlets on the major countries involved. We conduct a thorough content analysis of editorials from major newspapers in the People's Republic of China (PRC), Republic of Korea (ROK), Japan, and the United States (US) on two rocket and two nuclear tests conducted by the DPRK from 2009-2013. We analyze editorials immediately preceding and following the tests and draw from newspapers that represent a diversity of political ideology within each country. Using statistical means of analysis, we will test our hypotheses, which are that the nuclear tests will be covered more frequently and more negatively than the rocket tests, all right-leaning newspapers will cover the events more frequently and more negatively than the left-leaning papers, and newspapers in the ROK and Japan will have significantly more frequent and negative coverage than newspapers in the US or PRC. Our findings can be applied to future research concerning these four countries' foreign policy decisions regarding the DPRK. This might indicate a correlation between the tone and frequency of the countries' media coverage and their foreign policy decisions.

EnVISIONeD: Examining VISion among Inpatients with Diabetes

Victoria Moreira
Dr. Valerie Press, University of Chicago Medical Center

Diabetes Mellitus (DM) is the leading cause of blindness among adults in the US. However, patients often fail to obtain vision screening in the outpatient setting due to a myriad of patient and provider factors. There are also limited data for analyzing the hospital inpatient setting as a place to provide guideline recommended care to patients before discharge. Therefore, the present pilot study aimed to evaluate the prevalence of poor vision among inpatients with DM compared to the general medicine population. The study also sought to understand how to catch missed opportunities and to improve inpatient access to guideline recommended diabetic vision care. It was hypothesized that patients with DM would have a significantly

higher prevalence of poor vision. Vision was measured by a bedside Snellen eye chart test and data assessing characteristics of poor vision were also collected. It was found that participants with diabetes were more likely than those without diabetes to have insufficient vision (74/239, 31% vs. 101/466, 22%; p=0.007). As this is a pilot study, data collection is ongoing. However, these findings highlight the importance of utilizing other settings to catch missed opportunities for patients – especially those with DM at risk for developing severe comorbidities. Future studies should continue to evaluate this topic in a multi-site study to enhance the generalizability of results.

Investigation of Hand-Tool Mastery in Tufted Capuchins Using a Multiple-Jointed Tool

Jake Moskowitz, Amanda Heaton, Joshua Lukemire, Stephanie Villarreal
Dr. Kathy Simpson, Kinesiology, College of Education
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Using a hand tool effectively requires positioning it and applying appropriate force with it on the target object or substrate. The motor control strategies and spatial reasoning supporting tool use by nonhuman primates likely differ from those of humans, but the nature of the differences is unknown. Capuchin monkeys are the only genus of New World monkeys that spontaneously and regularly use hand tools. We report on an ongoing comparative investigation into how capuchins and chimpanzees use hand tools. Four individual capuchins in the Fragaszy laboratory at UGA were recorded individually using a rake tool to retrieve a token. Monkeys used the tool for 100 trials with a rigid handle, then 100 trials with one joint in it, and finally 100 trials with two joints (in orthogonal planes). In a second phase, they used the tool with the order of tool conditions varied randomly, and a new position for the blade of the rake included randomly. Four cameras placed at different angles recorded the monkey's actions with the tool. We are analyzing the monkeys' actions using ethological and kinematic methods. The findings will help us to understand how monkeys manage variable numbers of degrees of freedom in the tool and also contribute to resolving the theoretical debate surrounding the basis for variability across species in tool use. Supported by grant HD-060563 from the NIH.

Evidence for Indirect Effects of a Predatory Fish on the Size Distribution and Behavior of a Larval Caddisfly Species in Trinidadian Streams

Kelly Murray, CURO Summer Fellow
Dr. Catherine Pringle, Odum School of Ecology

It is important to understand both the direct and *indirect* effects of predators on their prey, given the cascading effects that can result from predator-prey interactions. Previous studies in Trinidadian streams indicate that an important prey item of killifish (*Anablepsoides hartii*) is larvae of the leaf-shredding caddisfly, *Phylloicus hansoni* (Trichoptera: Calamoceratidae). Since larval *Phylloicus* have been found to play a key role in controlling rates of leaf decomposition in Trinidadian streams, predator-mediated effects on *Phylloicus* are important to understand. *Phylloicus* occurs at significantly lower abundances in headwater streams dominated by high densities of killifish, relative to downstream reaches (below barrier waterfalls), where killifish are at lower densities and co-occur with guppies (*Poecilia reticulata*). These previous findings strongly suggest that high densities of killifish in upstream reaches exert *direct* top-down control on *Phylloicus* abundance. In this study, we examine potential *indirect* effects of killifish on *Phylloicus* size frequency distribution and behavior.

Analysis of size frequency distributions of larval *Phylloicus* from both killifish only (KO) reaches and killifish+guppy (KG) reaches (n=5 of each reach type) confirmed our prediction that different predation pressure by killifish alter the size structure of *Phylloicus* larvae: KO reaches exhibited a size frequency peak at a smaller size than in KG reaches. When exposed to killifish cues in *ex situ* laboratory studies, the leaf-shredding activity of larval *Phylloicus* from KO reaches was much greater than that of larvae from KG reaches. Therefore, predation pressure is likely important in shaping behavior and population characteristics of a dominant shredder species.

Analysis of Cancer Mutations in Protein Kinases Using Semantic Web Technologies

Anish Narayanan, CURO Summer Fellow
Dr. Natarajan Kannan, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Protein kinases are critical cell regulators, serving as initiators of signal transduction pathways and coordinators of cellular processes through the phosphorylation of target molecules. Given the importance of kinases in ensuring proper cell growth and development, the analysis of misregulatory kinase mutations is a hot target of cancer research. Despite the wealth of online kinase data compiled from various high throughput studies, previous computational approaches were limited due to the specialized nature of databases such as UniProt, COSMIC, and Reactome. To solve this daunting challenge of data integrability, our lab designed the Protein Kinase Ontology (ProKinO). This study utilizes ProKinO's unique sequence alignment of kinase mutations to PKA to generate heatmaps which identify mutation cooccurrence events. Oncogenic cooccurrences were found to be prevalent between two essential kinase subdomains: the glycine-rich loop that coordinates with ATP and the activation loop that interacts with the substrate. The biological effect of these tandem mutations was then evaluated by employing a data-mining approach. Applying natural language processing to the literature from Pubmed's Open Access Subset, mutations were labeled as having positive, negative, or neutral impact. Additionally, the type of impact was curated as either affecting phosphorylation activity, modulating resistance to kinase inhibitors, or altering substrate binding efficiency given computer-identified impact statements. This technique, in conjunction with crystal structure data, will be extended to develop a machine learning approach that accurately predicts the effects of novel kinase mutations. This will be of tremendous value in identifying personalized cancer treatments given patient genomes.

The DIY Phenomenon: Why We "Do It Ourselves"

Lindsay Nation
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The phenomenon of "DIY" or "do it yourself" refers to the lifestyle trend of self-sufficiency. This trend has had an effect on many industries, including the apparel industry. My paper investigates the economic, political, social, and psychological factors that have created the current DIY culture and its effects on dress production globally and locally. My research concluded that DIY tends to be popular in times of low economic prosperity and political unrest. The analysis of the social and psychological underpinnings of this trend also revealed that the main demographic that currently controls this trend is predominately upper-middle class white Americans, mostly women ages 15-50, who have a lot of leisure time and resources to look "different" and make things for themselves at their own pace. These

characteristics of the DIY trend are important for apparel companies, especially for local businesses. However, unless there are serious resource shortages, the global market will continue to be a mass merchandise market and DIY will likely have little effect on it. Despite this, DIY is a significant current trend; therefore, fashion industry leaders who are eager to predict the actions and preferences of consumers are closely watching it.

ChuW as a Class C Radical SAM Methyl Transferase

Anudeep Neelam
Dr. William Lanzilotta, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Iron is an essential metal for both pathogenic and symbiotic bacteria, and acquisition of iron can become a challenge during host colonization. Organisms can utilize heme and heme-containing proteins of the host as a source for iron. Located on a heme utilization operon and expressed under iron duress, ChuW from *Escherichia coli* O157:H7 is currently annotated as an oxygen-independent coproporphyrinogen III oxidase due to its additional "HemN-like" domain located on the C-terminus. However, HutW, a ChuW homologue, does not rescue a HemN mutant from *S. enterica*, and sequence analysis suggests similarities to class C radical SAM methyl transferases (RSMTs). Like HemN, ChuW may contain two SAM binding sites along with a [4Fe-4S]2+/+, which aids in radical generation and methylation. The structure and mechanism for Class C RSMTs have yet to be elucidated. In this work, we show ChuW contains an Iron-sulfur cluster and produces equivalent amounts of 5'-deoxyadenosine and S-adenosylhomocysteine, in the presence of an electron source, SAM, and Fe(II)-Deuteroporphyrin IX. In attempts to disrupt ligand binding and/or trap an intermediate, a predicted model of ChuW, derived from HemN, was generated to provide us with the amino acid targets for site-directed mutagenesis. By using EPR, UV-vis spectroscopies, and HPLC, we have characterized the variants Y61R and F76A, both of which displayed a bound iron-sulfur cluster; however, only the F76A expressed activity. ChuW is the first class C RSMT reported, hence, this research will help further our understanding of the mechanism of this subfamily of radical SAM enzymes.

"Please Excuse Me as I Am in Need:" Bondage and Freedom in Civil War-Era Athens

Laura Nelson
Dr. Christopher Lawton, History, Franklin College of Arts & Sciences

Studying the lives of slaves challenges outmoded, monolithic mythologies of the past and instead recognizes the enormous struggles and equal contributions of both black and white Americans. This research does so by reconstructing and examining the life of Aggy Mills (1827-1900), an Athenian woman enslaved by the elite Cobb family. She was remarkably literate, and through several extraordinary letters that she wrote to her owners, aspects of her life in slavery and freedom, like her role in her master's home and her place in the multicultural Athenian community, become apparent. Trace details of her life were first seen in these letters, but these only recount a portion of her life. To see Aggy as more than a servant, these letters are examined in conjunction with sources in the Athens-Clarke County Heritage Room, property deeds at the courthouse, census records, and various other local sources. Studying Aggy's life helps to give a more multifaceted version of the antebellum South, one where slaves' and whites' lives were intertwined, and slaves managed to define their own lives outside of the realm of their bondage. This research has been transformed into a digital sketch of Aggy's life as a part of

the Georgia Virtual History Project. Viewers can hear Aggy's story and see the places connected to her life via a downloadable app for smartphone or tablet. Additionally, this research will be presented at the annual conference of the Georgia Association of Historians.

Work-Sites with Physical Exercise Facilities and Their Effect on Employee BMI and Waist Circumference

Christina Nguyen
Dr. Jennifer Gay, Health Promotion & Behavior, College Of Public Health

Work-sites that provide employees with places to be physically active and allot a longer break period for physical activity may see an increase in the overall health of employees. We hypothesize that work-sites that offer onsite fitness centers and fitness rooms and have policies that support physical activities will be associated with a decrease in BMI and waist circumference of employees. Information was gathered about the work-sites using the Environmental Assessment Tool (EAT), such as offered time for physical activity during work hours, the presence of fitness equipment and walking routes and trails at work sites. Approximately two hundred employees had their weight and height measured to calculate their BMIs and waist circumferences. Average BMIs, average waist circumferences and frequency of employees that have access to physical activity programs will be calculated. T-tests will be calculated for BMIs and waist circumferences comparing employees at work-sites that have physical activities programs versus work-sites that do not have these programs. The importance of this research is to provide employers with data that would increase the overall health and productivity of their employees. Additionally, it would allow employers to determine if existing or planned exercise facilities are cost effective.

Metaphors of Color: The Linguistics of Internalized Racism

Minh Ngoc Nguyen
Dr. Chad Howe, Romance Languages, Franklin College of Arts & Sciences

This study proposes a history of the English word *whitewashed* based on quantitative and qualitative evidence from historical and modern language corpora. Analyzing the change from the word's original meaning to its racially imbued meanings, the paper also examines *whitewashed* as it pertains to the Vietnamese-American community in the context of other racially charged words and phrases (i.e. FOB, *fobby, fresh off the boat, acting white*). Based on the qualitative analysis, the data suggest that *whitewashed*, while particularly similar to the phrase *acting white*, retains a negative racial connotation that differs from the other expressions. This study explores the evolution of social meaning through the intersection of racial stereotypes and lexical semantic change.

Mitogen Activated Protein Kinase Flanking C-Terminal Tail: Structure and Function

Tuan Nguyen, CURO Honors Scholar, Ramsey Scholar, CURO Summer Fellow
Dr. Natarajan Kannan, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Living cells use networks of mitogen activated protein kinase (MAPK), a key cellular component of signal transduction, to respond to environmental signals. MAPK's cellular significance is underscored by its having been implicated in among the most prevalent aberrant signalling pathways in cancer. Although members of MAPK family have been extensively characterized at the biochemical, cellular, and structural level, an integrated evolutionary understanding of MAPK's functional divergence from a sequence level has been inadequate. Here, I

discuss how using genomic sequence comparison tools has shed light upon MAPK's structural evolution. I present evidence for co-evolution between MAPK's catalytic domain and MAPK's unique flanking C-terminal segment. Further implications of this work will be made in the talk.

Effects of Patellar Tendon Strapping on Lower-Extremity Kinematics

Pete Nkengasong
Dr. Cathleen Brown Crowell, Kinesiology, College of Education

Patellar tendinopathy is a musculoskeletal overuse injury, and treatments attempt to reduce pain by applying strap devices around the tendon. The mechanism causing pain reduction is not known, but using strapping may alter lower extremity kinematics of the ankle, knee, and hip in the sagittal plane. The purpose of this study is to determine the acute effect of patellar tendon straps on ankle, knee, and hip peak flexion angle during a drop jump with and without a Matt strap. We hypothesized that knee joint flexion would increase with strapping. Twenty-three recreationally active participants (14 females, 9 males, age=21.6 ± 3.5 years, height=174.2 ± 8.3 cm, mass=70.8 ± 10.9 kg) who experienced patellar tendon pain were fitted with 16 retro reflective markers, and data were collected via a 7-camera Vicon motion capture system. Participants performed a two-legged drop jump (DJ) off a 40cm box, landed on a force plate, and immediately jumped 50% of their maximum vertical jump. Five trials were performed with and without the Matt strap in a counterbalanced order. Paired sample t-tests ($p < .05$) were used to compare differences in peak flexion angles of the hip, knee, and ankle between strapping conditions. There were no significant differences in strap versus no-strap conditions, respectively, at the ankle (35.5 ± 10.1°, 34.6±8.6°, $p=0.52$), knee (76.3±13.3°, 74.0±13.6°, $p = .10$), or hip (58.1±11.7, 57.7±14.1°, $p=.74$). Acutely applying a strap appeared to have no influence on peak flexion angle in any lower extremity joint. Pain reduction may be caused by another mechanism.

***In Vitro* Protease Digestion and Reduction of Tropomyosin using Shrimp and Tropomyosin-Enriched Samples**

Kristyn Nock
Dr. Yao-Wen Huang, Food Science & Technology, College of Agricultural & Environmental Sciences

Of the vast range of foods responsible for adverse allergic reactions, crustaceans have been and continue to be a growing concern. The reaction caused by the consumption of crustaceans is IgE mediated, as IgE antibodies bind to the food allergen and induce a release of potent compounds, triggering symptoms of allergic reactions such as anaphylaxis, angioedema and morbilliform rashes. This study focuses on determining the most effective protease and conditions for reduction of the allergenicity of tropomyosin, the primary allergen responsible for adverse reactions from the ingestion of crustaceans. To reduce its allergenic activity, the goal of this study was to degrade tropomyosin into peptide fragments through protease digestion. Tropomyosin enriched samples and masticated shrimp samples were treated with either trypsin or α-chymotrypsin in simulated gastric fluid. Two methods of digestion were performed using a water bath and a gastrointestinal simulator. Hydrolysates were collected at various digestion times and samples were subjected to sulfate polyacrylamide gel electrophoresis (SDS-PAGE) to analyze alterations in the molecular weight of tropomyosin. The western blot method was additionally performed for further analysis of the degree of allergen reduction for particular digested samples. From multiple variable alterations throughout successive trials, the proteolytic ability of trypsin on tropomyosin at a 1:25 enzyme-

protein ratio was indicated. Upon expansion of this knowledge, it may be possible to incorporate the protease into crustacean-containing foods so that they may be nonallergenic and safe for consumption.

Hydrothermal Synthesis and Particle Size Study of Ancient Pigments

Isaiah Norris
Dr. Tina Salguero, Chemistry, Franklin College of Arts & Sciences

Egyptian Blue, $CaCuSi_4O_{10}$, and Han Blue, $BaCuSi_4O_{10}$, are among the first synthetically manufactured inorganic pigments from the ancient world. These two pigments are most notable for their vibrant blue hues that were used to color paintings. Modern interest in these pigments is due to their strong emission in the near infrared. Conventional solid state reactions for these pigments need extremely high temperatures of 950-1050 °C. We are developing two new ways to synthesize both pigments: hydrothermal and solid state with nanomaterials. The hydrothermal synthesis takes place in a Teflon-lined autoclave using water as a solvent and reduces the reaction temperature to 250 ºC. Future work with this method will be a time study of crystal size. We are also working on a study of what effect the size of starting materials has on the size, reaction temperature, and morphology of the product in solid state reactions of these two pigments by using scanning electronic microscopy to confirm particle size. We have found that when two of the starting materials are nanoparticles and the third micoparticles, the resulting product is reduced in size compared to the bulk synthesis using non-nanomaterials and has a decreased reaction temperature. Future work for this project will be to use all nanosize starting materials to see how small the product will be and how much of a reduction in reaction temperature we can obtain.

Proteomic Analysis of Erythrocyte Ghosts: The Effects of Zinc Supplementation

Kathleen Norris, CURO Graduation Distinction
Dr. Arthur Grider, Foods & Nutrition, College of Family & Consumer Sciences

Measuring plasma/serum zinc concentrations is used as a biomarker for assessing zinc status in human populations, but is neither sensitive nor specific for assessing individual zinc status. The purpose of this research is to identify zinc-responsive proteins within the erythrocyte membrane. Blood was collected as part of a larger study assessing the effects of 24 mg zinc supplementation for 4 weeks on bone growth biomarkers in Caucasian early adolescent females (9-13 years old) (PI: Richard Lewis). Samples were collected at baseline ($n=21$) and at 4 weeks ($n=20$), and plasma and erythrocyte ghosts (EG) prepared. Plasma zinc concentrations were measured by atomic absorption spectroscopy. EG proteins were separated by two-dimensional gel electrophoresis (2DE; isoelectric focusing (pH 3-10) and 10% denaturing polyacrylamide electrophoresis). The gels were stained with colloidal Coomassie blue, the images digitized, and densitometry was performed. Significance ($p \leq 0.05$) was determined using Student t-test. The plasma zinc concentration increased 1.2-fold $\pm$ 0.4(SD) after the four-week period of supplementation ($p<0.05$). Two EG samples from baseline and 5 EG samples from 4-week zinc supplementation were separated by 2DE. Three proteins exhibited zinc-dependent differential expression: 81.3 kDa, ~ pH 10 (1.7-fold increase); 45.7 kDa, ~ pH 7 (2.7-fold increase); and 134.9 kDa, ~ pH 6 (3.6-fold increase). These data support the up-regulation of certain proteins within the erythrocyte membrane in response to zinc supplementation. These proteins may ultimately serve as biomarkers for assessing individual zinc status following further validation.

Economic Transition and Psychological Distress as it Relates to Risk Factors for Cardiovascular Disease in St. Lucia

Mary Elizabeth Nuttall, CURO Honors Scholar
Dr. Colleen O'Brien Cherry, Global Health, College of Public Health

St. Lucia, a small island country in the Caribbean, has transitioned from an agrarian to a tourism-based economy. This economic transition has caused many socio-cultural changes, including an increase in psychological distress for much of the population as livelihoods change and the cost of living increases. Psychological distress is hypothesized to shape lifestyle behaviors, such as over-eating and alcohol consumption, both of which increase the risk for cardiovascular disease (CVD). Our research focuses on understanding the causes and outcomes of psychological distress and its effect on risk factors for heart disease in St. Lucia. After obtaining informed consent, we conducted informal one-on-one interviews with 25 participants concerning their cultural perceptions of CVD and its lifestyle risk factors. Using the themes uncovered in these interviews, we conducted 4 focus groups using photovoice, a method in which participants explained photographs reflecting their perceptions of health. An in-depth analysis of the interviews and focus groups is underway using NVivo software. Preliminary analysis indicates that economic pressures and family responsibilities are the two major causes of psychological distress that participants face. Additionally, we found that many participants cope with psychological distress by over-eating and drinking to excess. Few projects focus on the association between the risk factors for heart disease and psychological distress in St. Lucia and other middle-income countries undergoing similar economic transitions. Our research will provide a unique perspective on a growing global issue and ultimately could be used to stage culturally relevant CVD intervention programs focused on managing psychological distress.

Max Contracts: Savings or Reallocation?

Thomas Oliver
Dr. William Vogt, Economics, Terry College of Business

This essay argues that the maximum limit imposed on individual player salaries by the National Basketball Association's collective bargaining agreement in 1999 created an environment in the free agent market that led organizations to adopt a more inefficient spending style than the one employed in the era before the policy was in place. Specifically, the individual player salary cap resulted, in the first years after its imposition, in a transfer of salary from the best players to intermediate skill players, and, in more recent years, from the best players to lower skill players. Skill was measured with win shares, a standard basketball player performance metric. Data on contracts and win shares were collected for the 1995/6 through 2013/14 seasons. Since player contracts are typically multi-year and since aging has large effects on performance, it was necessary to forecast each player's future performance over the life of his contract based on age and past performance. This projected win share was the key player quality measure. Contract values were plotted against projected win shares both before and after the imposition of the individual salary cap policy and loess regression was run to confirm the graphical results. These results show that the relationship between salary and player quality became noticeably less steep and less convex immediately after the imposition of the cap, with intermediate quality players benefiting from the change. In more recent years, lower quality players appear to have benefited more from the salary cap, as a more convex relationship reasserts itself.

Analysis of P1 Function in *Mycoplasma pneumoniae* Adherence and Gliding

Babajide Oluwadare, CURO Honors Scholar, CURO Summer Fellow
Dr. Duncan Krause, Microbiology, Franklin College of Arts & Sciences

This study focuses on *Mycoplasma pneumoniae*, a human pathogen causing bronchitis and primary atypical, or "walking" pneumonia. Mycoplasma adherence to respiratory epithelium is mediated by a differentiated terminal organelle. Located on the surface of the terminal organelle is the P1 protein, which functions directly in both cell adherence and motility. There is evidence from recent studies to indicate that P1 repeatedly catches and releases sialic acids, present on airway cell surfaces, to thrust the mycoplasma cell forward. Furthermore, P1 is believed to exist in conformationally distinct subpopulations that shift when mycoplasma cells glide. Little is known about the specific mechanism by which the bacterium exhibits motility via the P1 protein. Learning about this unique form of movement can lead to new strategies for treatment of infections and a greater understanding of bacterial motility. By means of immunofluorescence microscopy with monoclonal antibodies specific for P1, mAB1 and mAB2, we sought to define quantitatively the location and relative amounts of P1 subpopulations. The antibodies mAB1 and mAB2 consistently yielded distinct labelling patterns, which were not the result of background or "noise." Furthermore, mAB1 appeared to bind only to a subset of P1 proteins and only at specific times, as opposed to mAB2, which appeared to bind to all P1 at all times.

Use of Synthetic AKAP Peptides to Assess the Importance of the Protein Kinase A Signaling in the African Trypanosome

Nina Paletta
Prof. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts & Sciences

Human African Trypanosomiasis (HAT) is a tropical disease caused by the protozoan parasite *Trypanosoma brucei*. Over 70 million people are at risk of contracting HAT, and current drug treatments can be highly toxic. Evolutionarily diverged cell cycle regulators may be promising targets for anti-trypanosome discovery. A-Kinase Anchoring Proteins (AKAPs) contribute specificity to cyclic-AMP signaling by protein kinase A (PKA) through binding the enzyme and its substrate targets. We are testing the efficacy of human AKAP-inhibitor peptides against *T. brucei*. These peptides are hypothesized to disrupt AKAP scaffolding, thus perturbing PKA signaling. We are taking three approaches to achieve our goals: 1) identify AKAP binding proteins, by immunoprecipitation, 2) localize AKAP binding proteins by fluorescence microscopy, and 3) determine antitrypanosomal properties of the AKAP inhibitor by flow cytometry. We treated trypanosomes with an AKAP inhibitor modified with a biotin label. After treatment, trypanosomes were lysed and passed through a streptavidin-coated bead column. A set of trypanosome proteins bound the AKAP peptide (as determined by SDS-PAGE). These proteins will be isolated from the gel and identified by mass spectrometry. The microscopy and flow cytometry experiments are currently underway. By analyzing the data from all three assays, we can better understand the contributions of AKAP scaffolding and PKA signaling in the trypanosome.

Bioluminescent Color Shifts in North American Fireflies

Jennifer Pallansch, CURO Summer Fellow
Dr. David Hall, Genetics, Franklin College of Arts & Sciences

A frequently overlooked feature of firefly light signaling is the natural color variation observed across species. This project documented extensive bioluminescent color variation among North American fireflies to expand upon current field data and to elucidate possible correlations between color shifts and environmental factors. Firefly emission spectra were recorded for over 600 individuals at 52 field sites. The use of a portable spectrometer minimized potentially modulating factors such as age and the effects of chemically induced flashing by capturing emission spectra in a natural setting. With this data, we tested environmental factors for associations. Because it has been theorized that color shifts are influenced by ambient light, each population was categorized by habitat and activity time to estimate the amount of background light in the environment. Habitat and activity time designations were compared with color shifts across all species data as well as population data collected from two main species, *Photinus pyralis* and *Photinus scintillans.* Statistically significant associations were not observed with activity times, but habitat showed significant correlations with both species and *P. scintillans* spectral data. By collecting comprehensive field data, we were able to examine several environmental factors possibly involved in the evolution of color shifts and provide an in-depth assessment of naturally occurring color variation in fireflies.

Exploring the Variable Weaning Strategies of Female Rhesus Macaques through Stable Isotope Biochemistry

Katherine Partrick, CURO Summer Fellow
Dr. Laurie Reitsema, Anthropology, Franklin College of Arts & Sciences

Weaning is an important life history phase because it directly affects a mother's fitness and infant development. Observational data traditionally used to assess weaning age can be imprecise due to the problems of comfort nursing and nursing at night. We employ an isotopic approach to more objectively assess age-at-weaning of captive rhesus macaques (*Macaca mulatta)*. We also examine factors thought to influence weaning strategies, including mother's rank, infant sex, and infant growth rate. We test two alternate hypotheses: (1) Infants are weaned at age 5 months (based on previous observations on captive *M. mulatta*) and (2) infants are weaned upon reaching 2/3 adult body size: ages X-Y months (the threshold weight hypothesis). Stable carbon and nitrogen isotope data were assayed from blood plasma of 8 mother-infant pairs of known age, rank, parity and weight housed at the Yerkes Primate Research Center. Mothers were sampled at ages 2 and 5 months. Infants were sampled at ages 2, 5-8, and 10 months. Mean values of the mothers over 10 months were δ13C=-19.3$\pm$0.37‰ and δ15N=6.9$\pm$0.3‰. Between 2 and 10 months, infant δ15N values dropped from 7.7$\pm$0.3‰ to 6.8$\pm$0.3‰, and δ13C values dropped from -18.0$\pm$0.28‰ to -19.9$\pm$0.44‰. Males were weaned earlier than females (age 6 months versus age 8 months). No relationship was found between isotopic values and infant growth rate or maternal rank, although the lowest ranking mother weaned her offspring earliest. The refined snapshots of weaning status obtained through isotopic analysis permit previously impossible hypothesis testing in primate weaning ecology.

Recombinant Protein Therapy: Generation and Purification of Various Fukutins

Niraj Patel
Dr. Aaron Beedle, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Protein therapy is a method of delivering therapeutic amounts of protein that would be otherwise absent or insufficient in individuals that have a disease. Because the loss of functional fukutin (Fktn) causes Fukuyama Congenital Muscular Dystrophy (FCMD), we seek to determine whether protein therapy can alleviate the disease temporarily. To test this question, we designed and generated various fukutin inserts (Tat-mini-Fktn, full-length Fktn, and Tat-full-length-Fktn) in the pET29a expression plasmid for recombinant protein expression. The Tat (Trans-Activator of Transcription) sequence was fused to several of the fukutin inserts because it has cell penetrating peptide properties, to promote cell entry. We then induced synthesis of the fukutin recombinant proteins in bacteria. Recombinant protein is purified and then tested in mice with fukutin-deficient muscular dystrophy. We aim to determine the localization, stability and potential therapeutic activity of the different fukutin protein variants in mouse skeletal muscle. Overall, these studies will help us to understand the function and activity of fukutin and its potential for therapeutic benefit.

Role of Salicylic Acid in Oxidative Stress Responses in *Arabidopsis thaliana*

Shreya Patel
Dr. C.J. Tsai, Genetics, Franklin College of Arts & Sciences

Plants are sessile organisms and face biotic and abiotic stress during their life cycles. As such, they have developed an inherent ability to survive unfavorable conditions through defense mechanisms. Salicylic acid (SA) is a phytohormone that is ubiquitously expressed in plants and is thought to play an important role in oxidative stress responses. We used transgenic *Arabidopsis thaliana* lines that exhibit varying levels of salicylic acid to assess its effects on oxidative heat response. Oxidative damage in plants involves oxidation of polyunsaturated fatty acid molecules in the lipid bilayer of the cell membrane and can be measured by the thiobarbituric acid-reactive substances (TBARS) assay, using malondialdehyde as the substrate. Known as the secondary end product of polyunsaturated fatty acid oxidation pathway, malondialdehyde reacts with thiobarbituric acid and generates an adduct, which can be measured spectrophotometrically. The FDIrp9 transgenic line engineered to accumulate high levels of SA showed drastically reduced MDA levels compared to the wild type. Interestingly, the NahG transgenic line with depleted levels of SA also showed a slight decrease of MDA. In response to heat stress, the wild type MDA levels were reduced, while those of the FDIrp9 and NahG plants were increased, with the NahG plant exhibiting the greatest increase in MDA content. Thus, the effects of SA on oxidative stress response appear to be complex and can be explained by differing mechanisms that might be directly or indirectly involved in maintaining plant homeostasis.

The Double Knockout of the Haptoglobin-Hemoglobin Receptor in Bloodstream-Form *Trypanasoma brucei brucei* Lister 427-Single Marker Clone

Hayes Patrick
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosome Lytic Factor (TLF-1) is a primate-specific subclass of high-density lipoprotein that is critical for immunity against certain species of parasites called African trypanosomes. The primary mechanism of trypanosome susceptibility to TLF-1 begins at

the haptoglobin-hemoglin receptor (HpHbR) in the flagellar pocket of trypanosomes. The flagellar pocket is a specialized region of the trypanosome cell surface. TLF-1 binds to this receptor, initiating a lytic pathway that leads to TLF-1 endocytosis into the lysosome of the cell. We show here that through the double knockout of the HpHbR in *Trypanosoma brucei brucei* (*T.b.brucei*), there is a significant increase in trypanosome resistance to TLF-1. The knockout of the HpHbR was visualized through a combination of qualitative and quantitative analyses. These data are consistent with the claim that the HpHbR is the primary source for TLF-1 binding and uptake. With the elimination of the HpHbR in our *T.b.brucei* cell line, we are now able to explore additional contributors to TLF-1 resistance. Through RNA-interference screening of a candidate construct into these cell lines, we can identify target proteins and begin to see what other factors contribute to trypanosome susceptibility to TLF-1. RNAi of candidates will allow us to knockdown target proteins and test for changes in sensitivity to TLF-1. If measurable changes are found, we can ectopically express tagged versions of those proteins in order to assess their functions, which could be shown through colocalization with TLF-1 or other steps along the TLF-1 lytic pathway.

Association between Body Composition and Serum Folate Concentrations in Women of Childbearing Age: Secondary Analysis across Three Studies

Meagan Patterson
Dr. Dorothy Hausman, Foods & Nutrition, College of Family & Consumer Sciences

Sufficient folate status is important before conception in reducing the risk of neural tube defects (NTDs). As maternal obesity is also a risk factor for NTDs, this study asked the question: "Is there a relationship between serum folate and body composition in women of childbearing age?" A secondary analysis was performed in normal weight and obese women using data from three previous studies in our laboratory (n=94; average age=24.3, range=18-40; average BMI=28.2, range=18.3–56.8), for which serum folate (microbiological assay) and body composition including total mass, fat mass and fat-free soft tissue measures (dual energy X-ray absorptiometry (DXA)) were available. Bivariate and partial correlations were determined using SAS. Across these three studies, fasting serum folate concentrations were lower in the obese as compared with the normal weight women (16.34±1.03 ng/mL versus 21.04±0.87 ng/mL, $p<0.001$) and inversely correlated with both BMI ($r=-0.366$, $p<0.0001$) and total body mass ($r=-0.374$, $p=0.0002$). The association between serum folate and total body mass remained significant after correction for age, diet, oral contraceptive use and parity ($r=-0.396$, $p=0.0003$); was attenuated by further correction for fat mass ($r=-0.247$, $p=0.028$); and eliminated by alternatively correcting for fat-free soft tissue ($r=-0.059$, $p=0.605$). This suggests that the lower serum folate concentrations in obese women of childbearing age may be explained, in part, by an increased amount of metabolically active fat-free soft tissue. These findings provide additional evidence for consideration of body composition in intake recommendations for improving folate status and reducing the risk of birth defects in women of childbearing age.

Issues in the Therapy Experience for the LGBT Community and Their Implications

Kinsey Pebley
Dr. Patricia Richards, Sociology, Franklin College of Arts & Sciences

Little work has been done to acknowledge or address the shortcomings of the therapeutic experience for lesbian, gay, bisexual, or transgender (LGBT) identified individuals. This topic is of particular importance given

that members of the LGBT community are at a higher risk for mental health difficulties, as they face unique stressors concomitant with heterosexism (Bos et al., 2008). While many therapists resolve to remain objective, they may inadvertently disrespect or display limited knowledge about the experiences and preferences of these individuals. Sixteen LGBT persons who had been to therapy participated in interviews in which they were asked to speak to their experiences, specifically if the experience was beneficial for them and what could have made it better. Salient themes that emerged from qualitative analysis of these interviews included use of sensitive language (such as use of gender-neutral pronouns), a desire for community, agency in seeking support outside of a traditional setting, and the challenges of identifying safe spaces. Psychologists are ethically bound to practice cultural competency ("Ethical principles of," 2014) and be sensitive towards the identities of their clients. These findings can help to fill the gaps of knowledge relating to issues prevalent in the LGBT community and provide a greater sense of safety within the therapeutic setting, thereby reducing the risk of mental health problems affecting these communities.

New Aid for Africa

Anne Pellegrino, Jonah Driggers, Elijah Scott, Meili Swanson, Luke Thompson, Patrick Wheat
Dr. Brock Tessman, International Affairs, School of Public & International Affairs

The nations of the Great Lakes region in Africa are struggling under the dual challenges of corruption within state governments and economic underdevelopment, which have both limited the effectiveness of foreign aid and foreign investment within the region. These issues spring from a combination of ineffectiveness and redundancy of current regional organizations, a lack of proper physical and institutional infrastructures, and a lack of current local incentive or regulation to limit corruptive influences within the nations themselves. To best combat these issues, USAID should employ a three-pronged economic approach: the creation of a micro-lending program to allow for allocations to be spent directly by citizens to grow their national economy, a focus on distributing aid towards public-private partnerships to increase domestic growth, and the reinforcement of funds to support pre-existing Regional Economic Communities within the African Union. These three approaches create the opportunity to broadly address these issues of corruption by removing corruptive factors from the distribution process, while creating the opportunity to stabilize the economies of the Great Lakes region. To demonstrate the effectiveness of this three-pronged policy approach, we will evaluate similar attempts in the Great Lakes region, and evaluate the success of such programs when applied to our three-pronged policy solution. Nations included in this evaluation will include the United Republic of Tanzania, the Republic of Kenya, the Republic of Uganda, the Federal Democratic Republic of Ethiopia and the Democratic Republic of the Congo.

Football Facemask Mass Influences Head Impact Location

Tracy Phan
Dr. Julianne Schmidt, Kinesiology, College of Education

Objectives: 1) To determine whether players with heavy facemasks have increased odds of sustaining impacts to the top of the head. 2) To determine whether there is a significant difference in head impact severity between players with heavy versus light facemasks. *Participants:* Twenty-five collegiate football players. *Interventions:* Facemask type and mass were determined. Head impact location and severity were captured for 7,135 head impacts using the Head Impact Telemetry System. *Main Outcome Measures:* 1) We categorized

facemasks as either heavy (>484g) or light (<=484g) using a median split. We computed the odds ratios for sustaining top of the head impacts between facemask groups using a random intercepts proportional odds model. 2) We compared head impact severity (linear and rotational acceleration) between groups using a random intercepts general linear model (α=0.05). Player position was included in all models. *Results:* Players with heavier facemasks had reduced odds of sustaining frontal (OR:0.42, 95%CI:0.22,0.81) and right side (OR:0.47, 95%CI:0.26,0.83) rather than top of the head impacts. Head impact severity did not significantly differ between groups. *Conclusions:* Players with heavier facemasks may have increased odds of sustaining impacts to the top of the head because they adopt a head-down tackling technique. Decreased odds of sustaining right side hits may be due to variable aspects such as player location or play. Other factors such as a player's tackling technique, physical fitness, and neck strength may also play a role in head protection.

Transferrin-Crosslinked Liposomes for Targeted Drug Delivery to *Trypanosoma brucei*

Aparna Philip
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosoma brucei is a protozoan parasite that causes African sleeping sickness in humans and nagana in cattle. Without treatment, both sleeping sickness and nagana are fatal, leading to thousands of human and millions of cattle deaths annually. Available therapeutics are fraught with severe side effects, difficult to deliver and prone to the development of resistance. Our laboratory has developed a small hydrophobic peptide (SDLGAVISLLLWGRQLFA) (SHP) that is uniquely toxic to the mammalian bloodstream developmental stages of *T. brucei*. Bloodstream form of *T. brucei* showed a LD50 (median lethal dose) of ~8 μM for SHP *in vitro*; however, the limited solubility of the peptide led us to investigate the development of drug delivery platforms that would increase the efficacy of SHP. Here we describe recent efforts to deliver SHP to these parasites via liposomes crosslinked to bovine-transferrin, using an N-linked lipid conjugate (cyanur-PEG), for receptor mediated endocytosis. First, we utilized liposomes loaded with the fluorescent dye calcein to monitor the binding of transferrin (an iron transporter) to its receptor in the flagellar pocket, the site of all endo- and exocytosis in *T. brucei*. Fluorescence microscopy was used to visualize the binding of calcein-loaded liposomes to the flagellar pocket of the trypanosomes at 3°C. Our data indicates that transferrin-crosslinked, but not the uncrosslinked, liposomes bind to the flagellar pocket. The efficiency of SHP binding and toxicity is currently under investigation.

Investigating Missense Mutations in O-GlcNAc Transferase that Lead to Human X-Linked Intellectual Disability

Sindhu Prabakaran
Dr. Lance Wells, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

O-GlcNAc modification is a distinct form of protein glycosylation that occurs on serine and threonine residues of cytoplasmic and nuclear proteins. This form of protein glycosylation is an abundant and inducible modification found in all higher eukaryotes, and is facilitated by two enzymes, *O*-GlcNAc transferase (OGT) and *O*-GlcNAcase (OGA). Recently, the Schwartz group identified mutations in OGT in three X-linked intellectual disability patients in a family that also displayed a short stature, small head circumference and fifth finger Clinodactyly. Additionally, two of the three had hypospadia. This linked a missense mutation, L254F, in OGT to a human disease for the first time.

The aim of our work is to elucidate the impact of L254F on the OGT enzyme. Using a combination of work with patient lymphoblasts and *in vitro* recombinant OGT enzyme we have determined that the mutant enzyme appears to be active but unstable. Also, we have uncovered a compensation mechanism, albeit imperfect given the patient phenotypes, by which a reduction in OGT levels leads to a reduction in OGA levels in an effort to maintain global O-GlcNAc levels. We are currently exploring both the stability and kinetic parameters of recombinant OGT, as well as the impact of this mutant on global transcriptional regulation.

A Yeast-based Screen for Drugs That Can Inhibit Human *Cdc6*

Ojaswa Prasad, Dennis Dwan
Dr. Edward Kipreos, Cellular Biology, Franklin College of Arts & Sciences

Cdc6 is a highly conserved protein that is required for the initiation of DNA replication in humans and most eukaryotes. We are using the fission yeast *Schizosaccharomyces pombe* for our studies. In fission yeast, the *cdc18+* gene encodes the *Cdc6* ortholog. Fission yeast cells are rod shaped and divide by medial fission. Their division cycle is quite rapid which, in addition to being inexpensive and easily manipulated, makes them easier to use in the laboratory. Cells lacking the *cdc18+* gene fail to enter S phase and undergo DNA replication, although the cells still undergo nuclear division according to Nurse and Kelly. Nurse and Kelly also found that overexpression of *cdc18+* results in cells arresting in S phase and increasing their DNA content to levels much greater than 2C through the aberrant process of re-replication. We want to screen for compounds that inhibit the overexpressed *Cdc18* protein, which will reduce the level of *Cdc18* activity so that cells do not arrest in S phase and undergo re-replication, and instead are able to proliferate. After optimizing growing conditions for the yeast, we successfully transformed three different plasmids containing the *cdc18+* gene into the fission yeast. We also successfully induced the overexpression of the *cdc18+* gene and saw the expected re-replication phenotype. Our goal is to clone the human *Cdc6* gene into a fission yeast expression construct. We want to introduce the human *Cdc6* gene into fission yeast and induce overexpression of the gene. If the overexpression of human *Cdc6* induces re-replication of the genome and an S-phase arrest then we can use this yeast in a screen for compounds that inactivate the human *Cdc6*, and thereby allow the yeast to proliferate normally. The yeast cells with overexpressed human *Cdc6* will be tested with numerous compounds from a small molecule library in Dr. Kipreos' lab to decrease or eliminate DNA re-replication and rescue the human *Cdc6* overexpression phenotype. This screen can identify lead compounds that specifically target human *Cdc6* and inhibit its function in DNA replication.

Suboptimal Time in Therapeutic Range (TTR) for International Normalized Ratio (INR) Measurements Observed in an Outpatient Cardiology Clinic: Impact of Gender, Ethnicity, Disease Etiology, CHADSVasc score, Physicians and Clinic Site

Sarah Premji
Dr. Karl Espelie, Biological Sciences, Franklin College of Arts & Sciences

TTR correlates inversely with ischemic stroke risk. Variations in TTR are common with a range of between 55-60% being normal and > 70% being optimal. It was previously unknown which factors impact TTR most in the community cardiology setting. Retrospective chart review was conducted of all patients (pts) being treated with warfarin in a single, multi-site suburban, outpatient cardiology practice for one year. Hypertension and hyperlipidemia were common, while diabetes, smoking, alcohol and aspirin use

were less. Atrial fibrillation was the most common reason for treatment followed by mechanical valves, venous system disease, and arterial system disease. An average of 12+5 INR readings/pt were done over the year. Average time on warfarin was 35+18 months. TTR for the overall group was 44.5 + 22.3%. TTR varied significantly among ethnicity, the seven individual physicians managing INR and the four clinic sites. Clinics and physicians having a higher proportion of African American pts tended to have lower TTR. TTR was worse in pts with arterial and venous disease vs. atrial fibrillation and mechanical valves. Our findings suggest that TTR may be substantially worse in clinical practice than previously published literature would suggest. Patient ethnicity, ordering physicians, clinic site, and disease etiology all affect TTR. Duration on therapy is the most significant factor and ethnicity is second contributing to TTR. Novel anticoagulants should be discussed more often with patients at higher risk of poor TTR. Confirmation of these findings in a broader population could have significant implications for future anticoagulation management and stroke prevention.

Validating *In Vitro* Cell Culture Models for Molecular Pathogenesis Studies in *Fktn*-deficient Muscular Dystrophy

Vedika Rajasekaran
Dr. Aaron Beedle, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Muscular dystrophies may be associated with a change in activity in the PI3K/Akt/mTOR signaling pathway that is important for cell survival and growth. Therefore, our objectives are to establish an experimental protocol to study this pathway using *in vitro* cultures of normal mouse skeletal muscle C2C12 cells, establish primary muscle cultures from inducible *Fktn* knockout mice, and evaluate changes in the pathway due to muscular dystrophy defects. We differentiated C2C12 cells into myotubes, then successfully inhibited and/or stimulated the PI3K pathway in serum starved cells as demonstrated by histological and biochemical analysis. In addition, we developed conditions for isolation and cultured skeletal muscle cells from *Fktn* muscular dystrophy mice and normal mice. Analysis of the PI3K/Akt/mTOR pathway in this model is ongoing. Overall, our *in vitro* studies offer the ability to complement our *in vivo* work in the role of the PI3K/Akt/mTOR signaling pathway in the pathogenesis of *Fktn*-deficient muscular dystrophy.

Purification of Xyloglucan-Specific Endo-β-1, 4 -Glucanase after Expression in *Escherichia coli*

Ramon Reddick
Dr. William York, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

A protein consisting of xyloglucan-specific endo-β-1, 4-glucanase (XEG) and enhanced Green Fluorescent Protein (eGFP) was prepared by heterologous expression of a genetically engineered plasmid in *Escherichia coli*. Initial experiments indicated that an eGFP-pET28a vector is efficiently expressed in *E. coli* to generate eGFPi. Another pET28a vector containing DNA encoding XEG fused to eGFP was then generated and transfected into *E. coli*, which expressed the desired chimeric protein. Conditions for optimizing the production of soluble forms of the fusion proteins were identified and the soluble proteins were purified. Mutagenesis of the XEG component of the protein inactivates the catalytic mechanism of XEG on xyloglucan, but still enables the protein to attach to the polysaccharide. Attachment to the polysaccharide without catalysis allows for the fusion protein to be administered in living plant tissue for further observation. These proteins are potentially powerful new tools for studying the chemical structure and physical properties of plant cell walls. For

example, they can be used to visualize and quantify xyloglucan in different cells as the plant develops. Such information may have important implications for technologies aimed at the economical production of biofuels from non-food sources.

Neonatal Mortality in Uttar Pradesh, India and Possible Policy Solutions

Hannah Reiss, Foundation Fellow
Dr. Richard Schuster, Health Policy & Management, College of Public Health

Neonatal death is defined as death within the first four weeks of an infant's life. According to a 2009 study published in the International Journal of Obstetrics and Gynaecology, nearly four million neonates die annually, and over one million of these die in India. The high neonatal mortality rate (NMR) in Uttar Pradesh, India drives up the national NMR. Because neonatal death comprises over 40% of death before the age of five, it also hinders the achievement of the fourth United Nations Millennium Development Goal, which is to reduce global child mortality by two-thirds by 2015. In addition to mortality, high NMR causes morbidity in the survivors. Low neonatal survival rates are associated with negative economic impacts and unsustainable population growth. Possible policy solutions to address high NMR in Uttar Pradesh include a home checklist for midwives, increased payment to Accredited Social Health Activists (ASHAs) to incentivize postnatal visits, and a tetanus immunization campaign. These three alternatives were evaluated through a multi-goal analysis to evaluate their impact, cost, and feasibility. Of the three alternatives, a home checklist for midwives best meets these criteria. This alternative would modify the World Health Organization's Safe Childbirth Checklist, which is currently undergoing efficacy trials in 120 hospitals in Uttar Pradesh.

Creating a Chimeric Chicken Resistant to Newcastle's Disease Virus

Hannah Reiss, Foundation Fellow
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Newcastle's Disease Virus (NDV) is a contagious disease that affects avian species. NDV causes respiratory symptoms in many birds, but it is especially virulent in chickens and often results in death. The Center for Food Security & Public Health reported in 2011 that NDV is the most economically detrimental virus in poultry worldwide. Because of its severe effect on chickens, NDV is also the largest pathological constraint in raising village chickens throughout Africa, according to a study conducted by J.G. Bell in 1991. Vaccine delivery to immunize village chickens is generally financially impractical because of the long distances between villages. Because vaccination is not feasible, genetic modification to improve the chicken immune system is now underway. The RIG-I gene begins a cascade immune response by signaling the mitochondrial antiviral signaling (MAVS) pathway and is thought necessary in staging an antiviral response to NDV. Chickens lack RIG-I, which is believed to account for their weak immune response to NDV. We hypothesized that transfecting human RIG-I into the chicken genome would allow the chicken a stronger immune response against the virus. We injected primordial germ cells (PGCs) that had been transfected with RIG-I into chicken embryos. We then dissected the embryos to see whether the PGCs had migrated to the gonads of the embryo seven days post-injection. Following dissection, we saw minimal integration of RIG-I into the gonads of the injected embryos.

College Credit Experience and Financial Literacy

Anthony Reyna, CURO Honors Scholar
Dr. Brenda Cude, Housing & Consumer Economics, College of Family & Consumer Sciences

The purpose of this research is to identify a correlation between college students' credit experience and their financial literacy. For this project, financial literacy was measured by financial knowledge based on percentage scores on a 30 question financial knowledge test. The test was administered at the beginning of the semester to University of Georgia students enrolled in the "Money Skills for Life" course (HACE 3110) from 2008-2012. Credit experience was measured in four ways – whether the student used credit (binary variable measured as 1 if the student's credit report consisted of any accounts attached to their name, zero otherwise), the ownership of the credit (a binary variable measured as 1 if the student had individual ownership of at least one credit account, zero otherwise), the debt-utilization ratio (the ratio of a student's total current balances to his/her total available credit), and a student's total number of open credit accounts. The credit experience data come from credit reports submitted as student assignments in HACE 3110 from 2008-2012. We used Microsoft Excel to build the dataset and the statistical analysis program SPSS to calculate the four correlation coefficients. By identifying the connection between financial literacy and certain aspects college students' credit experience, UGA will be better equipped to financially educate its students and assist them in improving their financial behaviors.

Searching for Noise-Induced Phase Transitions in Ecological Systems

Giovanni Righi, Foundation Fellow
Dr. John Drake, Odum School of Ecology

This project develops a model to represent photoinhibition of a phytoplankton population in a light-limited chemostat. Photoinhibition is the decrease in photosynthesis with an increase in light, which occurs at levels of light incidence that are "too high" for the species. This gives rise to an allee effect by which, in a mixed system, phytoplankton in the upper layer will shade the lower layer to prevent photoinhibition. As irradiance continues to increase, it will arrive at a threshold where the irradiance causes the self-shading to be insufficient and the population collapses. After that point, because the phytoplankton can no longer self-shade, it cannot survive in the higher levels of light incidence that it could prior to the collapse. The identification begins with a series of simulations in R. As in Veraart et al. (2012), we want to show that this model exhibits the properties of catastrophic collapse, but in this case due to a noise-induced phase transition. In this type of regime shift, a population is caused to collapse by a change [increase] in the variance of some stochastic environmental parameter rather than its mean or mode values. These have been shown to occur in other natural systems but not in ecological systems. Noise-induced phase transitions are a potentially transformative topic because environmental ("exogenous") variation is increasing in many systems and is recognized as the chief source of variation in systems; it could present a different cause of critical transitions that has not previously been studied.

Addressing Droughts and Water Overuse in the Flint River

Giovanni Righi, Foundation Fellow
Dr. Rob McDowell, Environmental Policy, Carl Vinson Institute of Government

Without further action to address low flows in the Flint River Basin (FRB), streams used primarily for agriculture and by many municipalities for wastewater discharge could increasingly run dry, particularly in drought years. These water limitations could threaten the Georgia agricultural heartland and its billion dollar revenues, further reduce habitat for the four endangered mussels, thirteen endangered plants, and other endangered species in the basin, and aggravate downstream users. Certain sections of the Flint River tributaries were already observed to be dry in 2012, but the Environmental Protection Division (EPD) had few regulatory tools available to sufficiently address the drought. The only strategy used to increase water flow in the FRB were the irrigation reduction auctions of 2001-2002, which have not been implemented since then because the state has not been willing or able to finance them. This demands that a new water management plan be developed for the FRB. This project explores the possibility for an expansion of irrigation efficiency projects, pricing water to fund an insurance program that can be used to compensate farmer losses during drought, and allowing for the trading of permits under certain conditions as tools for the state to reduce water demand. It makes a case for the necessity of water pricing using limited cost-benefit analysis.

1970s Czechoslovakia: A Foundation for the Study of International Human Rights Law

Marco Roca, CURO Honors Scholar
Dr. Daniel Hill, International Affairs, School of Public & International Affairs

1970s Czechoslovakia, the heart of the Eastern bloc during the Cold War, was one of the most interesting times and places in history. Soviet politics, the forced consolidation of the Czech Republic and Slovakia, and several other factors all sowed the seeds of rebellion during this period in Czechoslovakia's history. However, what sets 1970s Czechoslovakia apart from other dissident movements throughout the Eastern bloc is the dissident groups' distinct intensity, abnormally good documentation, and their success with the peaceful Velvet Revolution regime change. For all of the given background reasons, Dr. Hill and I decided to test our hypothesis that dissident groups use international law as a rallying point to raise support among a repressed population. My methodology was combing through various court cases, constitutions, primary sources, and historical analysis in an effort to synthesize evidence in favor of (or in opposition to) our hypothesis. Our findings indicate that dissident groups such as Charter 77 and VONS often cited international laws such as the ICCCPR and the Helsinki Accords. The implications are enormous, because we now have a well-documented case study in which international laws affected the domestic policies and human rights of people around the world. Using the research on 1970s Czechoslovakia as a foundation, I will use the second part of the presentation to demonstrate the additional research we have conducted with international law and its effects on human rights. Emphasis will be placed on recent research with human rights law and its effect on economic inequality worldwide.

An Integrated Approach for Verification of Rapid Focused Recharge Zones in the Arabian Peninsula Using Thermal and VNIR Remote Sensing

Rachel Rotz, CURO Graduation Distinction
Dr. Adam Milewski, Geology, Franklin College of Arts & Sciences

In the Arabian Peninsula, freshwater recharge is typically focused in small depressions that fill with seasonal runoff to form freshwater lenses. This study will substantiate previously hypothesized lens locations and detect water in the subsurface by using remote sensing techniques. We hypothesize, due to the unique heat capacity of water, recharge zones can be detected by identifying areas with lower diurnal changes in surface radiance values than neighboring dry areas after peak or sustained rainfall. We collected images in the visible near-infrared and thermal infrared wavelengths over the Arabian Peninsula. Overlapping diurnal images were subtracted to show surface radiance fluctuations and then compared with existing rainfall data. Results demonstrate the potential for groundwater detection through the presence of ephemeral water bodies in hyper-arid regions en masse. Several recharge zones, runoff channels, agricultural regions, and wetlands were detected in areas where radiance values change between 0.067 - 2.25 $w/m^2/sr/\mu m$ from day to night scenes. Additionally, two seasonal peak rainfall (~35mm/day) events correlate well with the surface radiance difference values. Surface radiance values for dry areas adjacent to the postulated lens locations range between 2.25 – 12.2 $w/m^2/sr/\mu m$. Radiance values in areas where small relative change occurred were compared to corresponding surface reflectance values and ranked. Highly ranked locations were interpreted as best candidates for recharge zones and freshwater lens locations.

Lester Moody: A Man, a River, and a Quest for Industry in the Twentieth Century South

Anthony Sadler, CURO Summer Fellow
Dr. Brian Drake, History, Franklin College of Arts & Sciences

Lester Moody brought great change to Augusta, the Savannah River, and the South during his tenure as the Secretary of the Augusta Chamber of Commerce. His campaigns for the development of the South's natural resources are barely mentioned in current historiography. Historians tend to group boosters into homogenized categories of environmental, racial, and agricultural villains or progressive, idealistic, and rational heroes of the "New South." The story of Lester Moody, the city of Augusta, and the Savannah River is more complicated. Moody is neither a hero nor villain, he is unique and typical of his status, time, place, and race—all of which were distinctly Southern. The environmental factor of Southern twentieth-century history is viewed as a side-note. The people of Augusta were devastated by a history of floods long before the boll weevil passed through cotton fields. Their environment, altered by centuries of intense farming was unforgiving and needed to be controlled, regulated. Within this psychological framework, Augusta's business leaders gave power to unelected leaders like Lester Moody to solve economic and environmental problems. He took that power, and with the help of more powerful allies such as Richard B. Russell, Jr., Walter F. George, and Strom Thurmond among others, secured three federally-funded dams, the Savannah River Plant, and the expansion of Camp Gordon into a Fort. He did much but was greatly empowered by the citizens of Augusta to do so, which explains the endurance of a positive legacy, one mired by contradictions, broken promises, and environmental disaster.

A Unique Mechanism in *Staphylococcus aureus* Ketopantoate Reductase

Joseph Sanchez
Dr. Zachary Wood, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Methicillin-resistant *Staphylococcus aureus* (MRSA) is a difficult-to-treat pathogen that is responsible for more than 11,000 deaths each year in the United States. There is an urgent need to develop new targets for discovery of drugs to treat *S. aureus* infections. Here we have examined the mechanism of *S. aureus* ketopantoate reductase (KPR), which produces the essential metabolite pantoate. It has been reported that KPR exists as a monomer and follows a sequential ordered mechanism of substrate binding in which NADPH binds before ketopantoate (KP). Here we show that the mechanism of *S. aureus* KPR is distinct from previously studied homologs. Combining analytical ultracentrifugation (AUC) with two new crystal structures, we show that KPR forms a dimer in solution. Furthermore, steady-state kinetics reveals that KPR displays kinetic cooperativity. This is a rare phenomenon in which KPR follows a kinetically preferred but not absolute order of binding substrate and cofactor. We confirm this result using equilibrium binding assays based on intrinsic protein fluorescence and fluorescent resonance energy transfer (FRET). Finally, we have solved a new 1.8 Å resolution crystal structure, which shows that KP binding to the large active site partially occludes NADPH from the cleft. This is consistent with our kinetic data showing that saturating concentrations of KP can inhibit the enzyme. The unique mechanism of *S. aureus* KPR suggests that it may be possible to specifically target this enzyme in rational drug design efforts.

Lesbian Dress: Recognizing and Being Recognized

Nancy Satola
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The lesbian community's use of dress should be of interest to the fashion industry because lesbian women interact with the industry differently than heterosexual women. Because lesbian women, just like every other social group, rely on fashion as a means of communication, a personal and political agenda exists in their use of fashion. My research focuses on three groups within the lesbian community. I start with the politics and influence of 2nd wave feminism on the butch lesbian community. Butch lesbians use dress as an in-your-face expression of their sexual orientation and to express the rejection of heteronormative values of mainstream society. The politics and dress practices of butch lesbians have created a demand for gender-neutral fashion and opened up the industry to androgyny, even in high fashion. Unlike butch lesbians, lipstick lesbians do not adhere to the values of 2nd wave feminism and wish to be perceived as fashionable and trendy. The lipstick lesbian aesthetic rejects the notion that women must discard traditional femininity to be recognized and accepted in the lesbian community. Finally, I examine how lesbian parenting couples assess their physical appearance when it influences the daily life of their children. I argue that these couples are conscious of their dress and manipulate their presentation in different situations for the sake of their children rather than their allegiance to the lesbian community.

Issues of Economic Efficiency in the Domestic Conservation Easement System

Mariana Satterly, Ramsey Scholar
Dr. Tianwei Zhang, Economics, Terry College of Business

Until the passage of federal legislation in the early 1980s incentivizing conservation easements, perpetual property contracts that prohibit building and other environmentally harmful actions on designated parcels, contracted private conservation efforts were rare. Today, however, the Land Trust Alliance estimates that well over 100,000 easements protect nearly 47 million acres of domestic land. While the current high rate of easement establishment is laudable for the sake of environmental stewardship, the incentive system tied to the easement process might be doing more harm than good. This literature review and quest for viable databases on conservation easement records illustrates that an inadequate amount of time and effort is currently devoted to monitoring easement establishment and the distribution of tax credits following the subsequent reappraisal of burdened lands. While legal papers and IRS statements have stressed more robust attention to the economic efficiency and possible exploitation of easements in the past decade, the non-uniformity of contracts and the difficulty of tracking community effects after easement establishment have limited research into the economic efficiency of the system, and studies specific to the tax effects of easement establishment are largely absent from the present literature. With the belief that *social* environmental benefits are the foremost concerns of easement establishment, this research attempts to outline the economic issues that should begin any discussion of easement efficiency, prompted by both nonexistent and present studies, before proposing several reform measures that could alleviate exploitation of the system and net social costs.

A Mechanistic Explanation of How Regional Winter Climate Differences Influence Lyme Disease Distribution

Scott Saunders
Dr. Andrew Park, Odum School of Ecology

Lyme borreliosis is the most prevalent vector borne disease in North America and affects more than 20,000 people every year. Why are there few cases of Lyme disease in the Southeast when compared with the Midwest, and Northeast United States? All three regions have populations of the required tick vector, vertebrate hosts and the *Borrelia burgdorferi* pathogen. One explanation for the dramatic difference in prevalence is that *B. burgdorferi* is not maintained at high levels in *Ixodes scapularis* (black legged tick) populations due to an interrupted transmission cycle. A model has been created to test the theory that winter duration and temperature structure the life cycle of ticks, so Northern ticks follow a strict two-year life cycle and Southern ticks are more variable. The consistency and timing of the tick development pattern can favor horizontal transmission of the bacteria through vertebrate hosts when infected nymphs and uninfected larva are abundant at similar times of year. Using only temperature data, and basic information on tick phenology the model stochastically simulates a population developing through the four life stages (egg, larva, nymph, adult), and records how the population grows. Varying the duration of winter in the model shows the population developing differently, and notes if significant transmission is likely to occur between nymphal and larval ticks. This model seeks to explain the distribution of Lyme disease and other tick borne diseases around the world, and contribute to our understanding of how Lyme disease could change in the future.

Investigations of a Protease (Ste24p) Associated with Progeroid Disease

William Saunders, CURO Summer Fellow, CURO Graduation Distinction
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Ste24p is a metalloprotease that is involved in the processing of prelamin A in humans. The most relevant human disease associated with Ste24p mutation is Hutchinson-Gilford Progeria Syndrome (HGPS). Ste24 is very well conserved across species. Much of what is known about Ste24p comes from its role in production of the **a-**factor mating pheromone in yeast and the work associated with this research takes advantage of **a**-factor as a reporter. The Schmidt lab is actively collaborating with a research group at UVA that was the first to determine the X-ray crystal structure of Ste24. The structure of Ste24p is interesting because it is a membrane bound protein that resembles an oil drum embedded in the membrane bilayer with no apparent point of entry to a central cavity that contains the proteolytic active site. This study used the crystal structure and selective mutation to change specific residues in the protein and genetic methods to test the mutant protein's activity level in order to establish a possible mechanism for the protein. We have confirmed the importance of residues proposed to be part of the active site, including residues that have functional overlap with those found in bacterial thermolysin. We have investigated several hinge points in the structure as possible mobile domains that would allow access to the active site. Results from this study reveal that residues are critical to the proper functioning of the protein and the implications of these findings will be discussed.

Vocal Repertoire of Red and Green Macaws

Natalie Schwob, CURO Summer Fellow
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences
Dr. Roberta Salmi, Anthropology, Franklin College of Arts & Sciences

Red and Green Macaws (*Ara chloropterus*) are highly encephalized, socially complex birds that form long-term pair bonds, often flying wingtip to wingtip with their mate. Despite abiding interest in Psattacids, limited research has been done on wild macaws, and basic features of their biology and behavior remain unknown. Here, we provide the first quantitative description of the vocal repertoire of the Red and Green Macaws living in the *Cerrado* (Brazilian savannah) landscape in northeastern Brazil. We digitally recorded 327 calls collected over 9 weeks of fieldwork. From those calls we selected 78 calls/notes based on acoustic quality for further analysis. We used discriminate functional analysis to determine how calls can be categorized by only their acoustic structure. The vocal repertoire of these macaws includes 10 different calls and 5 different notes, with 87.8% of original grouped cases correctly classified (83.8% cross-validation). Calls were used independently and notes are combined into longer sequences. Additionally, we describe the presence of non-linear phenomena in some of those calls including sunharmonics, biphonation, and non-random chaos. This study will provide the first description of the Red and Green Macaw's acoustic repertoire, which will assist in future macaw communication research.

Incidence of Anesthesia-Related Fatality in Birds

Amanda Seamon
Dr. Erik Hofmeister, Small Animal Medicine & Surgery, College of Veterinary Medicine

Anesthesia related fatality rates in dogs and cats are .17% and .24% respectively. Anesthesia related fatality rates in people are even lower at .02-.005%. The anesthesia related fatality rate in birds is unknown. The purpose of this project is to determine what the fatality rate is in birds due to general anesthesia. Our hypothesis is that birds will have a higher fatality rate due to anesthetics than the rates of dogs, cats, and humans. Cases were identified by searching the electronic medical records database at the University of Georgia's Veterinary Teaching Hospital for 'avian' and any anesthesia-related charge. Data collected from the record includes species, age, gender, wildlife status, weight, BCS, diagnosis, procedure, ASA status, premedication, analgesic technique, induction and maintenance medication, fluid type and route, anesthesia duration, surgery duration, recovery duration, crystalloid volume, colloid volume, HR nadir and peak, EtCO2 nadir and peak, inhalant nadir and peak, temperature nadir and peak, cost, estimated blood loss, and intraoperative events. Of the 120 files already completed, 15 fatalities have occurred, with 2 fatalities associated with anesthesia. This data will be later analyzed for correlations in different variables.

Parasite Selective-Pressure Alters Reproductive Strategy in *Littorina saxatilis*, an Intertidal Snail

Chelsea Sexton
Carolyn Keogh, Doctoral Candidate, Odum School of Ecology
Martha Sanderson, Long Island University, Brookville, NY
Dr. James Byers, Odum School of Ecology

Many organisms are known to alter life history strategies in the presence of parasites with strong fitness effects. *Littorina saxatilis*, the rough periwinkle snail, has a complex co-evolutionary relationship with the castrating trematode parasites that infect it. In European sites, Granovitch et al. (2009) found populations of *L. saxatilis* under high trematode pressure were more likely to have higher fecundity at smaller sizes which allowed them to successfully reproduce before infection castrates the snail. Our study focuses on whether there is also an effect of trematodes on brood quality in addition to timing. We will count and measure the embryos in brood pouches of snails collected along the New England shore. The size of ready-to-crawl embryos is a proxy for brood quality and correlated against trematode prevalence in the snails' susceptibility to infection, which has been quantified in previous studies. We expect to see similar results to Granovitch, with higher brood amounts in snails from high prevalence sites, but we also expect to see lower brood quality in these sites as well because these progeny are rushed before the host is properly prepared to allocate to reproduction. This study is part of a larger project aimed at understanding the impact of spatially heterogeneous parasite infection risk on host defense, as well as potential life history trade-offs that result from the host's response to the threat of infection.

Decreasing HIV Incidence in Russia through Needle & Syringe Programs

Rahul Shah
Dr. Meghan Skira, Economics, Terry College of Business

While the global HIV incidence rate has significantly declined within the last decade, it has been rising at an alarming pace in Eastern Europe and Central Asia since the late 2000s, with some estimates putting the increase at over 25%. Injection drug equipment is one of the most common ways through which HIV is transmitted, and in Russia in particular, injection drug users (IDUs) are disproportionately driving the country's HIV epidemic with approximately 37% of Russian IDUs currently infected with HIV. The rate of HIV incidence in Russia will likely continue to rise, as current HIV-prevention measures are not centered on the IDU population. Providing access to sterile needles and syringes is a highly effective method of reducing HIV infections among injection drug users. Needle & syringe programs (NSPs) provide injection drug users with access to sterile drug equipment in order to reduce the transmission of HIV by decreasing the sharing of contaminated needles among IDUs. Since a high HIV prevalence in IDUs can spread rapidly through sexual transmission to the general population, preventing the spread of HIV among IDUs will help to address the growing epidemic in Russia. NSPs are not only cost-effective, they are also cost-saving, with implementation costs of NSPs being offset with savings in healthcare. In order for Russia to significantly reduce the rate of new HIV infections, there needs to be strong governmental support in addressing the HIV epidemic among IDUs by supporting and funding a large-scale implementation of needle and syringe programs.

Reducing Vitamin D Deficiency among Individuals Aged 50 and Older in Georgia

Sheela Sheth
Dr. Richard Lewis, Foods & Nutrition, College of Family & Consumer Sciences

In Georgia, men and women aged 50 and older are often unaware that they are vitamin D deficient until they are diagnosed with osteoporosis or have a fracture. Georgia's population of individuals above the age of 50 is rising rapidly over the next few years, and the economic and social toll fractures have on society will rise proportionately. It is projected that there will be about 49,500 osteoporotic fractures and $570 million spent on caring for those with osteoporotic fractures in Georgia hospitals by year 2025. In Georgia, current policies do not address the need to educate patients on vitamin D intake, and current programs addressing osteoporosis prevention are underfunded. A literature review was conducted to investigate symptoms and causes of vitamin D deficiency, and stakeholders and successful policies addressing the issue or analogous issues in different contexts were examined. After analysis of the efficacy, cost-effectiveness, and feasibility of three different policy alternatives and the status quo, it was determined that issuing vitamin D guidelines through the Medical Association of Georgia for Georgia's providers to follow and incorporate into practice is the best alternative. By having providers address vitamin D deficiency in patients before fractures, patients will have one less risk factor for osteoporosis, and the medical costs associated with fractures should decrease.

Characterization of Proteoglycans in Prostate Cancer Cell Growth

Sheela Sheth
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Glypicans (GPC) and syndecans (SDC) are heparan sulphate proteoglycans involved in cell-cell and cell-matrix signaling at the plasma membrane of animal cells; however, increased expression of these proteoglycans is associated with carcinogenesis. Recent studies reveal that glypican-1 and syndecan-1 are enhanced in tumour stroma while reduced in epithelial cells in prostate cancer tissue compared to normal prostate tissue. There are six identified glypican isoforms (GPC-1 to 6) in animal cells; however, little is understood of their expression in non-cancerous and cancerous prostate cells. The goal of this research is to determine the role of glypicans and syndecans in cellular proliferation and metastasis in prostate cancer. Reverse transcriptase PCR (RT-PCR) showed that GPC-1, GPC-4, and SDC-1 were expressed differently in non-cancerous (PCS-440-010) and cancerous prostate cell lines (LNCaP, DU-145 and PC-3 cells), but RT-PCR did not detect GPC-2, 3, 5, and 6 mRNA expressions in these cells. Both GPC-1 and SDC-1 mRNA levels are downregulated in benign cancer cells (LNCaP) and increased in metastatic cell lines (DU-145 and PC-3). Interestingly, GPC-4 mRNA level is highly expressed in PC-3 while there is no difference in PCS-440-010, LNCaP and DU-145. These findings indicate that GPC-1, GPC-4, and SDC-1 are differentially expressed during neoplastic transformation in prostate cancer. These proteoglycans may be involved in cellular proliferation and metastasis of prostate cancer. To test this hypothesis, the expression of GPC-1, GPC-4, and SDC-1 will be knocked down by siRNA in PC-3 cells. Cellular proliferation and metastasis will be assessed by MTT and trans-well assays, respectively.

Genetic Assessment of the Role of TNF and its Receptors (RI and RII) in Placental Malaria Pathogenesis

Chris Slade
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Placental malaria (PM) is characterized by sequestration of malaria-parasite infected red blood cells and accumulation of mononuclear cells, mainly macrophages, in the intervillous space of a woman's placenta. Macrophages are the main producers of TNF, a pro-inflammatory cytokine. Previous experiments involving pregnant C57BL/6J mice infected with *Plasmodium chabaudi* AS- showed that TNF-neutralization could rescue pregnancy loss at mid-gestation. This suggests that TNF is associated with poor pregnancy outcomes during PM. TNF exerts its role through its receptors, TNFR1 and TNFR2, and induces inflammation and/or cell death. To understand more about the role of TNF in the immunopathology of PM, TNF and TNF receptors (R1 and R2) null mutants and wild-type B6 (C57BL/6J) mice were infected with *Plasmodium chabaudi* AS at day 0 of pregnancy. Mice were followed up and sacrificed at gestation day 10. Clinical metrics were measured at gestation day 0 and from day 6 to day 10. At sacrifice, the placenta was collected and fresh frozen in liquid nitrogen for RNA and protein isolation or fixed in neutral buffered formalin for histology. Preliminary data indicate that TNF and TNFR2 null mutants reach high parasitemia more quickly than TNFR1 null mutant and B6 mice. In addition, weight loss was most severe in infected pregnant (IP) TNF null mutant. However, IP TNFR2 null mutant did not have significant weight loss compared to uninfected mice. Almost all IP mice have anemia by day 9 except for TNFR2 null mutant. This study is ongoing and markers for oxidative stress and apoptosis will be assessed by ELISA, Real time PCR, and immunohistochemistry. Comparative analysis

may reveal a mechanistic role for TNF in the pathogenesis of PM.

The Lines are Drawn: Christian Apologies in Late Antiquity

Ryan Slauer
Dr. Erika Hermanowicz, Classics, Franklin College of Arts & Sciences

Early Christian apologies provide a unique lens through which we can glimpse the relationship between early Christianity and the "outside" (non-Christian) world. The reading of these texts is complicated, however, by the existence of multiple motives for the writers. Though often addressed to Roman authorities, the apologies were intended for Christian audiences as well, and interpretation of the portrayal of Christian communities is made problematic by the recognition of this Christian audience. More specifically, it means that we can only glimpse the relationship between Christianity and the outside world as through a lens, darkly. This research explores the development of the relationship between Christianity and the outside world through these texts, understanding the difficulties inherent in this analysis. The writings of Tertullian, Arnobius, Lactantius, and Augustine are considered, with particular attention given to these authors' political and legal philosophy. It will be seen that these apologies were not merely responses to persecution and to social and intellectual stigma, rather they were also the drawing of ideological lines in an attempt to differentiate Christianity from the Roman milieu and to instruct Christian communities regarding proper behavior. With these conclusions, this research aims to add food for thought to the historical analysis of early Christianity and its niche in Roman society.

Nut-Cracking Skill in Wild Capuchin Monkeys

Kristen Smith, Rhianna Baldree
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences
Dr. Michael Haslam, Oxford University

Skill, defined as fluid, effective performance under variable circumstances, is characteristic of humans' use of hand tools. The skilled features of tool use by nonhuman animals are relatively unexplored. We aim to contribute to knowledge regarding skillful tool use by nonhuman primates. Wild bearded capuchin monkeys habitually crack hard palm nuts by placing them on an anvil and striking them with stone hammers. Previous studies at the EthoCebus field site in Brazil have shown that monkeys are skillful in aspects of nut-cracking including nut positioning, hammer stone selection, and appropriate striking force. We asked if monkeys at this site handled the hammer stone skillfully prior to and during striking, and conducted a field experiment to investigate. Four adult monkeys voluntarily cracked nuts while we videotaped. Nuts and four stones, individually presented, were provided for the monkeys to use. Two stones (1100 g and 534 g) were symmetrical, and two were asymmetrical (1042 g and 455 g). From slow motion video (120 fps), we are coding when the monkey flipped or spun the stone, and how it positioned its hands on the stone. For each stone, at least 10 and up to 20 strikes by each subject will be analyzed. Evidence for skillful handling of stones will be found if monkeys increase spins and flips, and use more or different hand positions during striking with asymmetric stones while maintaining equal nut-cracking efficiency with both stone types. Supported by UGA, National Geographic Society, and the PRIMARCH project, European Research Council.

Genetic Analysis of the Role of *SMAX7* in Regulating Shoot Architecture

Ishwarya Soundappan
Dr. David Nelson, Genetics, Franklin College of Arts & Sciences

We can significantly impact crop yield by understanding how strigolactone, an endogenous plant hormone, controls tillering or branching in crops. MORE AXILLARY BRANCHING2 (MAX2) is an important regulator of strigolactone signaling, but its signaling pathway is not understood. The *max2* mutant displays multiple developmental defects. *SUPPRESSOR OF MAX2 (SMAX1)* controls some of these MAX2-dependent phenotypes. *SMAX1* and its seven homologs compose an uncharacterized protein family in *Arabidopsis thaliana*. We hypothesized that *SMAX1* homologs could control other *max2* phenotypes. We found that artificial microRNA suppression of *SMAX6, SMAX7,* and *SMAX8* reduces the increased branching phenotype of *max2*. In agreement with our findings, other researchers have shown that a dominant mutation in the *SMAX7* ortholog in rice produces an increased branching phenotype. This mutation is a five amino acid deletion and contributes to increased protein stability. To test the effect of this mutation in *A. thaliana*, and particularly which amino acids are responsible, we are conducting site-directed mutagenesis on *SMAX7*. We are also interested in determining if an EAR motif, which is highly conserved in the *SMAX1* homologs, is necessary for gene function. To further this structure-function study, we will create and transform various constructs of *SMAX7* with deleted domains into wildtype and *max2* backgrounds. An observation of the resulting branching phenotypes from the various constructs can elucidate the mechanism by which this gene and others in the family operate.

Native American Traditional Dress: Drawing the Line between Celebrating a Culture and Making a Mockery of It

Devon Sprague
Dr. Katalin Medvedev, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

The fashion industry has a long history of borrowing from a vast array of cultures and religions when creating new collections. My research suggests that using the conventional image of the Native American in the world of pop culture not only promotes harmful stereotypes, but is also a contributing factor in preventing them from overcoming consistently low socioeconomic conditions. By studying several academic journals, blogs, and news articles on the subject, I have discovered the historical importance of Native American dress, its misuse in the global fashion industry, and the devastating side effects of its misappropriations in fashion and culture today. Among Native Americans, traditional dress is closely tied to the wearer's dignity and sense of self. The headdress in particular holds deep spiritual meanings and is reserved for sacred ceremonies. Therefore, it is offensive when major retailers take this apparel item out of context and market it as just another trendy fashion accessory. Attempts by companies like Urban Outfitters and Victoria's Secret to do so in recent years has resulted in public backlash. The American sporting industry has also been guilty of using the American Indian image in a way that is reprehensible. With education rates lower than the national average and poverty rates that are much higher, it is evident that Native Americans are severely underprivileged. The practice of abusing and misappropriating their sacred symbols erases their current problems from the American consciousness, which in turn makes it difficult to bring about change.

Increasing Physical Education in American High Schools

Karishma Sriram, Foundation Fellow
Prof. Bryan McCullick, Kinesiology, College of Education

High schools across the nation are not meeting the appropriate physical education requirements to provide students with quality physical education. Studies have shown that states do not mandate the time requirement – 225 minutes per week for physical education classes at the high school level – suggested by the National Association for Sport and Physical Education (NASPE). As a result, nearly half of high school students do not receive the necessary physical education each week. Inadequate facilities, insufficient time during the school day, budget cuts, and poorly-written legislation are the main culprits behind the lack of acceptable levels of physical education, causing reduced physical activity, diminished quality of life, and increased economic costs to society, among other impacts. Furthermore, an increase in physical activity significantly improves individuals' mental and physical health. Physical education in schools is one of the most effective ways to encourage future physical activity participation, as every child has access to school and spends nearly eight hours a day in his or her school. When taught by a trained specialist, physical education classes in schools can effectively build a set of motor skills and a level of confidence to engage in physical activity. To address the lack of adequate physical education in high schools, literature concerning physical education was reviewed and policy solutions were created. After evaluating the proposed policy alternatives using a multi-goal analysis, the policy that prevents the use of substitutions for physical education requirements was determined to be the most effective way of increasing physical education among the high school students.

Bone Fracture Putty: A Combined Stem Cell and Lentiviral Approach

Karishma Sriram, Foundation Fellow
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Large bone defects require months of rehabilitation and often end with limb amputation. Mesenchymal stem cells (MSCs) accelerate bone fracture repair via mechanisms complimentary to bone morphogenic protein 2 (BMP2), which induces bone healing. We hypothesized that lentiviral BMP2-transduced MSCs will generate enough exogenous BMP2 to produce heterotopic ossification (HO) in a mouse model, and the MSC will release trophic factors, enhancing the effects of BMP2. First, *in vitro* studies were performed with human bone marrow-derived MSC and human umbilical cord-derived MSC. Cells were transduced with lentiviral red fluorescent protein (RFP) to determine transduction efficiency at 48, 72, and 96-hour time points. Multiplicity of infection (MOI) corresponding to greatest levels of fluorescence was used with cells transduced with lentiviral BMP2 and expression levels were measured with an ELISA at same time points. At 96 hours bone marrow MSC expressed 51,515 pg/mL BMP2 at 10 MOI and 94,940 pg/mL at 50 MOI, while umbilical MSC expressed more BMP2, with 69,958 pg/ml at 10 MOI and 174,592 pg/mL at 50 MOI. Therefore, umbilical MSCs will be used in future *in vivo* studies. Next, a non-obese diabetic/severely compromised immunodeficient (NOD/SCID) mouse model was utilized to test HO by injecting umbilical MSC transduced with lentiviral BMP2 into a leg muscle. HO was evaluated at 1 and 2 weeks post-injection via x-ray, showing circular soft tissue forming after one week and palpable bone after two. We expect to conclude – after further studies using HO, fracture injuries, and large animal models – that Lentiviral

BMP2 in MSC is effective at rapid bone healing.

The Effect of Telomere Dysfunction on Non-Allelic Recombination in the Subtelomere of *Kluyveromyces lactis*

Brianna Stadsvold
Dr. Michael McEachern, Genetics, Franklin College of Arts & Sciences

The subtelomeric region in eukaryotes has a complex repetitive structure, is rapidly evolving, and is under epigenetic regulation. Though this region lacks essential genes, it is enriched for genes critical for rapid adaptation to novel environments. However, the mechanism through which genetic variation is introduced is poorly understood. The adaptive telomere failure hypothesis proposes that, in times of stress, telomere capping can be relaxed in a way that promotes subtelomeric evolution. While functional telomeres are meant to protect chromosome ends, dysfunctional telomeres can be inappropriately repaired by mechanisms such as homologous recombination (HR). Subsequent genetic modifications could have a beneficial effect on the organism's fitness. In the yeast *Kluyveromyces lactis*, the flocculation (*FLO*) genes are thought to be responsible for cell adhesion and contain imperfect internal repeat sequences. It is believed that repeat number is directly correlated with cellular adhesion phenotype. Using the motif finding program MEME, internal repeats within the *FLO* genes found in the subtelomere of *K. lactis* have been identified. These repeats could provide a region of homology for which homologous recombination can undergo. To determine the rate of recombination, *URA3* will be inserted within a *FLO* gene and the rate of loop-out of *URA3* will be measured in wild-type and telomere dysfunction strains. Evidence that recombination is increased in strains with mild genetic telomere dysfunction would support the idea that environmentally-induced telomere function could modulate homologous recombination of subtelomeric genes and ultimately effect the cell's ability to adapt to stressful environments.

The Influence of Neuroticism, Openness, and Conscientiousness on Executive Functioning in Older Adults

Leslie Stapley
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

Executive functioning (EF) refers to one's ability to organize thoughts in a goal-directed manner, to plan ahead, and subsequently carry out goal-directed strategies. Several studies suggest that community-dwelling older adults employ EF abilities in order to perform activities of daily living. Declines in EF due to the aging process, therefore, place older adults at greater risk for errors in daily living activities and may compromise their ability to live independently. Research suggests personality traits may significantly predict EF performance in older adults; however, findings have been inconsistent. The purpose of the present study was to examine the relationship between EF and three of the Big Five personality traits: Neuroticism (N), Openness (O), and Conscientiousness (C), in a sample of 46 community-dwelling older adults. It was hypothesized that a) these three traits would carry combined predictive value on EF performance, and b) N, O, and C would each significantly account for unique variance in EF performance. Simultaneous regression revealed a significant combined predictive value of N, O, and C, over and beyond age and education ($R2 = .313$, $p=.023$). Three independent regressions, with an adjusted p-value of .017, revealed that N significantly predicted EF ($R2= .249$, $p=.014$), but O did not ($R2= .136$, $p=.619$). As hypothesized, but contrary to some findings in the literature, C had the largest predictive power on EF ($R2= .284$, $p=.005$). Results suggest that personality may be indicative of EF decline, also suggesting that C is a more

important predictor of EF than previously recognized.

The Linguistics of Artistic Language: Poetry, Complexity, and Mass-Market Novels

Ashleigh Starnes
Dr. Bill Kretzschmar, English, Franklin College of Arts & Sciences

Using the methodologies of complexity science as proposed by William Kretzschmar in his book *The Linguistics of Speech* (2009) – which addresses the statistical characteristics of emergent order in language – we can define stylistic distinctiveness in artistic texts by comparing the shapes and values of their word distributions to a general corpus of linguistic data (i.e. "normal" speech). This study offers a three-way comparison of "Language Poetry" from Ron Silliman's *In the American Tree* (1986), Peter Benchley's novel *Jaws* (1974), and the Brown Corpus (Kucera & Francis, 1961). Using the AntConc corpus program, this study found several parallels between the word distribution patterns in all three texts, despite the Language Poets' aesthetic claim to the distinctiveness of poetic language: the most frequent items were function words, and the word count and frequency of frequencies distributions formed asymptotic, hyperbolic curves characteristic of all language data of sufficient size (Kretzschmar 2009). On the other hand, this study found that unique words comprise about twice the percentage of total words in Language Poetry as opposed to *Jaws* (10.72% versus 5.73%, respectively), and comprise only 1.4% of the Brown corpus. Thus, while the general shape of the distributions are similar – as we would expect for all forms of speech – this data suggests a hierarchy of distinctiveness from "normal" speech patterns in works of language art. This study offers a generally unexplored method of analyzing artistic data and literary style, connecting language as a science and language as an art – a valuable interest for both fields.

Characterization of the *rsr-rtcBA* operon in *Salmonella typhimurium*

Cameron Story
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

The *rtcBA* operon, a conserved set of genes in many bacteria, encodes proteins whose homologues in metazoans and archaea are known to function in RNA repair, but have no known physiological role in bacteria. *In vitro* characterization of *E. coli* RtcA and RtcB demonstrated RNA 2'3' phosphate cyclase and RNA ligase activities, respectively. In *Salmonella typhimurium*, the *rtcBA* operon encodes an additional gene, *rsr* (Ro-sixty related ribonucleoprotein), and two non-coding RNAs. The goal of this research is to characterize the *S. typhimurium rsr-rtcBA* operon, which is controlled by a sigma54-dependent promoter and the activator, RtcR. To determine the environmental stressor that activates RtcR, allowing expression of the *rsr-rtcBA* operon, the promoter region of *rsr-rtcBA* was introduced upstream of *lacZ* on a plasmid. After exposure to stress conditions, promoter activity was monitored using β-galactosidase assays. Stressors investigated thus far include, cold shock, DNA damage via UV light, and exposure to antibiotics, such as chloramphenicol and cefotaxime, to test disruption of translation and cell wall synthesis, respectively. None of these conditions induced *lacZ* expression from the *rsr-rtcBA* promoter. To address a second project goal – identification of gene products that interact with RtcB – we are setting up a synthetic lethal assay. We created a *rtcB-lacZ* transcriptional fusion on an unstable plasmid that will be used to screen a transposon-mutant library of *S. typhimurium*. Mutants requiring maintenance of the *rtcB-lacZ* plasmid will point to genes whose products may interact with RtcB.

The Monkey Saddle
John Stroud, Foundation Fellow
Dr. David Gay, Mathematics, Franklin College of Arts & Sciences

In mathematics, a critical point of a function is a specific point where the function is level or unchanging. A monkey saddle graph is a three-dimensional surface, often studied in multivariable calculus courses, with an unusual type of critical point. The monkey saddle itself is similar to a normal saddle, but with three depressions instead of two, for the monkey's tail. The interesting feature of this saddle is that its critical point is always an inflection point and never a local minimum or maximum regardless of the intersecting plane. We wish to study the monkey saddle to better understand its unusual fixed point and how it changes and creates more fixed points as the parameters of the function change. My research concerns creating a short movie using Sage, an open-source Python-based mathematics software, to generate three-dimensional pictures of the monkey saddle changing as its parameters change. Other methods include using the Tachyon ray-tracing system that works on top of Sage to generate more realistic images.

Solution to Allworthy: The Magisterial Roles of Henry Fielding and Allworthy in *Tom Jones*
Lisa Ye Suh
Dr. Elizabeth Kraft, English, Franklin College of Arts & Sciences

The character of Allworthy in Henry Fielding's novel, *Tom Jones, a Foundling,* has proven problematic for both readers and critics who question Allworthy's true motives. Despite his social standing as a wealthy landowner and local magistrate, Allworthy shows unparalleled benevolence to his less exceptional, sometimes undeserving, counterparts. His altruism extends to his magisterial position in which Allworthy imposes lighter sentences on the accused, favoring redemption over punishment and thereby blurring the line between legal jurisdiction and moral judgment. The character's questionable exercise of authority is no accident as Fielding himself served as chief magistrate of Westminster and Middlesex for several years. Why then, does the author allow his most admirable character to demonstrate such deliberate disregard for English law? In examining Fielding's own legal career, comparisons may be drawn between the magisterial conduct of the author and his character – but what, exactly, is the significance of these parallels? Through a close reading of *Tom Jones* and *A Clear State of the Case of Elizabeth Canning,* Fielding's own account of his involvement in the famous 1753 criminal case, I attempt to answer these questions. Additionally, a biographical study of Fielding's days as magistrate as well as an examination of the 18th century legal system in England may support findings in the close readings. By exploring the function of the character of Allworthy, readers of *Tom Jones* may dispel what critics have dubbed "the problem of Allworthy," gaining insight into the author's literary motivations and juridical contributions in the process.

Fabrication of Hinged Nano-Motors Utilizing Metal Assisted Chemical Etching, Nano-Sphere Lithography, and Physical Vapor Deposition
Mehreen Sultana
Dr. Yiping Zhao, Physics and Astronomy, Franklin College of Arts & Sciences

Catalytic nano-motors are synthetic structures that carry an on-board catalyst and move autonomously using the chemical fuel from the environment by a catalytic reaction. Manipulation of their movement at such a small scale requires understanding of low Reynolds number hydrodynamics, where the viscous force dominates. In such an environment, the geometry of nanomotors

determines the motion and its efficiency. Therefore, investigating how novel geometries affect the motion by simple methods is desirable for the advancement of nanomotors. Here we focus on the design of hinged nanomotors. These structures contain two nano arms linked by a flexible joint, with one arm composed of Si and the other of TiO2. The Pt catalyst will be coated on the TiO2 arm that shall be free to move/rotate. Since the structure has multiple components, each component is fabricated using different strategies. The Si nano arm is fabricated using a 'top-down' approach by metal assisted directional chemical etching of crystalline Si substrate. This step is achieved by a combination of nanofabrication techniques such as metal-assisted wet chemical etching, nano-sphere lithography, and physical vapor deposition. The quality of metal assisted etching is determined using a scanning electron microscopy. The next phase of the fabrication includes creating 'ball-in-socket' joint, and the second arm using oblique angle deposition and glancing angle deposition. The speeds of catalytic micromotors can be measured and used for many biomedical and industrial applications such as DNA sensing, selective isolation of nucleic acids, oil spill cleanup, degrading organic water pollutants etc.

Ecology and Genetic Characteristics of Haemogregarines in Fresh Water Turtles

Scarlett Sumner, CURO Summer Fellow, CURO Graduation Distinction
Dr. Michael Yabsley, Warnell School of Forestry & Natural Resources

Haemogregarines are common intracellular parasites of freshwater turtles and aquatic leeches (the vector). Higher leech loads should be associated with higher prevalence rates and parasitemias; therefore, this study was conducted to assess differences in haemogregarine infections among various aquatic turtles with variable behaviors that impact leech burdens. During 2011-2012, 132 turtles of 10 species were sampled at numerous locations in Georgia, USA. Giemsa-stained blood smears were analyzed to determine prevalence of haemogregarines and parasitemias based on number of infected cells per 7,000 cells examined. To date, significantly higher prevalences were noted for nonbasking species (81%) compared with basking species (56%). Similarly, nonbasking species (0.26%) had significantly higher parasitemias compared with basking species (0.03%). These results indicate that basking behavior has a significant impact on the haemogregarine prevalence and parasitemia levels in turtles. Among the four most commonly sampled species, there was no difference in prevalence between the two nonbasking species (common snappers (*Chelydra serpentina)* [0.12%] and musk turtles (*Sternotherus odoratus*) [0.39%]) but parasitemias of the two basking species were different with sliders (*Trachemys scripta*) [0.05%] having significantly higher parasitemias compared with painted turtles (*Chrysemys picta*) [0.01%]. Lower parasitemias in basking species could be attributed to a reduction in leech exposure, an increase in the host immune response, biology of different haemogregarine species, or another unknown factor. Sequence analysis of partial 18S rRNA sequences from haemogregarines in turtles from Georgia, Canada, and Costa Rica suggests there are at least two parasite species that have little host- or geographic-specificity.

Improving Access to Screening for Post-Traumatic Stress Disorder in Operation Enduring Freedom and Operation Iraqi Freedom Veterans

Meili Swanson
Dr. Neale Chumbler, Health Policy & Management, College of Public Health

The high prevalence of post-traumatic stress disorder (PTSD) in Operation Enduring Freedom and Operation Iraqi Freedom

(OEF/OIF) veterans makes it difficult for veterans to integrate successfully back into society. PTSD in veterans has been linked to suicide, unemployment, substance abuse, homelessness, as well as domestic violence. There are limited policies currently in place that support the re-integration of OEF/OIF veterans back into society. The few current policies in place fail to identify many of the veterans who need treatment for PTSD. Three different policy alternatives were analyzed, evaluated, and compared to the current policy based on three criteria – effectiveness, cost, and political feasibility. According to the conducted research, telehealth is a mechanism that increases veteran access to PTSD screening and can facilitate their further treatment if needed. Telehealth involves using a Skype-like system to connect patients to their providers, face-to-face online. Telehealth applications are also a cost-efficient and politically feasible alternative to the current policies. By integrating telehealth into all VA medical centers, OEF/OIF veterans can be provided with not only more efficient access to care, but can also increase PTSD screening rates by their providers.

Assessing Mitochondrial Function and Fatigue in the Human Gastrocnemius with Near Infrared Spectroscopy (NIRS)

Stephanie Tan, CURO Graduation Distinction, Hannah Bossie, John Hann
Dr. Kevin McCully, Kinesiology, College of Education

Fatigue is known to be the number one symptom in all diseases. By using the NIRS device and the force transducer, assessment of muscle metabolism can be evaluated to assess the correlation between mitochondrial function and fatigue. Each participant was tested three times over the course of two days. The experiment focused on tetanic contractions and 35 Hz was used. The tests were done in the extended (relaxed) and flexed (stretched) positions with the foot at an angle of 70° and 90°, respectfully, with a 10-minute break in-between. During the test, we measured the amount of fatigue with a force transducer and the oxygen saturation consumption using a NIRS device. After the test, we measured the rate of recovery of oxygen saturation using MatLab. Significant inverse correlation was seen between mitochondrial capacity and the amount of fatigue. Stretched positions resulted in lower oxygen levels and slower rates of recovery of oxygen saturation than relaxed positions. This supports the cause of fatigue as impaired oxygen delivery. NIRS studies of muscle are either ongoing or planned for people with SCI, ALS, COPD, PAD, and heart failure. This study will be the first step towards validating a muscle fatigue test that represents muscle oxidative metabolism.

Oxidative Stress within the Placenta during Malaria Infection

Max Tarica
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

The pathology of placental malaria contributes to intrauterine growth restriction and premature birth, leading to low birth weight. In severe cases, abortion and stillbirth occur. These outcomes result from a lack of blood flow that brings the fetus its nutrients. A major cause of this problem in humans comes from the malaria parasites that specifically present with the VAR2CSA antigen, which allows its binding to glycoproteins within the placental intervillous space obstructing blood flow. Other factors, such as inflammatory responses and syncytiotrophoblast damage, are believed to contribute as well. The focus of this study revolves around the production of reactive oxygen species (ROS), which are known to cause cell damage and death. Since mice share a common immunological response with humans to malaria, a mouse model with four

groups of distinct genotypes was used. Mice were either null mutants for TNF (tumor necrosis factor) Receptor 1, Receptor 2, or both receptors of an intact genotype (B6 mice). The TNF family of receptors has been shown to promote cell death through the participation of ROS. For this study, the magnitude of ROS present was indirectly assessed by evaluating the expression of specific genes that are up-regulated during times of oxidative stress via real-time quantitative PCR. Associating the fetal outcome with the extent to which certain ROS are induced within the groups of mice can offer potential targets of interest for intervention that will improve and maintain cell health and function which could protect against malaria-induced fetal complications.

Examining the Function of O-GlcNAc in Regulating Inter- and Intracellular Signaling Pathways during Drosophila Development

Korry Tauber, CURO Summer Fellow, CURO Graduation Distinction
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The addition and removal of O-linked N-acetylglucosamine (O-GlcNAc) at serine and threonine residues is an essential regulator of intracellular signaling pathways. Like phosphorylation, O-GlcNAc modification acts to significantly alter the function of the protein to which it is attached. There has been considerable research documenting the functional implications of phosphorylation; such as acting as a regulator of cell growth and differentiation. However, the functions of O-GlcNAc are still being discovered and relatively little attention has been paid to the involvement of O-GlcNAc in cell processes. As with kinases and phosphatases, O-GlcNAc modification is controlled by regulated and compartmentalized enzymes; O-GlcNAc transferase (OGT) and O-GlcNAcase (OGA). Currently, it is impractical to study the function of O-GlcNAc in mammalian species because the loss of O-GlcNAc is lethal. However, the genetic tools provided by Drosophila allow us to examine the effects of increasing and decreasing O-GlcNAc levels in selected tissues. This project aims to better understand the function of O-GlcNAc by altering the expression of OGT within specific cells of *Drosophila melanogaster*. Our results indicate that diminishing the attachment of O-GlcNAc to intracellular proteins in engrailed-expressing cells reduces wingless protein secretion. In wing discs, decreased O-GlcNAc in the engrailed component results in the loss of the entire posterior wing section. Additional study has investigated the changes of O-GlcNAcylation in *Sugar Free Frosting (sff)* mutant flies. This project also aims to discuss how a change in expression of O-GlcNAc transferase can limit the effect of repressors that may promote *sff* expression. Further research will aim to examine downstream effects of O-GlcNAcylation in the insulin signaling pathway that may regulate the *sff* phenotype.

Differences in Children's Physical Fitness by Rural or Urban Location

Natalie Taylor
Dr. Jennifer Gay, Health Promotion & Behavior, College of Public Health

Past research reveals that obesity rates among children living in rural areas tend to be higher than those living in urban areas, with the lack of infrastructure (e.g. sidewalks, bike paths, recreational facilities, parks) being a likely determinant. This study aims to investigate whether school children residing in rural areas of Georgia report lower fitness levels compared to urban areas. If the claim holds true, it may suggest some association between the built environment and active living. Using the U.S. Census Bureau definition, towns and cities of Georgia were defined as an urban area (UA), urban cluster (UC), or rural area.

FitnessGram data was provided by 1,473 schools in Georgia to measure physical fitness levels by assessing aerobic capacity, muscular strength, muscular endurance, flexibility, and body composition. Frequencies were calculated for grade level, gender, and geographic location. One-way ANOVA was used to examine differences in the fitness categories by UA, UC, or rural area. Maps were generated using ArcGIS. The sample consisted of 50.1% boys and 55.8% elementary school students. UAs have a higher proportion of students in the healthy fitness zone compared to UC and RA students in cardiorespiratory endurance, body composition, and muscular strength and endurance part 2. Also, UCs were generally less fit than rural areas. All schools may benefit from more physical activity programs, particularly in UC areas. By collaborating with local government officials and businesses, school systems can create environments that are conducive to good health for all students.

Reexamining a Little-Known Aphrodite Anadyomene Statue from Ancient Stabiae
Chiara Tondi Resta
Dr. Mark Abbe, Lamar Dodd School of Art

An over life-size Roman, marble statue of Aphrodite Anadyomene (Greek: "rising from the sea") in the North Carolina Museum of Art is a little-known, but important sculpture. Reported to be from ancient Stabiae near Pompeii, it appears to have been buried in the eruption of Vesuvius, providing it a *terminus ante quem* of 79 A.D. The Aphrodite Anadyomene type was particularly important in central Italy and the Bay of Naples due to her associations with water and bathing which were valued especially by merchants and sailors. But what additional associations might this statue have had in Stabiae in the late republican and early imperial periods? The Roman general Sulla, who conquered the area in 89 B.C., credited Aphrodite for his victories, and the Julio-Claudian rulers of the first century A.D. claimed descent from the goddess herself. As one of the largest and best quality statues of the Aphrodite Anadyomene type known to date, the North Carolina statue is a critical example in understanding how the goddess of love was employed to convey particular political meanings. Using comparative material and some scientific analyses, this presentation will examine these issues as well as the date and probable ancient coloration of this high quality product of Greek craftsmanship.

Variables Affecting Attitudes toward Police
Tiffany Toteno
Dr. Natasha Ganem, Sociology, Franklin College of Arts & Sciences

Police officers have a very important job; protect and serve the community. Yet police can develop a bad reputation on college campuses. This paper seeks to determine what affects students' perceptions about police. There are two research questions presented in this paper: 1) does someone's past experiences with Athens-Clarke County police officers affect how they view the officers of the department and 2) do criminal justice (CJ) students have a more positive attitude toward police officers than students in other majors. This research is noteworthy because little literature is available that studies how CJ students view police, and only students of the University of Georgia were allowed to participate. A convenience sample method was used and each participant was given a link to an online survey in order to collect data. The two independent variables studied are 1) whether or not someone has had any interactions with an Athens-Clarke County police officer and 2) whether they are a CJ major or not. The dependent variable used a Likert scale consisting of five questions about perceptions of police and a Chi square was used for data analysis. The results of both of these studies were significant and proved that

past experiences with police and a student's major do affect how positively they view police officers. Lastly, an additional study was conducted using the first research question and controlling for CJ majors. The results of this study were not significant.

The Five-Fold Division: Shadow Personalities in Beckett's Three Novels
Julian Traas
Dr. Adam Parkes, English, Franklin College of Arts & Sciences

Samuel Beckett's often minimalist, confusing or downright contradictory descriptions of setting, character and situation problematize any plot sketch. Various scholarly articles have posited that the supporting characters in *The Unnamable* are facets of the titular character. Bearing in mind Beckett's interest in Freudian psychology, this paper investigates that notion to its logical conclusion, claiming that Moran, Molloy, Malone, et al., are all merely figments – shadow personalities – of the Unnamable's tortured mind, generated by the Unnamable itself in order to process a deeply embedded and poisonous psychological trauma. This paper's focused analysis of Beckett's *Three Novels* exposes the blatant similarities between each principal character – not limited to maddeningly similar names, fragile teeth, and relative immobility – and links these traits to the respective role each of these shadow personalities plays in the preservation of the Unnamable's psyche. Through scrutiny of each shadow personality's contribution to the Unnamable whole, it proposes a radical approach to Beckett's trilogy which embraces the narrative's scattered nature as part of the solution to its interpretation, rather than part of the problem.

Against All Reason: Rousseau and the Counter-Enlightenment
Brian Underwood, CURO Summer Fellow, CURO Graduation Distinction
Dr. Jennifer Palmer, History, Franklin College of Arts & Sciences

Scholars often count Swiss philosopher Jean-Jacques Rousseau as a chief proponent of Enlightenment thought, a movement at the heart of western intellectual tradition. It is surprising, however, that they consider Rousseau a member of that movement when he himself explicitly challenged Enlightenment tenets at their most fundamental levels. I demonstrate through this project that Jean-Jacques Rousseau was in fact an early figure in a burgeoning Counter-Enlightenment – a direct ideological confrontation of the reason-based philosophy of the Enlightenment, one that began in the eighteenth century and later heavily influenced the dominant continental philosophies of the nineteenth century. This project identifies those central ideas that make Rousseau's ideology distinct from Enlightenment philosophy as a whole, placing his ideology outside of that intellectual tradition. Examining the philosophy of Rousseau in this context offers insight into direct and immediate reactions to the Enlightenment while it was still in progress. In turn, the writings of Rousseau exhibit that the Enlightenment itself was not a monolithic intellectual entity, but instead was a contentious movement even at its height.

Nitrogen Resorption in *Helianthus* Species
Chinyere Uzoigwe
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

Nutrient resorption describes a plant's ability to re-absorb nutrients from senescing leaves. This ability is beneficial because such recycling increases available nutrient for

growth and reproduction. Nitrogen is typically the nutrient most limiting to plant growth and nitrogen resorption can be measured by the nitrogen content difference between green and senesced leaves. Nitrogen resorption efficiency and proficiency were measured in 2-3 populations each of 16 species of wild *Helianthus* grown in a common garden. The levels of resorped nitrogen across populations and species were compared with respect to growth form and life history, home habitat environmental factors, and relative placement along the leaf economics spectrum. First, it is hypothesized that annuals and erect deciduous perennials would have lower resorption ability than basal rosette perennials, which use rosettes of leaves as storage organs for overwintering. Second, it is hypothesized that species from more fertile habitats would have lower resorption ability than species from less fertile habitats, as resorption is costly and would not be favored where soil nitrogen is abundant. Third, it is hypothesized that higher nitrogen resorption would be favored in species with a more "conservative" leaf economics spectrum, as these species are typically found in infertile environments, often use leaves as storage organs, and have a longer leaf lifespan that allows more time for nutrients to be re-absorbed prior to leaf senescence.

A Proteomic Study of the *Botrytis cinerea*-Tomato Interaction

Jerin Varghese
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Botrytis cinerea is a model necrotrophic fungus that infects more than 200 plant species, one of which is the tomato. Significant protein-protein interactions occur as *B. cinerea* attempts to colonize its host plant. In this study, shotgun proteomics is used to identify the proteins solubilized in the *B. cinerea*-tomato (*Solanum lycopersicum*) interaction. Previous studies have indicated that ripening induces changes in the composition of the fruit cell wall, ultimately resulting in increased pathogen susceptibility. This hypothesis was tested through the use of tomato strains in various stages of ripening, as well as with strains in which ripening was inhibited. AcMG, CnrMG, and CnrRR mutant tomato fruit were infected with *B. cinerea* B05.10, and fungal and fruit proteins were identified post-infection. A total of 30 *B. cinerea* and 152 tomato proteins were identified. Following identification, two master lists (one each for *B. cinerea* proteins and tomato proteins) were compiled. The lists provided information on the function, gene ontology, pfam, CAZy, signal P, secrotome P, and TMHMM for each of the proteins. The identified proteins were then regrouped and analyzed based on which mutant fruit (AcMG, CnrMG, and CnrRR) the respective proteins were found in. Fungal and tomato proteins were found in the greatest frequency in the CnrRR variety. Over 36% of all fungal proteins and 19% of tomato proteins identified were unique to the CnrRR strand supporting previous research that indicated pathogen susceptibility in the *B. cinerea*-tomato interaction increases with ripening.

An Investigation of the Metabolic Changes Associated with Feeding a High-Fat/High-Sugar Diet in Swine

Emily Vermillion, CURO Honors Scholar
Dr. Robert Dove, Animal & Dairy Science, College of Agricultural & Environmental Sciences

The bio-medical community has expressed interest as to what types of changes might be seen in pigs fed high-fat, high-sugar diets. A pilot study was conducted to determine the metabolic changes in pigs fed high fat/high sugar diets. A total of 9 pigs were assigned to the study, with 6 pigs assigned to the experimental diet (2 pens), and 3 pigs assigned to a control diet (1 pen). The experimental

diet contained 20% fat, and 20% sugar and the control diet was formulated to meet NRC guidelines. Pigs were fed the diets for 12-16 weeks in amounts equal to approximately 70% of ad libitum intake. Pigs were weighed weekly and bled via a jugular stick on days 1, 28, 56, 84, 98, and 112. Blood samples were analyzed for glucose, triglycerides and insulin. Week 6 weights indicate that the pigs fed the experimental diet exhibited the expected weight gain, averaging 9 pounds heavier than pigs fed control diet. Triglyceride and glucose levels showed little variation between groups. On weeks 12, 14, and 16, one pig from each pen was harvested, and the heart, liver, kidney, and pancreas were collected for analysis. Livers of the experimental pigs weighed an average 300g more than the livers of the control pigs. Additionally, some liver streaking was noted in pigs fed the experimental diet, indicating possible early onset of fatty liver disease. Results of slaughter may indicate early onset of metabolic syndrome-type symptoms, however triglyceride levels show little evidence of this.

Mutations Impacting Copy Number Control and Host Cofactor Involvement in Retrotransposition of Ty1

Lucas Wachsmuth
Dr. David Garfinkel, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Ty1 is an LTR retrotransposon found in the yeast genus *Saccharomyces* that replicates via a process similar to that observed in retroviruses. Ty1 is comprised of two open reading frames: *GAG*, which encodes the structural capsid-like protein, and *POL*, which codes for the Ty1 protease (PR), integrase (IN), and reverse transcriptase (RT). Ty1 proteins along with Ty1 mRNA assemble into virus-like particles (VLPs), where the Ty1 mRNA is reverse transcribed into cDNA for insertion into the genome. Ty1 replication in the budding yeast host exhibits a phenomenon where transposition decreases as the number of Ty1 genomic copies increases, a process called copy-number control (CNC). In order to learn more about the mechanism of CNC we performed a mutant screen using error-prone PCR to identify CNC-resistant Ty1 *POL* mutants. In the mutants we identified, PR V115A and IN D391G/RT R288G, we measured transposition frequency and examined steady state protein levels. Additionally, to learn more about host factor involvement in Ty1 retrotransposition, we conducted a screen using a GAL1-regulated yeast cDNA expression library to identify host cofactor genes that are involved in the life cycle of Ty1. From these experiments we isolated two host cofactors, YRB1 and BMH2, that, when overexpressed, inhibit Ty1 retrotransposition. As the Ty1 proteins are homologs of retroviral Gag and Pol, by studying Ty1 transposition we can expand our understanding of the replication of other retroelements, an area that has important implications for human disease.

Ectopic Endodermal Expression of Foxn1 in a Murine Model

Lucas Wachsmuth
Dr. Nancy Manley, Genetics, Franklin College of Arts & Sciences

Foxn1 is a forkhead transcription factor that drives differentiation of the epithelial cell lines in the thymus, the organ responsible for maturation and selection of T cells. Normal expression of Foxn1 is crucial for proper thymic development and postnatal upkeep of thymic cellular organization, and expression defects lead to severe immunodeficiency due to impaired T cell colonization and maturation. Foxn1 has been described as a master regulator of thymic epithelial cell lineage due to its role in thymic epithelial cell patterning as an activator of downstream epithelial differentiation genes. The thymus arises from endoderm in the third pharyngeal

pouch, so it follows that Foxn1 expression in other endodermal tissues could have the potential to alter cell fates. However, Foxn1 expression is primarily localized to the pre-thymic areas, and the potential for Foxn1 to function as an endodermal transcription factor outside of the pharyngeal pouch has yet to be analyzed. Here we show that ectopic Foxn1 expression can be induced through the FoxA2CreER system and an inducible Foxn1 transgene in a murine model. Using this genetic approach we induce Foxn1 expression under the control of the FoxA2 gene, resulting in ectopic endodermal Foxn1 expression. Studying the development of these Foxn1-expressing cells located in endodermal tissues outside of the thymic primordium will further our understanding of the scope of Foxn1's effects on endodermal tissues. With more knowledge of Foxn1's involvement in cellular differentiation we can expand our understanding of its role in aspects of health such as age-related immune decline and immunodificiencies.

Cell Cycle Regulation of BMP Signal Transduction

Akshey Walia
Dr. Jonathan Eggenschwiler, Genetics, Franklin College of Arts & Sciences

Bone morphogenetic proteins (BMPs), belonging to the transforming growth factor beta (TGF-β) family of ligands, are thought to be responsible for a variety of developmental processes within the mammalian central nervous system, including neurulation, dorsal-ventral patterning, cellular differentiation, survival, and proliferation. Although BMP signaling plays an important role in cell cycle regulation, it is unclear whether the opposite relationship, in which the BMP pathway is active in only a specific phase of the cell cycle, also exists. To investigate this possibility, I have developed a quantitative assay using qPCR to detect unspliced pre-mRNA messages from direct target genes. Pharmacological inhibition of transcription will be used to determine the half-life of these messages. Next, cells will be sorted according to cycle phase using flow cytometry. I will then assess real time transcription of target genes as a function of cycle phase using housekeeping gene expression as an internal control. The possibility that cell cycle phase is differentially correlated with BMP target gene expression would argue that the BMP pathway both regulates and is regulated by the cell cycle. Insight regarding the BMP pathway with respect to cell cycle phase would have important implications with respect to the etiology and treatment of developmental and oncological pathologies associated with BMP signaling.

The Effect of the Protein Ras2 on the Biological Clock of the Fungus *Neurospora crassa*

Solomon Walker
Dr. Jonathan Arnold, Genetics, Franklin College of Arts & Sciences

The biological clock of most organisms is a complex interactome of many proteins that can control the various pathways and functions within an organism that relate to circadian rhythms. It is already known that a defect in the Ras2 gene in *Neurospora c.* causes conidal and cell wall growth defects, but it is not known if the gene has any effect on its biological clock. We utilized viability tests and growth tube tests of Ras2 knockout strains compared to wild type strains to analyze the defects caused by the absence of the Ras2 on the life span of individual conidia and core functions seen in other knockout strains, such as the banding seen in growth tube tests of Ras1 mutants. We also performed real-time PCR on aged and unaged cultures of Ras2 knockout and wild type strains to determine if the low expression in Ras2 knockout strains of Ras2 affects the expression levels of another key clock gene, frq, which could implicate Ras2 in being part of the clock

interactome. So far, the viability and growth tube tests remain inconclusive, but the upcoming real-time PCR tests could give more concrete results on whether or not Ras2 is a key gene in the clock regulation of *Neurospora crassa.*

Concussions from the Past Continue to Predict Present Symptomology Above and Beyond Mood Symptoms

Tiffany Washington
Doug Terry, Graduate student
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

Objective: Much research has been done in order to understand the consequences and impact concussions can have on professional football players such as the chronicity of symptoms associated with a concussion. However, there is limited research that assesses the long lasting impacts of a concussion on individuals who played football solely during their adolescence. Studies suggest that mood symptomology may be associated with history of concussions. Thus, we examined the relationship between depression and anxiety and concussion-like symptoms in individuals who have not had a concussion in many years. Moreover, we examined the addition of a third variable, number of past concussions, to see if it could further predict concussive-like symptoms. *Methods:* Twenty-eight community-dwelling former high school football players ages 40-65 participated in this study. The Beck Depression Inventory-II and Beck Anxiety Inventory as well as a measure of current concussive symptoms were completed. Participants also underwent the Acute Concussion Evaluation (ACE), semi-structured interview to assess how many previous concussions they endured. To find an association between the independent and dependent variables a hierarchical linear regression model was used in order to analyze the scores. *Results:* As expected, depression and anxiety contributed to explaining a significant amount of variance of self-reported concussion-like symptoms. Depression explained 30% of current concussive-like symptoms. Also, as predicted, the number of past concussions further predicts current concussion-like symptoms above and beyond mood symptomology. Adding the number of past concussions into the model explained a total of 39% of that variance in concussion-like symptoms. *Conclusion:* Predictably, an individual's current mood contributes to explaining variance in concussion-like symptoms. However, the number of past concussions was significantly related to concussive-like symptoms above and beyond one's mood symptomology in individuals who do not currently have a concussion. This study suggests that getting a concussion in one's adolescent years may have long lasting effects in one's adult years.

Mimicking the EGFR Dimerization Arm Using Triazolyl-Bridged Peptides: An Alternative Approach to EGFR Inhibition

Christopher Watkins
Dr. Eileen Kennedy, Pharmaceutical & Biomedical Sciences, College of Pharmacy

EGFR is a transmembrane receptor tyrosine kinase whose overexpression contributes to oncogenic phenotypes in multiple cancers, making it a candidate of choice for therapeutic treatments. Previous attempts have mostly relied on tyrosine kinase inhibitors (TKIs) and monoclonal antibodies, but these have had significant drawbacks, such as the development of secondary resistance and infusion reactions, making an alternative targeting strategy necessary. Our work has been to develop a library of triazolyl-bridged peptides that inhibit EGFR activity by mimicking the dimerization arm of its extracellular domain. The dimerization arm was chosen because blocking its interaction prevents dimerization of the receptor and the activation of the cytoplasmic tyrosine kinase

domain of EGFR, thus inhibiting downstream signaling. Our peptides were stabilized by locking the termini together into a β loop by formation of a triazolyl bridge. The lengths of the azido-amino acid side chains required for triazole formation were varied to identify the optimal cross-link length. Liquid chromatography-mass spectrometry (LC/MS) confirmed formation of the cyclized product, and reverse-phase high-pressure liquid chromatography (HPLC) was used to purify the peptides. The peptide with the shortest bridge, EDA2, showed the greatest decrease in the amount of phosphorylated EGFR and Akt in cell-based assays. Co-immunoprecipitation of fluorescein-labeled peptides revealed that our EDA2 peptide bound EGFR. The Duolink assay identified a decrease in EGFR dimers after incubation with EDA2. Our results show that EDA2 inhibits the dimerization of EGFR and subsequent downstream signaling, demonstrating that dimerization arm mimicking peptides may be a promising alternative targeting strategy for EGFR inhibition.

Polio Eradication: What's Still Needed?
Amelia Watson
Dr. Richard Schuster, Health Policy & Management, College of Public Health

Poliomyelitis is a devastating disease that attacks the central nervous system and often causes paralysis. About 2 to 5% of children and 15-30% of adults with paralyzing infection die, and the survivors' lives are irrevocably changed. The World Health Assembly sought to eradicate poliomyelitis in 1988, when the disease paralyzed more than 350,000 people each year. The most recent deadline of polio eradication, one of the many set, was missed in 2012. Unfortunately, polio is still endemic in three countries despite continual efforts towards eradication. The current state of control would cost more than ten billion dollars over the next 20 years with approximately 200 cases of paralytic polio each year, and circulating polio will threaten to have even larger outbreaks, affecting the health of the world. Because of vaccination refusals and security problems as well as the need for a new vaccination schedule, the policies put in place must be reassessed. Introducing IPV into every vaccination schedule is an important step in polio eradication's future. The challenges of this policy are that implementation is expensive and requires the intensive training of vaccination workers compared to OPV. However, this solution will increase demand for the vaccine, be more politically accepted, and prevent the most cases of polio.

Breaking Mendel's Laws: How Abnormal Chromosome 10 Causes Meiotic Drive
Amy Webster
Dr. Kelly Dawe, Genetics, Franklin College of Arts & Sciences

In *Zea mays*, abnormal chromosome 10 (Ab10) exhibits meiotic drive by segregating into approximately 80% of progeny instead of the Mendelian 50%. In addition to preferentially segregating itself, the presence of Ab10 causes the preferential segregation of certain knobs present on other chromosomes. These knobs are heterochromatic regions of tandem repeats composed of two sequences called Knob 180 and TR-1. Three haplotype variants of Ab10 have been found across subspecies of *Zea mays*, called teosintes, the wild progenitor of domesticated maize. They are denoted types I, II, and III and vary in knob content, but all exhibit meiotic drive. My goal was to determine which lines of teosinte have Ab10, which variant of Ab10 is present in each, and which genes are important for the meiotic drive phenotype. To do this, I found six lines of teosinte that have Ab10 present in at least one plant. I used fluorescent *in situ* hybridization (FISH) to probe for centromeres, TR-1 knob, and Knob180 on the chromosomes of teosinte lines, and

determined the type of Ab10 present in three plants positive for Ab10 using fluorescent microscopy. I genotyped *Zea mays* for the presence of ten genes on the distal tip of Ab10 to determine if they are present across teosintes and used qRT-PCR to compare expression levels of plants with functioning versus mutant Ab10. Through these experiments, I found one gene that is not important for meiotic drive and two genes that have significant changes in expression and are of interest for further study.

The Justification for Ethnic War
Patrick Wheat
Dr. Daniel Hill, International Affairs, School of Public & International Affairs

With a strong increase in ethnically focused conflicts in the past twenty years, the root of these conflicts remains a confounded issue in many respects. Through the use of analysis of case studies, along with dynamic and structural theories on the foundation of ethnic identity, I attempted to form a conclusion as to the core cause of ethnic conflict. While in many cases it appears that the actions of individuals who participate in ethnic conflicts appear to be the result of long-standing grievances, violence is more likely to be the result of manipulation of ethnically-based political cleavages by individuals in leadership positions, who engage in such behavior for the advancement of their own personal agenda or that of their ethnic or political bloc. Furthermore, these efforts are more successful when the leadership is able to manipulate ethnically-based cleavages characterized by a history of grievances. In this presentation, I will use the real world examples of the events leading up to the Rwandan Genocide, the Bosnian Civil War and the Sri Lankan Civil War alongside theoretical analysis of different theories on Ethnic Conflict to demonstrate the cause of this type of conflict as more likely to be the result of leadership manipulation rather than other factors, including Ethnic strife and "Ancient Hatreds" arguments.

The Rationality of Peacekeeping
Patrick Wheat
Dr. Andrea Everett, International Affairs, College of Public & International Affairs

The United Nations Department of Peacekeeping Operations has acted as one of the most well-known international organizations for the past sixty years, taking part in 67 operations aimed at stabilizing regional conflict and alleviating humanitarian concerns across the globe. Peacekeeping missions organized by the DPKO are comprised entirely of voluntary contributions of soldiers from individual nations. Because these contributions play such an important role in the DPKO's continued operations, understanding the factors that are likely to encourage or discourage states from participating in UN missions is of paramount importance. One of the most interesting aspects of this contribution question is understanding the factors that cause states with fewer military resources (personal, weapons, equipment, etc.) to contribute more than states with a large amount of resources. Most of this motivation appears to come from political will within the nation and from the financial compensation given from the UN to states who contribute forces to peacekeeping mission. If either of these factors is either lacking or unnecessary to the government of a state, the state is less likely to contribute based on this model. To demonstrate this, I will use case studies from nations such as Bangladesh, Ethiopia, Cambodia and Thailand.

The Utilization of Genetic Manipulation to Better Understand Kinative Function of CK1.2 in *Trypanosoma brucei*

Zachary Whitt, CURO Graduation Distinction
Prof. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts & Sciences

Human African Trypanosomiasis (HAT) is a disease caused by two subspecies: *Trypanosoma brucei gambiense* and *rhodesiense*. The drugs Pentamidine, Suramin and Melarsoprol have all been used for over 60 years to treat Trypanosomiasis; however, each has undesired, potentially fatal side effects. Over the past few decades, governments and international agencies have been pushing for safer and more effective treatments for HAT. To this end, the Mensa-Wilmot lab has identified AEE788, an epidermal growth factor receptor (EGFR) inhibitor, as a lead for anti-trypanosome drug discovery. Trypanosomes lack EGFR but AEE788 binds Casein kinase 1.2 (TbCK1.2) in the parasite. The biological functions of TbCK1.2 are not known. One approach to address the issue is to overexpress TbCK1.2 in *T. brucei*, and examine the genetically modified trypanosomes for new phenotypes. We are interested in learning whether the effects of AEE788 treatment of *T. brucei* is similar to overexpression of TbCK1.2. Overexpression of TbCK1.2 leads to a defect in segregation of a specific organelle, the kinetoplast which contains mitochondrial DNA in the parasite. We anticipate that elucidation of these pathways may lead to discovery of new targets for hit discovery in anti-trypanosome drug discovery.

The Expression of the Bile Acid Receptor TGR5 in Prostate Cancer Cells and its Role in Bile Acid-Induced Cell Death

Stephanie Wilding, CURO Summer Fellow, CURO Graduation Distinction
Dr. Brian Cummings, Pharmaceutical & Biomedical Sciences, College of Pharmacy

Bile acids mediate the digestion and absorption of fats and fat-soluble vitamins; however, pathological increases are associated with choleostasis and cell death. Recent studies show that high concentrations of bile acids can induce apoptosis in several cells, including cancer cells, by mechanisms that are not fully understood. Previous data in our lab demonstrated the novel finding that bile acids can induce cell death in three prostate cancer cell lines (PC-3, DU-145, and LNCaP); however, they do not determine the mechanisms involved. Bile acids are transported into cells by receptors, one of which is TGR5. Thus, we hypothesized that bile acid-induced cell death was mediated by TGR5; however, the expression of TGR5 in prostate cancer cells has not been reported. We used RT-PCR and immunoblot analysis to show that TGR5 is expressed in all three prostate cancer cell lines as well as a non-cancerous prostate cell line (RWPE-1). In general, the expression of TGR5 was highest in prostate cancer cells, and lowest in non-cancerous prostate cells. Transfection of PC-3 cells with plasmids encoding for shRNA against TGR5 decreased TGR5 mRNA and protein expression, as compared to cells transfected with scrambled shRNA. Analysis of MTT staining, a marker of cytotoxicity, showed that bile acids induced similar levels of cell death in wild-type cells as in TGR5 knockdown cells. These data show the novel finding that TGR5 is expressed in prostate cancer cells, but also suggest that TGR5 does not mediate the toxicity of bile acids.

The Role of Notch Signaling in Astrocyte and Oligodendrocyte Derivation

Elizabeth Wilkins, CURO Honors Scholar, CURO Summer Fellow
Dr. Steven Stice, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Astrocytes and oligodendrocytes are macroglial cell subtypes which play supporting roles for neurons in the central nervous system. During development, the ventral neural tube is spatially patterned into five specific domains by a gradient of Sonic Hedgehog from the floor plate and notochord. Temporally, the p2 progenitors sequentially generate interneurons followed by astrocytes, while the pMN progenitors produce motor neurons then oligodendrocytes in a process known as the glial switch. Notch-Delta signaling is a well-studied means of juxtacrine communication between cells and its downregulation has been implicated in this process, but its mechanism is poorly understood. We plan to investigate the role of Notch signaling in the glial switch. Embryoid bodies composed of mouse embryonic stem cells will be patterned using a SHH agonist to mimic the neural tube. At different time points, a global Notch inhibitor, DAPT, will be added to the media. We will use immunocytochemistry to image for astrocytic and oligodendritic markers. We hypothesize that Notch inhibition will yield greater amounts of secondary cell types, including astrocytes and oligodendrocytes. By understanding how progenitor populations are able to produce multiple cell types, we will better understand the developing neural tube and spinal cord, with implications for motor control diseases like amyotrophic lateral sclerosis and spinal cord injury. Moreover, understanding how progenitor populations generate post-mitotic cell types is highly translatable to other stem and progenitor cell niches which persist into adulthood. The knowledge gained could allow us to harness the capacity of these intrinsic progenitors for potential therapies.

Sigma-54 Promoter Activity and Gene Regulation in *Salmonella*

Leah Williams
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

Sigma factors interact with RNA Polymerase for recognition of promoters and initiation of transcription in prokaryotic organisms. Sigma-54 (RpoN) is an alternative sigma factor that regulates a subset of transcripts and functions in a mechanistically different manner than other known sigma factors, requiring an activator and ATP hydrolysis. To characterize the RpoN-dependent regulon of *Salmonella typhimurium*, we previously utilized chromatin Immunoprecipitation coupled with high-density tiled microarray and RNA microarray assays, defining >250 RpoN chromosomal binding sites and 22 RpoN-dependent transcripts, respectively. In addition, several operons were found to be down-regulated in the presence of RpoN and had adjacent or internal RpoN-binding sites. We are currently addressing the mechanism by which the RpoN binding sites may be negatively regulating the associated operon. Promoter activity for these sites is being assessed by transcriptional fusion to *phoA,* an alkaline phosphatase, in the presence of DctD250. We have adapted a protocol to assay production of PhoA and confirmed that the assay could be performed in *Salmonella.* Transcription fusions to *phoA* are being generated for five of the identified regulatory RpoN binding sites. PhoA activity is being assessed in wild-type and ⊿*rpoN* 14028s strains to ensure PhoA production is RpoN-dependent. Evaluation of these potential promoters will offer insight into possible alternative methods of RpoN-dependent transcriptional and post-transcriptional control of gene expression in *Salmonella.*

Fermentation of Cull Peaches Using a Pectinase Producing *Saccharomyces cerevisiae* Strain

Travis Williams, CURO Summer Fellow
Dr. Joy Doran Peterson, Microbiology, Franklin College of Arts & Sciences

Cull or spoiled peaches, normally a waste product, can be fermented to produce ethanol due to their high concentration of sugars in monomeric and in polymeric form. The sugar polymers in the peach biomass require enzymes for cleavage into available monomers. This set of experiments compared the fermentation performance of a pectinase producing yeast, *Saccharomyces cerevisiae* 09448, to the commonly used corn ethanol production yeast, *Saccharomyces cerevisiae* XR122N, and the engineered ethanologenic bacterium, *Escherichia coli* LY40A. First, *S. cerevisiae* XR122N fermentations were compared to fermentations with *E. coli* LY40A. Due to the high number of six carbon sugars in peaches, the biomass was best fermented by the *S. cerevisiae* XR122N. Next, the optimal enzyme loading for *S. cerevisiae* XR122N fermentations was studied using 15% w/v peach pomace and varying amounts of commercial enzymes. The lowest enzyme loading which produced the maximum amount of ethanol was 1.88 FPU of cellulase/g dw, 7.50 PGU of pectinase/g dw, and 6.25 CBU of cellobiase/g dw. *S. cerevisiae* XR122N fermentations with the same enzyme loading minus the pectinase yielded significantly less ethanol than the fermentation with pectinase. Finally, two sets of fermentations with *S. cerevisiae* 09448 were performed just as they were with the *S. cerevisiae* XR122N in the previous experiment. *S. cerevisiae* 09448 produced the same amount of ethanol in experiments with and without pectinase, indicating that the pectinase produced by *S. cerevisiae* 09448 was sufficient to completely replace commercial pectinase and maintain maximum ethanol yield in peach fermentations.

Interactions between Neutrophils and *Pseudomonas aeruginosa* Flagellum

Matthew Winn
Dr. Balazs Rada, Infectious Diseases, College of Veterinary Medicine

Neutrophil granulocytes are professional phagocytes providing the first line of defense against invading bacterial pathogens. Recently, a novel antimicrobial mechanism of neutrophils has been described: formation of neutrophil extracellular traps (NETs) composed of a DNA backbone decorated with granule enzymes. NET formation is an innate immune mechanism, but uncontrolled NET release can cause tissue damage associated with inflammatory diseases including cystic fibrosis (CF). CF airways are characterized by mucus hypersecretion, chronic bacterial infections and infiltration of neutrophils incapable of fighting bacteria, instead causing airway tissue damage. We seek to elucidate the interactions between neutrophils and *Pseudomonas aeruginosa*, an opportunistic gram-negative bacterium found in CF airways. Specifically, we focus on the role of *P. aeruginosa* flagellum, an organelle responsible for swimming motility and virulence. Interactions of neutrophils with flagellum are studied using the PAO1 laboratory strain, comparing response to wild-type PAO1 with response to flagellum-deficient DfliC PAO1. Compared to wild-type PAO1, DfliC PAO1 induces less activation of microbicidal pathways, such as phagocytosis and superoxide production, and induces decreased release of two neutrophil granule proteins, myeloperoxidase (MPO) and human neutrophil elastase (HNE). DfliC PAO1 induces less NET formation measured as release of extracellular DNA, MPO-DNA and HNE-DNA complexes. Interestingly, blocking Toll-like receptor 5, the main receptor for flagellin, does not seriously affect PAO1-induced neutrophil response, and purified flagellin does not elicit NET generation. These data indicate that the bacterial flagellum is vital for efficient human

neutrophil response to *Pseudomonas aeruginosa,* and interactions are mediated by mechanisms other than TLR5.

TLF2 Synthesis from Oxidized Lipids in TLF1

Christopher Witt
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosome Lytic Factor-1 (TLF1) and the more recently discovered TLF2 are both High Density Lipoproteins (HDLs) found in human serum. Each of these particles functions independently as part of innate human immunity through lysis of the bloodstream form of the protozoan parasite, *Trypanasoma brucei brucei*. TLF1 is the most highly characterized of these two HDLs and is distinguished from non-lytic HDLs by the presence of apolipoprotein L-1 (ApoL-1) and Haptoglobin related protein (Hpr). TLF2 also has ApoL-1 and Hpr but is twice as dense due mainly to the presence of bound IgM molecules which are not found in TLF1. Via Hpr, both TLF1 and TLF2 bind Hemoglobin (Hb). The mechanism of synthesis for TLF2 is unknown. Innate IgM molecules have been shown to bind oxidized phospholipids. Our model proposes that the lipids in Hb bound TLF1 (TLF1-Hb) are oxidized in the bloodstream, inducing recruitment of IgM, ultimately resulting in TLF2 synthesis. The purpose of these experiments was to use the TBAR assay method to demonstrate in vitro lipid peroxidation in TLF1-Hb. TLF1-Hb was shown to self-peroxidize in a time dependent manner at physiological pH in the presence of H2O2. The next step in providing evidence for our model was to demonstrate binding of innate IgM to peroxidized TLF1-Hb via immunoprecipitation. Further characterization of TLF2 synthesis may provide insight into the dynamics of HDLs and oxidized lipids and the role they play in our innate immune response.

Swath Size in Boa Vista's Bearded Capuchin Monkeys

Leigh Anna Young, CURO Summer Fellow
Dr. Marguerite Madden, Geography, Franklin College of Arts & Sciences

Primate social groups are often considered to be either fission-fusion or cohesive in their social structure. Recent work has shown, however, that primate social structure should be interpreted along a continuum of cohesiveness with fission-fusion and cohesive social groups representing extremes of that continuum. This study analyzed one aspect of the social cohesion of a group of bearded capuchin monkeys (*Sapajus libidinosus*): the spatial spread of the group throughout its home range. Swaths of the capuchin group were observed using a high resolution satellite image and a GPS enabled iPhone with Avenza PDF Maps application. Spatial measures of group cohesiveness, including swatch area, inter-individual distance and group density, were calculated using ArcGIS geographic information systems software. On average, 14 individuals were observed representing 59% of the group. The average swath was 613 square meters and average front-to-back distance was 50.2 meters. This front-to-back distance is similar to that of capuchin monkeys in a rainforest habitat. Spatial cohesion may be consistent across regions for capuchin monkeys, although further testing is necessary to confirm these measurements.

CURO

March 30, 2015

Dear Students, Faculty, and Guests,

Welcome to the 15th annual CURO Symposium, UGA's celebration of undergraduate research across the disciplines. Many individuals—administrators, faculty members, staff, graduate students, and, of course, undergraduate students—have collaborated to make the CURO Symposium the premier undergraduate academic event at UGA.

Each year, the Symposium has grown larger, and the 2015 Symposium is the largest to date, with 386 undergraduate researchers communicating their substantial accomplishments to their peers, mentors, and the public at large.

From its inception, the CURO Symposium has showcased research and scholarship in all disciplines. The 2015 Symposium continues that commitment, featuring presenters pursuing 79 different majors from 13 schools and colleges who are conducting research with 258 faculty members from 72 departments. Thus, this two-day event displays UGA's broad and substantial support of research and the invaluable commitment of UGA's administration and faculty to mentoring and providing exceptional learning opportunities for our undergraduates.

Thank you for your continued support of undergraduate research and CURO.

Sincerely,

Dr. David S. Williams, '79, '82
Associate Provost and Director

Dr. Martin P. Rogers, '01, '11
Associate Director

Acknowledgements

Special Assistance for 2015 CURO Symposium

Ms. Kate Belgum	Administrative Associate, External Affairs, Honors Program
Ms. Jami Gilstrap	Administrative Associate, CURO
Ms. Dorothé Otemann	Coordinator of External Affairs, Honors Program
Ms. Amanda Pruitt	Assistant to the Director, Honors Program

Technology Equipment and Support for 2015 CURO Symposium

Reviewers for 2015 CURO Research Mentoring and Best Paper Awards

Dr. Martin Rogers	Associate Director of CURO & Honors
Dr. David S. Williams	Associate Provost and Director of Honors and CURO

Oral and Poster Session Conveners for 2015 CURO Symposium

Ms. Mary Lee Cunill	Communication Studies
Ms. Laura Fletcher	Presidential Graduate Fellow, Department of Psychology
Ms. Jami Gilstrap	Administrative Associate, CURO
Mr. Steven Honea	Academic Advisor, Honors Program
Ms. Linnea Ionno	Department of Public Administration and Policy
Ms. Michele Johnson	Department of History
Ms. Amber Kaufman	Department of Public Administration and Policy
Mr. Adrian Klemme	Institute of Higher Education
Ms. Emily Myers	Administrative Associate, Foundation Fellowship Office, Honors Program
Ms. Kathleen Pieper	Presidential Graduate Fellow, Department of Genetics
Ms. Ricky Roberts	Academic Advisor, Honors Program
Dr. Martin Rogers	Associate Director of CURO & Honors
Mr. Greg Rountree	Administrative Associate, Office of Recruitment, Honors Program
Ms. Heather Smith	Academic Advisor, Honors Program
Mr. Jeremy Wheatley	Academic Advisor, Honors Program
Ms. Eleana Whyte	Program Coordinator, CURO

Schedule

Monday, March 30, 2015

Oral Session I **11:15 a.m.-12:05 p.m.**
Athena Breakout Rooms A, B, C, D, G, H

Oral Session II **12:20-1:10 p.m.**
Athena Breakout Rooms A, B, C, D, G, H

Oral Session III **1:25-2:15 p.m.**
Athena Breakout Rooms A, B, C, D, G, H

Oral Session IV **2:30-3:20 p.m.**
Athena Breakout Rooms A, B, C, D, G, H

Awards and Keynote Session **3:30-4:30 p.m.**
Athena Room E

Poster Session and Reception **4:30-6:30 p.m.**
Grand Hall South & Atrium (downstairs – use escalator in lobby)

Tuesday, March 31, 2015

Oral Session V **9:30-10:45 a.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

Oral Session VI **11:00 a.m.-12:15 p.m.**
Athena Breakout Rooms A, B, C, D, G

Oral Session VII **12:30-1:45 p.m.**
Athena Breakout Rooms A, B, C, D

Oral Session VIII **2:00-3:15 p.m.**
Athena Breakout Rooms A, B, C, D, G, H

Oral Session IX **3:30-4:45 p.m.**
Athena Breakout Rooms A, B, C, D, G, H, I, J

CURO Research Mentoring Awards

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the CURO Research Mentoring Awards, formerly the EURM awards, in 2001.

These awards recognize outstanding faculty who consistently engage undergraduate researchers through CURO Programming (courses, the symposium, summer fellows, JURO, theses, et al.) and enhance the learning experience of undergraduate researchers at the University of Georgia. Award recipients have provided superior research opportunities and mentoring and have collaborated with undergraduate researchers on publications and presentations at professional conferences.

Before 2014, awards were designated as "Early Career" and "Master Level" and were granted to corresponding faculty ranks.

2015

Dr. Jeb Byers, Professor, Odum School of Ecology

Dr. Erik Hofmeister, DVM, DACVAA, DECVAA, MA (Anesthesia), Associate Professor of Anesthesiology, Chief of Small Animal Surgery and Anesthesia, College of Veterinary Medicine

2014

Dr. Carl Bergmann, Associate Vice President for Research-Facilities; Associate Director, Complex Carbohydrate Research Center; Executive Director, Animal Health Research Center; Senior Research Scientist

Dr. Andrew Owsiak, Department of International Affairs, School of Public & International Affairs

2013

Master Level Faculty Award

Dr. Jennifer McDowell, Department of Psychology, Franklin College of Arts & Sciences

Early Career Faculty Award

Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

2012

Master Level Faculty Award

Dr. Lawrence Shimkets, Department of Microbiology, Franklin College of Arts & Sciences

Early Career Faculty Award

Dr. Michael Yabsley, Warnell School of Forestry & Natural Resources

2011

Master Level Faculty Award

Dr. Eric Stabb, Department of Microbiology

Early Career Faculty Award

Dr. John Drake, Odum School of Ecology

CURO Research Mentoring Awards

Program Award
Savannah River Ecology Laboratory
Dr. Kenneth McLeod, Interim Director

2010

Early Career Faculty Award
Dr. John C. Maerz, Warnell School of Forestry & Natural Resources

2009

Early Career Faculty Award
Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences
Dr. Anna C. Karls, Department of Microbiology
Dr. Dawn T. Robinson, Department of Sociology

2008

Master Level Faculty Award
Dr. John J. Maurer, College of Veterinary Medicine

Early Career Faculty Award
Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology

Program Award
Biomedical and Health Sciences Institute
Dr. Harry S. Dailey, Director

2007

Master Level Faculty Award
Dr. Timothy Hoover, Department of Microbiology
Early Career Faculty Award
Dr. Steven Stice, Department of Animal & Dairy Science

2006

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Department of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Department of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD candidate in Plant Biology

2005

Faculty Award
Dr. Gary Barrett, Odum School of Ecology
Dr. Sidney Kushner, Department of Genetics
Department Award
Department of Cellular Biology

CURO Research Mentoring Awards

2004

Faculty Award

Dr. William S. Kisaalita, Department of Biological & Agricultural Engineering

2003

Faculty Award

Dr. Jody Clay-Warner, Department of Sociology

Department Award

Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator

Program Award

The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Department of Plant Biology
Dr. Marie-Michèle Cordonnier-Pratt, Department of Plant Biology

2002

Faculty Award

Professor William D. Paul, Jr., Lamar Dodd School of Art
Dr. Katherine Kipp, Department of Psychology

Faculty Recognition

Dr. Susan Sanchez, College of Veterinary Medicine

Department Award

Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head

Program Award

"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Department of Physics & Astronomy
Dr. Heinz-Bernd Schuttler, Department Head, Department of Physics & Astronomy
Dr. Jonathan Arnold, Department of Genetics
Dr. Susmita Datta, Georgia State University
Dr. David Logan, Clark Atlanta University
Dr. William Steffans, Clark Atlanta University

2001

Faculty Award

Dr. Marcus Fechheimer, Department of Cellular Biology

Faculty Recognition

Dr. David MacIntosh, Department of Environmental Health Sciences
Dr. Dean Rojek, Department of Sociology

Department Award

Department of Genetics
Dr. John MacDonald, Department Head

Program Award

Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

CURO Symposium Best Paper Awards

Since 2001, CURO Symposium Best Paper Awards have recognized excellence in papers developed from work being presented at that year's Symposium.

Applicants may submit in one or more of the following categories: Arts, Humanities and Media; Business; Life Sciences; Physical and Environmental Sciences; Public and International Affairs; Social Sciences; and Technology, Engineering and Math.

Each recipient is recognized at the Symposium's Award and Keynote Session, and each award carries $100 in financial support, generously provided by the UGA Alumni Association. Winners from the 2015 CURO Symposium are listed below.

Arts, Humanities and Media:

Brett Bennett	The Forgotten Radical: Southern Women and the New Left Student Protests of the 1960s

Life Sciences:

Anish Narayanan	Analysis of Cancer Mutations in Protein Kinases using Semantic Web Technologies

Physical and Environmental Sciences:

Timothy Montgomery	*Gracilaria vermiculophylla's* Impacts on Herbivory in Georgia's Coastal Ecosystems

Public and International Affairs:

Sarah Lane	Syrian Civil War Victims Receiving Medical Care in Israel: Humanity in a War Torn Region

Social Sciences:

Joseph Coppiano	Age Related Effects on Brain Activation during Cognitive Control Tasks in Subjects with Schizophrenia

Technology, Engineering and Math:

Emily Wall	Using Artificial Neural Networks to Predict Solar Radiation in Georgia

Program: Monday, March, 30, 2015

Oral Session I: 11:15 a.m.-12:05 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Patrick Wheat**	The Enigmatic Country: Analysis of Russian Expansionism in the Modern Age
	Eytan Palte	Democratic Institutions and the Human Right to Health
	Brent Buck	Threat from Abroad, Conflict Within: Border Settlement and Civil War Onset
Room B	**Daniel Kanso**	Republicanism in the American South: From Strom Thurmond to Lindsey Graham
	Zachary Jones	Who Saved Thad Cochran?: Racial Politics and Voter Mobilization in a Deep South Runoff
	Alexandra Lilly	How Did Female Candidates Fare in the 2014 Election?
Room C	**Kelsie Flanigan, Charlotte Goldman, Tyler Stollman**	The Role of Executive Functioning in Adherence for Pediatric Solid Organ Transplant Recipients
	Jerica Bornstein	Examining Communication Patterns and Trait Self-Control Using the Actor-Partner Interaction Model
	Jonathan Dickens	Executive Function Moderates Relationship between Mobility and Functional Independence in Older Adults
Room D	**Christina Ethridge**	Characterization of Leigh's Syndrome Patient Human Induced Pluripotent Stem Cells for Clinical Research
	Sandip Minhas	Purification of Hirano Bodies in *Dictyostelium discoideum*
	Kurt Mueller	Function of Kinesin Proteins in *Toxoplasma gondii*
Room G	**Brittany Whitlock**	Influence of Maternal Diet on the Offspring Gut Microbiota
	Allison Koch	Size Labeling for Infant Clothing: Cultural Perspectives on Childhood Growth
	Whitney Okie	Genetic Determination of Obesity Induced Inflammation and Blood Brain Barrier Alterations
Room H	**Adam Kramer**	Studying the Kinetics of N-glycan Release by PNGase F with MRM Quantitation of the Glycopeptides from Human Serum Glycoproteins

	Danish Singh	Genotype-Phenotype Correlations in POMGNT1 and POMGNT2
	Suraj Kapoor	Characterizing the Novel 1,2-Propanediol Dehydratase and its Activating Enzyme from *Roseburia inulinivorans*

Oral Session II: 12:20-1:10 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Minh Nguyen**	A #whitewashed Landscape: Internalized Racism, Linguistic Discrimination, and the Policing of Ethnic Identity on Twitter
	Patrick Semanie	Is Everyone on Twitter Better Than You?: Correlations between Twitter and Exercise Motivation among College Students
	Spencer Hanlin	Describing Scrambling in Japanese
Room B	**Sarah Lane**	Syrian Civil War Victims Receiving Medical Care in Israel: Humanity in a War Torn Region
	Elizabeth Hardister	Hurricane Forecasting and Healthcare Facility Evacuations
	Abby Tyre	Health Care Policy Evaluation: A Case Study Examination of Workplace Wellness
Room C	**Santana Mowbray**	The Effect of Race and Household Structure on Adolescent Alcohol Use
	Elizabeth Wilkes	Reviving Our Roots: Reconnecting Teens to Agriculture
	Emily Maloney, Nneka Ewulonu, Mallory Harris	Reducing Teen Pregnancy: The Case for Comprehensive Sex Education in Georgia
Room D	**Keller Sheppard**	Mitigating the Spatial Mismatch of Social Service Provision and Demand: The Potential of Faith-Based Facilities
	Olivia Stockert	Understanding and Preserving the Practice of Medicinal Plant Cultivation and Use in San Luis, Costa Rica
	Rachael Hart	Investigating Resting State Oscillatory Dynamics Associated with Schizophrenia and High and Low Cognitive Control
Room G	**Scott Smith**	A GDOT Case Study for the Beneficial Use of HVFA in Concrete Pavements

	Delmaries Gonzalez	Development of a Lightweight Weeding Robot
	Thomas McBrearty, Daniel Sanchez, Andrew Angoyar, Carson Aft	Algorithmic Forecasting through Big Data Analytics
Room H	**Jacob Kennedy**	Highly Mobile Kenyan Runners: Transnationalism through Sport
	Morgan Green	Field Test Significance in Adolescents with Chronic Ankle Instability
	Cristian Escalera	Comparison of Spinal Motions Used during Running to Their Spinal Flexibility

Oral Session III: 1:25-2:15 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Angel Chen**	Pollen Competition
	Hiral Patel	Understanding Floral Trait Evolution in Wild Sunflowers
	Benjamin Miller	Evolution of Root System Morphology and Nitrogen Uptake in Genus *Helianthus*
Room B	**Christine Kil**	Alleviating Inequities in Georgia's Public School Funding
	Kathryn Mauldin	Changing Cones: Students' Images of a Dynamic Situation
	Rahul Shah	Promoting Success for English Learners: Dual-Language Immersion in Georgia
Room C	**Melissa DeVelvis**	The Importance of Personality and Emotion in Women's Support for Georgia's Secession, 1860-1861
	Caroline Jackson	The Strategy of the Early British Feminist Movement: Emily Davies and Feminist Networks, 1865-1905
	Brett Bennett	The Forgotten Radical: Southern Women and the New Left Student Protests of the 1960s
Room D	**Samantha Harris**	Chief Executive Officers' Personality Characteristics and How These Characteristics Affect Marketing in Their Company

	Anne Chen	Female Labor Force Participation and Wages: What Has Changed in the Last 30 Years?
	Lyndon Lee	Change the Channel: Can Firms Influence Consumer Channel Choice through Marketing Contacts?
Room G	**Tyler Stollman, Charlotte Goldman, Kelsie Flanigan**	The Influence of Caregiver Emotional Functioning on Perceived Barriers and Adherence in Adolescent Solid Organ Transplant Patients
	Dionnet Bhatti	Acute Intra-vmPFC Injections of Galanin Reduce Expression of Conditioned Contextual Threat in Rats
	Joseph Coppiano	Age Related Effects on Brain Activation during Cognitive Control Tasks in Subjects with Schizophrenia
Room H	**Kim Nguyen**	Giving Up Appointment Television: How Millennials Are Changing What It Means to Watch Television
	Haley Vann	Visual Brand Identity on Pinterest
	Sonja Petrovic	Spoken Word Activism in the Age of Social Media

Oral Session IV: 2:30-3:20 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Piyush Joshi**	Integrating of Human Neural Progenitor Cells into a Developing Chicken Embryo for a Toxicology Model
	Elizabeth Wilkins, Catherine Callaway	Development of a Chimeric Chick Neural Tube Injury Model incorporating 3D, mESC-Derived Neural Aggregates
	Lindsey Taylor	The Effects of Interval versus Continuous Conditioning on Physiological and Kinematic Parameters of Equine Fitness
Room B	**Joan Han**	The Effects of Size on Development Time and Fecundity in *D. subquinaria*
	Sora Park	Using the Chemical Reporter Strategy to Analyze Glycoproteins in Pompe Disease
	Lauren Dennison	Extracellular Vesicle Dependent Transfer of a Virulence Factor Confers Human Infectivity to *Trypanosoma brucei brucei*

Room C	**Hannah Weiss**	Does Georgia's Voter Identification Law Disproportionately Affect African American Voter Turnout in Georgia?
	Kasey O'Brien	The Effects of Incumbent and Challenger Campaign Spending on Election Results
	Aaron Conley	The Politicization of Soccer in Brazil, and the Effect of the 2014 FIFA World Cup on Brazilian Politics
Room D	**Samuel Baxter**	Progression of Lithium Ion Batteries
	Heather Huynh	Increasing Adoption of an Internet Standard: Internet Protocol Version 6
	Andrew Martin, Paul Cray	Expanding Polymer Usage for 3D Printing in Tissue Engineering
Room G	**Benjamin Landes**	Financial Literacy in College Students
	Victoria Glover	Examining Perceptions and Expectations of African American Faculty and Students
	Jillian Maloney, Cara Smith, Mackin D'Amico	Perception of Student-Athletes on UGA's Campus
Room H	**Audrey Wright**	Investigating Interest in Ingesting Insects
	Johnathan Mayfield	The Effects of TnAV-2a on the Complex Interactions between the Parasitoid *Microplitis demolitor* and Various Lepidopteran Species
	Daniel Skowronski	Profiling the Spatiotemporal Regulation of DNA Methylation in a Social Insect

Awards and Keynote Session: 3:30-4:30 p.m.
Athena Room E

Welcome and Introductions	Dr. David S. Williams, Associate Provost and Director of Honors and CURO
Remarks	UGA President Jere W. Morehead
Introduction to Awards	Dr. Martin Rogers, Associate Director of CURO & Honors
CURO Research Mentoring Awards	Dr. David C. Lee, Vice President for Research

Program: Monday, March, 30, 2015

2015 Symposium Best Paper Awards	Dr. Rahul Shrivastav, Vice President for Instruction Mrs. Meredith Gurley Johnson, Executive Director, UGA Alumni Association
UGA Libraries' Research Awards	Mrs. Caroline Barratt, Librarian, UGA Libraries
Keynote Address	Dr. Sonia Altizer, Associate Dean of Academic Affairs & UGA Athletic Association Professor of Ecology, "Infectious Diseases on a Changing Planet: How Ecology Drives Epidemics"
Closing Comments	Dr. David S. Williams, Associate Provost and Director of Honors and CURO

Poster Session and Reception: 4:30-6:30 p.m.
Sponsored by the Office of the President
Grand Hall South & Atrium (downstairs – use the escalator in the lobby)

Poster # 1	**Carson De Mille**	The Effects of Dietary Wheat Gluten on Swine and Poultry Growth Performance
Poster # 2	**Mary Mehegan**	Concussive Traumatic Brain Injury Therapy Using iPSC-NSCs in a Porcine Model
Poster # 3	**Nicole Bisel**	The Role of Chondroitin Sulfate Glycosaminoglycans in Glioma Cell Progression
Poster # 4	**Hannah Mason**	Elucidating the Functional Role of Chondroitin Sulfate Proteoglycans in the Extracellular Matrix for Use in Rationally Designed Glycomaterials
Poster # 5	**Karishma Sriram**	Bone Fracture Putty: A Combined Stem Cells and Lentiviral Approach
Poster # 6	**Courtni Young**	The Effect of Anesthetic Variables on Patient Outcome
Poster # 7	**Katherine Hogan**	Investigating Heat Treatment of Serum and Plasma Samples as a Means to Improve the Detection Sensitivity of Heartworm Diagnosis in Dogs
Poster # 8	**Susan Jones**	PCR Detection of SRY Gene of Male Dog Mesenchymal Stem Cells in Female Dog Brains with Acute Ischemic Stroke
Poster # 9	**Nina Navalkar**	Investigating the Influence of Rac1 and Rho Family GTPases in Hair Follicle Biology
Poster # 10	**Eric Malaney**	Mammary Gland Specific Deletion of Rac1 on MMTV-

Poster # 11	**Ijeoma Okoye**	Examining the Digestibility of Methionine in Poultry
Poster # 12	**Christian Kim**	Identifying Virulence Genes Associated with Emergent *Avibacterium paragallinarum* Isolates Associated with Acute Endocarditis in Chickens Using a Bioinformatic Approach
Poster # 13	**Melissa Jennings**	Biosynthesis of Base J
Poster # 14	**Megha Kalia**	Mechanism of Developmental Regulation of Base J Synthesis in *Trypanosoma brucei*
Poster # 15	**Brian Windle**	Characterization of the Inositol Hexakisphosphate Kinase (IP6K) of *Trypanosoma brucei*
Poster # 16	**Stacey Ikebudu**	Upregulation of Transferrin Receptor in *Trypanosoma brucei*
Poster # 17	**Bryan Aguanta**	Subcellular Localization of a Regulator of Transferrin Endocytosis in *Trypanosoma brucei*
Poster # 18	**Nathan Howell**	Apicoplast Function in *Plasmodium falciparum*
Poster # 19	**Brandon Sims**	The Role of the Chaperone-Protein Interactions in Driving Protein Trafficking in the Malaria Parasite
Poster # 20	**Omar Martinez-Uribe**	Effects of Tempol, a Superoxide Dismutase Mimetic, in Alleviating *Plasmodium chabaudi* Oxidative Stress during Pregnancy
Poster # 21	**Zil Ali**	Effect of Tumor Necrosis Factor on Placental Malaria in B6 and TNF Receptor Knockout Mice
Poster # 22	**Ha Truong**	The Effects of TNFR1 and TNFR2 on Low Birth Weight as Seen in Malaria-Infected Mice Models
Poster # 23	**Kerryn Roome**	Fetal Outcome of Pregnant C57BL/6 Mice Infected Late Pregnancy with 10^3 *Plasmodium chabaudi chabaudi* AS
Poster # 24	**Caleb Studstill**	Cryptosporidiosis: New Methods for Combating an Important Disease
Poster # 25	**Jennifer Hardister**	Localization of Rv3351c Protein in *Mycobacterium smegmatis* and BCG
Poster # 26	**Ashitha Rajeurs**	Surveying *Mycobacterium tuberculosis* Gene Function by Complementation

Poster # 27	**Jaclyn Speer**	Development of an Improved Tuberculosis Vaccine
Poster # 28	**Preston Samowitz**	Evaluation of Novel Antiviral Drug NSC95397 for Treatment of Swine Influenza Infections in Pig Cells
Poster # 29	**Michael Cheng**	*S. cerevisiae* as a Model System for the Oligomerization and Aggregation of Aβ Peptides using Cup1p as a Reporter
Poster # 30	**Jesse Hu**	Design of Novel Reporters for Monitoring CaaX Proteolysis
Poster # 31	**Colby Samuelson-Ruiz**	Functional Consequences of Different CAAX Motifs
Poster # 32	**Sarah Evans**	Effect of O-GlcNAc Expression on Cancer Stem Cells and the Role of LGR6
Poster # 33	**Anish Narayanan**	Analysis of Cancer Mutations in Protein Kinases using Semantic Web Technologies
Poster # 34	**Samuel Kennedy**	Nano Formulation of Platin-A and Associated Inflammation
Poster # 35	**Nivita Sharma**	Formation of Mitochondria-Targeted Blood Brain Barrier Penetrating Biodegradable Nanoparticles for Stroke Treatment
Poster # 36	**Sheela Sheth**	Role of Glypican-1 in Prostate Cancer Cell Growth
Poster # 37	**Maria Orlando**	Analysis of the Effects of High-Fat and Low-Fat Diets on Blood Lipid Profiles
Poster # 38	**Mugdha Joshi**	Role of RGS10 in Regulating Neuroinflammation in Microglia
Poster # 39	**Seema Mustafa**	Carbohydrate T cell Recognition and Presentation
Poster # 40	**Hammad Khalid**	O-Linked Glycosylation Patterns at the Interface of Cervical Mucins and HIV Infection
Poster # 41	**Leah Caplan**	Genetic Interactions between Pigmentation Pathways and Protein Glycosylation
Poster # 42	**Rachel Vecchione**	Analysis of Heparan Sulfate Fragments by NMR Spectroscopy
Poster # 43	**Anoosh Bahraini**	Locating a Suppressor Gene for the LF4 Protein

Poster # 44	**Pei-Ying Chang**	Ultrastructural Change in the Mitochondria of *Euglena gracilis* Grown in Progressively Anaerobic Conditions
Poster # 45	**Jeffery Lanier**	Identification of the Mechanism for Ciliary Gliding in Heterotrophic Euglenids
Poster # 46	**Spencer Robinson**	Regulation of Mitochondrial Dynamics in *C. elegans*
Poster # 47	**Linda Egbosiuba**	Purification of Endopolygalacturonase from *Aspergillus niger*
Poster # 48	**Heather Steckenrider**	The Effects of a Fucosyltransferase 3 (FUT3) Gene Knockout in *Arabidopsis thaliana*
Poster # 49	**Fatai Olorunsola**	Investigating the Cell Walls of *Arabidopsis thaliana* Organs using Screenings with Glycan-directed Monoclonal Antibodies and Electron Microscopy
Poster # 50	**Chederli Belongilot**	Investigating Regulation of Germline Stem Cell Division Frequency in *Drosophila melanogaster*
Poster # 51	**Kip Lacy**	Factors Influencing Gut Microbial Community Structure in Mosquitoes
Poster # 52	**Maha Khan**	The Impact of Sugar during Larval Development on Growth Rate, Energy Stores, and Behavior
Poster # 53	**Kathryn Clark**	Introgression of a *Wolbachia* Infection into a Non-Native Host
Poster # 54	**Randall English**	Male Mate Choice between Sympatric and Allopatric Populations of *Drosophila subquinaria* and *Drosophila recens*
Poster # 55	**Sarah Cunningham**	Quantitative Modeling of Circadian Rhythms
Poster # 56	**Romik Srivastava**	Retinal Development with IFT122
Poster # 57	**Kaley Desher**	Stresses Induce Alternate Growth Phenotype in *K. lactis* Yeast Cells
Poster # 58	**Patrick Griffin**	Natural Epigenetic Variation of SVP Results in Acceleration of the Floral Transition in *Arabidopsis thaliana*
Poster # 59	**Kitra Cates**	In-Vitro DNA-Protein Interaction Analyses of *Glycine max* Transcription Factors

Poster # 60	**Amy Hodges**	The Role of Kinesins in Meiotic Spindle Development in Zea Mays
Poster # 61	**Alison McWhorter Anderson**	Examination of Localization of *Mycoplasma pneumoniae* in relation to Tethered Mucins MUC1 and MUC4
Poster # 62	**Chetan Hebbale**	An Overexpression Screen to Determine How *Legionella pneumophila* Effector Protein LegC7 Disrupts Class C Tethering Complex Formation
Poster # 63	**Stephanie Duff**	The Effect of Yopt2 and Ssae Proteins in Wasp Development of Aphids
Poster # 64	**Scott Schaffer**	Understanding the Role of *Helicobacter pylori acxABC* in an *Escherichia coli* Model System
Poster # 65	**Selin Odman**	Transcriptional Interference and Regulation of the Hyb Hydrogenase Operon of *Salmonella*
Poster # 66	**Anquilla Deleveaux**	Analysis of the Physiological Role of a Bacterial RNA Repair System in *Salmonella*
Poster # 67	**Justin Kimsey**	A Synthetic Lethal Mutant Screen in *Salmonella* Typhimurium to Identify Genes whose Products Cooperate with RNA Ligase, RtcB, in RNA Repair
Poster # 68	**Leah Brown**	Lignin-Modifying Enzymes in Termite Digestive Tract as Potential Biological Pretreatment Component in Cellulosic Ethanol Production
Poster # 69	**Vedika Rajasekaran**	Validation of CRISPR/Cas9 for Genome Editing of Fktn in C2C12 Mouse Myoblast Cell Lines
Poster # 70	**Noreen Syed**	Assembly of a Dual-Selection Cassette for Gene-Specific Targeting by CRISPR/Cas9 to Recapitulate Dystroglycanopathies
Poster # 71	**Claudia Alvarado**	Structural Studies of Non-Coding RNAs
Poster # 72	**Hanna Nune**	Cloning and Constructing of a Complete RNA Polymerase from *Acinetobacter*
Poster # 73	**Paige Lane**	Drug Discovery and Structural Studies of an Essential Transcriptional Regulator, ACIAD0746
Poster # 74	**Kathryn Moore**	Cloning, Expression and Purification of MexT and AmpR from *Pseudomonas aeruginosa*

Poster # 75	**Peter Liaw**	Design of a 1,5-Substituted Triazolyl-Bridged Peptide to Inhibit EGFR Activation
Poster # 76	**Sterling Tran**	The Src Homology 3 Binding Domain is required for Lysophosphatidic Acid 3 Receptor-Mediated Cellular Viability in Melanoma Cells
Poster # 77	**Ian Dunne**	Use of Pre-Pen Skin Testing as an Antimicrobial Stewardship Initiative in a Not-for-Profit Community Health System
Poster # 78	**Robert Barnes**	Engineering *E. coli* Strains for the Increased Production of Glucosylated Organic Compounds
Poster # 79	**Charles Van Brackle**	Using Model-Based Analysis to Develop a More Robust Measure of Flow-Mediated Dilation
Poster # 80	**Kathryn Youngblood**	Estuarine Flow Rates in Coastal Georgia
Poster # 81	**Bhaskar Lokanathan**	Electronic and Photonic Modeling of GaN/InGaN Multiple Quantum Well Light Emitting Diodes
Poster # 82	**Grace Power**	Controlling Contamination of Algal Grazers Using Nitrogen Sources
Poster # 83	**Emily Wall**	Using Artificial Neural Networks to Predict Solar Radiation in Georgia
Poster # 84	**Thomas McBrearty, Daniel Sanchez, Andrew Angoyar, Carson Aft**	Algorithmic Forecasting through Big Data Analytics
Poster # 85	**Andrew Kane, Samantha Cao**	A New Analysis Strategy for Designs with Complex Aliasing
Poster # 86	**Zack Stokes**	Design and Analysis of Reactive Red Dye 120 Absorption by Nanocellulose Gel
Poster # 87	**Nolan Williamson**	Simultaneous Vibration Isolation and Energy Harvesting
Poster # 88	**Bryan Grommersch**	Carbon Encapsulated and Magnesiothermically Reduced Diatoms as a Lithium-Ion Battery Anode
Poster # 89	**Haley Daniel**	Energy Systems Module
Poster # 90	**Mehreen Sultana**	Capabilities of Detecting Atmospheric Cosmic Ray Induced Muon Showers by the NOvA Far Detector

Poster # 91	**Zachary Chilton**	Automated Stellar Classification
Poster # 92	**James White**	The Relationship between CH, CO, and Dust in MBM 12
Poster # 93	**John Dupuy**	Atomic Hydrogen Sticking on Amorphous Water-Ice
Poster # 94	**Elizabeth McMillan**	The Photodissociation of SH+ in the Interstellar Medium
Poster # 95	**Katherine Zarada**	Time to Extinction in Deteriorating Environments
Poster # 96	**Mary Baxter**	Phylogenetic Investigation of Metal Hyperaccumulation Evolution in Wild Sunflowers
Poster # 97	**Allison Koch**	Clearing Natural Forest Lowers Decomposition Rates and Results in Less Diverse Macrofauna and Mesofauna Communities
Poster # 98	**Stuart Sims**	Will Butterfly Gardens Take Off? Butterfly Dynamics and Recruitment in Response to Planted Gardens

Program: Tuesday, March, 31, 2015

Oral Session V: 9:30-10:45 a.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Jiacheng Chen**	Paper Art in Expanded Forms
	Lazarus Roth	Reflections on the City: Urban Space and Ideology
	Connor Hamm	Thomas Cole's Architectonic America
Room B	**Carson Aft**	The Impact of Monsoon Severity on Southeast Asian Bond Markets
	Kirstie Hostetter	Measuring Willingness to Pay for Sea Level Rise in Coastal Communities of Georgia
	Blake Mathews	Financial Stress among College Students
	Thomas McBrearty	The Impact of Severe Weather Events on Market Returns
Room C	**Mehreen Sultana**	Capabilities of Detecting Atmospheric Cosmic Ray Induced Muon Showers by the NOvA Far Detector
	Lewis Schendowich	Microwave-Assisted and Benzotriazole-Mediated Synthesis of 1,2,4-Triazole-Based Peptidomimetics
	Logan Morrison	High Dynamic Range Imaging For X-ray Image Acquisition
	Lauren Tolbert	Pretreatment of Cellulose Powder and Nanocellulose Gel Production
Room D	**William Robinson**	Resolving Offensive and Defensive Realism
	Matthew Oldham	Evaluating the United States Counterterrorism Strategy Regarding Violent Extremism
	Thomas Trahan	Fostering Peaceful Nuclear Infrastructure Sharing in Southeast Asia
	Paola Rivera	State-Driven Development Initiatives under Kenya's Vision 2030 and Perceptions by Project-Affected Persons in the Northern Rangelands
Room G	**Babajide Oluwadare**	Analysis of P1 Function in *Mycoplasma pneumoniae* Adherence and Gliding
	Tyler Simmonds	The Complete Genome of *Diachasmimorpha longicaudata* rhabdovirus: A Symbiont of Parasitoid Wasps

	Alexander Hedaya	Superparasitism as a Strategy to Overcome Resistance in an Aphid-Parasitoid Interaction
	Tiffany Jenkinson	Tissue Factor-Altered Mice Show Upregulated Pro-Inflammatory Cytokine Gene Expression in Experimental Cerebral Malaria
Room H	**Allison Fialkowski**	Evaluating Pre-Medical Students' Experience with/Understanding of Autism Spectrum Disorders
	Zoheb Sulaiman	Investigating Student Satisfaction and Social Ties in a Biology Research Network
	Mitra Kumareswaran	Addressing the Lack of Access to Public Assistance for Adults with Autism
	Jesse Cann	A Look at the Relevance of Sociology Concepts, Theories, and Methods through the Lens of Health Professionals
Room I	**Amanda Seamon**	Incidence of Anesthesia-Related Fatality in Birds
	Kayla Hargrove	Necessity of Universal Pre-Operative Blood Work in Otherwise Healthy Canines
	Alyssa Wuellner, Kayla Hargrove	Prevalence of Pain in Dogs with Cancer
	Jordyn Whitfield	Quantifying Replicating and Latent CFPHV in Symptomatic and Asymptomatic Infected Turtles
Room J	**Elizabeth Ridgeway**	Nostalgia Inverted: The Golden Age Motif in Strepsiades' Pre-Dramatic History
	Trace Calloway	*The Kalevala* as Tolkien's Inspiration
	Meredith Paker	Theatrical Imagery in Nabokov's *Invitation to a Beheading*

Oral Session VI: 11:00 a.m.-12:15 p.m.
Athena Breakout Rooms A, B, C, D, G

Room A	**Pomi Yun**	The Effects of Preferred Listening on Anxiety, Nausea, and Claustrophobia of Cancer Patients during Radiation Treatment
	Caroline Ray	Effect of Music on People with Developmental Disabilities during Physical Activity

	Taj Shorter	Asymmetric Functional Movement Screen Scores and Injury Occurrence in Collegiate Female Athletes
Room B	**Giselle Fernandez**	Insects in Shakespeare's Works
	Hannah Klevesahl	*Oklahoma!*: The Building of the Dream Ballet in Two Different Mediums
	Jennifer Milley	Practical Grant Writing
Room C	**Laura Pontari**	Closing the Achievement Gap: Elementary Second Language Education in Philadelphia Schools
	Seyi Amosu	Overview of Interdisciplinary Clinics and Community Agencies
	Carver Goodhue	Policy Solutions to Cycles of Poverty and Food Insecurity in Athens, GA
	Bailey Palmer, Mallika Madhusudan	Reducing the Disparity between Federal Sentencing of Crack and Powder Cocaine
Room D	**Joy Maduka**	Type of Infant Feeding, Weight, and Body Composition Changes in Early Infancy
	Mallory Little	Disruption of Signaling at Oocyte MTOCs Leads to Meiotic Division Errors and Embryonic Loss
	Matthew Weber	High-Fat Diet Consumption and Behavioral Dysfunction: What Are the Roles of Maternal vs. Post-Weaning High-Fat Intakes?
	Meredith Paker	The Welfare Effects of Off-Label Prescriptions
Room G	**Charles Bond**	Review of the Potential for Coproducing Bioplastics and Biofuels from the *Spirulina*
	Rachel Usher	Response of Stream Biofilms across an Urbanization Gradient

Oral Session VII: 12:30-1:45 p.m.
Athena Breakout Rooms A, B, C, D

Room A	**Erin Hollander**	Fighting Pain with Pills: Overprescribing and the Opioid Addiction Epidemic
	Amber Davidson	Exploring Resistance to Change through Concern for Diversity

	Davis Parker	Rolling the Dice: The Economic Impact of Casinos
	Anthony Reyna	College Students' Credit Experience and Behavior
Room B	**Kristen Farley**	*Escherichia coli* Uses an IlvA/TrpD-Dependent Mechanism for Thiamine Synthesis
	Leah Brown	Lignin-Modifying Enzymes in Termite Digestive Tract as Potential Biological Pretreatment Component in Cellulosic Ethanol Production
	Fahim Thawer	Role of tRNA Nucleotidyl Transferase and 3' Exonucleases in the Biogenesis of Functional tRNAs in *Escherichia coli*
	Amy Webster	Molecular and Genetic Analysis of the Ab10 Meiotic Drive Haplotype in Maize and Teosinte
Room C	**Morgan Walker**	The Prevalence of Hemoparasites in Seabird Populations on Middleton Island, Alaska
	Alyssa Wuellner	The Severity of Cases Admitted into a Small Animal Hospital and the Phase of the Full Moon
	Emily Vermillion	The Mini-FLOTAC: An Analysis of a Novel Fecal Egg Counting Technique
	Shibo Xu	Effects of Bisphenol A on Macrophages when Controlled with Genistein
Room D	**Sarah Perry**	Differential Consumption of *Eurypanopeus depressus* When Infected by *Loxothylacus panopaei*
	David Stoker	Leaf Litter Quality, Not Local Adaptation of Macroinvertebrate Communities, Drives Leaf Decomposition in Forested Headwater Streams
	Kaleigh Davis	Sponge Colonization across Varying Salinity Regimes

Oral Session VIII: 2:00-3:15 p.m.
Athena Breakout Rooms A, B, C, D, G, H

Room A	**Tifara Brown**	Something to Pass Down: Black Family Stories and the Legacy of Slavery and Jim Crow
	Lucille Reynolds	The Evolution of Quail Hunting Attire in South Georgia and Northern Florida

	Laura Nelson	"Please Excuse Me as I Am in Need:" Bondage and Freedom in Civil War-Era Athens
	Connor Hamm	Towards a Parametric Architecture?
Room B	**Kaitlyn Beck**	The Figure of Constantine the Great in Cynewulf's "Elene"
	Kelsey Lowrey	The Presentation of Victimhood and Virtue in the Holocaust-Focused Works of George Tabori
	Manisha Banga	On Sexuality in Female Ancient Greek Monsters
Room C	**Jason Moraczewski**	Assessment of Proteomic and Glycomic Profiling of Medaka (*Oryzias latipes*) to further the Understanding of the Physiological Response to Low Level Ionizing Radiation
	Erin Hollander	Cas Protein Function in Adaptation of *Streptococcus thermophilus* Type II-A CRISPR-Cas System
	Viral Patel	Expression and Purification of PRMT1 and Mutant Variants
	Justin Dumrongkulraksa	Identification of CRISPR Adaptation Complexes and Associated Nucleic Acids in *Pyrococcus furiosus*
Room D	**Stefania Barzeva**	The Physiological Functioning of Children with Anxiety: A Review of the Literature
	Vanessa Aguilera	Preschoolers' Emotion Knowledge: Relationships to Parental Socialization and Child Behavior Problems
	Megan Kelley	The Effects of Prior Knowledge of Trial Type on Saccade Task Behavior
	Meredith Osborne	The Effects of Lutein and Zeaxanthin on Cognitive Function and Neural Efficiency in Older Adults with and without Cognitive Impairment
Room G	**Holly Boggs**	An Analysis of International Media Coverage of North Korean Nuclear Events
	Margaret Touchton	Truth & Testimony
	Rachel Surminsky	The Evolution of Presidential Unilateral Powers and Congressional Reaction Mechanisms

	Sarah Hedges	Women's Participation in Non-State Militaries Founded on a Secular or Religious Ideology: The Case of Chechnya and Dagestan, Hamas, The PKK
Room H	**Aneek James**	Embedded Bi-Directional FBG Curvature Sensor
	Frederick Hohman	3D Printing the Trefoil Knot and its Pages
	Jackson Hopper	Abundancy and Multiply Perfect Numbers

Oral Session IX: 3:30-4:45 p.m.
Athena Breakout Rooms A, B, C, D, G, H, I, J

Room A	**Kristin Henry**	Something Old, Something New? A Postfeminist Analysis of the Myth of the "Big Day"
	Aashka Dave	Participatory Media: Self-Image and Perception in Women
	Molly Dodd	Hollywood's Risqué Years: Female Body Exposure in Pre-Code Film
Room B	**Caroline Coleman**	Behavioral Testing for Cognitive Deficits in Traumatic Brain Injury Piglets
	Kathryn Sellman	Behavioral Testing on Piglets to Assess Cognitive Deficits of a Traumatic Brain Injury
	Courtney Haviland	Effectiveness in Curing Existing Intramammary Infections and Preventing New Cases in Bred Holstein Heifers
	Onyinyechi Ochiobi	Ryanodine Channel Protein in Insects: A Novel Pesticide Target
Room C	**Christopher Morgan, Kyle Ledesma, Rebekah Trotti, Parker Thomas**	The Effects of Travel on Team-Based Performance
	Mckenzie Benson, Steven Pugh, Rebecca Gaines, Mary Catherine Kelley	The Impact of Rest and Game Location on NBA Team Performance
	Madison Krieger	The Potential Protective Effects of Anthocyanins on Liver Insulin Signaling

	Shubam Sharma	Body Mass Index and Performance-Based Functional Independence in Older Adults
Room D	**Erin Todd**	American Film's Portrayal of CEOs: An Increase in Complex and Confusing Personalities from the 1930s
	Shelby Reilly, Adam Lowe	The Relationship between CEO Risk-Taking Behavior and Employee Attraction and Retention
	Dennis Hardigree, Alex Cole	Correlation between Narcissism and Turnover within the Workplace
Room G	**Catherine Klein**	Inefficiencies of Water Use in Animal Agriculture
	Shreya Ganeshan	Cutting Commercial Energy Costs in Atlanta – One LED Retrofit at a Time
	Mathieu Trunnell	Modeling a Baseline of Forest Energetics: A Method for the Evaluation of Sustainable Practices and Technologies
	Jonah Driggers	Cutting Carbon in the Empire State of the South: A Policy Proposition for Putting Georgia ahead of the Curve
Room H	**Tyler Daugherty**	Spintronics in π-Conjugated Semiconductors: Investigating MEHPPV OLED Magneto-Property Temperature Dependence
	John Stroud	Properties of the Monkey Saddle
	Timur Cetindag	Asteroseismological Age Dating Utilizing a Bayesian Monte-Carlo Search
	Michael Biddle	Continuing Investigation of Electronically Excited States in Indole: Transitioning from Gaseous to Condensed Phase Studies
Room I	**Megan Cannon**	Neural Correlates of Schizotypal Traits in Healthy Participants with High and Low Cognitive Control
	Megan Murphy	Neural White Matter Alterations in Schizophrenia
	Nathan Farr	The Effects of Ethinylestradiol and Levonorgestrel on the Central Nervous System and Behavior in Rats
	Kharine Jean	The Predictive Power of Self-Reported Computer Usage on Processing Speed and Reasoning Scores

Room J	**Yimeng Shi**	An Investigation of Anaerobic Methane Oxidation by Consortia of Methanotrophic Archaea and Bacterial Partners Using Process-Based Modeling
	Malcolm Barnard	Utilization of *Spirogyra grevilleana* as a Method of Algal Filtration for Reduction of Limnetic Nutrient and *Escherichia coli* Levels
	Jack Owen	Using Environmental DNA to Detect and Track Dispersal of the Island Apple Snail Invasion in Lake Seminole, Georgia
	Rachel Ehlinger	Technique of Soil Fractionation for AMS Radiocarbon Analyses

Effect of Carbohydrate and Organic Acids on Anti-*Salmonella* Activity of Cecal Cultures from Broiler Chickens

Belema Abere, CURO Research Assistant
Dr. Mark Harrison, Food Science & Technology, College of Agricultural & Environmental Sciences

This project will examine the ability of undefined cecal cultures from broiler chickens to metabolize glucose to produce substances that inhibit growth of the foodborne pathogen, *Salmonella* Typhimurium. Ceca will be collected from a local commercial poultry processing facility. Cecal cultures will be prepared by inoculating bacterial media with cecal contents and incubating the inoculated media. Test media will be prepared by supplementing a basal medium with various concentrations of glucose. Supplemented test media will be inoculated with 1) cecal culture 2) a nalidixic acid resistant strain of *Salmonella* Typhimurium, or 3) cecal culture and nalidixic acid resistant strain of *Salmonella* Typhimurium. Inoculated media will be incubated for 14 days and media will be sampled in 7 day intervals to enumerate total cecal bacteria and *Salmonella* Typhimurium. Findings from the study will provide information on substrates that can be used by cultures of probiotic bacteria to inhibit colonization of intestinal tract of poultry by *Salmonella* Typhimurium.

The Impact of Monsoon Severity on Southeast Asian Bond Markets

Carson Aft, CURO Research Assistant
Dr. Jeff Netter, Banking & Finance, Terry College of Business

Considering how essential the issuance of bonds can be to the functionality of governments, it is important to understand the deep relationship that they have with the exogenous. Beyond market conditions, clearly many things can have deep impacts. As markets become more quantified and global, it is possible to observe and isolate these external effects. It is from this, that the most natural question arises: How much difference does the weather make? It is obviously too ambitious to aim the microscope at the entire world, but specificity lends itself to clearer results. The more specific question becomes: Does monsoon severity impact local bond markets? This is the question to answer. The significance is that it helps form an understanding of how financial markets, a very abstract construction, interact with something as concrete as the weather. A better understanding leads to more accurate valuation of international bonds, which is important on both national and international scales. It is also appropriate to test whether different timescales impact how strongly the weather changes the markets. For the analysis of daily data, a GARCH model is implemented, looking at daily returns as the best quantifier of bond markets. As for monthly data, the better analysis takes place by observing realized volatility of bonds as a function of both weather deviations as well as recent market volatility. Preliminary data analysis as well as the literature review point in the direction of weather having a significant impact on bond markets in many Southeast Asian countries.

Subcellular Localization of a Regulator of Transferrin Endocytosis in *Trypanosoma brucei*

Bryan Aguanta
Dr. Kojo Mensa-Wilmot, Cellular Biology, Franklin College of Arts & Sciences

Human African Trypanosomiasis (HAT), also known as sleeping sickness, is a neglected disease endemic to rural communities in Sub-Saharan Africa, and is caused by the protozoan parasite *Trypanosoma brucei*. Because all current treatment methods for HAT are difficult to administer and carry a high risk of adverse reactions in patients, there is a need for the characterization of cellular signaling pathways within the parasite, as this may

highlight new targets for drug discovery efforts. *T. brucei* proliferates in the bloodstream of a mammalian host and takes up host transferrin as an essential source of iron via endocytosis. Preliminary findings suggest that the enzyme glycogen synthase kinase-3, beta isoform (GSK3β), is an essential regulator of transferrin endocytosis in *T. brucei*. However, its localization within the cell has yet to be defined. We hypothesize that GSK3β localizes to organelles in the trypanosome endocytic pathway, such as the endocytic vesicles and endosomes. To evaluate this hypothesis, we will use endogenous protein tagging constructs, followed by immunofluorescence assays, which will allow us to visualize the distribution of GSK3β in relation to proteins in known cellular structures. We will also use protein tags to identify other proteins with which GSK3β may interact. In doing this, my goal is to aid future drug discovery endeavors by defining the localization and protein interaction network of an important signal transduction component in the trypanosome.

Preschoolers' Emotion Knowledge: Relationships to Parental Socialization and Child Behavior Problems

Vanessa Aguilera
Dr. Anne Shaffer, Psychology, Franklin College of Arts & Sciences

Understanding causes of emotions is a crucial part of social development (Seidenfeld et al., 2014). Supportive parental responses to children's emotions predict better child emotional understanding (Denham et al., 1994). Poor emotion understanding, in turn, is associated with increased internalizing problems and emotion regulation difficulties in school-aged children (Fine et al., 2003; Hudson & Jacques, 2014). However, research has yet to evaluate relations of child emotion knowledge to parental emotion socialization and child emotional/behavioral problems among preschoolers. We hypothesize that supportive emotion parenting is positively correlated with emotion understanding, and in turn, that accurate emotion understanding is negatively associated with child emotional/behavioral problems. The sample includes 110 mother-child dyads with children ages 3-5. Emotional knowledge was measured via a puppet task (Denham, 1990), scoring accurate and inaccurate identified causes of various emotions. Mothers reported child internalizing and externalizing behaviors (CBCL; Achenbach & Rescorla, 2000) and their own emotion socialization practices (CCNES; Fabes et al., 1990). Preliminary analyses indicate that supportive parental responses to children's emotions were associated with increased accuracy in identifying causes of fearful (r=.23, p=.04) and angry (r=.25, p=.03) emotions. Greater child internalizing problems were associated with higher *inaccurate* causes of happy emotions (r=.24, p=.04) and lower *accurate* causes of sad emotions (r=-.27, p=.02). No significant relations were found between child externalizing problems and emotion knowledge. These findings suggest that emotion knowledge is salient for internalizing, but not externalizing, child problems. Further analyses will compare groups based on child enrollment in formal preschool and other socio-demographic variables.

Effect of Tumor Necrosis Factor on Placental Malaria in B6 and TNF Receptor Knockout Mice

Zil Ali
Dr. Julie Moore, Infectious Diseases, College of Veterinary Medicine

Malaria is a deadly infectious disease that kills over one million people per year, especially pregnant women and children. Placental malaria has been linked with poor pregnancy outcomes such as low birth weight, stillbirth, and abortion. Unfortunately, there is insufficient knowledge about malaria-associated unsuccessful pregnancies. We believe that a key player necessary for

understanding this is tumor necrosis factor (TNF), a pro-inflammatory cytokine. TNF stimulates cells through two surface receptors, TNFR1 and TNFR2. The effects of TNF through these receptors are cell death and cell survival, respectively. We hypothesize that mice lacking TNFR1 will be more likely to overcome a poor pregnancy compared to TNFR2 knockout and B6 (CF7BL/6) mice. TNFR2 knockout mice are expected to have more unsuccessful pregnancies. Each strain of mice will be divided into infected pregnant, infected not-pregnant and uninfected pregnant mice. The mice will be injected intravenously with 1000 *Plasmodium chabaudi* AS-infected red blood cells. The weight and anemia will be assessed at baseline (day 0). On different gestation days (day 9-12), the mice will be sacrificed and the uteroplacental unit and liver will be removed. Half of the organs will be flash frozen in liquid nitrogen and half will be fixed in formalin to be processed for histology. RNA and proteins will be isolated from tissues and markers of apoptosis, necroptosis, and autophagy will be assessed by PCR and western blot. This study is ongoing but we expect it to reveal insight into our understanding of the molecular mechanisms of malaria-associated poor pregnancy outcomes.

Structural Studies of Non-Coding RNAs

Claudia Alvarado, CURO Research Assistant
Dr. Cory Momany, Pharmaceutical & Biomedical Sciences, College of Pharmacy
Dr. Liming Cai, Computer Science, Franklin College of Arts & Sciences
Dr. Russell Malmberg, Plant Biology, Franklin College of Arts & Sciences

RNA plays a central role in many biological processes. RNA can be genetic information, catalyze reactions as ribozymes, or regulate expression of macromolecules. The number of non-coding RNAs (ncRNA) is currently unknown, and only a few ncRNA 3-D structures have been obtained. Our research goal is to optimize experimental methods so that we can produce ncRNAs in large scale, crystalize them, and determine their structures. Initial studies will focus on *E.coli* sRNA families, specifically: Spot-42, GcvB, and RyhB. Methods that will be evaluated include the use of *in vivo* expression of RNA molecules engineered inside tRNA anticodon loops, co-transcription of up- and down-stream ribozymes, the use of crystallization chaperones, and the use of *E. coli* strains with reduced RNAase activities. Assembly of the production systems requires that appropriate DNA segments encoding the RNA molecules be introduced into T7 promoters/terminators and ribozymes be created using PCR amplification. The pET28 vector has been modified to introduce BspQI sites for rapid, single step cloning of sRNA. *In vivo* expression calls for T7 components and the sRNA encoding DNA to be duplicated (up to 50 copies) in tandem into a vector. sRNA interactions with Hfq, an RNA binding protein, will be studied through construction of a vector to allow for over expression and purification of Hfq. The sequences encoding GcvB have been PCR amplified. Structures obtained from crystallography will be compared to those predicted by bioinformatics approaches.

Factors Influencing Folate Status in Hispanic Women

Courtney Alvis, CURO Research Assistant, CURO Graduation Distinction
Dr. Dorothy Hausman, Foods & Nutrition, College of Family & Consumer Sciences

Folate, a water-soluble B vitamin, is essential during pregnancy to support maternal physiological changes as well as fetal growth, organ differentiation, and cell division. There is an inverse relationship between low folate status in the periconceptual period and the likelihood of having a baby with neural tube defects (NTDs). To reduce this risk, folic acid fortification of flour has been mandatory in

the US since 1998. It is recommended women capable of becoming pregnant consume 400 μg of folic acid daily from supplements, fortified foods, or both while also consuming food folate from a varied diet. Despite these measures, Hispanic women have a lower folate status and increased risk for NTD affected pregnancies when compared to African American and Non-Hispanic White women. The primary goal of my research project is the characterization of potential nutrition-related factors that have a detrimental effect on folate status in Hispanic women of child bearing age based on published reports of dietary intake and blood folate levels. In addition, I will also be analyzing preliminary diet recall data from Hispanic, African American, and Non-Hispanic White women of child bearing age from an ongoing study being conducted by my research group. I anticipate the Hispanic women will consume fewer folic acid fortified foods and have a lower total folate intake as compared to the other race/ethnic groups. This would mean that further support is needed to improve the folate status of Hispanic women such as fortification of corn masa flour, a staple in most of their diets.

Overview of Interdisciplinary Clinics and Community Agencies

Seyi Amosu
Dr. J. Maria Bermudez, Child & Family Development, College of Family & Consumer Sciences

Interdisciplinary clinics are a form of community agency that aims to provide clients with services in several related fields in one convenient location. Although several theories exist highlighting the benefits of interdisciplinary work for clients and providers, not much research has been produced in the subject area. The goal of this study is to review the nature of interdisciplinary clinics and to specifically examine client characteristics from the interdisciplinary clinic at the University of Georgia. A random sample of closed case files from the ASPIRE Clinic, located at the University of Georgia, was used to collect demographic information about the client population. The demographic variables included age, gender, race/ethnicity, relationship status, number of children, highest level of education, employment status, annual income, and session fee. Results revealed that the predominant client profile was Anglo women with some college education, varied relationship statuses, and mostly employed full-time. Results of this study add to the growing body of literature about interdisciplinary clinics and who is utilizing such clinics. Suggestions for future research are offered, as well as suggestions for outreach strategies for increasing the utilization of interdisciplinary clinic services by diverse populations.

Perceived Social Consequences of Seeking Psychological Help

Seyi Amosu
Dr. Nathan Carter, Psychology, Franklin College of Arts & Sciences

The purpose of this study is to better understand attitudes towards seeking professional psychological help by examining the influence of perceived social consequences of seeking psychological help. A set of scales was developed to measure perceived social consequences (PSC) of seeking psychological help in regard to: a) friends; b) family; and c) acquaintances. We hypothesized that individuals with a high level of perceived negative consequences from their social groups would have negative beliefs about mental illnesses as well as a high level of stigma about seeking help personally. This in turn was expected to lead to low willingness to seek help as well as low intentions to seek counseling. Results from this study provide evidence that an individual's perceived social consequences related to acquaintances have

the most impact on his/her intentions to seek out and attend therapy, in the sample of college students. Suggestions for future research are offered, as well as recommendations for outreach aimed at combating the effects of social consequences on therapy attendance on college campuses.

How Quality of Parenting Affects the Emotions and Attitudes about Hooking Up

Bryant Anthony, CURO Graduation Distinction
Dr. Leslie Gordon Simons, Sociology, Franklin College of Arts & Sciences

Hooking up is a popular phenomenon on many American college campuses. College students are aware of the phenomenon and some undergraduate students actively engage in various activities that coincide with hooking up while others choose not to participate in the hook-up culture. Past research has found that hooking up is associated with an increased use of alcohol and other drugs as well as an increased risk of experiencing sexual coercion. Both of these behavioral outcomes are associated with risky sex. Few studies, however, have examined the emotional feelings and consequences of hooking up. This paper will focus on the association between hooking up and the positive and negative emotions after hooking up. Furthermore, this study will seek to find whether these feelings vary by gender or if family and individual factors, specifically quality of parenting and attachment style, alter a person's risky sexual behavior. It is reasonable to project that students who have a secure-based attachment will be less likely to hook up in adult romantic relationships in college than students who have an insecure-based attachment. It is also reasonable to project that of those college students who do hook up will report more positive feelings if they are male or have a secure-based attachment. The results collected in this study were collected through a sample of 965 students attending the University of Georgia in the fall of 2013.

Vector Field Augmentation - Augmented Reality and Learning

Alexander Ashkeboussi, CURO Research Assistant
Dr. Kyle Johnsen, College of Engineering

Science and engineering education involves the teaching of abstract concepts of physical sciences. Courses such as 'Fluid Mechanics' rely on traditional deductive teaching methods that often result in students being unable to recall or understand these unintuitive ideas. The emergence of augmented reality and the ubiquity of high performing mobile platforms allows the development of guided, interactive learning applications. The purpose of this research is to first develop an interactive vector-field augmented system that allows 'Fluid Mechanics' students to learn principles of hydrostatics. Then, the relative understanding of the lessons by students using this inductive learning system compared to a control group will illustrate the value of augmented reality as a tool in physical sciences course education.

Effects of Physical Activity and Alcohol Consumption on Metabolic Syndrome

Jayme Astarita, CURO Research Assistant
Dr. Ellen Evans, Kinesiology, College of Education

The transition to college marks a period when many unhealthy behaviors can be developed in young adults. Unfortunately, only 22 % of college students accumulate the recommended amount of physical activity (PA). Low levels of physical activity in these emerging adults may influence health outcomes later in life. In addition to too little involvement in PA, 18-24 year olds have the highest rates of alcohol use among US adults. Metabolic Syndrome (MetS) is a clustering of

cardiovascular disease risk factors (hypertension, dyslipidemia, elevated waist circumference, impaired fasting glucose) that may be influenced by alcohol-related behaviors and PA. The prevalence of MetS for the adult population is estimated to be about 20 to 25% and continues to rise. Due to the high prevalence of alcohol consumption and reported low levels of PA in college students, the primary aims of this study are to examine the independent and interactive associations of alcohol and PA on MetS risk. Study participants (aged 18-24 yrs.) were enrolled at the University of Georgia. PA was measured objectively using the NL-1000 accelerometer (minimum 4 days, >10 hours/day). Blood markers (glucose, triglycerides, HDL) were measured using standard clinical practice following a 12-hour fast. Alcohol consumption was measured as the number of standard drinks containing alcohol consumed in the past 7 days. It is anticipated that greater alcohol consumption will be associated with an unfavorable MetS risk profile, and PA will be inversely associated with MetS risk.

Filipinos' Perceptions of the Immigration Journey to the United States

Danielle Augustine, CURO Research Assistant
Dr. Denise Clark Lewis, Child & Family Development, College of Family & Consumer Sciences

This poster addresses the influence of migration on transnational Filipino family relations. It highlights decisions influencing migration and migration experiences, perceptions, challenges, and struggles of Filipino immigrants. Data were collected through semi-structured, in-depth interviews in both Tagalog and English languages with nine Filipino immigrants. One member of the research team is fluent in both languages; all interviews conducted in Tagalog were translated into English. Data analysis was completed using ATLAS.ti 7 Qualitative Data Analysis software. Two members of the research team performed independent analyses, met to reach consensus on codes, and co-developed a codebook. Using ecological systems and life course theoretical lenses, researchers identified four major themes regarding Filipino immigrants' reasons for migrating to the United States: (1) career opportunities, (2) educational opportunities, (3) political unrest, and (4) family cohesion. Stress, exhaustion, and legal issues (e.g., obtaining visas and traveling with children), were common challenges associated with the migration process. Participants experienced culture shock and adjustment difficulties related to unrealistic expectations of life in the United States. Some of these included differences in language pronunciation, environment, weather, and securing employment. Perceptions of American lifestyle, separation from family, and mastering life skills increased stress. Regrets associated with immigration were separation from Philippine-based family and not instilling Filipino customs in children. Participants reported that having realistic expectations of the United States and open mindedness helped make the adjustment process easier. Most participants reported satisfaction with the migration journey and a positive outlook for their families' futures in the United States.

Locating a Suppressor Gene for the LF4 Protein

Anoosh Bahraini, CURO Research Assistant
Dr. Jacek Gaertig, Cellular Biology, Franklin College of Arts & Sciences

Cilia are cell projections that contain microtubules, and mediate important sensory and motile functions. The Long Flagella Protein 4 (LF4), a MAP kinase, serves as a regulator for the length of the cilia (making cilia shorter). When this gene is overexpressed in the ciliate *Tetrahymena*, the cilia shortens to

the degree where the cell can no longer swim. The phosphorylation target of LF4 is unknown and therefore the mechanism of cilia length regulation by LF4 is not understood. The goal of our experiments is to identify a suppressor gene that allows cilia to assemble despite the overproduction of LF4. We optimized a simple method that selects rare motile cells among the large non-motile population of *Tetrahymena* based on the ability of swimming cells to overcome gravity. We attempted to isolate dominant suppressors by mutagenizing a strain of *Tetrahymena*, crossing it to an LF4-overproducing strain and selecting for heterozygous progeny, but this approach did not produce the desired suppressors. Currently, we are screening for homozygous suppressors by mutagenizing an LF4-overproducing strain and producing its progeny using a self-fertilizing cross known as UniParental Cytogamy (UPC).

On Sexuality in Female Ancient Greek Monsters

Manisha Banga
Dr. Benjamin Wolkow, Classics, Franklin College of Arts & Sciences

This paper employs a literary and feminist approach in an examination of the intersections between sexuality and monstrosity in female ancient Greek monsters. The uniqueness of the female monster lies in the presence of sexuality—insofar as sexuality is synonymous with desirability—in her narrative. This results in the construction of either hypersexuality or desexualization, resulting in an unattainable or undesirable female monster. The researcher argues that the destruction of normative female sexuality, wherein female sexuality is inherently submissive, is a prevalent theme in the construction of female monsters. The first case explores hypersexual monsters and studies the Sirens along with the triad of the Empousa, Lamia, and Mormo. These sexual monsters are dangerous and unattainable because their aggressive actions attract men and ultimately result in male deaths. The second case explores desexualized monsters and studies Medousa, Scylla, and the Amazons. These three mythological entities have their feminine sexuality destroyed in various ways, resulting in desexualized and undesirable monsters. In all cases, the monsters' sexuality is unnatural and ultimately dangerous to men. By subverting the inherently submissive female sexuality, these monsters threaten patriarchal civilization and thus acquire monstrosity. This paper seeks to understand these relationships between femininity, sexuality, and monstrosity.

Utilization of *Spirogyra grevilleana* as a Method of Algal Filtration for Reduction of Limnetic Nutrient and *Escherichia coli* Levels

Malcolm Barnard, Ramsey Scholar
Dr. James Porter, Odum School of Ecology

The freshwater alga *Spirogyra grevilleana* can be used in an algal filtration system to reduce levels of *Escherichia coli,* nitrates and phosphates. Multiple samples of m3 of water were collected from a 2.32 ha lake in North Metro Atlanta, Georgia, USA and maintained under constant laboratory conditions with sixteen hours of continuous lighting on a daily basis. This water was run at a rate of m3 hr-1 continuously through the filtration devices under laboratory conditions with two concentrations of *S. grevilleana*. Samples from both trials were tested over time for *E. coli*, nitrate, phosphate, dissolved oxygen, and pH levels. At either the high or low concentration, the algal filtration devices utilizing *S. grevilleana* reduced *E. coli* by 100% with negligible deviations. In the first trial, the *S. grevilleana* significantly reduced nitrate concentrations by 30% and phosphate concentrations by 23% while maintaining dissolved oxygen and pH levels. Utilizing *S. grevilleana* in an algal filtration device could potentially provide a sustainable, flexible, and low-cost method of

E. coli reduction in freshwater lakes worldwide. Initial results indicate that the use of *S. grevilleana* in conjunction with an algal filtration device is potentially capable of creating potable water.

Engineering *E. coli* Strains for the Increased Production of Glucosylated Organic Compounds

Robert Barnes, CURO Research Assistant
Tian Xia, Graduate Student
Dr. Mark Eiteman, College of Engineering

Glucosylation alters the functionality and bio-availability of many complex and interesting organic compounds such as flavonoids. Specific glucosides are often expensive and difficult to obtain in large quantities. Glycosyltransferases mediate the transfer of glucose from the donor molecule UDP-glucose to the acceptor organic molecule. We have an interest in the design of effective processes to produce these glycosylated compounds, and have studied such processes using two model conversions: quercetin to quercetin-3-glucoside by the glycosyltransferase UGT73B3 and indole-3-acetic acid to 1-O-indole-3-acetyl glucose ester (IAGE) by the glycosyltransferase UGT84B1. *E. coli* strains transformed with these glycosyltransferases and grown under optimal conditions accumulate over 1 g/L of these glycosylated derivatives.

Invalid Test Performance during ADHD Evaluations of College Students

Stefania Barzeva, CURO Research Assistant, CURO Graduation Distinction
Dr. Jason Nelson, Psychology, Franklin College of Arts & Sciences

An increasing number of students with Attention-Deficit Hyperactivity Disorder (ADHD) are entering college. Between 2000 and 2008, rates of postsecondary enrollment for students with ADHD nearly tripled. This increase may be partially attributed to malingering (i.e. fabricating psychological symptoms) for secondary benefits (e.g. extended testing time), as indicated by the high rates of poor symptom validity during ADHD assessments of college-aged individuals. The purpose of the current study was to establish the estimated rate of invalid performance during ADHD assessment based on embedded symptom validity test (SVT) failure and to examine the differences between valid- and invalid-performing individuals. Test scores were collected from the archives of 362 students who had undergone a comprehensive psychological evaluation to determine eligibility for academic accommodations. Participants were included if they were administered embedded SVTs within the Integrated Visual and Auditory Continuous Performance Test, Wechsler Adult Intelligence Scale, and Conner's Adult ADHD Rating Scale. Invalid performance was defined as scoring below the established cutoff of at least one SVT. Twenty-three percent of individuals demonstrated invalid performance on at least one SVT. Individuals who performed below the cutoff of at least one SVT endorsed more ADHD symptoms and demonstrated lower cognitive ability and academic achievement compared to individuals who did not perform below any cutoffs. The significance of this study lies in its contribution to the literature that examines postsecondary ADHD assessment regarding the identification and rates of malingering, diagnostic validity, unfair secondary gains in academia, stimulant medication abuse, and the fair distribution of resources.

The Physiological Functioning of Children with Anxiety: A Review of the Literature

Stefania Barzeva, CURO Research Assistant, CURO Graduation Distinction
Dr. Cynthia Suveg, Psychology, Franklin College of Arts & Sciences

Abstracts

Anxiety disorders are the most prevalent category of psychiatric disorders, with over half of diagnosed individuals reporting onset during childhood. Anxiety disorders affect cognitive, behavioral, and physiological functioning of children. Although research has progressed immensely in understanding childhood anxiety, research examining the physiology of children with anxiety disorders has only recently commenced. Studies consistently estimate that the majority of children diagnosed with anxiety disorders endorse at least one physical symptom. Many of the symptoms of anxiety have important physiological origins that could be measured objectively, and perhaps more accurately than self-reports, with standardized physiological assessments such as heart rate and respiratory sinus arrhythmia (RSA). Heart rate and RSA can be used as indicators of parasympathetic nervous system activity which functions in decreasing emotional reactivity. Children with anxiety disorders often have difficulties decreasing physiological expressions of emotional reactivity, but more research is needed to establish the underlying mechanisms. A review of the current literature is necessary to advance our knowledge in this domain through summarizing our current understanding and noting the gaps in knowledge of the physiology of children with anxiety. The purpose of this review was to (1) summarize the extant literature on the relations of physiological functioning, such as heart rate and RSA, of children with anxiety, (2) to analyze the results of these studies in the broader context of developmental psychopathology, and (3) to acknowledge limitations and propose future directions in the application of physiological assessments in the treatment of childhood anxiety.

Phylogenetic Investigation of Metal Hyperaccumulation Evolution in Wild Sunflowers

Mary Baxter, CURO Research Assistant

Dr. Anne Marie Zimeri, Environmental Health Science, College of Public Health

Plants that have the ability to accumulate extremely high concentrations of metals in their foliage are considered hyperaccumulators. The evolution of plant hyperaccumulation has become of increased interest due to its application towards using plants to clean up environmental contaminants (phytoremediation) or extract valuable metals from soil (phytomining). There are varying hypotheses as to the adaptive benefits of hyperaccumulation. The elemental defense hypothesis, which suggests that high leaf metal concentrations help deter herbivores and inhibit microbial growth, has the most empirical support. We examine the elemental defense hypothesis using a generalist herbivore *Vanessa carduii* (Painted Lady butterfly larvae), and 14 wild sunflower species (*Helianthus*). Species of *Helianthus* were grown under high concentrations of nickel and cadmium, harvested, and then fed to *V. carduii* under nonchoice and choice conditions. *V. carduii* larvae assigned to non-choice experiments were fed either a metal-grown or a control leaf, while larvae assigned to choice experiments were given a choice between a metal-grown and a control leaf of the same species. The percentage of each leaf eaten was measured, and other leaves of each plant were used to measure concentrations of nickel and cadmium along with other putative leaf defense traits such as leaf mass per area, leaf water content, and trichome density. The evolutionary history of nickel and cadmium hyperaccumulation in *Helianthus* was explored using ancestral state reconstruction, and the relationship between herbivory deterrence and leaf metal concentration was assessed. This study constitutes the first ever phylogenetically explicit assessment of the elemental defense hypothesis.

Abstracts

Progression of Lithium Ion Batteries
Samuel Baxter
Dr. Tina Salguero, Chemistry, Franklin College of Arts & Sciences

Lithium Ion batteries have come a long way since their original development. Over the years materials scientists of all kinds have implemented new cathode and anode materials that can increase the performance and cost effectiveness of these batteries. As far as cathode materials go, one that has attracted much attention from researchers is Lithium Cobalt phosphate. The material itself has many beneficial characteristics including High thermal stability, High capacity/potential, inexpensiveness, and it is chemically stable in the electrolyte solutions of a battery. Within the battery, the lithium ions that migrate throughout the electrolyte solution have to travel through the LiCOPO4 material in order to intercalate into the anode material at the other side of the battery. In order to optimize this migration of Lithium ions, we are creating a path of least resistance for them to travel. This path of least resistance involves taking an exfoliated nanosheet morphology of the material and implementing it in the battery instead of its bulk counterpart. There are many steps in this process, but the worthwhile result of a nanosheet battery make the struggle worth pursuing.

The Figure of Constantine the Great in Cynewulf's "Elene"
Kaitlyn Beck, CURO Summer Fellow
Dr. Jonathan Evans, English, Franklin College of Arts & Sciences

The goal of this research project was to examine the Old English poem entitled "Elene," which is Old English for Helena, the mother of Constantine the Great. The primary focus of the project was Constantine the Great, one of the most important political and religious figures in history. I looked at how successful the propaganda of Constantine, particularly his personal connection to Sol Invictus and Jesus Christ, was through how it continued in the poem. To help answer that question, I also tried to determine who the main character of the poem was, and what was Constantine's role within the text. Most of my research involved dealing with primary texts. I looked at "Elene" in Old English and Eusebius' *Life of Constantine*. I also examined scholarly material related to the study. Through my research, I found that while Constantine was certainly elevated to a saint-like status, he was not the true focus of the poem. While Cynewulf is undoubtably influenced by Eusebius' propaganda, it seems that he uses it for his own purposes in highlighting the True Cross in his poem "Elene."

Investigating Regulation of Germline Stem Cell Division Frequency in *Drosophila melanogaster*
Chederli Belongilot, CURO Research Assistant
Dr. Cordula Schulz, Cellular Biology, Franklin College of Arts & Sciences

Stem cells are undifferentiated cells that have the potential to become various cell types. Elucidating the pathways that regulate stem cell division may provide insight into novel therapeutics in repairing or replacing damaged tissue, aging, and cancer. Specifically, the regulation of division frequency in germline stem cells is not well characterized. Using *Drosophila melanogaster* as a model organism, we are investigating the pathway that is responsible for the increase in division frequency in response to mating that is shown in *Drosophila*. To do this, mating experiments are performed using organisms with a specific RNA interference construct in their genome. When the RNAi is active, it can block the translation of a selected candidate protein involved in the pathway. The flies then either go through three rounds of mating with

Drosophila virgins, or remain unmated. Controls that do not have activated RNAi also go through this process. After mating, the testes are dissected, fixed, and then stained with antibodies that label different cells in the testes. Fasciclin III labels the hub, Vasa labels germline stem cells, and Phospho-histone 3 labels the nuclei of dividing cells. Once they are stained, the testes tips are imaged, so the fraction of dividing stem cells can be calculated from each experimental group. If an activated RNAi group shows no increase in stem cell division frequency when mated, the protein coded by the RNA targeted by the RNAi is a likely part of the pathway controlling germline stem cell division frequency in *Drosophila*.

The Forgotten Radical: Southern Women and the New Left Student Protests of the 1960s

Brett Bennett, CURO Summer Fellow
Dr. Brian Drake, History, Franklin College of Arts & Sciences

The narratives of the 1960s student protests revolve around the major campuses of Berkeley, Columbia and other Northern and West Coast universities and much emphasis is placed on the male-dominated roles of speaking and writing. However, were women and southern universities such as the University of Georgia also involved in radicalism and the New Left movement? While ignored in most histories of the decade, student left protests reached the Deep South as well. Students at the University of Georgia staged sit-ins, marches, and formed radical groups. Yet, even within these so-called 'radical' groups, women struggled to be allowed the same opportunities to speak and organize as their male peers. If the Southern radical is overlooked in historical narrative, the female radical is nearly forgotten, as she had to fight for her voice to be heard within even the New Left movement itself. The narrative that leaves out women and the South fails to show the widespread effect and impact of the student left. Using old issues of the *Red and Black* and the papers of major UGA administration members I found the story of radicalism at UGA, focusing particularly on how women involved in sixties radicalism set the stage for the women's liberation movement, arguably one of the biggest successes of the New Left.

The Impact of Rest and Game Location on NBA Team Performance

Mckenzie Benson, Steven Pugh, Rebecca Gaines, Mary Catherine Kelley
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

In today's globalized society, travel has become an accepted element of work. However, travel is associated with factors that have the potential to affect performance. Previous research shows a negative relationship between traveling and performance. It has been found that people perform better in familiar environments. Rest has the capacity to counteract the negative effects of traveling. Sports data have been used to analyze these relationships due to the availability of information. For example, the game's home versus away status can be used to measure an unfamiliar environment, point differentials can measure performance, and days rest can objectively measure time between games. For this study, we examined home versus away status and the amount of rest between games using NBA data. We expected that teams playing at an away location would attain less sleep, and therefore away games would amplify the negative impact of lack of rest on performance. Results show that teams performing at away games, who received less rest, performed worse. Teams lost more frequently at away locations than at home. Results support the original prediction of a negative relationship between away game location and performance. Results found from this study can be applied to the

work environment by suggesting that managers give employees adequate rest time while traveling. Traveling employees given ample rest time could offset some of the negative effects of travel. Therefore, business managers should allow for recovery time upon arrival at their business trip destination or run the risk of increased exhaustion and decreased performance.

Nut-Cracking Skill and Efficacy in Wild Capuchin Monkeys

Margaret Bergmann, Rhianna Baldree, Kristen Smith
Dr. Dorothy Fragaszy, Psychology, Franklin College of Arts & Sciences

Skill is defined as fluid and effective performance of a specific action, or set of actions, under varying circumstances. Wild bearded capuchin monkeys typically crack tough palm nuts by placing them on a log or stone anvil, and striking them with stone hammers that weigh a considerable portion of a monkey's body mass. To evaluate nut cracking skill we videotaped twelve habituated male and female adult and adolescent monkeys using an unfamiliar stone hammer of an average weight and size. We documented the monkeys' behavior with the stone during nut-cracking in slow- motion playback. We coded three exploratory actions with the stone (preparatory lifts, spins, and flips), the position of the monkey's hands on the stone each time it moved the stone, the angle of the strike, and outcome (stone dropped; nut cracked). We determined the frequency of actions and outcomes for the first 20 strikes of each individual and report these data for six monkeys. The monkeys cracked 0 to 3 nuts in 20 strikes and produced between 0.6 and 2.35 exploratory actions per strike. The three kinds of actions occurred in approximately equal proportions. Monkeys rarely struck the nut at a slant but four monkeys dropped the stone 1 to 7 times. Exploratory actions may help the monkeys position the stone for an effective strike but in our sample the frequency of these actions did not predict efficiency. Supported by UGA, National Geographic Society, and the PRIMARCH project (European Research Council).

Acute Intra-vmPFC Injections of Galanin Reduce Expression of Conditioned Contextual Threat in Rats

Dionnet Bhatti, CURO Research Assistant, CURO Graduation Distinction
Dr. Philip Holmes, Psychology, Franklin College of Arts & Sciences

Rationale. Previous work has implicated galanin in the modulation of anxiety-like behaviors, yet its potential for facilitating the extinction of aversive memories has not yet been investigated. *Objective.* We evaluated the role of galanin in the medial prefrontal cortex (mPFC) on the expression and extinction of conditioned threat by measuring freezing behavior in a contextual threat-learning paradigm. We asked: Does galanin reduce the expression of the conditioned threat response and does it enhance the acquisition of the learned extinction? *Methods.* Sprague-Dawley rats were conditioned to an aversive context on day one. 20 minutes before the extinction trial on day two, the rats received bilateral microinjections of galanin (0.6 nmol/side) or vehicle (aCSF) into the ventromedial prefrontal cortex (vmPFC). On the third day, the rats were placed into the context once again to further assess the retention of the extinction. *Results.* Bilateral intra-vmPFC injections of galanin reduced freezing, evident in the first few minutes of the extinction session immediately following the intracranial injections. No differences in freezing were evident during the drug-free extinction session occurring on the third day. *Conclusion.* Our results suggest that galanin suppresses the expression of contextual threat-induced defensive behavior without affecting the retention of the extinction learning or

disrupting the initial acquisition of the learned threat association.

Continuing Investigation of Electronically Excited States in Indole: Transitioning from Gaseous to Condensed Phase Studies

Michael Biddle, CURO Summer Fellow
Dr. Susanne Ullrich, Physics & Astronomy, Franklin College of Arts & Sciences

Skin cancer is the most widespread form of cancer in the United States, and is possibly initiated by ultraviolet (UV) radiation damaging DNA contained in skin cells. Certain constituents within our skin, like the polymer eumelanin, naturally protect our bodies from DNA photodamage. However, the mechanism responsible for this UV-shielding is not yet fully understood. Studying the relaxation dynamics of the eumelanin chromophore indole is an important step in explicating the UV photo-protective properties of the eumelanin polymer itself. Multiple techniques, utilizing various excitation wavelengths, were used to study relaxation dynamics of indole in the gas phase. These techniques include time resolved photoelectron spectroscopy, time resolved kinetic energy release, and time resolved ion yield. The 1La and 1Lb states (both possessing $1\pi\pi^*$ character) and the $1\pi\sigma^*$ relaxation pathway were shown to be involved in relaxation at excitation wavelengths ranging from 201 nm – 273 nm, the involvement of the latter ceasing at wavelengths greater than ~263 nm. As eumelanin in the body is in the condensed phase, the next logical step is to replicate a more biologically relevant environment by investigating indole dynamics in various solvents. These solvents will be of differing polarities – such as cyclohexane, ethanol, and water – in order to determine the effects on relaxation dynamics. Time resolved transient absorption spectroscopy (TR-TAS) will be employed to investigate the temporal evolution of neutral electronically excited states and the appearance of solvated electrons (in polar solvents).

The Role of Chondroitin Sulfate Glycosaminoglycans in Glioma Cell Progression

Nicole Bisel, CURO Research Assistant
Dr. Lohitash Karumbaiah, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Glioblastoma multiforme is an aggressive, devastating type of brain tumor characterized by a highly invasive nature. Chondroitin sulfate proteoglycans (CSPGs) and their associated glycosaminoglycan (GAG) side chains have often been implicated in promoting tumor invasiveness. However, conclusive evidence to suggest that CSPGs or their associated CS-GAGs induce brain tumor invasion is currently lacking. We aim to provide evidence that suggests that tumor cell proliferation, migration, and invasion can be affected by the level of sulfation of CS-GAGs in the tumor extracellular matrix. Our goal is to demonstrate that the sulfation of the CS-GAG chains (and not the core protein itself) directly effects tumor cell progression. This will be tested *in vitro* by encapsulating the invasive glioma cell line U87MG-EGFP into differently sulfated CS-GAG hydrogels. We hypothesize that hydrogels containing the oversulfated GAG CS:E will inhibit general tumor growth while hydrogels containing monosulfated GAGs (CS:A and CS:C) will enhance tumor cell progression. Here we will establish a baseline for brain tumor growth in a neutral environment by encapsulating the U87MG-EGFP cells in 1% agarose gels. The nature of cell progression in these control hydrogels will act as a reference point from which we will compare tumor growth in the differently sulfated CS-GAG hydrogels. If glioma malignancy is indeed correlated with the level of sulfation of CS-GAGs, this work could contribute to our knowledge of treatments for brain cancer and potentially

lead to better patient prognoses in clinical medicine.

An Analysis of International Media Coverage of North Korean Nuclear Events

Holly Boggs, CURO Research Assistant
Dr. Brock Tessman, International Affairs, School of Public & International Affairs

Recently, Shin Dong-hyuk, a North Korean defector, admitted to falsifying key aspects of his testimony before the United Nations. That prior testimony was crucial in generating support for a UN Security Council Resolution that proposed sanctions against North Korea for human rights abuses. Shin's testimony, and his falsifications, highlight the role that subjective interpretations play in global politics: states and international organizations frequently make major policy decisions based on interpretations of reality that have been filtered through the lens of individuals and – even more importantly – global media coverage. The first part of this research project analyzed international media coverage of events related to North Korean nuclear weapons and missile tests between 2009 and 2013. Newspaper editorials addressing four North Korean nuclear tests and rocket launches were collected, and then a method of content analysis was used to assess editorial coverage between newspapers and countries according to frequency and ratio of positive-to-negative tone. This project expands upon prior research by exploring three new propositions: that China's media coverage of specific events will be more consistent in tone than that in other countries; frequency of coverage in 2012 will be, on average, lower than in other years because of domestic leadership transitions in South Korea, Japan, and the United States; for South Korea and Japan, geographic proximity to North Korea increases perceived vulnerability and will lead to more frequent, negative editorial coverage of the North's nuclear and missile tests. Findings offer insight about the extent of global media subjectivity in international relations.

Review of the Potential for Coproducing Bioplastics and Biofuels from the *Spirulina*

Charles Bond, CURO Summer Fellow
Dr. Sudhagar Mani, College of Engineering

The potential for coproducing bioplastics and biofuels from algae is known, but the question of what technological processes are necessary has yet to be answered. This research lays the groundwork for such an answer by reviewing the possible technologies and techniques that could be used in such a commercial-scale coproduction system based on the algae *Spirulina*. Alternative systems were roughly designed and compared, with an emphasis on reducing costs to be competitive with petroleum-based fuels and plastics. Varied methods of cultivation, biomass drying, lipid and/or protein extraction, and fuel conversion are considered. Through examining these options, this research makes recommendations for future research, such as experimentation with supercritical fluid extraction of lipids from dried algae for conversion into biodiesel via transesterfication, and the conversion of subsequent residual protein-rich biomass into bioplastics via mixing and molding with glycerol. Through this research, the case is made that a system that produces both renewable fuels and biodegradable plastics is possible, but that the costs must be comprehensively assessed before it is known whether it can compete economically with conventional petroleum products.

Examining Entitlement: How Age and Length of Time in a Position are related to a Sense of Entitlement in CEOs

Zach Borg, Benjamin Listyg
Dr. Brian Hoffman, Psychology, Franklin College of Arts & Sciences

Recent literature indicates that narcissism ratings have been rising over time (Westerman et al., 2011). Higher narcissism rates are a potential cause of concern for organizations, as employee entitlement, a subset of narcissism, is related to counterproductive work behaviors (Fisk, 2010). Yet again, little research examines how leader tenure and age, for example, is related to narcissism. It makes sense that how long a leader has worked at a company could be related to how narcissistic the leader is. However, despite its potential negative organizational impacts, little research examines the relationship between leader tenure and narcissism. To examine this relationship, surveys were administered to CEOs from firms of varying size within a Western European country (n = 156). Our entitlement items came from the Narcissistic Personality Inventory (Raskin & Terry, 1998). Age was self-reported by each CEO, and CEO tenure within their organization was also self-reported. Partial correlations controlling for firm size were run to examine the relationship between CEO age and entitlement. Our results show that younger CEOs tend to score higher on entitlement (r = -.22, p = .01) and that the less time CEOs had been with their organization, the higher their levels of entitlement were (r = -.20, p = .02). These findings suggest that in order to prevent this rise in entitlement amongst younger leaders within organizations, on-boarding programs should be developed to appropriately train new young managers for when they take on more senior positions.

Examining Communication Patterns and Trait Self-Control Using the Actor-Partner Interaction Model

Jerica Bornstein, CURO Summer Fellow, CURO Graduation Distinction
Dr. Michelle vanDellen, Psychology, Franklin College of Arts & Sciences

High self-control is associated with positive relationship outcomes but less is known about how self-control is related to processes that facilitate relationships outcomes. We conducted a study to examine how self-control is related to communication patterns between romantic partners. In this study, 38 couples (76 participants) reported on personal qualities such as mental health, self-control, and personality characteristics. They additionally reported on relationship processes, including communication patterns. Results revealed main effects of actor and partner self-control on mutually constructive communication and demand/withdraw. Additionally, actor and partner self-control interacted to predict mutual avoidant communication patterns. One reason people with high self-control may have better relationships is because they communicate better within those relationships.

Characterizing the College Diet

Carley Borrelli, CURO Research Assistant
Dr. Jim Stringham, Psychology, Franklin College of Arts & Sciences

Little is known about the composition of the college student diet. Diet is often measured using the Food Frequency Questionnaire (FFQ) or self-reporting of daily food consumption. Prior studies have noted that these methods are often skewed and time-consuming. This study aimed to simplify characterization of the college diet by reporting food group percentages. To characterize regular food consumption, we administered a questionnaire that assessed food intake in six groups: fruits, vegetables, protein, dairy, grains, and junk food. Participants were asked to assign percentage estimates of volumetric consumption to each group, with the sum of all groups adding up to 100. Forty college students, aged 18-23, completed the questionnaire. Analysis of results showed that junk food was significantly inversely related to vegetable consumption (r = -0.408, p = 0.009) and grain consumption (r = -0.342, p = 0.031)

respectively. Consumption of grains was also significantly inversely related to fruit consumption ($r = -0.312$, $p = 0.050$). Mean food group values were: 12.05% for fruit consumption, 16.975% for vegetable consumption, 27.975% for grain consumption, 9.85% for dairy consumption, 24.3% for protein consumption, and 8.9% for junk food consumption. These findings characterize the food group percentiles for the college diet and suggest that, in terms of energy consumption, substitution may take place between junk food, vegetables, and grains. Further research is necessary to draw concrete conclusions about these relationships.

Lignin-Modifying Enzymes in Termite Digestive Tract as Potential Biological Pretreatment Component in Cellulosic Ethanol Production

Leah Brown, CURO Research Assistant, CURO Graduation Distinction
Dr. Joy Doran-Peterson, Microbiology, Franklin College of Arts & Sciences

Cellulosic ethanol provides an environmentally advantageous alternative energy source, and is produced by fermentation of sugars from cellulose (and hemicellulose) harbored in the cell walls of relatively untapped biomass resources (e.g., switchgrass and pine). A primary economic obstacle is the biomass pretreatment to overcome the barrier of lignin, a phenolic heteropolymer contributing to the structure of plant cell walls. Current pretreatments require harsh physical and chemical conditions to degrade lignin and release the fermentable carbohydrates. However, a biological pretreatment may exist within the digestive tract of termites, who can extract most of the available sugar in its exclusively lignocellulosic diet. To investigate the mechanism of lignin modification in termites, a transcriptomic differential expression analysis was employed. Termites were fed either filter paper (cellulose) or pine wood (lignocellulose) for seven days to establish distinct expression profiles based on diet. Termite foregut and midgut segments (where lignin modification has been demonstrated to occur) were extracted. RNA was isolated, sequenced, and assembled into a *de novo* reference transcriptome, from which differentially expressed genes were analyzed to identify putative lignin-modifying motifs. Each differentially expressed transcript was automatically annotated against a protein database and manually annotated to confirm automatic annotation results. Two promising transcripts up-regulated in the wood-fed termites were found, and their respective genes were synthesized and placed on an expression vector. Protein products will be purified and assayed for substrate specific activity on model lignin compounds to assess their potential as supplementary components in pretreatment of lignocellulose for the production of ethanol.

Something to Pass Down: Black Family Stories and the Legacy of Slavery and Jim Crow

Tifara Brown
Dr. Barbara McCaskill, English, Franklin College of Arts & Sciences

This project began with a photograph posted on a Facebook page connecting my Louisiana-born relatives, entitled "The Descendants of Coffee and Ella Webb." The image contains these two of my maternal ancestors: Edward "Coffee" Webb (1882-1944), the alleged white son of a Rapides Parish slave owner, and his alleged wife Ella (1885-1954), an enslaved woman. However, Coffee's archival record (such as his death certificate and his World War I registration card) contradicts this story by indicating that Coffee was African American. Discrepancies aside, the Webbs take pride in these maternal ancestors, alongside early paternal relatives, even though their family may be rooted in a union

considered socially taboo and racially corrupting. Instead of evaluating whether or not these stories are true, this research examines how and why such stories of survival, loss, and recovery have functioned during slavery and Jim Crow in African American families descended from Southern bondspeople. In order to consider the relationship between such stories and the families who tell them, this research evaluates archival documents, oral histories, and literature about enslavement and segregation. This investigation finds that instead of wealthy heirlooms, such stories pass down values and codes of conduct: resilience, pride, dignity, sacrifice, and community cohesion. Additionally, this research finds merit and legitimacy in these narratives within the communities that continue creating and remaking them despite the fact that scholars have privileged written over oral texts.

Threat from Abroad, Conflict Within: Border Settlement and Civil War Onset
Brent Buck
Dr. Andrew Owsiak, International Affairs, School of Public & International Affairs

Does the removal of a salient external threat effect the likelihood of civil war? I argue that once a state resolves an external threat to its security the probability of civil war temporarily increases through the mechanisms of demilitarization and decentralization. Previous research has argued that the presence of external territorial threat decreases the probability of civil war both during and after the resolution of the threat. This article challenges those findings by using a series of case studies to illustrate: 1) demilitarization and decentralization follow a state's settlement of its borders 2) that the processes of demilitarization and decentralization decrease the state's capacity to repress its people and maintain order, thereby increasing the probability of civil war following a state's resolution of its borders. Thus, this paper builds on the existing body of research on state capacity arguments for civil war onset and seeks to critique the previous findings linking civil war onset with external threat by claiming the probability of civil war increases (rather than decreases) following the resolution of the threat. These findings suggest that states with recently settled borders must be wary, lest their progress toward interstate peace devolve into intrastate war.

The *Kalevala* as Tolkien's Inspiration
Trace Calloway, CURO Honors Scholar
Dr. Jonathan Evans, English, Franklin College of Arts & Sciences

This research examines the roots of J.R.R. Tolkien's *Lord of the Rings* and his published collection of Middle-earth's myths in *The Silmarillion*, specifically by examining the Finnish *Kalevala*, a compendium of traditional Finnish oral myths collected by Elias Lonnrot. By examining Lonnrot's work, Tolkien's letters, and the research of several other authors in *Tolkien and the Invention of Myth* edited by Jane Chance, I uncover previously undiscussed parallels between Lonnrot's *Kalevala* and Tolkien's *Silmarillion*, and I argue that this Finnish work and its language served as a primary inspiration for Tolkien's interest in myth-making.

A Look at the Relevance of Sociology Concepts, Theories, and Methods through the Lens of Health Professionals
Jesse Cann, CURO Research Assistant
Dr. James Coverdill, Sociology, Franklin College of Arts & Sciences

In recent years there has been much debate over how informed physicians should be on concepts from the behavioral and social sciences. This debate has ultimately led to the restructuring of the Medical College Admissions Test to include an entire section that focuses on these theories and ideas. The

aim of my research was to demonstrate just how relevant many of the concepts from Sociology are to the medical field by helping Dr. Coverdill in redesigning an Introductory Sociology (SOCI 1101) course to emphasize material of particular importance and interest to those who aim to enter the health professions. This was accomplished by searching through medical and health-focused social science journals to identify and screen material for incorporation into lectures or as readings of the class. What was discovered is that sociological ideas are widely found throughout the domain of healthcare from the socialization of medical students learning to deal with death to the disparity of healthcare quality and access between different social classes. Framing these ideas with material and illustrations grounded in the health professions allowed for the development of an introductory sociology course that will be especially appealing and useful to those who seek to enter the health professions. In a broader sense, making prospective health professionals aware of the issues they may face in the world of medicine is the first step in finding solutions to these issues.

Neural Correlates of Schizotypal Traits in Healthy Participants with High and Low Cognitive Control

Megan Cannon
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Schizotypal Personality Disorder (SPD) is part of the schizophrenia spectrum, a group of related disorders that differ in severity. Research shows that schizotypal traits occur in some healthy people and are related to symptoms seen in schizophrenia, including difficulties in cognitive control. Previous research reveals brain activation (measured by fMRI) during cognitive control tasks is correlated with schizotypal traits in healthy populations. Previous studies only examined healthy populations as one group. Healthy populations vary on their cognitive control ability. This study examined whether the relationship between schizotypal traits and brain activation is different in people with low versus high cognitive control. For this study, healthy participants were sorted into high or low cognitive control groups based on results of working memory tasks. Each subject completed the Schizotypal Personality Questionnaire (SPQ) and performed antisaccades in the MRI scanner. The antisaccade task is a measure of cognitive control that involves inhibiting a reflexive response to glance toward a target and instead direct a glance in the opposite direction. Results show a significant negative relationship between positive and negative scales of SPQ and activation in the thalamus in the high cognitive control group. There was a significant positive relationship between positive and negative scales of SPQ and activation in the prefrontal cortex and striatum in the low cognitive control group. These results suggest there are possible neural differences along the schizophrenia spectrum, specifically related to those with poorer cognitive functioning. Understanding these differences could provide information on susceptibility to disorders like schizophrenia.

Genetic Interactions between Pigmentation Pathways and Protein Glycosylation

Leah Caplan, CURO Research Assistant
Dr. Michael Tiemeyer, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Glycoprotein glycans regulate cell-cell interactions, but little is understood about the genetic and biochemical pathways that influence cell- and tissue-specific glycosylation. We generated mutations in *Drosophila melanogaster* (*sff* and *ms16*) that alter the expression of neural-specific glycans in the embryo. In the course of analyzing these mutations, we noticed that their phenotypic

penetrance was affected by mutations in the *white* gene, which encodes for an ABC transporter that transports tryptophan and guanine into the cell. Its absence (*w-*) results in white-eyed adults and is accompanied by neurological and behavioral defects, suggesting that *white* functions in metabolic processes other than just pigmentation. The ABC transporter formed by *brown* and *white* transports guanine into the cell while other pigmentation genes, *cinnabar, vermillion,* and *henna*, modify transported substrates for the production of pigment precursors. The genes *cinnabar* and *vermillion* assist in the modification of tryptophan substrates and *henna* of guanine substrates. To comprehensively determine the extent to which pigmentation genes might also influence tissue-specific glycosylation, we screened pigmentation mutants for genetic interactions with *sff* and *ms16* in regards to the expression of neural-specific glycans. All four pigmentation mutants exhibited genetic interactions with the *sff* and *ms16* glycosylation mutants, indicating that multiple components of pigment production pathways also impact glycoprotein glycosylation. We hypothesized that pigmentation precursors transported by ABC transporters contribute to the formation of nucleotide sugars, essential substrates for glycosylation reactions. To test this hypothesis, nucleotide sugar levels in wildtype and mutant embryos will be quantified by high pressure liquid chromatography.

In-Vitro DNA-Protein Interaction Analyses of *Glycine max* Transcription Factors

Kitra Cates
Dr. Robert Schmitz, Genetics, Franklin College of Arts & Sciences

Soybeans (*Glycine max*) serve as an integral world crop used for oil production, livestock and aquaculture feed, and are a major protein source in the human diet. Soybean root nodules, formed from a symbiotic relationship with soil *Rhizobia*, facilitate nitrogen fixation and nutrient exchange between the two organisms. Research concerning regulatory pathways associated with transcription in nodules is necessary to study the influence of *Rhizobia* on the genetic regulatory pathways in legumes. WRKY-35 and NF-YA1, two transcription factors involved in stress response and nodulation in *Glycine max*, were artificially synthesized for Gateway cloning purposes. The synthetic genes were cloned into an entry vector plasmid, *pDONR207*, and transformed into *Escherichia coli*. Sequential cloning into a destination vector, *pixHALO*, added a HALO motif sequence to the gene sequences and placed the genes under an inducible promoter. Next steps in this project are to demonstrate protein: DNA interactions. Cloned genes will be expressed and translated using an established *in vitro* protocol. We plan to use the synthetic hybrid protein to isolate DNA targets of our transcription factor. Purification with an anti-HALO antibody coupled with high throughput sequencing will identify any targets of our transcription factors, providing novel data on the role of these transcription factors in nodule development and function. This study will serve to simultaneously develop a novel *in vitro* DNA-protein interaction protocol, built to parallel the widely-used, but extremely costly, chromatin immunoprecipitation sequencing protocol. This will provide an efficient, scalable production of transcription factors and the potential to manipulate regulatory networks of interest.

Asteroseismological Age Dating Utilizing a Bayesian Monte-Carlo Search

Timur Cetindag, CURO Research Assistant
Dr. Inseok Song, Physics & Astronomy, Franklin College of Arts & Sciences

Estimations of stellar ages have historically been very difficult for all but very young stars, and this has placed constraints on astrophysical modeling of stellar interiors and stellar evolution. Modern techniques can

measure the ages of mature (several billion years [Gyr] old) Sun-like stars with large (50-80%) uncertainties while age-dating precisions for young (<1 Gyr) stars are much better (<10%). The poor stellar age-dating precision has limited further detailed analysis of various stellar astrophysics. Over the past several years, with the extreme sensitivity and high cadence survey by the Kepler Space Telescope, scientists began detecting subtle variations in brightness due to stellar interior oscillations, whose study is called asteroseismology. Because these oscillations probe the stellar interior, analogous to Earth's interior being analyzed by terrestrial seismic waves, asteroseismology can be utilized to study the internal state of a star and greatly increase the age-dating precision down to the ~1% level for even old stars. In our research, we comb through a collection of ~2500 stars that are of interest to the Kepler Asteroseismic Science Operations Center (KASOC) and search for oscillation signatures of young, hot, active stars. Our goal is to (1) detect unambiguous stellar oscillations among young stars, (2) estimate ages of these young (<1 Gyr) oscillating stars, and (3) compare and cross-calibrate age-dating methods for young (<1 Gyr) and old (1-10 Gyr) stars. We approach this issue by utilizing a Bayesian Monte-Carlo simulation to search for an oscillation signal in the frequency power spectrum of each target.

Ultrastructural Change in the Mitochondria of *Euglena gracilis* Grown in Progressively Anaerobic Conditions

Pei-Ying Chang
Kathryn Dye, Graduate Researcher
Dr. Mark Farmer, Biological Sciences, Franklin College of Arts & Sciences

Some eukaryotes can survive in anaerobic conditions by generating ATP via fermentation and chemiosmosis coupling alone. Based on presence of genes in *Euglena gracilis* it is hypothesized that in this single celled protist glucose can be converted into wax esters generating ATP through substrate level phosphorylation. To test this hypothesis, cells of *Euglena gracilis* were grown in progressively anaerobic conditions. The independent variable of light was also added in the second set of experiments to prevent *Euglena gracilis* from producing oxygen through photosynthesis. Following repeated transfers of cells to conditions with progressively less free oxygen, a stable culture of mostly anaerobic *Euglena gracilis* were established. Using a combination of microscopy techniques (both electron microscopy and fluorescence microscopy) the mitochondria of oxygen deprived *Euglena gracilis* cells were examined for changes in structure and/or physiological function.

Pollen Competition

Angel Chen, CURO Research Assistant
Dr. Shu-Mei Chang, Plant Biology, Franklin College of Arts & Sciences

In hermaphroditic plants, fitness is comprised of female and male components. Female fitness is often measured as seed production of a plant, and male fitness can be measured as siring success through pollen grains. Though seed production has been studied extensively, we know less about how pollen success varies among individuals. In *Ipomoea purpurea* (common morning glory), previous studies showed plants that produce larger pollen grains consistently outperform their smaller pollen counterparts (Foltz & Chang, unpublished data). We have two main goals for this study: first, test the hypothesis that faster pollen tube growth rate is the reason underlying the success of larger pollen grains and second, examine whether small pollen grains can be maintained and coexist with larger pollen grains in nature. To test the first hypothesis, we analyzed the effect of pollen size and inbreeding level on pollen tube growth rate in the common morning glory, *Ipomoea purpurea*. We compared two lines

of plants that produce either large or small pollen and are either outcrossed or inbred and found that larger pollen produce pollen tubes that grow significantly faster than those produced by smaller pollen while inbreeding level has no significant effect on growth rate. To address the second goal, we performed a common garden experiment allowing plants to interact naturally with their pollinators and analyzed differences in their reproductive traits and male and female fitness using molecular markers. Using the results from this study, we will discuss how pollen size variation might be maintained in natural populations.

Female Labor Force Participation and Wages: What Has Changed in the Last 30 Years?

Anne Chen, CURO Summer Fellow, CURO Research Assistant
Dr. Christopher Cornwell, Economics, Terry College of Business

Goldin (2014) suggests that "the converging roles of men and women are among the grandest advances in society and in the economy in the last century." Indeed, women have made great strides in educational attainment, labor-market participation and wages over the last hundred years. They now earn almost 60 percent of bachelor's degrees and comprise a majority of the workforce. Understanding these changes is important for both future labor-market and marriage market implications. In this paper, I hope to study whether the factors contributing to the increase in female labor force participation and wages have changed significantly over time. The primary motive to understanding this topic is that women have come to dominate the U.S. college campus. There are many questions that arise given this fact: why male college enrollment has been stagnant, how that translates to the U.S. labor market, and how social norms may change in the future based on changing economic incentives. The project will have three components. First, I will compile a review of the literature on the advancement of women in the labor market, its effects on household formation, and opposing arguments against popular explanations as to which is the main contributor. Second, I will construct my analysis samples using NLSY data I have extracted and organized. Finally, I will construct my empirical models and apply the appropriate econometric methods to assess the relative importance of the factors in explaining gender disparities in wages and age at first marriage across the two cohorts.

Paper Art in Expanded Forms

Jiacheng Chen, CURO Summer Fellow, CURO Research Assistant
Prof. Eileen Wallace, Lamar Dodd School of Art

Traditionally, the art of papermaking was dedicated primarily to the arts of the book and calligraphy. Today, paper has been widely experimented with as a primary material for sculptural works and is considered an independent art as well. The polychotomous nature of paper to have multiple applications from the same basic material makes paper as an art form difficult to categorize. The first issue that I explored was paper formation. Paper formation occurs through the fibrillation of the fibers via beating and then reconstitution of the fibers through sheet formation. To investigate the correlation between the raw materials and procedural differences, I applied two variables to my experiment, cooking times of the raw plant fibers and beating times for the processed fiber. The results showed a distinct correlation between the variables and the resulting variations in paper qualities and characteristics. That information would help an artist with the knowledge to achieve a specific and ideal paper for artwork. It has also been my research interest to explore contemporary oriental aesthetics, particularly

in the idea of "dissolved imagery". Firstly, images are generated through photographic printing (cyanotype), screenprinting or pulp painting on wet paper. When the paper was air dried, natural forces of shrinkage and distortion moved the fibers and therefore the imagery, too. In this way, the imagery's original consistency is dissolved. The artist relinquishes a certain amount of control as the paper dries without restraint. Theoretically, this methodology aligns itself with the "blank-leaving" (*liu-bai*) aesthetics of ancient *shanshui* painting.

S. cerevisiae as a Model System for the Oligomerization and Aggregation of Aβ Peptides using Cup1p as a Reporter

Michael Cheng, CURO Research Assistant
Dr. Walter Schmidt, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Alzheimer's disease (AD) is a progressive neurodegenerative disorder. The accumulation of amyloid beta (Aβ) peptides observed with AD, combined with their toxicity, implicates them as a causative agent of the disease. Aβ peptides, particularly Aβ1-40 and -42, are prone to form oligomers and aggregate into amyloid plaques. It is the oligomer form that is widely accepted as the most cytotoxic form of Aβ. The purpose of this research is to build a useful tool for the expression and evaluation of Aβ peptides in a simple, cost-effective genetic system (*S. cerevisiae*). Because Aβ peptides are nontoxic to yeast and do not produce an easily assessable phenotype, an Aβ-Cup1p fusion will be used as a reporter. Cup1p is a small protein metallothionein that mediates resistance to high concentrations of copper. We predicted that aggregation of the Aβ-Cup1p fusion would result in the inhibition of Cup1p activity, thus increasing sensitivity to copper. Varying levels of sensitivity to copper were observed in yeast strains expressing Aβ1-19, -28, -40 and -42 fused with Cup1p. Using this system, various Aβ formation and degradation mechanisms are being investigated, such as the ability of Insulin Degrading Enzyme (IDE) to cleave Aβ peptides and disaggregate Aβ-Cup1p to restore Cup1p function.

Automated Stellar Classification

Zachary Chilton, CURO Research Assistant
Dr. Inseok Song, Physics & Astronomy, Franklin College of Arts & Sciences

Measuring stellar properties is a very time consuming process. Key properties — such as effective temperature, surface gravity, radial velocity, rotational velocity, and metallicity— are tediously calculated from the many absorption features in a star's approximately-blackbody spectrum. We worked to develop an autonomous method of calculating these properties using theoretical stellar spectra. High resolution theoretical spectra have been calculated for stars with many combinations of physical parameters. After creating a database of theoretical spectra, we implemented various computational methods to find the theoretical spectrum that best matches the input observed spectrum. We then assign the key properties that generated the theoretical spectrum to the observed star. We can identify these stellar parameters in a matter of minutes.

Assessing the Effects of Different Types of Parental Care on Nestling Survival in a Migratory Songbird

Ryan Chitwood
Joanna Hatt, Researcher
Mason Cline, Graduate Student
Dr. Robert Cooper, Warnell School of Forestry & Natural Resources

Nest predation has been shown to limit the productivity of forest-breeding migratory songbirds, with implications for both the conservation and evolution of life history strategies of these species. Skutch's hypothesis (1949) offers that nest predation should

increase with nest activity. Because provisioning of young dominates nest activity during the nestling stage, high provisioning rates should coincide with low nestling survival in spite of the direct benefits of provisioning. Many studies have tested Skutch's hypothesis by comparing predation risk between the incubation and nestling stages with little consensus. Here, we studied the effects of different strategies of parental care on Black-throated Blue Warbler *(Setophaga caerulescens)* nestling survival. We hypothesized that during the nestling stage male provisioning rates should correlate positively with nestling survival, allowing females to provision at lower rates. We measured provisioning rates for each parent in addition to other parental care types. Female provisioning rate was the top predictor of nestling survival for all models followed by male provisioning rate. Covariate predictions showed a relatively strong negative influence of female provisioning rate on survival and the opposite trend for male provisioning rate. Our results suggest that the optimal parental care strategy incorporates a shared provisioning burden that allows both parents to spend more time investing in other activities.

Mapping the Genetic Basis of Floral Traits in Cultivated Sunflowers

Erin Clark, CURO Research Assistant
Dr. Lisa Donovan, Plant Biology, Franklin College of Arts & Sciences

The goal of this study is to quantify the amount of genetic variation in floral architecture in cultivated sunflowers (*Helianthus annuus*), as well as identify the genetic basis of key floral traits. Despite their agricultural and horticultural importance, the genetic bases of most floral traits have yet to be determined in crop sunflowers. Recent efforts have established a 288-line association mapping panel for the purposes of determining the genetic basis of key phenotypic traits. This panel captures about 90% of the genetic variation across varieties of crop sunflowers, and each line has been heavily genotyped for over 5500 SNPs. With the use of this association mapping panel and its known genotype data, floral traits of interest can be mapped to the genome. It is hypothesized that the floral architecture of *Helianthus annuus* is most likely based on many genes of small effect, though there may be individual regions of very large effect present as well. Based on phenotypic variation in floral traits in wild *Helianthus*, it is also hypothesized that variation in floral architecture is independent of overall flower size, and that these traits map to distinct regions.

Introgression of a *Wolbachia* Infection into a Non-Native Host

Kathryn Clark, CURO Research Assistant
Dr. Kelly Dyer, Genetics, Franklin College of Arts & Sciences

Wolbachia are maternally inherited endosymbiotic bacteria that infect upwards of 60% of all insects. Their effect on the insect host varies depending on the strain of *Wolbachia* and the genetic composition of the insect host. In two closely related species of *Drosophila*, the same stain of *Wolbachia* causes different effects. In *D. recens*, the *Wolbachia* infection causes all the offspring to die. In *D. subquinaria*, however, this same *Wolbachia* strain causes only the males to die. The amount of male-killing varies within this species, potentially based on where the line is located geographically. In order to further analyze the effects of *Wolbachia* in non-native hosts and to ask how common the gene that suppresses male killing was, I attempted to move a *Wolbachia* infection into a *D. subquinaria* line that was not resistant to male-killing. This would enable further understanding of the evolutionary history of *Wolbachia* in these species and how the genetics of host and bacteria interact to drive

the evolution of this association. To do this, I established crosses between females from hybrid *D. subquinaria* lines (lines with mitochondrial DNA from *D. recens* and nuclear DNA from *D. subquinaria*) and males of either *D. subquinaria* or *D. transvera*. In each cross, I collected all the offspring and counted the number of males and females, looking to see if a female bias was present in the offspring sex ratio. After many generations of backcrossing, no male-killing was found among the various backgrounds of introgressed lines.

Potential Health Risks of Teen Online Behaviors

Jasmine Clayton, CURO Research Assistant
Dr. Maria Len-Rios, Grady College of Journalism & Mass Communication

With the rapidly changing technological structure of our society, many adolescents are growing up where smart phones and social media are a significant part of their lives. These media provide constant means for their social communication online, whether through direct or indirect interaction. The goal of our research is to explore how these online portals affect the psychological and physical well-being and health of adolescents. To begin our process, we will conduct a literature review. Our search will be guided by Festinger's social comparison theory. According to a previous study (Spurr, Shelley, Berry, Lois & Walker, 2013), teens often compare their bodies with media images, leading to unhealthy actions in an effort to attain an idealized image or persona. In another study (Wang, Jackson, Gaskin & Wang, 2014), there was positive relation between a user's well-being and the use of social networking sites for social communication. For this study, we plan to conduct six focus groups with adolescent boys (2) and girls (4) at middle schools in Henry County in order to learn how adolescents' use of social media impacts their views on body image and level of self-esteem. Then we will transcribe the interviews, engage in data analysis and write up the research results for publication. This research is significant because social media has a growing impact on adolescents. We can use our research to propose ways to combat any negative effects social media has on the health and well-being of adolescents.

Csmd1—a Novel Candidate Gene Related to Kidney Disease

Erica Coe, CURO Research Assistant
Dr. Robert Pazdro, Foods & Nutrition, College of Family & Consumer Sciences

Kidney disease is one of the top ten causes of death in the United States, affecting millions of people each year. The endogenous antioxidant glutathione (GSH) is a key regulator of renal oxidative stress and the ratio of GSH to its oxidized form (GSSG) is an informative indicator of oxidative stress. We quantified GSH concentrations and GSH:GSSG in kidneys isolated from 30 genetically-diverse inbred mouse strains. We performed genome-wide association mapping by efficient mixed model analysis (EMMA). We discovered that phenotypic variation of renal GSH concentrations and GSH:GSSG ratios were associated with 19 single nucleotide polymorphisms (SNPs) located within the Csmd1 gene on chromosome 8. We predict that Csmd1 is a regulator of renal oxidative stress and possibly renal disease. To validate our results, we used statistical analyses and EMMA to evaluate several renal function strain survey data sets in the Mouse Phenome Database (MPD), a community resource that facilitates the sharing of strain data. To experimentally validate Csmd1 and its role in renal oxidative stress and disease, we ordered a litter of Csmd1 knockout mice, which were successfully cryorecovered by the mutant Mouse Regional Resource Centers (MMRRC). In our next study, we will test whether Csmd1 knockout mice exhibit a higher incidence of

renal disease compared to wild-type and heterozygous littermate control mice.

The Relationship between Insulin Resistance and Distal Radius Cortical Bone Geometry

Derek Coger, CURO Research Assistant
Dr. Richard Lewis, Foods & Nutrition, College of Family & Consumer Sciences

Insulin is a pancreatic beta cell-derived hormone responsible for glucose regulation and activation of bone-forming osteoblasts. Insulin resistance has been associated with suboptimal cortical bone density and geometry of adolescent boys and girls, but these relationships have not yet been investigated at the distal radius, a common fracture site in children. The purpose of this cross-sectional analysis was to determine the relationships between insulin resistance and distal radius cortical bone measures in non-Hispanic white early-pubertal girls (breast development stage 2/3; mean age = 11.5 years; N=39) who participated in a zinc supplementation trial. Total body fat mass and fat-free soft tissue (FFST) mass were determined by dual-energy X-ray absorptiometry (Discovery A, Hologic Inc). Radius cortical bone geometry was assessed at the 20% site relative to the distal growth plate via peripheral quantitative computed tomography (Stratec XCT 2000). Fasting serum insulin and glucose concentrations were measured, and the homeostasis model assessment of insulin resistance (HOMA-IR) was calculated. Multiple linear regression controlling for FFST, fat mass, and breast development revealed HOMA-IR as a positive predictor of radial cortical bone area and thickness, but a negative predictor of volumetric bone mineral density. These findings suggest that insulin resistance differentially influences cortical bone size versus density. Bone strength depends on both size and density so future studies should investigate the clinical significance of these differential bone responses to insulin resistance.

Behavioral Testing for Cognitive Deficits in Traumatic Brain Injury Piglets

Caroline Coleman, Foundation Fellow
Dr. Franklin West, Animal & Dairy Science, College of Agricultural & Environmental Sciences

According to the CDC, traumatic brain injuries (TBI) are a contributing factor to over 30% of injury-related deaths in the United States every year, with children aged 0-4 at the highest risk. Currently, there are limited therapy options available for the treatment of TBI and the resulting cognitive and neurobehavioral deficits, but human induced pluripotent stem cell-derived neural stem cells (iNSCs) have recently become an option for injury treatment. Due to similarities in brain structure and early development, we are using a piglet model to 1) develop quantifiable and repeatable behavioral tests, 2) determine cognitive deficits following a TBI and 3) explore the effects of subsequent iNSC treatment on these deficits. Two behavioral tests that we will develop for use in the study are the open-field test and the social recognition test. In the open-field test, piglets will be placed in a 12 x 14 foot arena and observed to determine their exploratory interest, motor behaviors, and normal/abnormal behaviors. We expect that normal piglets will have high exploratory interest and will not exhibit any motor deficits or abnormal behaviors. The social recognition test will measure sociability and the ability to recognize familiar pigs from unfamiliar pigs, or social memory. We expect that normal pigs will be highly social and will be able to distinguish familiar pigs from unfamiliar pigs, demonstrating a high level of social memory. The successful development of these tests will satisfy the first objective of creating a quantifiable and reliable behavioral assessment of cognitive abilities in piglets.

The Politicization of Soccer in Brazil, and the Effect of the 2014 FIFA World Cup on Brazilian Politics

Aaron Conley, CURO Honors Scholar, CURO Summer Fellow
Dr. Barry Hollander, Grady College of Journalism & Mass Communication

The role of soccer has come to play a significant role in the culture of many nations. In Brazil, soccer is more culturally significant than in almost any other state. Soccer has even successfully affected Brazilian politics, especially in regards to the 2014 FIFA World Cup. The tension began in Brazil immediately following its successful bid for the tournament but increased to climax following Brazil's semi-final loss to Germany, the eventual champions. Through analyzing social media, especially Twitter, in Brazil throughout the tournament, the 2014 FIFA World Cup was shown to have a significant impact on the nation's presidential election in October 2014. Prior to the tournament, President Dilma Rousseff possessed a significant lead in the polls, but she only won re-election by approximately 4% of the vote in a runoff. Polling data, as well as sentiment analysis on social media, shows the gap between Rousseff and her main opponent, Aécio Neves, closing over the course of the tournament. Sentiment analysis is a method of analyzing social media that places individual posts on a 0-100 scale from negative to positive, determining the overall sentiment of a specific topic or individual over a specific period of time. This type of analysis was performed on Twitter in Brazil throughout the 2014 FIFA World Cup and showed that soccer could truly have a political effect on one of the fastest growing nations in the world.

Age Related Effects on Brain Activation during Cognitive Control Tasks in Subjects with Schizophrenia

Joseph Coppiano, CURO Research Assistant
Dr. Jennifer McDowell, Psychology, Franklin College of Arts & Sciences

Cognitive Control (CC) is vital to daily functioning. One aspect of CC is the ability to filter out irrelevant information in order to perform task-related responses. Functional magnetic resonance imaging (fMRI) research over CC circuitry has sought to better understand the effects of factors such as age or psychiatric disorders. A model of CC is antisaccade task performance. The task requires subjects to fixate on a central cue and instructs them to redirect their gaze towards the mirror image location (opposite direction, same distance) when it moves to the side. Despite well-documented findings that subjects with schizophrenia (SZ) (a psychiatric disorder) perform poorly on antisaccade tasks (more errors and longer reaction times) and display lower brain activations compared to healthy controls, studies of age effects on antisaccade performance are minimal. Through dividing diagnostic groups, SZ (N=24) and healthy controls with low cognitive control (LCC) (behaviorally comparable to SZ) (N=24), into age groups of younger (n=10) and older (n=14) adults, this study seeks to observe the effects age has upon antisaccade CC circuitry. We hypothesize that group and age will have no effect on behavioral measures, but that imaging measures will show higher activation in LCC than SZ and display negative age effects. As hypothesized, there were no differences in behavioral performance. Analyzing the effects of group and age using a 2x2 ANOVA, it was found that SZ had less activation than younger LCC but similar activation between older diagnostic groups. The results demonstrate that SZ does display brain-circuitry changes with age.

Factors Associated with HPV Diagnosis and Perceived Risk for Cervical Cancer among Unmarried, Sexually Active College Student Females

Clayton Cowart, CURO Research Assistant
Dr. Matthew Lee Smith, Health Promotion & Behavior, College of Public Health

Background: The human papillomavirus (HPV) has been identified as the leading cause of cervical cancer in the United States. While risk factors for contracting HPV have been well studied, less is known about the characteristics of those living with the virus and their perceptions about associated health ramifications. The purposes of this study were to examine factors associated with unmarried college student females': (1) HPV diagnosis and (2) perceived risk of getting cervical cancer in future years. *Methods:* Data were analyzed from 1,106 unmarried, sexually active college student females aged 18 to 26 using an internet-delivered questionnaire. Binary logistic regression was performed to compare HPV-related knowledge, HPV vaccination-related perceptions, HPV vaccination mandate support, healthcare utilization, sexual behaviors, and personal characteristics across participants' HPV status. Multinomial logistic regression was performed to assess the degree to which these factors were associated with participants' perceived risk of getting cervical cancer. *Results:* Relative to those who had not been diagnosed with HPV, participants who had more lifetime sex partners ($P<0.001$), had unprotected sex during last intercourse ($P=0.003$), had a Pap test in the past year ($P<0.001$), and perceived themselves to be at higher risk for cervical cancer ($P<0.001$) were significantly more likely to be diagnosed with HPV. Those with HPV were also significantly more likely to support HPV vaccination mandates for school-aged youth ($P=0.036$) and have fewer friends vaccinated against HPV ($P=0.002$). Participants who were uninsured ($P=0.011$), diagnosed with HPV ($P<0.001$), and had a family member ($P<0.001$) or friend ($P<0.001$) diagnosed with cervical cancer were more likely to perceive themselves to be at risk for developing cervical cancer in future years.

Quantitative Modeling of Circadian Rhythms

Sarah Cunningham, CURO Research Assistant
Dr. Jonathan Arnold, Genetics, Franklin College of Arts & Sciences

Many genes of *Neurospora crassa* are under the control of the biological clock in the cell. The clock consists of a closed network group involving the genes *white collar-1, white collar-2, frequency,* and *clock controlled genes* and their RNA and protein products. A model has been proposed that improves upon published models by differentiating between reactions in the cytoplasm and nucleus of the cell. Computer simulations and ensemble runs were used to test these models and refine them. The model created was found to fit experimental data collected from *Neurospora* better than previously published models. A better model could improve research done on all areas of the clock and further our understanding of circadian rhythms.

Energy Systems Module

Haley Daniel, CURO Research Assistant
Dr. Tim Foutz, College of Engineering

An energy system was analyzed based on the full supply chain from primary energy resource availability to consumer demand in order to develop an energy systems module for use in a freshman-sophomore engineering education setting. Each step in power generation and consumption was studied and analyzed in order to emphasize the importance of understanding the process from an engineering standpoint. Aspects of sustainability at each level were also considered. A flow chart of pertinent data and information in the power sector was compiled

and included transportation, power generation, emissions, transmission, distribution, and consumer demand. It is suggested here that this could supplement coursework in various engineering disciplines. From this analysis, data for each component in the system were compiled and detailed, with one being that the average household energy consumption in the state of Georgia was determined to be 13,176 kWh in 2012. This module can be used as a guideline for understanding the interconnectedness of the energy systems process and can serve as a basis for conceptualizing improvements to an existing system.

Spintronics in π-Conjugated Semiconductors: Investigating MEHPPV OLED Magneto-Property Temperature Dependence

Tyler Daugherty, CURO Research Assistant
Dr. Tho Nguyen, Physics & Astronomy, Franklin College of Arts & Sciences

We present findings from the investigation of the effects on magneto-properties of OLEDs when exposed to high-temperature environments. We fabricate organic light emitting diodes (OLEDs) using an organic polymer mixture of MEHPPV and PDOT and test under high thermal conditions in a cryostat with oscillating magnetic field application. The research is important for the development of OLEDs, specifically for integration into common technology which necessitates functionality at a wide birth of temperatures and fields.

Participatory Media: Self-Image and Perception in Women

Aashka Dave, CURO Research Assistant
Dr. Leara Rhodes, Grady College of Journalism & Mass Communication

Participatory media is a developing concept in today's media landscape. A form of media that combines the typically disparate fields of content creation and content consumption, participatory media is very nearly eponymous. Audience members submit content for publication and consumption by other audience members, making audiences both content creators and content consumers. This research investigates participatory media and how it influences body-image and self-perception in women and girls. The research also discusses audience receptivity to furthered media messaging as a result of image and perception influences. A content analysis examined content from three participatory media platforms: *Rookie Magazine*, *Interrupt Magazine*, and *BuzzFeed*. *Rookie Magazine*, founded in September 2011, has a large following among its audience of teenage girls and is continuing to grow. *Interrupt Magazine* has an audience of women in their twenties, but also caters to the LGBTQ community. *BuzzFeed*, as a more mainstream media platform, rounds out the research, providing an opportunity to examine participatory media on a larger scale. Content from these publications was examined through five different themes: body, personality, perception, image, beauty, and size. Content was labelled according to eleven negatively and positively perceived emotions in conjunction with these themes. This information formed the basis for a discussion on the positivity or negativity of participatory media platforms as they relate to image and perception, and resulting audience receptivity. The research consequently determines that participatory media platforms are a positive source of self-image and perception-based thought processes through the emotions that they induce.

Exploring Resistance to Change through Concern for Diversity

Amber Davidson, CURO Research Assistant, CURO Graduation Distinction
Dr. Karl Kuhnert, Psychology, Franklin College of Arts & Sciences

Resistance to change is a common challenge faced by organizations. There are more changes in the workplace today than ever before, especially as organizations strive to bring in innovation, creativity, and a more heterogeneous workforce, which ultimately creates a more diverse work environment. Resistance to change can be viewed in two ways. First, resistance can be interpreted negatively: as a problem, threat, or an enemy to be done away with through any means necessary. Second, resistance to change can be seen more positively: as a way to communicate or a way to interpret discomfort or hesitancy from employees. Colleges and universities also experience resistance to change as they keep up with changing rules and regulations, and which perspective of resistance they take can impact their success in the future. In order to explore resistance to change, the present study examines the importance of openness to new ideas at a university in the southeastern United States. This study found that employees at the university who were more open to new ideas saw a need for increased diversity. When accounting for length of time spent at the organization, this study further found that newer employees' resistance to change and diversity is not different than that of longer-tenured employees. Interestingly, this implies that longer-tenured employees, who are generally older too, are not more likely to resist attempts to increase diversity practices. Greater attention should be directed at gaining the support of all employees, not just new employees, when introducing new diversity programs.

The Role of Leader Experience on Employee Turnover

Amber Davidson, CURO Research Assistant, CURO Graduation Distinction
Kelsey Hamilton
Dr. Brian Hoffman, Psychology, Franklin College of Arts & Sciences

Recent research suggests that leader experience may be a catalyst for employee turnover (Hamori & Koyncu, 2015; Heavey, Holwerda, & Hausknecht, 2013). Given the importance of retaining top talent in the modern world of work (Ployhart, Weekley, & Baughman, 2006), organizations should examine leadership experience as a potential influence on employee turnover. In the current study, N = 155 CEOs from various Italian companies completed a survey. The average level of work experience for the CEOs was 18.24 years (SD = 9.25), while their followers had an average level of work experience of 11.79 years (SD = 8.80). Financial data came from the company Aida, software version 81.00, on 12/08/2014. Our study explores the impact of CEO work experience on staff turnover rates and turnover costs. Our results show a positive relationship between CEO work experience and staff turnover rates $r = 0.27$, $p = 0.04$. Additionally, the relationship between CEO work experience and turnover costs was positive $r = 0.34$, $p = 0.01$. In other words, the more experience a CEO had, the more frequently employees left their organizations. This indicates that a leader's experience on the job may have a negative impact on employees, and that leadership training may be necessary to help leaders maintain positive relationships with followers (Bond & Naughton, 2011). Leader experience is often seen as vital for a company, but if it negatively impacts employee outcomes, its role in leader selection efforts should be diminished.

Sponge Colonization across Varying Salinity Regimes

Kaleigh Davis
Dr. Jeb Byers, Odum School of Ecology

The boring sponge, *Cliona celata*, occupies oyster shells and other calcareous substrate in marine environments. *C. celata* colonization reduces bivalve shell strength, resulting in increased predation vulnerability and

potentially habitat exclusion. Low salinity has been suggested to limit *C. celata* populations. We tested the effect of mean and variable salinity on *C. celata* colonization and survival, first with an observational study of field patterns. Oysters were collected from reefs with episodic freshwater pulses (high salinity variability) and from reefs with more stable salinity regimes to examine the percent cover of *C. celata*. Next, in a manipulative lab mesocosm trial we collected *C. celata* samples in the field and exposed them to different experimentally controlled salinity regimes. We quantified survival time, both over a stable salinity gradient and over high salinity variability (freshet like). We predict *C. celata* will be less tolerant of consistently low salinity and even less tolerant of freshwater pulses. Determining sponge tolerance to different salinity regimes will improve our ability to predict where *C. celata* will have a significant impact on oyster reefs, informing oyster restoration project design. We hope to extend this research to look for relationships between historical oyster reef locations and changes in *C. celata* range as a result of decreased freshwater input in coastal Georgia.

The Associations between Visceral Fat and Appendicular Bone Geometry in Healthy Prepubertal Boys and Girls

Sarah Dawson, CURO Research Assistant
Dr. Richard Lewis, Foods & Nutrition, College of Family & Consumer Sciences

Visceral adipose tissue (VAT) is considered a pathogenic fat depot implicated in numerous metabolic and musculoskeletal conditions. In adults, VAT has been shown to negatively predict cortical bone area and strength at the midshaft of the femur, whereas these associations in adolescents have not been studied. This project aimed to determine the relationships between VAT and cortical bone parameters from data collected on a group of healthy children, participants from a previously conducted vitamin D trial. Participants were black and white boys and girls in the early stages of puberty (mean age=11.3 years; sexual maturation stage 2/3; N=159). Measures of VAT (g), total body (TB) fat mass (kg), fat-free soft tissue (FFST; kg), bone area (TBBA; cm2), and bone mineral content (TBBMC; g) were determined by dual-energy X-ray absorptiometry (Delphi-A, Hologic Inc). Mid-radius and tibia bone geometry were measured via peripheral quantitative computed tomography at the 66% site from the distal growth plate (Stratec XCT 2000). Partial correlations correcting for maturation, race, sex, and FFST revealed negative associations between VAT and both tibia ($r=-0.194$, $p=.037$) and radius ($r=-0.219$, $p=.018$) cortical volumetric BMD (vBMD). Additionally, VAT was negatively correlated with both TBBA ($r=-0.353$, $p<.001$) and height-adjusted TBBMC ($r=-0.338$, $p<.001$). Since vBMD is an important determinant of cortical bone strength, our results suggest that higher VAT may contribute to the increased risk for skeletal fractures in obese adolescents. Further studies should explore the mechanisms through which VAT affects cortical bone.

The Effects of Dietary Wheat Gluten on Swine and Poultry Growth Performance

Carson De Mille, CURO Research Assistant
Dr. Michael Azain, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Wheat gluten is a high-protein ingredient that is commonly used in pet food and milk replacers, but not commonly in swine or poultry diets. Two studies were conducted to determine the effect of dietary wheat gluten on growth performance in weaned pigs and broiler chicks. The first study utilized 48 pigs that were weaned at approximately 21 days and blocked according to weight and gender (16 pens, 3 pigs/pen). There were 4 dietary treatments: 2 control diets and 2 experimental diets with 5 or 10% wheat gluten added at the

expense of corn and soybean meal. Dietary treatments were randomly assigned to pens. Test diets were fed for 2 weeks post weaning, followed by common diet an additional 2 weeks. The second study used 120 day-old broiler chicks that were randomly allotted to pens (20 pens, 6 birds/pen). Birds were assigned to one of 4 dietary treatments: 2 control diets and 2 experimental diets with 5 or 10% wheat gluten. The birds were weighed and feed intake was measured twice weekly for 2 weeks. In both pig and broiler studies, the animals fed diets with 5% wheat gluten grew significantly faster than the animals on other diets ($P<0.05$). Growth rate of pigs or chicks fed the 10% wheat gluten diets was similar to the control diets. These results suggest that the addition of 5% wheat gluten to swine or poultry diets results in a stimulation of growth. This response may be related to the unique amino acid profile of wheat gluten.

Analysis of the Physiological Role of a Bacterial RNA Repair System in *Salmonella*

Anquilla Deleveaux, CURO Research Assistant, CURO Graduation Distinction
Dr. Anna Karls, Microbiology, Franklin College of Arts & Sciences

Salmonella is a pathogen known to cause food poisoning. A specific strain of *Salmonella* known as *Salmonella enterica* subsp. *enterica* serovar Typhimurium is associated with gastrointestinal disease in humans. The pathogen is responsible for over a million illnesses, tens of thousands of hospitalization cases, and hundreds of deaths every year. In our lab, we are characterizing the components, regulation, and physiological role of an RNA repair system that is part of the RpoN regulon of *Salmonella*. RtcR is the transcriptional regulator of the operon that encodes the primary genes of this repair system. However, the environmental stimulus to activate RtcR is unknown. The RNA repair operon is not transcribed under most laboratory growth conditions, including in minimal or rich media; thus far, only the stress of treatment with Mitomycin C (MMC) has been found to induce expression of the RNA repair operon. MMC is an antibiotic that is known to cause RNA and DNA damage, but the mechanism of how MMC activates RtcR is unclear. Other components of the system include enzymes RtcA, RtcB, Rsr (Ro-sixty related protein) and noncoding Y RNAs, YrlA and YrlB. Although we know the enzymatic function of the components of the RNA repair system, their physiological importance is unknown. Therefore, the overall goal is to learn more about the system and how it functions. We want to know if there is an advantage to having the genes expressed from this operon under stressful conditions by stressing the cells with MMC and measuring viability.

Extracellular Vesicle Dependent Transfer of a Virulence Factor Confers Human Infectivity to *Trypanosoma brucei brucei*

Lauren Dennison, Foundation Fellow
Dr. Stephen Hajduk, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

Trypanosoma brucei rhodesiense is the causative agent of human African sleeping sickness. The related subspecies *Trypanosoma brucei brucei* is able to establish infection in cattle, but is highly susceptible to lysis by a subclass of human high-density lipoproteins called trypanosome lytic factor (TLF) and therefore unable to cause human African trypanosomiasis. *T. b. rhodesiense* is resistant to TLF due to the serum resistance-associated (SRA) protein, a virulence factor localized to the parasite endosome that binds and inhibits TLF following endocytosis. Recently, our lab has shown that African trypanosomes produce nanotubes that arise from initial budding of the flagellar membrane and vesicularize into heterologous 100 nm

extracellular vesicles (EVs). Western blot analysis of EVs purified from trypanosomes expressing the virulence factor SRA showed that SRA was a component of EVs. We next investigated if transfer of SRA to non-human infectious *T. b. brucei*, via EVs, contributed to pathogenesis. We confirmed EV mediated SRA transfer to *T. b. brucei* by flow cytometry and showed that direct addition of SRA containing EVs to wild-type *T. b. brucei* cells leads to increased survival upon incubation with TLF. Additionally, co-cultivation of *T. b. brucei* and SRA expressing *T. b. rhodesiense* in a trans-well chamber which blocked direct cell-cell contact but allowed EV diffusion conferred TLF resistance to *T. b. brucei*. Our findings show that cell-cell communication, mediated by EVs, can alter the pathogenicity of African trypanosomes.

Stresses Induce Alternate Growth Phenotype in *K. lactis* Yeast Cells
Kaley Desher, CURO Research Assistant
Dr. Michael McEachern, Genetics, Franklin College of Arts & Sciences

When exposed to stresses, *Kluyveromyces lactis* yeast cells exhibit altered cell growth phenotype. It was shown that cells grown on medium containing 0.5 mM sodium arsenate were converted at 50-90% frequency to either of two growing alternate colony morphologies. These altered forms were able to switch back to the normal faster growing morphology at high frequency, indicating the possibility of an epigenetic switch in the growth behavior of *K. lactis* cells. Various strains of *K. lactis* were exposed to different stresses to evaluate which strains are capable of generating the slow growing phenotype at high frequency as well as whether these colonies are more resistant to stresses. Several *K. lactis* strains were plated on YPD plates as well as starvation, 1.2 M NaCl, and 1.5 M KCl stress plates. Dilutions of colonies from each condition were performed so that the presence of the different colony phenotypes could be quantified for comparison purposes.

The Importance of Personality and Emotion in Women's Support for Georgia's Secession, 1860-1861
Melissa DeVelvis, CURO Graduation Distinction
Dr. Stephen Berry, History, Franklin College of Arts & Sciences

Last semester, I completed my honors thesis titled "From 'great excitement' to 'gloomy and threatening:' White Women's Responses to Georgia's Secession, 1860-1861." Through studying letters, journals, and newspaper articles written and read by upper-class antebellum women, I argued that their opinions regarding secession were heavily influenced by personality and degree of contentment with their antebellum lives. Women who felt restricted by plantation life, for instance, often embraced secession as a sign of change and opportunity. Others, more prone to anxiety and worry, denounced secession and predicted the devastation of war. To best illustrate the importance of emotion and personality in deciding one's opinion on secession, I used the letters of sisters Florence and Georgia King of St. Simon's Island, Georgia. Both were raised wealthy on the same isolated plantation, and both were greatly burdened by their mother's death and their ensuing responsibilities. Florence, always a worrier, immediately sensed that secession would wreak havoc on the South and fretted over the ensuing changes. Her sister Georgia responded in the opposite manner, delighting in the escape from her dull life offered by the exciting debates in Milledgeville. These findings are significant in that they reveal mixed opinions surrounding secession in Georgia, rather than unanimous support. Using primary sources such as letters and journals has granted me greater insight into women's history during the time period, an area less explored. Finally,

a study in Civil War events as they occurred differs from the dominant "Lost Cause" memory discussed by historians.

Executive Function Moderates Relationship between Mobility and Functional Independence in Older Adults

Jonathan Dickens, CURO Research Assistant, CURO Graduation Distinction
Dr. L. Stephen Miller, Psychology, Franklin College of Arts & Sciences

Prior research has shown a positive relationship between executive function (EF) and mobility. Similarly, mobility is positively related to functional independence in older adults. This study examined EF as a moderator of the relationship between mobility and functional independence in 62 cognitively intact older adults (39 female) aged 64 to 99 (M = 72.02, SD = 7.46). Mobility was measured using the Short Physical Performance Battery (SPPB); balance, gait, and chair stand subtests were summed to obtain a total score. EF and functional independence were assessed via the CNS-Vital Signs cognitive battery and the Direct Assessment of Functional Status-Revised (DAFS-R), respectively. Hierarchical moderation analysis was conducted first with EF, SPPB total score, and EF x SPPB as predictors of DAFS-R, and then with each of the SPPB subtests independently. Significant interactions were further investigated via simple slopes analysis at ± 1 SD of EF. Age was controlled in all analyses. EF x SPPB predicted DAFS-R ($F = 5.099$, $p = .028$), and significant subtest interactions included gait x EF ($F = 6.470$, $p = .014$) and chair stand x EF ($F = 4.275$, $p = .043$). Simple slopes analyses indicated that SPPB ($t = 2.13$, $p = .038$) and gait ($t = 2.20$, $p = .031$) predicted DAFS-R only at lower levels of EF. Results confirm that EF and mobility interact to predict functional independence in healthy, older adults. In older adults with poor EF, slower gait and weaker lower extremity strength may indicate greater risk for functional decline.

The Refugee Health Care Process: Israel and Syria

Jacqueline DiStefano, CURO Research Assistant
Dr. Denise Clark Lewis, Child & Family Development, College of Family & Consumer Sciences

Since the civil unrest in Syria began in 2011, over four million Syrians have fled and another 6.5 million have become internally displaced. Despite the long and tense history between Israel and Syria, Israel has been providing healthcare to fleeing and injured Syrian children, civilians, and fighters since early 2013. This form of conflict and distance can cause a dehumanization of enemy nations by creating a negative stereotypical image of the individuals based on the greater geopolitical landscape. My research on this situation focuses on individual human relationships between Israeli healthcare providers and Syrian patients. I want to understand the dynamics of their interactions, specifically, how their relationships were influenced by the healthcare process. Participants were Israeli healthcare providers who came from a variety of different cultural, religious, and social backgrounds as well as different healthcare careers. Qualitative data were carefully analyzed by two researchers through Atlas TI in order to bring out a variety of themes showing if and how their relationships evolved over time and what types of barriers they overcame. Overall, the study is intended to show the experiences of the healthcare providers and their Syrian patients and how these experiences influence bidirectional humanization.

Hollywood's Risqué Years: Female Body Exposure in Pre-Code Film

Molly Dodd, CURO Research Assistant
Dr. Patricia Hunt-Hurst, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences

Hollywood's allure has fascinated Americans since the industry's inception. To some dismay, the silver screen's molding influence surpassed that of traditional centers of influence, such as home, church, and school (Griffith & Mayer, p. 191, 1970). Hollywood's power to directly transmit messages to an impressionable population unsettled many over the fear of Hollywood's ability to perpetuate "immoral behavior." The classification "Pre-Code" describes movies produced prior to the 1934 implementation of Motion Picture Producers and Distributors' Code. The Code banned the portrayal of "immoral behaviors;" however, prior to 1934 "Hollywood made movies for adults who didn't want to be lied to about human nature…[it was] a complex, diverse, socially responsive American cinema" (Viera, p. 6, 1999). In this research, I analyzed female body exposure in fifteen Pre-Code films spanning from 1925 to 1934, including, *Hula* (1925), *Glorifying the American Girl* (1929), and *The Gold Diggers of 1933* (1933). Considered "Hollywood's risqué years," my research provides summary statistics on the portrayal of body exposure in its frequency, function, and degree in comparison with film criticism. My research hypothesizes the influence of female body exposure in Pre-Code film on the progression of female exposure found in socially acceptable fashion and dress. It is considered that "American morals and manners were sped up more by the screen than by any other agency except possibly the automobile" (Griffith & Mayer, p. 198, 1970). Thus, the portrayal of females in Pre-Code films can be considered a catalyzing factor in the social emancipation of women.

Understanding Elementary Reading Fluency and Reading Comprehension

Justin Dooly, CURO Research Assistant
Darrian Bailey
Dr. Paula Schwanenflugel, Educational Psychology, College of Education

The Physical Activity and Learning (PAL) program is a five-year federal grant program designed to study the effects that physical activity has on literacy and reading comprehension. This five day a week program took place at Fowler Drive Elementary School and Chase Street Elementary School in Athens, GA. The method in which this research was conducted was based on grade level. Students participated in one of two groups (2nd and 3rd graders; and 4th and 5th graders) so the students could read grade-level passages and receive grade-level instruction. Research was conducted in order to determine the effects of the PAL program and subsequent exposure to expository texts on students' fluency and comprehension. In the reading fluency enrichment, choral and echo reading strategies were employed in order to determine these practices' effectiveness in the classroom. These strategies were introduced to ensure that these students attained the knowledge for fluency as they progress in the education system. Reading comprehension was a secondary approach to the research. As a result, several strategies were implemented into daily practice. Such procedures included understanding the significance of bolded, highlighted, or otherwise simple queues for important vocabulary; providing experience with questions after reading the material; as well as subjecting students to various forms of questions they may encounter in the future. Ultimately, this research will not only help identify effective practices for improving reading fluency and reading comprehension, but it will also provide an academic jumpstart for those in the program.

Cutting Carbon in the Empire State of the South: A Policy Proposition for Putting Georgia ahead of the Curve

Jonah Driggers, Foundation Fellow
Dr. Jennifer Rice, Geography, Franklin College of Arts & Sciences

Climate change is already having, and will continue to have, profound implications around the world. These impacts include intensification of tropical storms and hurricanes, increased temperatures, rising sea levels, and drought-induced water shortages in both the residential and agricultural sectors. These physical changes will in turn impact social and economic systems. Response to the current and potential impacts of climate change is growing in the US and beyond: the Obama Administration has taken steps to address the role of the US as the largest cumulative emitter of greenhouse gases, thousands of protests have taken place worldwide, and billions of dollars have been divested from fossil-fuel companies. Despite these political and social responses, Georgia remains reluctant to address climate change. By failing to act early on this issue, Georgia is putting both its citizens and its reputation as a national leader at risk. This paper argues that the state should establish itself as a leader in energy innovation and sustainability for both economic and social benefits. To this end, a literature review and subsequent cost-benefit analysis were conducted to evaluate the status quo and three policy alternatives: a revenue-neutral carbon tax in Atlanta; introduction of net-metering technology statewide; and energy labeling and comparison of energy consumption. Based on this evaluation, this paper advocates the implementation of a revenue-neutral carbon tax in Atlanta as the most effective tool to mitigate carbon emissions and place Georgia in a strategic position in the years to come.

The Effect of Yopt2 and *Ssae* Proteins in Wasp Development of Aphids

Stephanie Duff
Dr. Vincent Starai, Microbiology, Franklin College of Arts & Sciences

Some *Acyrthosiphon pisum*, or the pea aphid, contain the endosymbiotic bacteria *Hamiltonella defensa* that is infected with the bacteriophage APSE, which prevents larval development of parasitic wasps such as *Aphidius ervi* from developing within the aphid. The pea aphid is unable to be eliminated by common pesticides, unlike other insects, which increases the chances for crop loss due to its massive population size. My objective is to use yeast as a simple eukaryotic model system and characterize the function of the *SsaE* and *YopT2* effectors from *H. Defensa*. Some include identifying the effects on yeast physiology and membrane trafficking pathways. The procedures include spot plating to test for toxicity and staining with FM4-64 (many of the effects are not known yet but further research progress will result in more findings). The effects will shed light on the mechanisms by which this protein disrupts wasp development. Plasmids with and without the *YopT2* effector protein proved to be nontoxic to the eukaryotic cells. Performing this study to better understand the host-symbiont-pathogen interactions in *A. pisum-H. defensa-A. ervi* system through a yeast model may help to prevent the massive population of pea aphids from killing agriculturally important crops.

Identification of CRISPR Adaptation Complexes and Associated Nucleic Acids in *Pyrococcus furiosus*

Justin Dumrongkulraksa, CURO Honors Scholar, CURO Research Assistant
Dr. Michael Terns, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

CRISPR (Clustered, Regularly Interspaced, Short Palindromic Repeats) loci and their

associated genes (Cas) comprise an adaptive defense system in bacteria and archaea. This immune system protects the organism against phages and other foreign genetic elements. Immunity is conferred via the acquisition and incorporation of invader DNA into the CRISPR locus. The locus is then transcribed to produce an RNA complement (crRNA), which guides Cas nucleases in targeted invader DNA or RNA destruction. In the archaeon *Pyrococcus furiosus*, our lab has recently obtained genetic evidence linking four Cas proteins (Cas 1, Cas 2, and Cas4-1 and 4-2) to the function of integration of new invader sequences in a process called CRISPR adaptation. However, the individual roles of each protein in the process are unknown, and will be an area of exploration in my research. To examine how each of these proteins functions in the cell, a number of experiments will be performed in order to test whether or not each protein is a member of a larger functional complex. Additionally, the ability of each protein to bind, recognize, or capture CRISPR and invader DNA will be tested. A CRISPR locus sequence called the leader is required for adaptation. As Cas 1, Cas 2, Cas 4-1, and Cas 4-2 are believed to have some role in adaptation, the leader along with invader DNA is expected to be found when these proteins are immunoprecipitated. This finding would provide substantial insight into this relatively new system.

Use of Pre-Pen Skin Testing as an Antimicrobial Stewardship Initiative in a Not-for-Profit Community Health System

Ian Dunne
Dr. Lindsey Welch, Division of Experience Programs, College of Pharmacy

Pre-Pen (benzylpenicilloyl polylysine) is a penicillin skin test antigen indicated for the assessment of penicillin hypersensitivity in patients with a history of penicillin allergy. Reported penicillin allergies increase both antibiotic costs and resistance by requiring use of alternatives such as carbapenems, vancomycin, and clindamycin. Pre-Pen offers potential to allow safe use of penicillin or related beta-lactam antibiotics resulting in cost savings while avoiding risks of increasing resistance from unnecessary overuse. The objective of this study is to determine clinical and financial impacts of Pre-Pen implementation in patients with a history of suspected IgE-mediated penicillin allergy. In 2014, Pre-Pen was added to the health-system formulary and restricted for use by infectious disease physicians or the antibiotic stewardship team. A pre-approved protocol for nurse administration of Pre-Pen was developed as well as a process for the team to contact physicians in the event of needed therapy changes based on test results. This retrospective chart review included adult inpatients admitted to the health system who received Pre-Pen between August 2014 and February 2015. Included patients had a suspected or confirmed infection that could be treated with beta-lactam antibiotics. Patients were excluded based on history of anaphylaxis, immunocompromised status, or any condition interfering with interpretation of test results. The primary outcomes of this study include antibiotic therapy before and after Pre-Pen and antibiotic acquisition cost data. Secondary outcomes include skin test results and the number of tests ordered secondary to stewardship team recommendations.

Atomic Hydrogen Sticking on Amorphous Water-Ice

John Dupuy
Dr. Phillip Stancil & Dr. Steven Lewis, Physics & Astronomy, Franklin College of Arts & Sciences

Gas-grain reactions have been invoked to explain the formation of many molecules in the interstellar medium (ISM). Molecular hydrogen is one such molecule. Utilizing

classical molecular dynamics, we are in the process of simulating the sticking and/or scattering process of a hydrogen atom on an amorphous water-ice slab (about 20 angstroms thick). Two temperatures of the slab (10 and 70 K) and a variety of kinetic temperatures (10 - 600 K) for the atom are used to model conditions of the ISM. We will determine the sticking probabilities and coefficients using one hundred simulations at each kinetic temperature of the atom for each temperature of the ice. The goal is to verify our results with previous simulations and experiments so that we can move forward with different molecular species (such as O_2) whose primary formation mechanism is through gas-grain reactions. As of now, we are in the process of determining interaction parameters to be utilized for the H-H_2O potential interaction. Once these parameters are calculated, the simulation will be run and analyzed to verify that these parameters describe the system in a physical way.

Evaluating the Climatic and Hydrologic Triggers for the Onset of Harmful Algal Blooms in Inland Water Bodies

Elizabeth Dyer
Dr. Adam Milewski, Geology, Franklin College of Arts & Sciences

Harmful algal blooms (HABs) are a serious environmental problem. They can form in both saltwater and freshwater and can cause serious health problems for wildlife, humans, and agriculture. The formation of saltwater harmful algal blooms has been studied more than freshwater blooms. Therefore, this study focused on looking at the factors that cause the development of HABs in freshwater, to see if they are similar to the factors that cause their presence in saltwater. It is important to ascertain these factors in order to find ways to avoid, prevent, or manage decreased water quality in public water supply. HABs are usually caused by an excess of nutrients being permitted to settle in one place by the timing of environmental factors; this excess of nutrients allows an algae bloom to grow very quickly. We investigated environmental factors (e.g., temperature and streamflow) in Lake Lanier, GA to evaluate the controls of two important parameters. It was hypothesized that we will find that harmful algal blooms are more likely to develop during warm weather and low streamflow, which allows the nutrients and algae to accumulate. The temperature of the water was gathered from field testing, and streamflow was obtained from the USGS. The presence or absence of harmful algal blooms in the lake was determined from Chlorophyll-A field testing and remote sensing algorithms. The results show a strong correlation between high streamflow during the seven days before sampling and lower Chlorophyll-A values; no correlation was found between water temperature and Chlorophyll-A values.

Freggie's Green Machine: The Development of an Entertainment Education Nutrition Intervention for Low-Income Preschool Children

Laura Eckhardt, CURO Research Assistant
Dr. Caree Cotwright, Foods & Nutrition, College of Family & Consumer Sciences

Childhood obesity is a major issue in America, with more than a third of children being overweight or obese. An ideal location to deliver nutrition education is in early childcare centers due to the amount of time spent in that environment and the development of children's food preferences at an early age. One way to promote healthy behavior is to encourage higher intakes of fruits and vegetables. The purpose of this study is to examine the effectiveness of an entertainment education nutrition intervention (i.e. interactive lessons, songs, puppet shows) on young children's fruit and vegetable preferences. The study will be conducted at two low-income childcare centers in Clarke County, Georgia and will include children

ages 3 to 5. One center will serve as the intervention and the other will be the control. The intervention will include nutrition lessons and tastings for three fruits (blueberries, peaches, kiwi) and three vegetables (beets, sweet potatoes, broccoli). The intervention will be conducted for 6 weeks with one new fruit or vegetable being introduced each week. All nutrition lessons will be introduced by Freggie (fruits + veggies), a fun character that will inspire healthy choices with his Green Machine (fruit and veggie cart). We hypothesize that an entertainment education nutrition intervention will improve young children's fruit and vegetable preferences, which will be measured via a previously validated taste and rate protocol, teacher survey, and parent survey. The results of this study will be used to make recommendations for future nutrition interventions targeting low-income preschool children.

How Can We Create a Sustainable Campus? An Assessment of Students' Awareness and Attitudes toward Food Waste and Sustainability in On-Campus Dining Halls

Emily Edwards, CURO Research Assistant
Dr. Juan Meng, Grady College of Journalism & Mass Communication

Roughly one-quarter of the University of Georgia student body is enrolled in the UGA Food Services' meal plan, which offers unlimited access to five on-campus dining halls. However, a substantial amount of food waste is generated in these facilities each day. Therefore, this study is designed to better understand UGA students' awareness, attitudes, and behaviors towards sustainability practices and food waste generation. Two research methods were employed in this study to investigate the topic. First, the researcher conducted an online survey to collect information from UGA undergraduate students who are currently or have been enrolled in the meal plan. Secondly, in-depth interviews with selected employees at UGA Food Services were carried out. The research findings indicated that while UGA students perceive sustainability as an important issue, they do not general act on these beliefs. Research also indicated that students are generally unaware of Food Services' sustainability practices and thus do not act in ways to engender the success of those practices. Lastly, research suggested increasing awareness of sustainability practices could change student behavior; thus, the findings of the study could point to messaging strategies that can be developed and implemented to change student attitudes and behaviors and ultimately reduce food waste generation on campus.

Purification of Endopolygalacturonase from *Aspergillus niger*

Linda Egbosiuba, CURO Research Assistant
Dr. Carl Bergmann, Biochemistry & Molecular Biology, Franklin College of Arts & Sciences

The enzymes produced by fungi that degrade plant cell wall pectin play crucial roles in both agriculture and industry. Crop loss due to phytopathogenic fungi is a worldwide problem. Dr. Bergmann's lab studies the biochemistry of cell wall degrading enzymes (CWDE). The goal is understanding the biochemical properties and specificity of these enzymes. Pathogenic fungi use cell wall degrading enzymes (CWDEs) as virulence factors to macerate host tissues both in the establishment and expansion phases of infection. Thus, knowing the mechanisms by which CWDEs function in the host plant cell wall and which proteins are secreted by the fungus during infection is key to understanding the interactions of this pathogen with plants. We focus on endopolygalacturonases (EPGs) from *Aspergilus niger*. EPGs are among the first enzymes produced by the pathogen to break down the plant cell wall. EPGs specifically
