CURO Symposium 2003

Center for Undergraduate Research Opportunities

University of Georgia, Tate Student Center
April 14-15, 2003

CALL FOR ABSTRACTS

The Center for Undergraduate Research Opportunities at the University of Georgia provides a forum for all undergraduates to present original research sponsored by faculty members. Undergraduate students from all disciplines are encouraged to participate. Representatives of public and private higher education institutions in Georgia are encouraged to apply.

Presentations may be in the form of an oral presentation, poster session, exhibition, performance, or work of art. Students can also present a tutorial about a research methodology or new technology. Undergraduate researchers who are at various stages of the research process are encouraged to submit abstracts describing where they are in the research process and the issues they face. Those who wish to present their work should submit an application located on the CURO Website, an abstract of a maximum of 250 words, and a brief supporting letter from the sponsoring faculty member no later than January 10, 2003. Group research projects should be submitted with one application and one letter of faculty support. All abstracts will receive student peer review with faculty guidance. All participants accepted into the symposium will be notified by February 14, 2003, and their abstracts will be published in a book of abstracts. Sponsoring faculty will be invited to preside at their students' sessions. Abstract submission is open to all undergraduate researchers.

Best Paper Awards
Papers on work being presented at the CURO symposium submitted by March 7, 2003 will be considered 'best paper' awards in humanities, sciences, and social sciences.

Purpose of the Symposium:
- Highlight excellence in research by undergraduate students.
- Enrich the undergraduate experience by promoting communication and cooperation between faculty and students.
- Inform undergraduates at the University of Georgia about the many existing opportunities available for collaboration with faculty to produce original research projects at the University of Georgia.
- Provide an opportunity for undergraduate researchers in the state of Georgia to engage with their peer researchers.

Criteria for Selection:
- Originality and quality of research.
- Quality of written abstract.
- Ethical and responsible research.
- Extent of involvement of the undergraduate student in the development of the research design and execution of the project. Research presented at the CURO Symposium should go beyond work completed for a class paper or project.
- A letter of support from supervising faculty.

This event will be free and open to the public. All interested faculty and students are encouraged to attend the CURO Symposium. For more information, contact Dr. Pamela B. Kleiber, Associate Director, Honors Program, 203 Moore College, Athens, Georgia, 30602, CURO@uga.edu, (706) 542-3240.

CURO 2002 Symposium at Glance

Monday, April 15, 2002

Concurrent Oral Sessions **9:05 a.m. -3:20 p.m.**
Tate Student Center Conference Rooms 138, 139, 140, 141, 142

Opening Sessions and Welcome **4:00 p.m.**
Tate Student Center, Georgia Room

Keynote Address **Dr. Steven Stice**
Georgia Research Alliance Eminent Scholar
Department of Animal and Dairy Science

A View from the Laboratory:
Scientific Possibilities and Ethical Restraint in Human Stem Cell Research

Reception and Poster Presentations **5:00 p.m. – 7:00 p.m.**
Sponsored by the Honors Program
Tate Center, Georgia Room

Tuesday, April 16, 2002

Visual and Performing Arts Presentations
Memorial Ballroom

Welcome **9:00 a.m.**

- **Gallery Talks**
- **Poetry Reading**
- **Dance Performances**
- **Musical Performances**

Closing Session
Memorial Ballroom

Reception sponsored by the Honors Program **3:30 p.m.**

Awards Ceremony **4:00 p.m. – 6:00 p.m.**

Evening Concert **8:00 p.m.**
Hodgson Hall

Monday, April 15, 2002

Concurrent Sessions
Tate Student Center Conference Rooms 138, 139, 140, 141, 142

9:05-9:55 a.m. **First Concurrent Session**

Room 138	**Siobahn Beaton**	Progress toward the Partial Purification of a Pectin Biosynthetic Gene
	Faculty Mentor	Dr. Debra Mohnen, Complex Carbohydrate Research Center, University of Georgia
	April Harper	Expression of Putative Arabidopsis UDP-Glucuronic Acid 4-Epimerase Genes
	Faculty Mentor	Dr. Debra Mohnen, Complex Carbohydrate Research Center, University of Georgia
	Donte Howard	Use of a Non-Radioactive Gel Assay to Assess whether Protein Purification Separates a Pectin Degradative Activity from the Pectin Biosynthetic Enzyme Alpha-1, 4-Galacturonosyltransferase
	Faculty Mentor	Dr. Debra Mohnen, Complex Carbohydrate Research Center, University of Georgia
Room 139	**Jacoby Hudson, Cassandra Kirkland, and Crystal Oliver**	Identifying Expressed Genes in Sorghum
	Faculty Mentors	Dr. Marie-Michèle Pratt and Dr. Lee Pratt, Department of Botany, University of Georgia
	Dipinder Singh Keer	An Online Analytical Processing Approach to Single Nucleotide Polymorphism Discovery and Analysis
	Faculty Mentors	Dr. Marie-Michèle Pratt, Dr. Chun Liang, and Dr. Lee Pratt, Department of Botany, and Dr. Mark Huber, Department of Management Information Systems, University of Georgia
	Dmitri Kolychev	Analysis of Microsatellites in Sorghum ESTs
	Faculty Mentors	Dr. Marie-Michèle Pratt, Dr. Lee Pratt, and Dr. Suchendra M.Bhandarkar, Department of Botany, University of Georgia
Room 140	**Eirin Kallestad**	It Was Broken, but They Did Not Fix It: Italian Election Reform in the Nineties
	Faculty Mentor	Dr. Christopher S. Allen, Department of Political Science, University of Georgia

	Matt Edwards	Evaluating the Moscow Center for Export Control's Role as a Non-Proliferation Epistemic Community Member
	Faculty Mentor	Dr. Gary Bertsch, Department of Political Science, University of Georgia

10:10-11:00 a.m. **Second Concurrent Session**

Room 138	**David Cureton**	Development of an *In Vitro* Packaging System for Streptomyces Bacteriophage
	Faculty Mentor	Dr. Janet Westpheling, Department of Genetics, University of Georgia
	Amanda Hudson	Screening Mutant Yeast Strains for Abnormalities in the Localization of snoRNA
	Faculty Mentor	Dr. Michael Terns, Department of Biochemistry and Molecular Biology, University of Georgia
Room 139	**Kristen Bryant**	Rapid Detection of *Salmonella* Using Three DNA Extraction Methods in Conjunction with Polymerase Chain Reaction
	Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia
	Quyen Dam	Clones of Resistant *Enterococcus faecium* Found in Humans and in Their Pets
	Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia
	Jessie Hopkins	Comparison of Several DNA Extraction Methods in Conjunction with PCR for the Rapid Detection of *Rhodococcus equi* and *Steptococcis equi*
	Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia
Room 140	**Lotus Seeley**	The Construction of the Lesbian Identity in the Undergraduate Classroom
	Faculty Mentor	Dr. Bonnie Dow, Women's Studies, University of Georgia
	Carrie Brooks	Reaching Across Cultures: An International Teaching Experience
	Faculty Mentor	Dr. Carole Henry, Art Education, University of Georgia
	Robert Brown	Risk/Resilience Systems and Child Behavioral Development
	Faculty Mentor	Dr. R. W. Kamphaus, Department of Educational Psychology, University of Georgia

Room 141	**Robin Seagraves**	New Balance Athens: "Endorsed by No One but Our Valued Customers"
	Faculty Mentor	Dr. Michael Lomax, Department of Physical Education and Sports Studies, University of Georgia
	Sara Smith	Optimization of Textural and Structural Properties of a Refrigerated Soy Based Dessert
	Faculty Mentor	Dr. Milena Corredig, Department of Food Science and Technology, University of Georgia
	Margaret Young	Adintern.com: A Website to Assist Advertising Focused Students in Finding, Getting, Keeping, and Leaving an Internship
	Faculty Mentor	Dr. Kirsten L. Strausbaugh, Department of Advertising/Public Relations, University of Georgia
Room 142	**Applying and Getting Accepted to the National Conference on Undergraduate Research (NCUR): A Panel**	
11:15 a.m.-12:05 p.m.	**Third Concurrent Session**	
Room 138	**Peter Harri**	Gene Expression in *Leishmania*: Control of Protein Synthesis in *Leishmania* 5' Untranslated Regions
	Faculty Mentor	Dr. Kojo Mensa-Wilmot, Department of Cellular Biology, University of Georgia
	Sharon Ballew	Bumblebee and Wildflower Species Associations
	Faculty Mentor	Dr. John Pickering, A & S Institute of Ecology, University of Georgia
	Amanda Casto	Analysis of the Role of the Protein Hfq in the Regulation of Polyadenylation in *Escherichia coli*
	Faculty Mentor	Dr. Sidney Kushner, Department of Genetics, University of Georgia
Room 139	**Jeff Halley**	Cell Wall-Degrading Enzymes from the Fungus That Causes the Devastating Rice Blast Disease
	Faculty Mentor	Dr. Sheng Cheng Wu, Department of Biochemistry and Molecular Biology, University of Georgia
	Lindsay Boozer	Lack of Utility of Creatinine Concentration for the Diagnosis of Feline Chronic Renal Insufficiency
	Faculty Mentors	Dr. Scott Brown, Department of Physiology and Pharmacology, University of Georgia
	Gregory Fonzo	The Effects of Exercise of Brain Derived Neurotrophic Factor
	Faculty Mentor	Dr. R. K. Dishman, Department of Exercise Science, University of Georgia

Room 140	**Heather Howdeshell**	Ceramic Analysis at Lake Springs (9Cb22): A Late Archaic Site of the Savannah River Valley
	Faculty Mentor	Dr. Mark Williams, Department of Anthropology, University of Georgia
	Crystal Leaver	Motivations of U.S. Southern Homegardeners: Preserving the Past in the Modern World
	Faculty Mentor	Dr. Virginia D. Nazarea, Department of Anthropology, University of Georgia
	Kathleen Teeples	Biometric Differences between Otoliths of Two Species of Sea Catfish
	Faculty Mentor	Dr. Elizabeth Reitz, Georgia Museum of Natural History, University of Georgia
Room 141	**Adam Cureton**	Differences in Cognitive Content between Propositions with Equivalent Referential Truth Conditions
	Faculty Mentor	Dr. Yuri Balashov, Department of Philosophy, University of Georgia
	Adam Cureton	Privacy as Autonomous Control of Personal Information
	Faculty Mentor	Dr. Clark Wolf, Department of Philosophy, University of Georgia
	Joshua Striker	Time and Myth: Literary/Philosophical Accounts/ Representations
	Faculty Mentor	Dr. Thomas Cerbu, Department of Comparative Literature Department, University of Georgia
Room 142	**Finding Opportunities for Extramural Undergraduate Research: A Panel**	
12:20 p.m. **1:10 p.m.**	**4th Concurrent Session**	
Room 138	**Claudia Vargas**	The Genomic Study of Multigene Families of *Pneumocystis carinii* for Potential Drug Targets
	Faculty Mentor	Dr. Jonathan Arnold, Department of Genetics, University of Georgia
	Kate Smith	Immunohistochemical (IHC) Detection of Natural Killer Cells in Fish
	Faculty Mentor	Dr. Kenneth S. Latimer, Department of Pathology, University of Georgia

	John Woodruff	The Generation of Mutations in the N-Terminal Region of the Protoporphyrinogen Oxidase of *Bacillus subtilis* to Create a Protein Capable of Mitochondrial Targeting in Mammalian Cells
	Faculty Mentor	Dr. Harry Dailey, Department of Microbiology, University of Georgia
Room 139	**Parul Shah**	Induction of Apoptosis by Rabies Virus Proteins
	Faculty Mentor	Dr. Zhen F. Fu, Department of Pathology, College of Veterinary Medicine, University of Georgia
	Jai Sikes	Developing a Sensor for Measuring Suspended-Sediment Concentrations
	Faculty Mentor	Dr. Bruce L. Upchurch, Department of Biological and Agricultural Engineering, University of Georgia
	Glorianne de Guzman and Joseph Moore	Application of Bioinformatics for Analysis of Sorghum ESTs
	Faculty Mentors	Dr. Marie-Michèle Pratt and Dr. Lee Pratt, Department of Botany, University of Georgia
Room 140	**Charlie Pitts**	Georgian Computer Usage
	Faculty Mentor	Dr. James Bason, Survey Research Center, University of Georgia
	Jennifer Byrne	An Assessment of Judicial Review and Judicial Behavior: The Factors That Influence the Supreme Court Decision Making Process
	Faculty Mentor	Dr. Stefanie Lindquist, Department of Political Science, University of Georgia
	Sayan De	The Progress and Modernization of Former East German Healthcare after Communism
	Faculty Mentor	Dr. Max Reinhart, Department of Germanic and Slavic Languages, University of Georgia
Room 141	**Andrew Littlejohn**	Ferdinand Warren: Artist, Craftsman, American Aristocrat
	Faculty Mentor	Dr. William Eiland, Georgia Museum of Art, University of Georgia
	Lorina Naci	"each morning I get up with one word in mind: plastik…"
	Faculty Mentor	Professor William Paul Jr., Drawing and Painting, School of Art, University of Georgia
	Lynn Nguyen	Chinese Classical Dance
	Faculty Mentor	Dr. Mark Wheeler, Department of Dance, University of Georgia

Room 142 **Association of Women in Science: A UGA Chapter Panel**

1:25 5th Concurrent Session
2:15

Room 138	**Chris Hartley**	Experimental Study of Male-Male Combat in a Parasitoid Wasp
	Faculty Mentor	Dr. Robert W. Matthews, Department of Entomology, University of Georgia
	Tricia Rodriguez	Amphibian Declines and the Frog Fungus Disease: Effects of Infection of Frog Eggs and Tadpoles
	Faculty Mentor	Dr. David Porter, Department of Botany, University of Georgia
	Buudoan V. Tran	Parameter Development and Application of the Glycam Force Field for Sialic Acid Derivatives
	Faculty Mentors	Dr. Karl N. Kirschner and Dr. Robert J. Woods, Complex Carbohydrate Research Center, University of Georgia
Room 139	**Kenneth Miller**	Synthesis and Use of Caged Compounds to Explore Cellular Processes
	Faculty Mentor	Dr. Timothy Dore, Department of Chemistry, University of Georgia
Room 140	**Chandler McClellan**	A Data Envelopment Analysis of the Efficiency of Georgia Politicians
	Faculty Mentor	Dr. David Mustard, Department of Economics, University of Georgia
	Jeffrey Pugh	Public Perception of "FONAG": An Ecuadorian Watershed Sustainability Program Case Study
	Faculty Mentor	Dr. Fausto Sarmiento, Center for Latin American and Caribbean Studies, University of Georgia
Room 141	**Julie Orlemanski**	In the Room: A Performative Text of Story, Poetics, and Criticism
	Faculty Mentor	Dr. Richard Menke, Department of English, University of Georgia
	Ben Emanuel	Shakespeare on Screen: Henry in Hollywood
	Faculty Mentor	Dr. Frances Teague, Department of English, University of Georgia
	John Stark	Friendship in the Age of Sensitivity: The Correspondence between Johann Wilhelm Ludwig Gleim and Johann Georg Jacobi
	Faculty Mentor	Dr. Mark Kagel, Department of Germanic and Slavic Languages, University of Georgia

Room 142 **Publishing as an Undergraduate Researcher: Editors of JURO@GA and The Undergraduate Science Bulletin (TSUB)**

2:30- 3:20 p.m. **6th Concurrent Session**

Room 138	**Marina Kozak**	Differential Glycosylation of Normal and Neoplastic hCG
	Faculty Mentor	Dr. J. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia
	Eric Morishige	Transgenic Study of a Conserved Neuropeptide Network for Feeding Regulation in *Drosophila*
	Faculty Mentor	Dr. Ping Shen, Department of Cellular Biology, University of Georgia
	Alexandra Isabel Sahora	Cellular Tropism of an Undescribed Ehrlichia from White-Tailed Deer
	Faculty Mentors	Dr. William R. Davidson, Southeastern Cooperative Wildlife Disease Study (SCWDS), Dr. Elizabeth W. Howerth, Department of Pathology, Dr. David E. Stallknecht, Department of Medical Microbiology and Parasitology, College of Veterinary Medicine, Dr. Danny Mead, Southeastern Cooperative Wildlife Disease Study (SCWDS), University of Georgia
	Eric Wright	Isolation and Characterization of Novel Anaerobic Thermophilic Iron (III) - Reducing Bacteria
	Faculty Mentor	Dr. Juergen Wiegel, Department of Microbiology, University of Georgia
Room 139	**Vanessa Reynolds**	Cozaar Fails to Block Pressor Response in Cats
	Faculty Mentor	Dr. Scott Brown, Department of Physiology and Pharmacology, University of Georgia
	Amy Sexauer	Immunohistochemical Detection of Newcastle Disease Virus in Chickens Inoculated with Wild-Type and Infectious-Clone-Derived Newcastle Disease Virus
	Faculty Mentors	Dr. James Stanton and Dr. Corrie Brown, Department of Pathology, College of Veterinary Medicine, University of Georgia
	Julie Seale	Nitric Oxide Synthase mRNA Levels in *Trypanosoma cruzi* Infected iNOS Knockout and Wild Type Mice
	Faculty Mentor	Dr. Rick Tarleton, Department of Cellular Biology and Center for Tropical and Emerging Global Diseases, University of Georgia

Room 140	**Rodricus Ficklin**	The Multicultural Experience: Pre-Service Education Students in Early Childhood Education Related to Multicultural Beliefs and Attitudes
	Faculty Mentor	Dr. Judith Reiff, Department of Elementary Education, University of Georgia
	Cori Pelletier	Music Therapy with Premature Infants
	Faculty Mentor	Dr. Roy Grant, Music Therapy, School of Music, University of Georgia (Emeritus)
	Ryan Keen	Gender Differences in Internal and External Thought Focus among Prepubescent Children
	Faculty Mentor	Dr. Katherine Kipp, Department of Psychology, University of Georgia
Room 141	**Denny Aldridge**	Are We or Aren't We? Adorno and Aciman on Emigrant Identity
	Faculty Mentor	Dr. Katharina Wilson, Department of Comparative Literature, University of Georgia
	Drew Goldsmith	Received with Open Arms; A Study of the Parable of the Prodigal Son
	Faculty Mentor	Dr. Katharina Wilson, Department of Comparative Literature, University of Georgia
	Karen Viars	Joan of Arc: History's Conflicted Warrior
	Faculty Mentor	Dr. Katharina Wilson, Department of Comparative Literature, University of Georgia
Room 142	**Qualitative Research as a Method of Inquiry: A Panel –** Anne Ciccone, Ivo Ivanov, Matt Lerner, Julie Orlemanski, and Nadine Sumner	
	Faculty Mentor	Dr. Kathleen DeMarrais, Social Science Education, University of Georiga

Opening Session

Tate Student Center, Georgia Room A

4:00 p.m.	Welcome	Dr. Pamela B. Kleiber Associate Director, Honors Program and CURO
	Opening Remarks	Dr. Karen Holbrook, Senior Vice President for Academic Affairs and Provost
	Opening Presentation	Melissa Daniel Profiles of UGA Researchers
	Faculty Mentor	Dr. Carolina Acosta-Alzuru, Department of Public Relations, University of Georgia
Introduction of Dr. Steven Stice		Allison Mitchell, Humanities and Arts Editor of JURO@GA, English Major, and Biology Minor
	Keynote Address	Dr. Steven Stice Georgia Research Alliance Eminent Scholar Department of Animal and Dairy Science

A View from the Laboratory:
Scientific Possibilities and Ethical Restraint in Human Stem Cell Research

Announcement of the CURO 2002 Summer Research Fellowship Recipients	Dr. Harry Dailey, Department of Microbiology

5:00-7:00 p.m. Reception sponsored by the Honors Program (Georgia Room B) and Poster Presentations

Poster Presentations

Robert F. Adams Faculty Mentor	Daily Progeny Production and Sex Ratio in a Parasitoid Wasp Dr. Robert W. Matthews, Department of Entomology, University of Georgia
Laurie L. Barton Faculty Mentor	The Association of Service to Tolerance of Diversity: A Study of College Student Involvement in Community Service Dr. Lynda Henley Walters, Department of Child and Family Development, University of Georgia

Amanda Beggs, Matthew Jackson, Venus Jolly, Judith Niehuser, Ashley Pollock, Drew Prosser, Emily Toriani	Mate Preference and Offspring Fitness in *Drosophila pseudoobscura*
Faculty Mentors	Dr. Wyatt W. Anderson and Dr. Yong-Kyu Kim, Department of Genetics, and Dr. Patricia A. Gowaty, A & S Institue of Ecology, University of Georgia
Anna Biagi	Metamorphic History of the Shoulderbone Ultramafic Intrusion
Faculty Mentor	Dr. Michael Roden, Department of Geology, University of Georgia
Amanda M. Blackmon	Pain Factors Associated with a Strength and Power Training Program in Older Adults
Faculty Mentor	Dr. M. Elaine Cress, Department of Sports and Exercise Science and the Gerontology Center, University of Georgia
Amanda Casto	Analysis of the Role of the Protein Hfq in the Regulation of Polyadenylation in *Escherichia coli*
Faculty Mentor	Dr. Sidney Kushner, Department of Genetics, University of Georgia
Quyen Dam	Clones of Resistant *Enterococcus faecium* Found in Humans and in Their Pets
Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia
Glorianne de Guzman and Joseph Moore	Application of Bioinformatics for Analysis of Sorghum ESTs
Faculty Mentors	Dr. Marie-Michèle Pratt and Dr. Lee Pratt, Department of Botany
Lawrence Dougherty	Exploring Olfactory Response in *Drosophila melanogaster* and Evolutionary Theory of Aging
Faculty Mentor	Dr. Daniel Promislow, Department of Genetics, University of Georgia
Joseph Kirk Edwards	Refining the Pig Cloning Process: The Effect of Ovarian Follicle Diameter and the Amount of Cumulus Cells on *In Vitro* Maturation of Porcine Oocytes
Faculty Mentor	Dr. Steven Stice, Department of Animal and Dairy Science, University of Georgia
Daniel Folkers, Jai Sikes Sam Utley	Characterization of Nonlinear Viscoelastic Properties of Biomaterials, through High-Speed Linear Based Transformation
Faculty Mentor	Dr. Guigen Zhang, Department of Biological and Agricultural Engineering, University of Georgia

Holly H. Garner	Effect of Fill Weight and Initial Temperature on Processing Time for a Home Pickled Jicama Relish
Faculty Mentor	Dr. Elizabeth L. Andress, Department of Foods and Nutrition, University of Georgia
Brian Gerwe	Structural Genomics Using a Model Microorganism
Faculty Mentor	Dr. Michael W.W. Adams, Department of Biochemistry and Molecular Biology, University of Georgia
Leah Givens	Relative Pathogenicity of Two Strains of Canine Distemper Virus Originally Isolated from Lions
Faculty Mentors	Dr. James Stanton and Dr. Corrie Brown, Department of Pathology, College of Veterinary Medicine, University of Georgia
Scott Harelik	Identification of the NDV-Fusion Protein and NDV-Phosphoprotein in Transgenic Soybean Plants
Faculty Mentor	Dr. Wayne Parrott, Department of Crop and Soil Sciences, University of Georgia
Jessie Hopkins	Comparison of Several DNA Extraction Methods in Conjunction with PCR for the Rapid Detection of *Rhodococcus equi* and *Steptococcis equi*
Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia
Lindsay Hoskins	The Formation of Hirano Bodies in Mammalian Cell Culture
Faculty Mentors	Dr. Ruth Furukawa and Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia
Jacoby Hudson Cassandra Kirkland and Crystal Oliver	Identifying Expressed Genes in Sorghum
Faculty Mentors	Dr. Marie-Michèle Pratt and Dr. Lee Pratt, Department of Botany, University of Georgia
Ryan Keen	Gender Differences in Internal and External Thought Focus among Prepubescent Children
Faculty Mentor	Dr. Katherine Kipp, Department of Psychology, University of Georgia
Dipinder Singh Keer	An Online Analytical Processing Approach to Single Nucleotide Polymorphism Discovery and Analysis
Faculty Mentors	Dr. Marie-Michèle Pratt, Dr. Chun Liang, and Dr. Lee Pratt, Department of Botany, and Dr. Mark Huber, Department of Management Information Systems, University of Georgia
Emily Kirk	The Stevens Clinic - A Sports Medicine Facility
Faculty Mentor	Dr. Jane Lily, Interior Design, University of Georgia

Heather Kling	Utilization of Cover-Boards by Eastern Tiger Salamander (*Ambystoma tigrinum tigrinum*) Metamorphs at Brookhaven National Laboratory
Faculty Mentor	Dr. Timothy Green, Brookhaven National Laboratory, Upton, NY, and Dr. Karl Espelie, Department of Entomology, University of Georiga
Dmitri Kolychev	Analysis of Microsatellites in Sorghum ESTs
Faculty Mentor	Dr. Marie-Michèle Pratt, Dr. Lee Pratt, and Dr. Suchendra M. Bhandarkar, Department of Botany, University of Georgia
Meenakshi Lambha	Development of Cognitive Inhibition in Preschool Children
Faculty Mentor	Dr. Katherine Kipp, Department of Psychology, University of Georgia
Shelley Ledford	The Colorfastness of an Interlock T-shirt Material Laundered with a Detergent Compared to Laundering with a Detergent Plus Enzyme
Faculty Mentor	Dr. Nolan Etters, Department of Textiles, Merchandising, and Interiors, University of Georgia
Rachel Lewis	Neuropeptide Y as a Factor in Ethanol Consumption in Zucher Rats
Faculty Mentor	Dr. Gaylen Edwards, Department of Physiology and Pharmacology, College of Veterinary Medicine, University of Georgia
Cliff McLeroy	An Analytical Study of Interfacial Stresses in Bonded Materials
Faculty Mentor	Dr. Guigen Zhang, Department of Agricultural and Biological Engineering, University of Georgia
Eric Morishige	Transgenic Study of a Conserved Neuropeptide Network for Feeding Regulation in *Drosophila*
Faculty Mentor	Dr. Ping Shen, Department of Cellular Biology, University of Georgia
Sara Morris	Fish Oil: The Effect on Insulin Sensitivity When Incorporated into a High-fat Diet
Faculty Mentor	Dr. Dorothy B. Hausman, Department of Foods and Nutrition, University of Georgia
Cori Pelletier	Music Therapy with Premature Infants
Faculty Mentor	Dr. Roy Grant, Music Therapy, School of Music, University of Georgia (Emeritus)
Linda Pierce **Christine Oshansky**	Chimpanzees' Manipulation of Objects within the Hand
Faculty Mentor	Dr. Dorothy M. Fragaszy, Department of Psychology, University of Georgia

Jennifer Reingold	The Relationship between Critical Flicker Fusion Thresholds and Resting Systolic Blood Pressure
Faculty Mentor	Dr. Billy R. Hammond, Department of Psychology, University of Georgia
Tricia Rodriguez	Amphibian Declines and the Frog Fungus Disease: Effects of Infection of Frog Eggs and Tadpoles
Faculty Mentor	Dr. David Porter, Department of Botany, University of Georgia
Shomari Ruffin	Polar Endemism in Archaea: A Comparison of Archael 16S rDNA Sequences from the Arctic and Southern Oceans
Faculty Mentors	Dr. James T. Hollibaugh and Dr. Nasreen Bano, Department of Marine Sciences, University of Georgia
Alexandra Isabel Sahora	Cellular Tropism of an Undescribed Ehrlichia from White-Tailed Deer
Faculty Mentors	Dr. William R. Davidson, Southeastern Cooperative Wildlife Disease Study (SCWDS), Dr. Elizabeth W. Howerth, Department of Pathology, College of Veterinary Medicine, Dr. David E. Stallknecht, Department of Medical Microbiology and Parasitology, College of Veterinary Medicine, Dr. Danny Mead, Southeastern Cooperative Wildlife Disease Study (SCWDS), University of Georgia
Katrice Saudargas	Children's Friendship Groups: The Wannabes in the Clique Hierarchy
Faculty Mentor	Dr. Michele Lease, Department of Educational Psychology, Research and Measurement, University of Georgia
Amy Sexauer	Immunohistochemical Detection of Newcastle Disease Virus in Chickens Innoculated with Wild-Type and Infectious-Clone-Derived Newcastle Disease Virus
Faculty Mentor	Dr. Corrie Brown, Department of Pathology, University of Georgia
Sonbol Alexandria Shahid-Salles	Purification of Hirano Bodies in *Dictyostelium discoideum*
Faculty Mentors	Dr. Marcus Fechheimer and Dr. Ruth Furukawa, Department of Cellular Biology, University of Georgia
Jai Sikes	Developing a Sensor for Measuring Suspended-Sediment Concentration
Faculty Mentor	Dr. Bruce L. Upchurch, Department of Biological and Agricultural Engineering, University of Georgia
Lauren Stanchek	The Effect of Light Intensity on the Transformation Frequency of Soybean Somatic Embryos
Faculty Mentor	Dr. Wayne Parrott, Department of Crop and Soil Sciences, University of Georgia

Tracy K. Van Ells	The Use of Innunohistochemistry to Diagnose Chytridiomycosis in Frogs
Faculty Mentor	Dr. Corrie Brown, Department of Pathology, University of Georgia
Heidi Woessner	Cytoskeleton Induced Apoptosis of HeLa Cells
Faculty Mentors	Dr. Ruth Furukawa and Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia
Amber Wright	The Effect of Genetic Background on Stress Resistance in Transgenic Fruit Flies
Faculty Mentor	Dr. Daniel Promislow, Department of Genetics, University of Georgia
Eric Wright	Isolation and Characterization of Novel Anaerobic Thermophilic Iron(III)-Reducing Bacteria
Faculty Mentor	Dr. Juergen Wiegel, Department of Microbiology, University of Georgia

Tuesday, April 16, 2002
Memorial Ballroom

Opening of CURO Art Exhibition

9:00 a.m.	Welcome	Dr. Betty Jean Craige, Director, Center for Humanities and Arts, and University Professor of Comparative Literature
	Breakfast Reception	
9:15 - 10:15 a.m.	Gallery Talks Introduction	Dr. Carmon Colangelo, Director, Lamar Dodd School of Art

Stephanie Anderson
Faculty Mentor — Professor Edward Lambert, Fabric Design, Lamar Dodd School of Art, University of Georgia

Antibiotic Art
Jeff Edwards
Faculty Mentor — Professor Robert Stackhouse, Lamar Dodd Professorial Chair, Lamar Dodd School of Art, University of Georgia

Caitlin Martell
Faculty Mentor — Professor Melissa Harshman, Printmaking, Lamar Dodd School of Art, University of Georgia

Amanda Gary
Faculty Mentor — Professor Edward Lambert, Fabric Design, Lamar Dodd School of Art, University of Georgia

"each morning I get up with one word in mind: plastik…"
Lorina Naci
Faculty Mentor — Professor William Paul, Jr., Drawing and Painting, Lamar Dodd School of Art, University of Georiga

Theresa Marie Sporer
Faculty Mentor — Professor Larry Millard, Sculpture, Lamar Dodd School of Art, University of Georgia

Art Exhibit arranged by Professor Edward Lambert

Performing Arts Presentations
Memorial Ballroom

10:15 – 10:30 a.m.	**Jennifer Srygley** Faculty Mentor	Poetry Reading Professor Judson Mitcham, Department of English, University of Georgia

10:45 – 11:45 a.m.	**Lynn Nguyen** Faculty Mentor	Chinese Classical Dance Dr. Mark Wheeler, Department of Dance, University of Georgia
	Elizabeth Lide Faculty Mentor	Improvisation in the Choreographic Process Dr. Bala Sarasvati, Department of Dance, University of Georgia

12:00 – 2:30 p.m. **Instrumental and Vocal Music Performances**

Performances arranged by Lisa Bartholow, School of Music

Closing Session

Memorial Ballroom

3:30 p.m. Reception sponsored by the Honors Program

4:00 – 6:00 p.m.	Awards Ceremony	Professor Jere W. Morehead, Associate Provost and Director, Honors Program Dr. Karen Holbrook Senior Vice President for Academic Affairs and Provost

Presentation of the Excellence in Undergraduate Research Mentoring Awards

Presentation of the Georgia Museum of Natural History Joshua Laerem Award for Undergraduate Research

Presentation of the Best Paper Awards in Science and Social Science

8:00 p.m. Evening Concert Hodgson Hall

The Excellence In Undergraduate Research Mentoring Award

The Office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2000. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students. Awards are presented at the CURO Symposium Awards ceremony, Tuesday, April 16, 4:00 p.m. Memorial Hall Ballroom.

2002

Faculty Awards
Professor William D. Paul, Jr. Professor of Art
Dr. Katherine Kipp, Associate Professor of Psychology

Faculty Recognition
Dr. Susan Sanchez, Assistant Professor of Veterinary Medicine

Department Award
Department of Biochemistry and Molecular Biology,
Dr. J. David Puett, Department Head

Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Professor, Physics and Astronomy

Dr. Heinz-Bernd Schuttler, Professor and Department Head, Physics and Astronomy
Dr. Jonathan Arnold, Professor, Genetics
Dr. Susmita Datta, Professor, Georgia State University
Dr. David Logan, Professor, Clark Atlanta University
Dr. William Steffans, Professor, Clark Atlanta University

2001 Selection Committee

Chair, Dr. Pamela B. Kleiber, Associate Director, Honors Program and CURO Coordinator
Dr. Marcus Fechheimer, Professor, Cell Biology
Dr. Sylvia Hutchinson, Professor, Institute of Higher Education
Dr. Katarzyna Jerzak, Assistant Professor, Comparative Literature
Dr. David MacIntosh, Associate Professor, Environmental Health Sciences
Dr. Vaun MacArthur, Research Scientist, Savannah River Ecology Laboratory
Dr. Dean Rojek, Associate Professor, Sociology

2001

Faculty Awards
Dr. Marcus Fechheimer, Professor of Cell Biology

Faculty Recognition
Dr. David MacIntosh, Associate Professor of Environmental Health Sciences
Dr. Dean Rojek, Associate Professor of Sociology

Department Award

Daily Progeny Production and Sex Ratio in a Parasitoid Wasp

Robert F. Adams
Dr. Robert W. Matthews, Department of Entomology, University of Georgia

The parasitic wasp *Melittobia digitata* (Hymenoptera: Eulophidae) parasitizes various insects. Progeny develop gregariously in groups of 100-800 (depending on host size). The extremely female biased sex ratio (95:5) is unusual among insects, and males develop from unfertilized eggs. The entire brood emerges over a period of two weeks, but males appear to develop on an accelerated schedule relative to females. The goals of this study were to determine (1) whether females lay unfertilized (male producing) eggs first or space male production over their entire tenure on a host, and (2) to determine the average daily progeny production and sex ratio. Fifty-six cultures were established using single females placed on mud dauber hosts. These cultures were divided into 14 groups of four replicates each. Beginning three days later, females were removed from four cultures; this was continued daily thereafter over the next 13 days until all females (four per day) had been removed from their hosts. In a parallel set of experiments, individual females were transferred to a new host each day over 17 days. All experiments were conducted at 25^{o} C. Progeny produced in both experiments were allowed to complete development, and the emerged adults were sexed and counted. Results showed that females space male production over their tenure on a host, averaging 4.2/day (range 1-8) and that daily egg production increased to about 63 over the first seven days, then tapered off as the host became fully exploited. Results are interpreted in the context of the wasp's natural history.

Are We or Aren't We? Adorno and Aciman on Emigrant Identity

Denny Aldridge
Dr. Katharina Wilson, Department of Comparative Literature, University of Georgia

Theodor Adorno fills his *Minima Moralia* with his stance on topics ranging from Snow White to Proust to the demise of communication. Of particular interest to Adorno is the plight of the intellectual in emigration. In his scathingly truthful tone, Adorno asserts that "every intellectual in emigration is, without exception, mutilated, and does well to acknowledge it himself." Adorno's philosophy struck me particularly while reading Andre Aciman's *Out of Egypt*, in which Aciman details his Jewish family's identity struggle as exiles living in Alexandria, Egypt. I therefore undertook the task of methodically applying Adorno's abstract ideas on emigrant identity to Aciman's autobiographical account. The more I read into the texts, the more strikingly parallel they became. More important than my literary analysis, however, is the insight that both authors offer into the psychological and social processes that all emigrants go through in order to assert their rightful place in their new "homeland." Adorno states that "for a man who no longer has a homeland, writing becomes a place to live." In writing *Out of Egypt*, Aciman escapes the shackles of emigrant alienation prescribed by Adorno. He breaks the cycle in his family and becomes an American citizen. In my comparative analysis, I shed light on the oftentimes overlooked status of emigrants, many of which, like Aciman, find refuge within America's borders.

Bumblebee and Wildflower Species Associations
Sharon Ballew
Dr. John Pickering, A & S Institute of Ecology, University of Georgia

The Internet is a means to improve teaching and research. It provides a powerful tool to enable citizen scientists and children to study nature and report their observations. In February 2002, for example, over 40,000 participants in the Great Backyard Bird Count reported observations of birds throughout North America via the Web www.birdsource.org. Research is needed to assess the quality of data reported by non-experts. Nature Days is a program in which students and other citizens establish ecological study sites and collect data to better understand and conserve nature. Participants will be assigned to a group with a designated leader who has natural history expertise. In 2002, these leaders will serve as mentors and monitors of groups studying pollination associations among bumblebees, butterflies, and flowers. The presentation will demonstrate how Web users can identify species and report their observations via their browser using online identification guides. These guides are primarily image-based and minimize technical terms. They have the potential to allow anyone anywhere to contribute to our understanding of all living things. More information can be found under Idnature Guides at www.discoverlife.org.

The Association of Service to Tolerance of Diversity: A Study of College Student Involvement in Community Service
Laurie L. Barton
Dr. Lynda Henley Walters, Department of Child and Family Development, University of Georgia

Community service has become an increasingly important factor in institutions of higher education for the personal development of college and university students. This research concerns the association of participation in community service with the personal development of university students. I am also interested in how exposure to diverse populations through community service affects tolerance of diversity. Data (psychosocial maturity such as identity development and commitment to community attitudes; attitudes toward community service, and involvement in community service) will be collected from students in large classes at the University of Georgia through the use of a questionnaire. The questionnaire will include inquiries based on the three scales: the community service attitude scale, the tolerance scale, and the developmental measure of personal maturity. The questionnaire will be distributed to approximately 300 students. Results will yield information about motivation for community service, the intrinsic and extrinsic benefits of participation in community service, and the tolerance of diversity that results from one's participation. With these results, it will be possible to begin to discriminate between the effects of developmental maturity, prior attitudes, and experience. The results will be helpful to researchers and practitioners whose interest is the personal development of college students.

Progress toward the Partial Purification of a Pectin Biosynthetic Gene
Siobahn Beaton, CURO Summer Research Fellow
Dr. Debra Mohnen, Complex Carbohydrate Research Center, University of Georgia

Cellulose, hemicellulose, and pectin are the major types of polysaccharides that comprise the primary plant cell wall. Homogalacturonan (HGA) is one of the pectic polysaccharides. HGA accounts for 60% of pectin. HGA is a linear polymer of 1,4-linked α-D-galactosyluronic acid residues (GalA). The transfer of GalA from UDP-GalA onto HGA is catalyzed by a galacturonosyltransferase (GalAT) that has its catalytic site facing the lumen of the Golgi. The goal of my research was to facilitate the purification of GalAT from *Arabidopsis thaliana*. Specifically, I fractionated partially purified *Arabidopsis* cell extract over ten different dye affinity resins and characterized those fractions enriched for GalAT activity. I used column chromatography followed by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) of the column fractions to analyze the complexity of proteins present in the different fractions. Based on the SDS-PAGE and GalAT activity results, one of the dye affinity resins, RY3, was shown to effectively enrich for GalAT activity. This resin is currently being used for the further purification of GalAT.

Mate Preference and Offspring Fitness in *Drosophila pseudoobscura*

Amanda Beggs, Matthew Jackson, Venus Jolly, Judith Niehuser, Ashley Pollock, Drew Prosser, and Emily Toriani
Dr. Patricia A. Gowaty, A & S Institute of Ecology, Dr. Wyatt W. Anderson, Dr. Yong-Kyu Kim, and Kyungsun Kim, Department of Genetics, University of Georgia

Natural selection is expected to adjust behavior to increase fitness. We tested this hypothesis with *Drosophila pseudoobscura* while observing the relationships between mate preference and fitness. Mate preference was determined in small arenas where a single fly was allowed to choose between two flies of the opposite sex eliminating all possibilities for male-male competition, female-female competition and male coercion or manipulation of females which were involved in ordinary mate choice studies. Matings were arranged with preferred (P) and non-preferred (NP) partners. We measured fecundity of females (number of eggs laid daily) and egg-to-adult viability of offspring. Our early studies have demonstrated that fecundity was higher in NP matings but not statistically significantly different from in P matings. However, offspring viability was significantly higher in P matings. Subsequently, we measured fitness of males while counting number of sperm delivered to females during copulation. In both male and female choice situations, NP matings delivered significantly more sperm to females than P matings. These results suggest that 1) freely expressed mate choice affects the fitness of offspring; and 2) the increase in fecundity and sperm observed in NP matings may be compensatory behavior for a low viability of offspring from these matings. As attempts to pinpoint the proximate cues for choosing partners in mate preference trials, we measured wing length of flies, which was proportional to their body size. We also measured quantities of cuticular hydrocarbons extracted from individual flies using gas chromatography/mass spectrometry (GC/MS). Preferred partners, regardless of sexes, were significantly bigger than NP partners. There was a nonsignificant tendency that NP partners produced more cuticular hydrocarbons than P partners did. Overall, our data provide evidence that social constraints are important in mate preference and offspring fitness.

Metamorphic History of the Shoulderbone Ultramafic Intrusion

Anna Biagi
Dr. Michael Roden, Department of Geology, University of Georgia

Georgia's Piedmont is underlain primarily by igneous and metamorphic rocks. These rocks formed throughout the Paleozoic during events coinciding with the Appalachian orogeny. Isolated bodies of ultramafic rocks may represent fragments of oceanic crust emplaced in the continental crust during the orogeny. The Shoulderbone schist, located northwest of Sparta, Georgia, is one such ultramafic body, and I hypothesize that it is a fragment of ocean crust. Seven samples have been taken from where the schist runs along Georgia Highway 16 and Centennial Road in Hancock County. Their mineralogy has and will be noted using a binocular-scope, a light microscope, and an electron microprobe. Preliminary research has found the mineralogy to include chlorite, olivene, amphiboles, and oxides. Further work with the microprobe will help determine which amphiboles and oxides are present, as well as the composition of the olivene. The major elements in the schists are SiO_2, MgO, and Fe_2O_3 (determined by the microprobe). The bulk chemical composition of these ultramafics will then be compared to those found in the ocean crust. The relationship of the minerals to each other and the presence of foliations also will be noted and compared between samples. Research of the Shoulderbone ultramafics will elucidate the metamorphic and tectonic history of the outcrop. Although this research only focuses on one small outcrop, it will be a step towards understanding the evolution of the Appalachians, which has been a mystery for nearly a century.

Pain Factors Associated with a Strength and Power Training Program in Older Adults

Amanda M. Blackmon
Tanya A. Miszko, Dr. M. Elaine Cress, Department of Sports and Exercise Science and the Gerontology Center, University of Georgia

Pain is often cited as a barrier to participation in an exercise program among older adult populations. Yet, once in an exercise program, research shows that exercise can have an analgesic effect, especially in those older adults with osteoarthritis. We know that exercise is necessary to maintain health and function, and inactivity can lead to declines in the neurological, musculoskeletal, and metabolic systems. Despite the known benefits of exercise, more than 60% of older adults are physically inactive. Therefore we asked the question: Does pain affect compliance and adherence to a strength and power training program with sessions 3 times/week for 16 weeks? The study included 25 older adults, with ages ranging from 65 to 82, with a mean age of 73.36. The participants reported the intensity, unpleasantness, and anatomical site of any pain. We are comparing the change in strength and physical function in those with chronic pain (CP; n=8) with the remainder of the group, that we considered the non-pain group (NP; n = 17). CP did not alter compliance or adherence. We found that the CP group realized a 28% increase in strength compared to a 20% increase in the NP group. Functional performance in the CP group increased 11-14%, which was similar or higher than the NP group. NP and CP did not differ in adherence or compliance. The CP group's gain in strength and function may represent an analgesic effect of exercise allowing those in chronic pain to improve function.

Lack of Utility of Creatinine Concentration for the Diagnosis of Feline Chronic Renal Insufficiency

Lindsay Boozer
Leslie Cartier, Susanne Sheldon, Sheerin Mathur, and Dr. Scott Brown, Department of Physiology and Pharmacology, University of Georgia

Clinically, mild to moderate chronic renal insufficiency is a frequent problem in cats. While serum creatinine is most often used to assess renal function in cats, each laboratory traditionally establishes its own normal ranges and the utility of these normal ranges to diagnose early chronic renal insufficiency has been challenged. To assess the utility of measurement of serum creatinine concentration in the diagnosis of renal insufficiency in cats, serum samples were taken from 15 cats with various levels of kidney function and submitted to laboratories located at academic institutions (n=8) or commercial facilities (n=4). The laboratories used various blood chemistry analyzers to assay for serum creatinine levels. While the study was not control-based, the subjects measured were both affected and unaffected by renal infarction or dysfunction. There was substantial variation among laboratories for serum samples obtained simultaneously from the same cat. Results were analyzed statistically for coefficient of variation and standard deviation calculations in order to adjust the values for comparison. When reported results were compared to established "normal" ranges at each laboratory, diagnostic errors were noted, such as false negative and false positive diagnoses. Using these laboratory "normal" ranges, some cats with normal kidney function were incorrectly diagnosed as having renal insufficiency while other cats with proven renal insufficiency were diagnosed as normal. Our results indicate that a reference range individualized to each laboratory is needed and that results from different laboratories cannot be directly compared. Critically, veterinarians relying upon currently published laboratory "normal" ranges for serum creatinine concentration for identifying the presence of chronic renal insufficiency in cats will experience a high probability of both false negative AND false positive results.

Reaching Across Cultures: An International Teaching Experience

Carrie Brooks
Dr. Carole Henry, Art Education, University of Georgia

The purpose of this research project was to investigate the potential success and possible benefits of art education students having practical classroom experience teaching art to non-English speaking students in another culture. During Spring Break 2001, I was one of three art education students who traveled to Cortona, Italy as part of a pilot program designed to explore the possibilities of teaching art in the Italian elementary school. We prepared lesson plans and taught in the Italian language to the students. Our project's goal was to make it possible in the future for Art Education classes to be offered as part of the UGA Studies Abroad Program in Cortona. Each of us had previously studied in Cortona as art students. I used my familiarity with the Italian language to help translate throughout the project and learned much about teaching in the process. We gathered data after each lesson through audio taped interview sessions and had these tapes transcribed. I analyzed the data to determine what I learned about working with non-English speaking students in another culture, what suggestions I had for other students attempting to do this in the future, and what I learned about myself as a teacher. I learned that it is possible to communicate depth of content despite language barriers. What was so unique about this project was that the nature of children and of visual art transcended verbal language. Recommendations based on the data were also developed for teachers teaching non-English speaking students in this country. These recommendations will be presented.

Risk/Resilience Systems and Child Behavioral Development

Robert Brown, CURO Apprentice
Dr. R. W. Kamphaus, Department of Educational Psychology, University of Georgia

This study tested Ann Masten's (2001) theory that most children develop adaptive behavioral repertoires. Masten proposed that three risk/resilience systems are responsible for the typical behavioral adjustment of children: relationships with parents, intelligence, and socioeconomic status. This pilot investigation tested part of her theory with a sample drawn from a larger longitudinal investigation of 800 children. This study assessed a sample of 58 children from grades 3 through 5 in three Athens/Clarke County elementary schools. Three groups were formed: 1) "well adapted" (children rated by two consecutive teachers as having few behavior problems in comparison to a national normative sample), 2) "disruptive behavior problems" (children rated by two consecutive teachers as having significant behavior problems), and 3) "changers" (children rated as having disruptive behavior problems in year one, but as having fewer behavior problems as rated by a new teacher in the following academic year). Dependent variables included parent/teacher relationship and intellectual/academic achievement, thus allowing for a preliminary test of two risk/resilience systems from Masten's theory. Analyses of variance were conducted comparing the three groups on each of six dependent variables. The results supported Masten's theory. Children who either were well adapted or were changers had better indicators of parent/teacher relationships and intellectual/academic development than children who remained in the disruptive behavior problems group. Teacher/child relationships were also found to be important for promoting adaptive behavioral development.

Rapid Detection of *Salmonella* Using Three DNA Extraction Methods in Conjunction with Polymerase Chain Reaction

Kristen Bryant
Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia

Controlling outbreaks of *Salmonella enterica* in horses when they arise can be extremely challenging; therefore, it is crucial to have a quick, very sensitive method that allows for rapid detection of this bacteria in asymptomatic horses so these animals are not put in contact with others. The primary objective of this study was to determine which DNA extraction method yields more DNA for prompt detection of *Salmonella*. Three DNA extraction methods were employed: the boding method, Ultra Clean ™ Fecal DNA Isolation Kit (Mo Bio Laboratories, Inc., Solana Beach, CA) and QIAamp DNA Stool mini kit (Qiagen Inc., Valencia, CA). The boiling method and the Ultra Clean ™ kit were used on duplicate logarithmic dilutions of a selenite broth containing over night growth of *Salmonella*. These DNA extractions were followed by amplification by polymerase chain reaction of a 475bp fragment of the *InvA* gene present only in *Salmonella*. The dilution method was able to detect only 10^6 bacteria, while Ultra Clean ™ was able to detect $3.6x10^3$ bacteria. In addition to the logarithmic serial dilutions, six selenite broths and three fecal samples from real clinical cases were also tested. These samples were extracted using Ultra Clean ™ and Q1Aamp DNA, always in duplicate Ultra Clean detected 6 positive selenites in comparison two only two by QIAamp. Three fecal samples were tested directly; two were negative by both test and one sample positive for both tests. Although the Ultra Clean ™ kit is the most time consuming, it appears to be the most effective in extracting the most DNA in both the quantitative serial dilutions, as well as in the clinical samples.

An Assessment of Judicial Review and Judicial Behavior: The Factors That Influence the Supreme Court Decision Making Process

Jennifer Byrne
Dr. Stefanie Lindquist, Department of Political Science, University of Georgia

In this study, I propose to develop an integrated case-related model, using a multivariate time series analysis to explain United States Supreme Court decisions in judicial review cases. In order to ascertain why the Supreme Court decides to uphold or strike down a piece of legislation in a given case, I examine eight factors that have been previously identified by scholars as contributing to the Court's decision in these cases. Specifically, I intend to test the impact of five different models that encompass the independent variables that I hypothesize will influence the Supreme Court's decision to strike down a federal statute as unconstitutional. The attitudinal model addresses the impact of justice ideology, measured by the criteria set forth by Segal and Spaeth (1993), including past voting behavior to predict votes in subsequent cases, facts from the lower court records of cases decided by the Supreme Court and editorials published in advance of nominee confirmation of the justices. The institutional model examines the impact that the solicitor general, congress, and interest groups have on the Supreme Court decision-making process. The issues model looks at the type of statute challenged and controls for the lower court decision, while the party capability model examines the impact of the type of litigant in a given case. Finally, the role of public opinion is examined through the use of the Stimson Public Mood Indicator, compared to how liberal the Supreme Court is in a given session. By combining several factors into a comprehensive multivariate model, a greater understanding of the judicial decision-making process can be achieved.

Analysis of the Role of the Protein Hfq in the Regulation of Polyadenylation in *Escherichia coli*
Amanda Casto
Dr. Sidney Kushner, Department of Genetics, University of Georgia

Polyadenylation is a term that refers to the enzymatic addition of adenine residues to the 3' end of mRNA transcripts. In prokaryotes, poly(A) tails are believed to promote the decay of mRNA transcripts by serving as binding sites for ribonucleases that degrade them. The purpose of this research is to investigate the effects of a protein known as Hfq on polyadenylation in *Escherichia coli*. Previous studies have indicated that poly(A) tails found in Hfq^- strains are significantly shorter than those found in wild type strains, presumably because Hfq either protects poly(A) tails from enzymatic degradation or aids in the action of poly(A) polymerase I (PAP I), the enzyme primarily responsible for poly(A) tail synthesis in *E. coli*. This hypothesis was initially tested by sequencing poly(A) tails from an Hfq^- strain. These tails were found to be of normal length, but contained non-A residues and were attached to the mRNA transcripts at positions where tails are not typically observed in wild type strains. The next step in this project will be to clone and sequence poly(A) tails from an *E. coli* strain deficient in both Hfq and polynucleotide phosphorylase (PNPase), an enzyme that is known to synthesize poly(A) tails containing non-A residues. Thus, the tails in this double mutant are expected to be homopolymeric and attached to the transcripts in positions where tails are usually observed in wild type strains.

Qualitative Research as a Method of Inquiry: A Panel
Anne Ciccone, Ivo Ivanov, Matt Lerner, Julie Orlemanski, Nadine Sumner
Dr. Kathleen DeMarrais, Social Science Education, University of Georgia

In the quest to understand the world around us, questions inevitably arise that cannot be addressed by quantitative research alone. Instead, a discipline of inquiry that probes individual and non-quantifiable issues is needed; in a word, certain questions demand qualitative research for their answering. Through our CURO research seminar, we explored the specific strengths, techniques, and limitations of qualitative research in their application to our own pilot projects. This panel will focus on our individual experiences of learning through qualitative research, learning not just about our chosen subjects but also about the research process in general. Each student will speak briefly about his or her experience and findings, and the panel will then accept questions from the audience. We intend to focus on the organic demands for a qualitative approach inherent in our research questions, on the actual process and techniques that we used, and on the final conclusions and evaluations to which our pilot projects lead us. Qualitative research experience on the undergraduate level is rare; thus we feel it is important that we share our insights and experiences of using qualitative research in hopes of stimulating more interest in and employment of this valuable mode of inquiry.

Differences in Cognitive Content between Propositions with Equivalent Referential Truth Conditions
Adam Cureton
Dr. Yuri Balashov, Department of Philosophy, University of Georgia

In everyday language, we often assert that two things are identical. We assert that 'the Morning Star is the Evening Star' or that 'Clark Kent is Superman' and intuitively understand the content of such statements. When we attempt to provide a philosophical underpinning for our intuitions, however, we arrive at a problem: When we assert that two things are identical, what exactly are these 'things.' Frege famously suggested that when we assert an identity, we assert that the names refer to the same objects. 'Morning Star' is the name we use to refer to the planet Venus, and 'Evening Star' is also used to refer to that same planet. Therefore, when we say that 'the Morning Star is the Evening Star' we mean that the terms 'Morning Star' and 'Evening Star' refer to the same object, Venus. If this is the case, however, how are we to differentiate between statements like 'Clark Kent is Clark Kent' and 'Clark Kent is Superman,' since both sets of names refer to the same object? The two statements appear to communicate different ideas, whereby the former is an uninteresting tautology, while the latter provides interesting information. I suggest that the difference in cognitive content between these classes of statements consists of differences in meta-linguistic facts and differences in ability to perform cognitive housekeeping functions. When I learn that 'Clark Kent is Superman,' I learn facts about how the terms 'Clark Kent' and 'Superman' are used in our language that I do not learn when I am told that 'Clark Kent is Clark Kent.' Also, when I learn that 'Clark Kent is Superman,' I am able to adjust some of my other beliefs given the new information that I would not be able to perform if I only learned that 'Clark Kent is Clark Kent.'

Privacy as Autonomous Control of Personal Information
Adam Cureton
Dr. Clark Wolf, Department of Philosophy, University of Georgia

Most of us have little trouble identifying cases in which we take our privacy to have been violated. Privacy violations seem to be clear-cut, and we consider other people as morally wrong if they participate in such actions. Once we examine our intuitions more closely, we find that our concept of privacy seems to be intimately connected with individual autonomy. I take up such an analysis in this project. I attempt to provide necessary and sufficient conditions for privacy infringements so that we are clearly able to identify such cases. Understood in the way I suggest, privacy interests amount to the range of autonomous actions an individual takes which concern the protection of self-regarding information. A violation of a person's privacy therefore amounts to a failure to respect that person's autonomy. Since most attribute a great deal of moral value to autonomy, analyzing privacy in terms of autonomy helps ground the moral value that most attribute to privacy, and thereby helps to justify the status of privacy as a moral right rather than merely an interest.

Development of an *In Vitro* Packaging System for a *Streptomyces* Bacteriophage

David Cureton, CURO Summer Research Fellow
Dr. Janet Westpheling, Department of Genetics, University of Georgia

Streptomyces are gram-positive, soil bacteria that produce most of the natural product antibiotics used in human and animal health care. *Streptomyces* have an unusual cycle of cellular differentiation and synthesize these antibiotics as part of their normal development. The stereochemistry of the compounds produced by *Streptomyces* is extremely complex, making them impossible to produce synthetically. Consequently, the genetic manipulation of commercially valuable species of *Streptomyces* may provide a means of generating novel antibiotics. The ability to transfer DNA from one *Streptomyces* species to another is crucial for generating recipient cells with recombinant genotypes. Recently, generalized transduction, a common method of transferring DNA between cells using bacterial viruses, or phage, was adapted for use in *Streptomyces* in the Westpheling lab. An extension of this technique is to use components of the phage to package DNA *in vitro* for the transduction of specific DNA sequences. The procedures for generating phage particles *in vitro* were adapted from similar systems developed for phages λ, P22, and ϕ29. The protocol includes the establishment of a growth curve to determine the time at which immature (empty) phage heads can be isolated and the conditions under which the nascent particles will mature after the incorporation of exogenous DNA. An important application of this technology will be the use of *in vitro* packaging to transduce antibiotic biosynthesis genes between species of *Streptomyces* to facilitate recombinatorial biosynthesis of novel antibiotics.

Clones of Resistant *Enterococcus faecium* Found in Humans and in Their Pets

Quyen Dam
Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia

By phenotypically and genotypically characterizing enterococci isolated from the feces of humans and their pets, this project examined whether enterococci can be transferred between hosts. *E. faecalis*, *E. faecium*, *E. avium*, and *E. hirae* were the species identified in a total of 199 isolates from eight households both from owners and their pets. Genotypic characterization by three PCR methods allowed identification of two households where the same *E. faecium* clones were carried in the feces of a human and their pet. *Enterococcus* resides in the intestinal tract of humans and animals without normally causing disease. Recently, infections caused by *Enterococcus* spp., particularly in hospitals, have become a major problem due to the trend in increasing antibiotic resistance. As a result, the manner and facility with which enterococci acquire resistance is of great importance. Transmission of resistant bacteria can take place through various routes and has raised concerns as to the possibility transmission through animals. Much study has been undertaken to investigate feed animals as a source of resistant bacteria; however, there has been little study on household pets as another source. In human medicine, administration of antibiotics is heavily scrutinized. In veterinary medicine, which employs many of the same antibiotics, administration is not as closely monitored. While the clones that we found common between humans and their pets might only be indicative of transient colonization, horizontal gene transfer could take place with other bacterial species within the intestinal tract resulting in a higher degree of antibiotic resistance in the normal flora *Enterococcus* spp. of humans.

Identifying the Risks of China's Nuclear Weapons Command-and-Control System in the Event of Political Crisis

Jon E. Davis, CURO Summer Research Fellow
Dr. Gary Bertsch, Department of Political Science, University of Georgia

The purpose of this study is to assess, as far as possible, the exact nature of China's nuclear command-and-control system in the hopes of identifying possible areas of risk of unauthorized or accidental launch in times of crisis. A qualitative case study will examine past weaknesses in China's nuclear weapons command-and-control structure; the current state of civil-military relations with regard to China's Strategic Missile Force (SMF); China's current strategic forces modernization program and its implications; the SMF's chain of command and leadership structure; and whether or not China's nuclear weapons contain use-control devices. The present study will be conducted in close conjunction with experts on nuclear security and nuclear weapons command-and-control at the Center for International Trade and Security/UGA. The study will utilize a variety academic publications, Chinese language newspapers and periodicals, and interviews of specialists on China's strategic forces and military affairs. Much like with the Soviet system over a decade ago, arms control experts have expressed concern about the reliability of China's command-and-control system in times of upheaval. A variety of centrifugal forces undermine the stability and continuity of the current regime. Rapid economic change, a weakening communist regime, growing numbers of riots and protests, and the political succession next year may contribute to potential future crises. Such crises could increase risks that China's nuclear controls could weaken or that these weapons could be used. This study identifies the weakest links in China's command-and-control system during crises, providing a useful framework for analysis of nuclear risks in China.

The Progress and Modernization of Former East German Healthcare after Communism

Sayan De, CURO Summer Research Fellow
Dr. Max Reinhart, Department of Germanic and Slavic Languages, University of Georgia

It is almost accepted fact that healthcare standards and methods of treatment in the developed world are relatively uniform. However, after the fall of the Iron Curtain, many distinct contrasts emerged both in the conditions of the facilities and the attitudes toward medical care. This study focuses on the efforts of the former East German sector to standardize healthcare services with the West from the perspective of healthcare professionals, public health officials, and objective health reports from various German cities. All subjective information was acquired through interviews and questionnaires with attending physicians (of various medical subspecialties) and spokespeople of health departments of six large cities in former East Germany. The interviews and surveys for physicians centered around, but were not restricted to, patient volume since 1991, the advances in technology, the frequency of continuing medical education, hospital funding for research, and their philosophy on modern patient care. Public health officials answered the same questions and also described trends in immunization, infant mortality, and public sanitation before and after 1991. The results of the interviews addressed a broad spectrum of opinions; however, a definite division of ideologies existed between older physicians educated under the communist system and younger physicians, who were raised during the communist regime, but educated after the fall of the Berlin Wall. The evidence seems to indicate a shift towards Westernization (i.e. capitalism) throughout the healthcare system, from the higher ranks of government and hospital administration to the patients.

Application of Bioinformatics for Analysis of Sorghum ESTs

Glorianne de Guzman and Joseph Moore, CURO Apprentices
Mrs. Aynsley Eastman, Mr. Manish Shah, Dr. Marie-Michèle Pratt, and Dr. Lee Pratt, Department of Botany, University of Georiga

At the Laboratory of Genomics and Bioinformatics at the University of Georgia, 117,924 high quality expressed sequence tags (ESTs) of sorghum that have been entered into the GenBank database. Bioinformatics has been used to analyze these ESTs for the discovery of Single Nucleotide Polymorphisms (SNPs), a variation in the genetic code at a specific point on the DNA. The location of SNPs serves as place markers in the sorghum genome allowing regions of gene expression to be identified. Although the majority of the SNPs may not affect the biology of the plant, they provide distinctions between individual genes. SNP analysis using bioinformatics has helped describe and create a detailed map to the genome of the sorghum plant. Bioinformatics, the science of using computers for organizing and processing biological data, allows scientists to decipher wet lab results in an ordered and systematic way. Computer programs such as Phrap, Phred, Polyphred, and Consed assign a numerical quality value to each nucleotide, align the sequences based on overlapping DNA regions, identify SNPs, and display the information in a logical presentation, respectively. These programs serve as tools of the bioinformaticist. The combination of these computer programs with a relational database makes it possible to analyze the massive amounts of data to compare DNA sequences and discover SNPs. After running Phred and Phrap, 10,697 gene clusters were identified by comparing high quality sequences to each other to look for homology. Ploy phred was then run on the gene clusters to detect SNPs by looking for high quality discrepancies in the same location in different contigs. Out of the 10,697 gene clusters, 625 sequences were assembled into 135 contigs and manually viewed to verify Polyphred results. 17 SNPs were confirmed in 5 of these contigs, resulting in 3.7% of the contigs viewed containing a SNP; therefore, by applying this percentage to the entire data set 396 contigs of the 10,697 contigs are hypothesized to contain at least one SNP. New techniques and data mining are being explored to find more efficient and economical means by which to locate and study SNPs. Success in this endeavor could provide a blueprint to mapping out other, more extensive genomes, such as the human genome.

Exploring Olfactory Response in *Drosophila melanogaster* and Evolutionary Theory of Aging

Lawrence Dougherty, CURO Summer Research Fellow
Dr. Daniel Promislow, Department of Genetics, University of Georgia

Experiments in biodemography have shown there is a genetic basis to aging. Aging is typically measured as the increase in probability of mortality. Many think that the cause of this increase is physiological decline. Experiments in gerontology have shown that genetically based physiological/behavioral traits of organisms change with age. The purpose of the current study is to incorporate approaches from both fields to more clearly understand the aging process. We hope to investigate the correlation between experimentally observed variation in aging and genetically based rates of change in physiological/behavioral traits. Genetically different lines of *Drosophila melanogaster* were studied by implementing experimental approaches from both fields. For demography, mortality data was collected. Olfactory response, a genetically controlled physiological trait, was examined for genetic variation at various ages to investigate age-related decline. Flies from each line were placed in a vial with a Q-tip treated with a fly repelling odor. The average number of flies located in the region of the vial farthest from the scent at time intervals was recorded to give an "avoidance score." The purpose of the study was to confirm that the test was sensitive enough to detect response differences and to see if results changed within lines as flies aged. For inbred female lines, significant genetic variation was detected in olfactory ability at an early age, and the rate at which the ability deteriorated showed variation as well. There is evidence to support continued study of genetic variation for physiological decline and eventually attempt to correlate olfactory response data with mortality data.

Refining the Pig Cloning Process: The Effect of Ovarian Follicle Diameter and the Amount of Cumulus Cells on *In Vitro* Maturation of Porcine Oocytes

Joseph Kirk Edwards
Dr. Kazuchika Miyoshi, Dr. Scott Pratt, Dr. Steven Stice, Department of Animal and Dairy Science, University of Georgia, and Dr. S. Jacek Rzucidlo, Prolinia, Inc.

In cloning procedures, there is considerable need for oocytes with superior ability to mature *in vitro*; however, the collection efficiency of such oocytes is hindered by the lack of evidence attributing maturation rates to any physical discriminating factors. It has been speculated, though, that ovarian follicle diameter and cumulus oocyte complex (COC) size may affect oocyte maturation rates, and thus, in this experiment, these factors are analyzed for such correlations. COCs collected from pig ovaries were separated into groups based on the diameter of the follicle they originated from (follicle diameter $<$ or $\geq$ 3mm) and the amount of cumulus cells surrounding the oocyte (COC size $<$ or $\geq$ 2x the diameter of the oocyte). The COCs were then cultured for a period of time, after which cumulus cells were removed and the oocyte's chromatin was examined under UV microscope to determine the maturity of each oocyte. Results of repeated tests showed that follicle diameter and COC size were not a factor in maturation progress after 24 hours, but rather were important at the 42 hours time span (the final stage of *in vitro* maturation); specifically, large follicles and large growths of cumulus cells favored an oocyte to reach nuclear maturity. In conclusion, oocytes derived from big follicles and having large cumulus cells investment exhibited superior ability for nuclear maturation. Therefore, these experiments showed that the tested criteria for aspiration and selection of COCs are crucial for obtaining high quality oocytes; these criteria can now be implemented in cloning procedures.

Evaluating the Moscow Center for Export Control's Role as a Non-Proliferation Epistemic Community Member

Matt Edwards, CURO Summer Research Fellow
Dr. Gary Bertsch, Department of Political Science, University of Georgia

The Moscow Center for Export Control (CEC) is a nongovernmental organization in Russia that runs seminars to teach private Russian firms proper export control compliance procedures. In order to understand whether the CEC may play a significant role in promoting export control compliance, it is necessary to understand what role the CEC plays *vis a vis* the targeted firms. Preliminary research indicates that an "epistemic community" is a *de facto* group of individuals and organizations that shares values, policy goals, and ideas of causal models. These groups may influence the actions of policy actors under conditions of uncertainty and ignorance. For the purposes of this research, the CEC is regarded as the epistemic community member, while private firms are treated as "policy actors." Information on the CEC was collected from four main sources. First, information on the "conditions of uncertainty" was collected from literature published by the CEC and other organizations. Second, witness accounts of the actual CEC seminars showed what information was presented to the "policy actors," and how it was presented. Third, interviews of individuals with extensive firsthand experience with the CEC provided insights on how effectively the CEC was providing this information. Fourth, the Center for International Trade and Security's (CITS) report to the U.S. government was used to determine the effectiveness of these seminars. Research indicates that where private firms are uncertain of export control compliance, the CEC can provide information that alters the rational calculations that businesses make. The CEC-provided information introduces new parameters into the decision-making process, decreases the costs, and increases the benefits associated with compliance. The theory predicts that under these conditions, the "policy actors" can be expected to behave differently after attending the seminars. The CITS report indicates that firms will behave differently after absorbing the CEC information, which supports the theory.

Shakespeare on Screen: Henry in Hollywood
Ben Emanuel, CURO Summer Research Fellow
Dr. Frances Teague, Department of English, University of Georgia

Part of a larger paper on the presence of William Shakespeare's canon in cinema, my presentation at the CURO Symposium would use video clips to explore the intertextual relations among two films deriving mainly from Shakespeare's *Henry IV, Part One* and *Henry IV, Part Two*: Orson Welles' *Chimes at Midnight* (1965) and Gus van Sant's *My Own Private Idaho* (1991). Implicit in this pairing is a double issue of adaptation: both filmmakers are interpreting Shakespeare's plays, but van Sant came upon the plays only through Welles' film and he alludes directly and extensively (despite his statements to the contrary) to his cinematic predecessor. The generation gap between the two directors, of course, makes for important contrasts between the two films. Thus, these two removals from the original texts sharpen the basic question of whether Shakespeare is still Shakespeare in productions on screen instead of on stage. In addition, they display the different approaches taken to adapting Shakespeare by two filmmakers of very different generations and traditions, one who spent a good bit of his career on Shakespeare (Welles produced and acted in stage productions and directed three Shakespearean films throughout his career), and one who has dealt with Shakespearean material only in the film at hand. The use of video clips in my presentation will allow me to detail the intertextual visual and cinematic relationships between these films in hopes of exploring their relationships to and removal from Shakespeare, keeping in mind the intertextual network of English chronicle histories and Elizabethan drama out of which the plays were originally born.

The Multicultural Experience: Pre-Service Education Students in Early Childhood Education Related to Multicultural Beliefs and Attitudes
Rodricus Ficklin, CURO Apprentice
Dr. Judith Reiff, Department of Elementary Education, University of Georgia

Given the increase of diversity in the United States public schools, all educators and students must face the reality of cultural diversity. This diversity takes place in and outside of the classroom. Often times, teachers are not trained in a diverse or multicultural environment. Introducing a multicultural curriculum or multicultural courses will provide pre-service teachers with the experience and knowledge that they need to be successful in teaching in a multicultural classroom. Information about various learning styles and concepts will be incorporated in this process. This investigation is an analysis of pre-service education students, and their multicultural beliefs and attitudes based on several administered instruments. Some of these instruments will include case studies, internet searches, readings related to diversity, and surveys.

Characterization of Nonlinear Viscoelastic Properties of Biomaterials through High-Speed Linear Based Transformation
Daniel Folkers, Jai Sikes, and Sam Utley
Dr. Guigen Zhang, Department of Biological and Agricultural Engineering, University of Georgia

This paper demonstrates how engineering principles can be applied to solve biomedical problems, such as characterizing the behavior of nonlinear viscoelastic materials. Viscoelastic materials exhibit stress/strain performance that is frequency, history, and path dependent. Likewise, a general mathematical expression is not available to describe nonlinear viscoelastic behavior. Characterization of the complex dynamic stiffness/modulus properties of nonlinear viscoelastic materials will help lead to optimization of biomedical and industrial products that utilize these materials. Common examples include medical devices, such as prosthetic limbs and orthopedic implants, manufacturing equipment, and consumer products. A new method to characterize nonlinear viscoelastic behavior has been developed. The new method employs analyzing the stress/strain response of a nonlinear viscoelastic material with Fast Fourier Transformation and high-speed data acquisition. With the new method, we demonstrate that nonlinear viscoelastic behavior can be characterized by our high-speed linear based transformation technique. These current findings are being used to design a physical apparatus to determine material characteristics of nonlinear and viscoelastic materials using both dynamic and static loading. It is our objective to produce such a device that is also highly accurate, user-friendly, and inexpensive for the public.

The Effects of Exercise on Brain Derived Neurotrophic Factor

Gregory Fonzo, CURO Apprentice
J.D Van Hoomissen, H. A. Chambliss, P. V. Holmes, and Dr. R. K. Dishman, Department of Exercise Science, University of Georgia

Brain derived neurotrophic factor (BDNF) is associated with depression. Exercise has been shown to increase BDNF in the hippocampus, similar to the antidepressant pharmacotherapy. This may provide insight into the biological mechanisms of the therapeutic effects of exercise on depression. The purpose of the study was to investigate the effects of exercise and antidepressant drugs on BDNF messenger ribonucleic acid (mRNA) in the olfactory bulbectomy animal model of depression. Male Long-Evans Rats (N=80) were randomly assigned using a 2 x 2 x 2 factorial design to the following conditions: 1) Sedentary (SED) vs. Activity Wheel (AW); 2) Saline (SAL) vs. Imipramine (IMP); 3) Sham (SHAM) vs. Olfactory Bulbectomy (OBX). All animals underwent either sham or OBX surgery, which requires bilateral removal of the olfactory bulbs. Rats were given daily injections (i.p.) of imipramine (10 mg/kg) or saline. One-half of the rats remained sedentary while the other half received an activity wheel in the cage. The entire experiment lasted 21 days. *In-situ* hybridization histochemistry with autoradiography was used to examine levels of BDNF in the hippocampus and dentate gyrus. There was a significant drug (SAL vs. IMP) x exercise (SED vs. AW) interaction ($p < .005$) in the dentate gyrus, and CA1, and CA3 regions of the hipppocampus. Chronic exercise elevated levels of BDNF mRNA in the saline but not the imipramine treatment groups. These results may help to examine the biological adaptations made in the brain following chronic exercise, which may help with the treatment and prevention of depression.

Effect of Fill Weight and Initial Temperature on Processing Time for a Home Pickled Jicama Relish

Holly H. Garner
Dr. Elizabeth L. Andress, Department of Foods and Nutrition, University of Georgia

The objective of this study was to determine the effects that typical consumer procedural variations have on heat penetration when processing pint glass jars of an acidified jicama relish recipe in boiling water. It is necessary to use thermal processing methods when making pickled products in order to prevent mold, yeast, and/or bacterial growth that produce spoilage when the product is stored. It was hypothesized that (1) as fill weight increases, required processing time will increase and (2) as initial fill temperature of jars decreases, required processing time will increase. To locate the cold spot for processing this product in pint canning jars, heating curve slopes (f_h values) were determined for each of five potential cold spots in each of 10 canner loads. Product temperatures were then measured at the cold spot throughout a 35-minute boiling water canning process for three treatments: control (standard canning procedure), high fill weight (HFW), and low initial temperature (IT). HFW resulted in decreased maximum jar temperature and a longer process requirement. A decrease of 5°C (64.5 vs. 69.7) in IT had no effect on either maximum jar temperature reached at the end of come-up (time to bring canner to boiling) or the 35-minute process at boiling. The major conclusion to be drawn from this study is that overfills should be avoided to insure expected heating rates and final maximum temperatures. Publishing a minimum number of jars to fill with a home canning recipe is one way to achieve this.

Structural Genomics Using a Model Microorganism

Brian Gerwe
Dr. Michael W.W. Adams, Department of Biochemistry and Molecular Biology, University of Georgia

The genome of *Pyrococcus furiosus,* a hyperthermophilic Archaeon, has been completely sequenced. The genome size is 1.908 Mbp and contains 2197 putative open reading frames (ORFs). The long-term objective in our laboratory is to develop a high-throughput cloning and protein expression system for use on a genome-wide scale. An analysis of the *P. furiosus* genome suggests that only about 23 % of the ORFs encode single subunit cytosolic proteins with no complex cofactors. It is evident that no single protocol will be able to accommodate expression of all proteins in the genome. The initial approach involves cloning each ORF into a modified *Escherichia coli* expression vector (pET-24d) such that the protein contains a N-terminal His-tag, $MA[H]_6GS$, used for affinity chromatography purification. Initial expression utilizes a range of standard growth protocols that are amenable to a high throughput procedure (i.e. temperature, growth media and inducer concentration) using commercial robotics. ORFs that do not yield soluble proteins in this protocol will enter alternative protocols that utilize conditions of increasing complexity. This will require the development of novel protocols to express genes that encode multisubunit proteins (mORFs), proteins that are membrane-associated, contain complex cofactors or a combination of all three. I will be presenting preliminary data on the cloning and expression of *P. furiosus* genes. Our initial results demonstrate a high success rate for both cloning and expression. Systematic variation of simple growth conditions greatly influences protein expression. This approach allows multiple conditions to be analyzed to optimize expression.

Relative Pathogenicity of Two Strains of Canine Distemper Virus Originally Isolated from Lions

Leah Givens
Dr. James Stanton and Dr. Corrie Brown, Department of Pathology, College of Veterinary Medicine, University of Georgia

Canine distemper virus (CDV) caused a 1994 epizootic among a population of lions in Tanzania's Serengeti National Park through contact of these lions with infected wild dogs. A similar outbreak occurred in 1991 and 1992 in captive felids at the Wildlife Waystation in San Fernando, California, resulting in the deaths of 17 cats, including leopards, tigers, lions, and jaguars. In this study, a post-mortem analysis compared ferrets infected with the African strain of the virus to those infected with the California strain, with an emphasis on the relative virulence and biology in each group after two, three, and four weeks post-infection. Immunohistochemical techniques revealed that the African strain tended to follow a stable course of infection with a less consistently fatal outcome when compared to the California strain. While ferrets infected with the California strain showed less viral load in the early stage of infection, the virus proved fatal for all such ferrets by four weeks post-infection. Some of the ferrets infected with the African strain, in contrast, developed only mild clinical signs and seemed to have recovered. However, at four weeks post-infection, viral antigen from the African isolate was detected in brain and salivary tissues. The significance of these particular findings lies in the discovery that the chronic nature of the African strain allows for increased viral transmission via salivary secretion, but may ultimately still prove fatal due to infection of the central nervous system.

Received with Open Arms; A Study of the Parable of the Prodigal Son
Drew Goldsmith
Dr. Katharina Wilson, Department of Comparative Literature, University of Georgia

Simply stated by both professors and critics alike, a parable is a story used to illustrate an idea. While the underlying concept of the parable as a form of teaching remains simple, its relativity to all people regardless of age, education, gender, or nationality has held steadfast through the ages. Because of his effectiveness and passion, a carpenter named Jesus drew large audiences of men, women, and children who were eager to listen to his parables. For example, all of society could emotionally identify with the themes and even with the characters within Jesus' parable of the prodigal son. Of utmost significance, the parable is still the perfect teaching tool, because the parable applies to all ages, influences all classes, and universalizes all themes. As I look at the effectiveness of the parable, my research includes interpretive, historical, as well as biblical influences. These three influences are critical to understanding the parable's continued use and impact upon varied societies and cultures.

Cell Wall-Degrading Enzymes from the Fungus That Causes the Devastating Rice Blast Disease
Jeff Halley
Dr. Sheng Cheng Wu, Department of Biochemistry and Molecular Biology, University of Georgia

The fungus *Magnaporthe grisea* is the pathogen responsible for the devastating Rice Blast disease. After entry into the rice plant, the fungus begins releasing xylanases that degrade xylan, an important component of rice cell walls. Six different xylanases have been discovered in *M. grisea*, and despite their importance, very little is known about how these enzymes function in *M. grisea*'s attack on the host. Because these enzymes are difficult to obtain they have yet to be studied in depth. Using genetic engineering technologies, we are now able to produce these enzymes in sufficient quantities for kinetic, structural, and biological studies. The heterologous organism we are investigating for xylanase production is *Pichia pastoris*, a eukaryotic fungus. We have shown that the *Pichia* cells transformed with each of the *M. grisea* xylanase genes result in the production of the enzyme under inductive conditions. Therefore, we are one major step closer to understanding precisely what role xylanases play in Rice Blast disease.

Identification of the NDV-Fusion Protein and NDV-Phosphoprotein in Transgenic Soybean Plants

Scott Harelik
Dr. Wayne Parrott, Department of Crop and Soil Sciences, University of Georgia

Newcastle Disease Virus (NDV) is one of the most serious problems affecting the poultry industry. The virus causes a major decline in the number of chickens produced for both commercial and economic purposes. For example, in 1971, the poultry industry in California suffered an outbreak of NDV. Eradication cost $56 million in federal funds and resulted in the destruction of 12 million birds. Preventive measures require the use of vaccines, achieved by inoculating chickens with either inactivated or live-forms of the virus. An extension of this method is the production of an oral vaccine using transgenic plants. Previous studies have demonstrated the effectiveness of using transgenic plants in the production of edible vaccines against a variety of other pathogenic antigens. In each of these studies, transgenic plants expressing pathogenic antigens induced an immune response in the host organism. The main objective of this project is to determine if NDV proteins produced in genetically engineered soybean (*Glycine max* L. Merr.) plants elicit an immune response in chickens (*Gallus gallus*). DNA sequences encoding two of the viral proteins, the phosphoprotein (P) and fusion (F) protein, were transformed into soybean plants by gene bombardment. This research will primarily investigate the immunogenicity of P. Although P has been shown to have a high amount of antigenicity, no research has been reported to show that P is immunogenic. If P is found to be immunogenic, then it could be used as an edible vaccine for NDV. DNA from transgenic plants will be analyzed for the presence of the transgene through Southern blotting. Thus far, eight lines have tested Southern positive: two containing the F gene and six containing the P gene. Lines testing Southern positive will be tested for the expression of the phosphoprotein and fusion protein through Western blotting. The immunogenicity properties of the plant lines expressing the P and F proteins will be determined through an immunoblot. An affinity-purified rabbit polyclonal antibody will be used as the primary antibody and a goat antirabbit-horseradish peroxidase will be used as the secondary antibody. Soybean lines producing an immune response in vitro will be tested in vivo.

Expression of Putative *Arabidopsis* UDP-Glucuronic Acid 4-Epimerase Genes

April Harper
Dr. Debra Mohnen, Complex Carbohydrate Research Center, University of Georgia

Pectin is an abundant polysaccharide found in the primary cell wall of all plants. Pectin is comprised of the complex polysaccharides homogalacturonan (HGA), rhamnogalacturonan I (RG-I), and rhamnogalacturonan II (RG-II). Each of these pectic polysaccharides contains large amounts of galacturonic acid (GalA). UDP-GalA is the activated form of GalA that is required for pectin synthesis. Thus, the enzymes that produce UDP-GalA are essential for pectin synthesis. In plants UDP-GlcA is converted to UDP-GalA by UDP-glucuronic acid 4-epimerase (UDP-GlcA 4-EP). We have identified and cloned several *Arabidopsis* cDNAs that likely encode several isoforms of this epimerase. The goal of the research was to express these putative *Arabidopsis* UDP-GlcA 4-EP genes and confirm their activity. Two experimental approaches were used. First, we transiently expressed the genes of interest in *Nicotiana benthamiana* plants using a tobacco mosaic virus (TMV) expression system. Whereas a control green fluorescent protein (GFP) construct did yield tobacco plants that produced GFP and fluoresced, the TMV:UDP-GlcA 4-EP infected plants expressed neither the putative UDP-GlcA epimerase mRNA nor the epimerase activity. We do not know why the TMV infected plants did not express the UDP-GlcA 4-EP genes. However, we propose that the TMV:UDP-GlcA 4-EP construct was unstable in the *Nicotiana benthamiana* plants. Our second strategy is to over-express the genes in *Arabidopsis*. Currently we are constructing plant binary expression vectors that contain the various UDP-GlcA 4-EP isoforms. *Arabidopsis* transgenic plants that over-express the putative epimerase will be generated and used to test for UDP-GlcA epimerase activity. The recovery of higher than background levels of UDP-GlcA-epimerase activity in the transgenic plants would be the first conclusive evidence that these genes do indeed encode functional UDP-GlcA-epimerases and would provide essential tools to study pectin synthesis.

Gene Expression in *Leishmania*: Control of Protein Synthesis in *Leishmania* 5' Untranslated Regions

Peter Harri, CURO Summer Research Fellow
Dr. Kojo Mensa-Wilmot, Department of Cellular Biology, University of Georgia

Efficient protein synthesis in prokaryotes and eukaryotes calls for different sequences upstream of coding regions. In the parasitic protist *Leishmania*, the 5'-untranslated regions (UTR) that promote prolific translation have not been defined. We have found that a 15-base sequence, termed Leishmania Translation Enhancer (LTE), positioned upstream of a reporter gene can influence protein synthesis 30-fold. We are interested in determining the essential sequences in *Leishmania* translational enhancer. Our experiments were designed to test if different sequences of the 5'-UTR of a reporter can affect translation in either *Leishmania tropica* or *Eschericha coli*. Using high fidelity PCR-mediated mutagenesis, mutant 5'-UTRs were linked to the coding region of a glycosyl phosphatidylinositol phospholipase C (GPI-PLC) gene from *Trypanosoma brucei*. We focused on a polypurine sequence AGGAGG, and produced related sequences TCCTCC, AGAAGA, GAAGAA, and GGGGAA. The AGGAGG was also deleted entirely from one 5'-UTR. DNA fragments were ligated into pBluescript II SK (+) for testing in *E. coli* and pUTK, a *Leishmania* expression vector, for expression in the parasite. After selection with ampicillin for *E. coli* and G418 for *L. tropica*, the cells will be assayed for the GPI-PLC enzyme activity, and specific activity of the enzyme will be determined. The results of this research are still pending. Currently, only 5 of the 10 desired mutations have been ligated into the desired plasmids, so no transformation or transfection has been performed. More cloning is needed to construct all of the desired plasmids. These studies will make contributions to our understanding of how *Leishmania* ribosomes decipher information in mRNA for the purpose of protein synthesis, which is important because gene expression is regulated post-transcriptionally in Leishmania.

Experimental Study of Male-Male Combat in a Parasitoid Wasp

Chris Hartley
Dr. Robert W. Matthews, Department of Entomology, University of Georgia

The parasitic wasp *Melittobia digitata* (Hymenoptera: Eulophidae) is a gregarious external parasite of various insects, including the common organ pipe mud dauber wasp. Sexual dimorphism in this species is extreme, and the males possess greatly enlarged mandibles. Males commonly engage in fierce, often fatal, fights with other males. The mandibles are the main weapons used, and injuries inflicted vary greatly in severity. This study had three objectives. The first objective was to determine whether engaging in fights was so energetically costly as to shorten a male's lifespan. The results supported this hypothesis. Males that had engaged in fights lived on average 9.65 days compared to isolated male lifespan of 12.3 days. The second objective was to determine whether fighting behavior changed with age. The hypothesis was that older males whose energy reserves would be nearly depleted would be more subdued fighters relative to young males. Isolated one-day-old and five-day-old inexperienced males were paired in observation arenas, and outcomes were recorded. Results supported the hypothesis; young males fought quickly and violently compared to older males. Older males fought less often and inflicted fewer and less severe injuries. The incidence of fatal fights, however, remained the same among young and old males. The final objective was to investigate whether males can learn to be more efficient fighters as a result of experience. It was predicted that winners of fights should, in subsequent battles, display more stereotyped fighting behavior and go for the "quick kill." Results are currently being analyzed.

Comparison of Several DNA Extraction Methods in Conjunction with PCR for the Rapid Detection of *Rhodococcus equi* and *Steptococcis equi*

Jessie Hopkins
Dr. Susan Sanchez, Athens Diagnostic Laboratory, College of Veterinary Medicine, University of Georgia

Rhodococcus equi and *Streptococcus equi* are bacteria that cause severe disease in horses. Using traditional bacteriology culture the isolation and identification of this organisms typically takes 48 to 72 hours. Polymerase chain reaction can facilitate the diagnosis of these bacterial infections. Bacteria can be detected within hours of sampling, and it is more sensitive and theoretically can detect fewer bacterial cells. Choosing the right DNA extraction method is crucial for diagnostic PCR. Our aim was to choose a reliable, rapid, and simple method for routine DNA purification from trans-tracheal washes, lymph node aspirates and swabs. Three different DNA extraction methods were examined namely, MasterPure ™, QIAamp® DNA kit, and guanidium thiocyanate DNA extraction. These protocols were compared quantitatively by using each method to extract DNA from three logarithmic serial dilutions of reference bacteria and three trans-tracheal washes and using these extractions for amplification using PCR, and visualization by gel electrophoresis. The MasterPure DNA purification kit allows for the detection of $2x10^2$ cfu/ml for *S. equi* and $6x10^2$ cfu/ml for *R. equi*. In contrast, QIAamp purification only allowed for the detection of $1.5x\ 10^4$ cfu/ml for *S. equi* and 10^4 cfu/ml for *R. equi*. Finally, guanidium thiocyanate extraction was as good as MasterPure for the extraction of *S. equi,* but only allowed for the detection of 10^5 cfu/ml for *R. equi.* All known positive clinical samples for either of the microorganisms were positive when extracted by the chosen method and amplified by PCR.

Formation of Hirano Bodies in Mammalian Cell Culture

Lindsay Hoskins
Rich Davis, Dr. Ruth Furukawa, and Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia

Hirano bodies are paracrystalline, intracellular, actin-rich inclusions discovered in the brain specimens of patients stricken by neurodegenerative diseases such as Alzheimer's. Hirano bodies are present in several regions of the brain but most commonly found within the hippocampus. The role of Hirano bodies in the progression of disease is unknown. Recent findings have demonstrated that the expression of a mutated form of the 34kDa actin cross-linking protein in *Dictyostelium discoidum* induces the formation of Hirano bodies. This is the first *in vivo* model of Hirano body formation. The goal of this project is to develop a cultured cell model for studies of Hirano bodies in mammalian cells. Transiently transfected fibroblasts exhibited significant actin rearrangement to form large aggregations. Scanning electron microscopy demonstrated a significant alteration in the topography of the transfected cells. There are atypical cellular protrusions that are consistent in size and dimension with the Hirano bodies visualized by fluorescence microscopy. Cofilin, but not tubulin, is localized with these aggregations. These results support the interpretation that a model for formation of Hirano bodies in mammalian cells has been developed. This model can now be employed for studies of the cell type specificity of the response and the effects of Hirano bodies on cell function.

Use of a Non-Radioactive Gel Assay to Assess whether Protein Purification Separates a Pectin Degradative Activity from the Pectin Biosynthetic Enzyme Alpha-1, 4-Galacturonosyltransferase

Donte Howard
Dr. Debra Mohnen, Complex Carbohydrate Research Center, University of Georgia

The plant cell wall is composed of approximately 90% polysaccharide. About 30% of the polysaccharide in the cell wall of dicots and nongraminaceous monocots is pectin. Pectin is a polysaccharide with many biological activities and uses. It is a major component of fiber that has beneficial effects on human health. Pectin is also essential for plant growth, development, and defense against pathogenic attack. Homogalacturon (HGA) is the most abundant pectic polysaccharide accounting for 60% of pectin. HGA is a linear polysaccharide of a 1,4-linked alpha-D galactopyranosyluronic acid (GalA) residues that maybe methyl esterfied at C6. The enzyme that synthesizes HGA is galacturonosyltransferase (GalAT). The goal of my research was to use a non-radioactive polyacrylamide gel electrophoresis assay (GalAT PAGE assay) to study reaction products produced by partially purified GalAT. During efforts to purify GalAT in plant tissue extracts, it was previously found that an HGA degradative activity was also present. The activity degraded the GalAT reaction product and thus interfered with the analysis of GalAT activity during protein purification. Prior analysis of the degradative activity suggested that it was a putative exopolygalacturonase, an enzyme that degrades HGA. In this presentation, we use the GalAT PAGE assay to show that the HGA degradative activity present in *Arabidopsis thaliana* tissue extracts can be separated from GalAT during protein purification. The GalAT PAGE assay is also being used to determine if the degradative activity can be inhibited by high concentrations of galacturonic acid or digalacturonic acid, reaction products of the degradative enzyme. The results of these experiments will also be presented.

Ceramic Analysis at Lake Springs (9Cb22): A Late Archaic Site of the Savannah River Valley

Heather Howdeshell
Dr. Mark Williams, Department of Anthropology, University of Georgia

In 1951, Joseph Caldwell excavated the Lake Springs site (9Cb22) as the waters of the Clark Hill Reservoir on the Savannah River rose around him. While more than 10,000 artifacts had been recovered by him before the site was flooded, that collection had been lost for most of the last 50 years. In September 2001, the 23 boxes of artifacts from the site were discovered unlabeled at the Southeast Archaeological Center of the U.S. National Park Service in Tallahassee, and were transferred to the University of Georgia Laboratory of Archaeology in Athens. Caldwell never published a site report for Lake Springs, thus the overall objective of my project is to produce a final site report using his field notes, illustrations, and the recently discovered artifacts. In this specific paper I will present an analysis of the ceramic collection from Lake Springs. The majority of ceramics are Stallings Island Fiber Tempered bowls of plain and drag-and-jab varieties. These varieties suggest that the main occupation of the site was during the Mill Branch and Lover's Lane phases of the Late Archaic, between 2200 and 1350 B.C.

Screening Mutant Yeast Strains for Abnormalities in the Localization of snoRNA

Amanda Hudson, CURO Summer Research Fellow
Dr. Michael Terns, Department of Biochemistry and Molecular Biology, University of Georgia

The small nucleolar RNAs (snoRNAs) are located in the eukaryotic nucleolus. These RNAs are essential for the production of rRNA, which is involved in protein synthesis. The transport and localization of these snoRNAs to the nucleolus is not well understood. My project this summer was to participate in a screen of mutant *Saccharomyces cerevisiae* yeast strains, looking for phenotypic abnormalities in the localization of the U3 snoRNA. Each one of these mutant yeast strains contains a gene that has been mutated in a yeast genome. Thus, isolating the mutant yeast, that displays an abnormal localization phenotype, can identify the gene responsible for snoRNA localization. A collection of ~1,000 thermosensitive (t.s.) strains were screened. Using FISH (fluorescence in situ hybridization), the subcellular localization of the U3 snoRNA in wildtype and mutant yeast strains was determined using a DNA probe complementary to the U3 snoRNA with an attached fluorescent molecule, cy3. The concentrated DNA in the nucleus was stained with DAPI, a fluorescent stain. The normal and abnormal localization of the snoRNA could then be analyzed by fluorescence microscopy. The results from this screen identified 46 possible gene mutations involved in snoRNA localization. Of these 46 mutants, those that are found with outstanding abnormalities at the nonpermissive temperature (37°C) but not the permissive temperature (22°C) will aid in confirming the genes responsible for this localization. Ultimately, these genes will be studied further to understand the role of the identified gene product in the proper (functional) localization of the snoRNA.

Identifying Expressed Genes in Sorghum

Jacoby Hudson, Crystal Oliver, and Cassandra Kirkland, CURO Apprentices
Mrs. Aynsley Eastman, Mrs. Vickie Wentzel, Dr. Marie-Michèle Pratt, and Dr. Lee Pratt, Department of Botany, University of Georgia

Sorghum, a plant closely related to sugarcane and maize, is scientifically interesting due to its small genome size and ability to tolerate stress. The purpose of this sorghum EST, or expressed sequence tag, project is to identify expressed genes under various environmental stresses and from different tissues. 2,304 plasmids containing EST inserts were purified and sequenced to potentially allow for the identification and characterization of expressed genes. These plasmids contain DNA inserts which when sequenced allow for the identification and characterization of expressed genes. These plasmid DNA were first amplified in *E. coli,* and then lysed. The plasmid DNA was then purified by precipitating the bacterial membrane, proteins, and genomic DNA and then precipitating the plasmid DNA. The pure plasmid DNA was then thermal cycled to add fluorescent tags to each nucleotide in the DNA sequence, and sequenced via a 96 sample capillary electrophoresis machine. This machine produces images representing DNA sequences of expressed genes. Each side of the plasmid was sequenced to try and cover the entire length of the unknown EST sequence. This raw data from the sequences will be uploaded into a database where various computer programs analyze it for quality, *E. coli* contamination, and vector presence. Sequences passing quality control will be compared to public databases of other sequences for possible identification. Functional assignments could be made to other sequences hitting with a high homology to other sequences with a known function. Because these ESTs are sequences that come from expressed genes in sorghum, any sequences not hitting to known gene sequences could be potentially identified as a new gene.

It Was Broken, but They Did Not Fix It: Italian Election Reform in the Nineties

Eirin Kallestad
Dr. Christopher S. Allen, Department of Political Science, University of Georgia,

The purpose of this study is to investigate the Italian electoral reforms implemented over the last decade. In the early nineties, the Italian electoral system changed quite drastically. Reformers sought to create a stable, bi-polar political arena similar to the American one, but the Italians now resort to large coalitions consisting of parties or groups with differing foci. The new system created new problems without really solving the old ones. The reforms also caused the established parties to loose ground and new "parties" like Silvio Berlusconi's *Forza Italia* to prosper. This paper explores different aspects related to the electoral reforms. First, why were the reforms necessary? Secondly, how did the reforms fail? The reforms were crucial in a time of corruption scandals and little faith in the government. However, the party structure was falling apart *before* the reforms, due to a general decline in political culture. My study shows that while the reforms certainly contributed to the destruction of the established parties, they were not solely responsible. Therefore, political reorganizers must remember that officially implemented laws and reforms can only be successful if the environment they are inserted into is receptive.

Gender Differences in Internal and External Thought Focus among Prepubescent Children

Ryan Keen
Dr. Katherine Kipp, Department of Psychology, University of Georgia

Gender differences in cognitive response patterns to depression have been theoretically and empirically linked to the disproportionate numbers of women and adolescent girls experiencing depression (e.g., Nolen-Hoeksema, 1994, 1987; Ingram, 1990). Butler and Nolen-Hoeksema (1994) found that women tend to respond to depression by ruminating about their difficulties (i.e., internal focus), whereas men tend to distract themselves by focusing their thoughts on sports or other activities (i.e., external focus). This paper examines the developmental history of gender differences in internal and external focus by examining focus differences in third graders and a sample of college students. We posit that gender differences in internal and external focus might exist prior to the onset of gender differences in depression. Participants were drawn from 3rd grade classes at an elementary school and a large university, both in the southeastern United States. Each group included 40 students (20 males, 20 females) for a total of 80 participants. Focus of thought is being assessed using two free-thought measures. During six data collection sessions, individuals will either write their thoughts or draw for 10 minutes. Participant's writing transcripts are analyzed for focus of thought by first identifying all thought units and the coding each thought unit as being either internally or externally focused. The drawings are analyzed for thematic content. Correlations among tasks will examine the feasibility of using drawings as a metric of thought focus in younger children who are unable to complete written or verbal measures. Data analysis is underway, and no results are available at this time.

An Online Analytical Processing Approach to Single Nucleotide Polymorphism Discovery and Analysis

Dipinder Singh Keer
Dr. Marie-Michèle Pratt, Mr. Manish Shah, Dr. Chun Liang, Mr. Robert Sullivan, Mrs. Aynsley Eastman, and Dr. Lee Pratt, Department of Botany, and Dr. Mark Huber Department of Management Information Systems, University of Georgia

A Single Nucleotide Polymorphism (SNP) represents an alternate nucleotide in a given and defined genetic location at a frequency exceeding 1% in a given population. SNPs are considered to be a major source of phenotypic variability leading to differences in individuals within a given species. A variety of SNP analysis tools are available for detecting SNPs in the large volumes of data produced in high-throughput sequencing projects. The variation in the output format of these SNP detection programs and the need for further screening of the SNPs that are detected prompt the need for a data management process to standardize this data and make it available for aggregate analysis. This process involves the parsing of relevant data from these outputs, conversion to a standardized format, and storage of the data in a database designed for efficient mining, confirmation, and analysis. The relational database is designed to support ad-hoc querying and data mining of SNP data. A supporting query interface will be developed as an Online Analytical Processing (OLAP) tool for mining of SNPs from the data gathered. This approach will be demonstrated by accurate SNP identifications in sorghum and horse ESTs (Expressed Sequence Tags), which are representative data sets typical of sequence-based SNP discovery.

The Stevens Clinic – A Sports Medicine Facility

Emily Kirk
Dr. Jane Lily, Interior Design, University of Georgia

The design of a sports medicine clinic can play an important role in a patient's recovery from injury. Research indicates that an effective facility provides its patients with a comfortable, stimulating environment for treatment and exercise. The Stevens Clinic, a 21,000 square foot orthopedic and physical therapy suite, demonstrates how an interior can facilitate healing. This project investigates common solutions in sports medicine space planning. Interviews with a health care design specialist, a clinic manager, and a patient present key concepts in programming the space. A floor plan and rendered illustrations display conceptual design solutions for the practice. Written explanations accompany and clarify these drawings. The Stevens Clinic displays innovative space planning for recovering athletes and their physicians.

Utilization of Cover-Boards by Eastern Tiger Salamander (*Ambystoma tigrinum tigrinum*) Metamorphs at Brookhaven National Laboratory

Heather Kling
Dr. Timothy Green, Brookhaven National Laboratory, Upton, NY, and Dr. Karl Espelie, Department of Entomology, University of Georgia

The eastern tiger salamander has been designated an endangered species in New York State, and loss of habitat has been the primary factor contributing to its extirpation from heavily developed western Long Island. The intention of this investigation is to determine whether tiger salamanders demonstrate a propensity for use of artificial cover, and whether they exhibit any preference regarding board choice. The results of this experiment will contribute a basis for all future studies to better divulge salamander behavior relating to migration patterns immediately following emergence. For the cover-boards, half sheets of plywood were arranged around two ponds, determined by relative salamander population size, on the Brookhaven National Laboratory (BNL) site. Larval sampling was done by seining, carried out in approximately fifteen-minute sessions using a ten-foot minnow seine with quarter inch mesh. At only two of the ponds on site, one with a sample size just over 30 individuals and the other just under 30 individuals, were there significant larval salamander populations to warrant the placement of cover-boards. Measurements, including snout-vent length, total length, and weight, were taken on all salamanders sampled, both larvae and adults; these helped contribute to the hypothesized existence of age cohorts. There is difference between the ponds concerning numbers of adults sampled, totaling thirty-seven at one and eight at the other, as well as average sizes of individuals, notably larger at one than the other. Regardless of any difference between the two ponds, the salamanders demonstrated use of the artificial cover-boards showed little preference regarding specific board choice.

Analysis of Microsatellites in Sorghum ESTs

Dmitri Kolychev
Dr. Marie-Michèle Pratt, Dr. Lee Pratt, Mr. Manish Shah, Mrs. Aynsley Eastman, and Dr. Suchendra M. Bhandarkar, Department of Botany, University of Georgia

Finding SNPs, microsatellites, and other certain patterns in ESTs provides a key to understanding the genetic data. A database of ESTs provides the ability not only to find the microsatellites, but also gives a tremendous amount of ancillary information about the genes in which the microsatellites are found. Microsatellites, or simple sequence repeats, are genetic loci where several nucleotide bases are repeated in tandem. The utility of microsatellites is mostly due to slipped-strand mispairing during DNA replication, repair, or recombination; this makes them exhibit extreme length polymorphism, and they occur rather frequently in coding regions of DNA. Furthermore, since they can be easily analyzed by PCR using unique flanking primers, they are considered excellent genetic markers in making genetic linkage maps. This project involves not only building a database of high quality microsatellites found in sorghum ESTs but also searching for the effect these microsatellites have in different genotypes. An extra repeat within the microsatellite could have tremendous effect on the phenotype of an organism; likewise, a mutation within a microsatellite locus could have either disastrous or beneficial consequences for the organism that carries it. A careful analysis of obtained data will yield the stochastic link between the occurrence of certain microsatellites in different genotypes; however, final results are not yet known since extensive review is still under progress.

Differential Glycosylation of Normal and Neoplastic hCG

Marina Kozak
Dr. J. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

Human chorionic gonadotropin (hCG), one of four related heterodimeric glycoprotein hormones involved in reproduction and metabolism, is produced by the trophoblastic cells of the placenta during pregnancy. Some malignant cells also produce hCG with a glycosylation pattern different from that of normal cells. Previous glycosylation studies required purification of large quantities of hCG, restricting the analysis of many transformed cell lines. The goal of this study was to develop an ELISA to rapidly examine the differences in glycosylation profiles between hCG produced during pregnancy and malignancy, concentrating mainly on trophoblastic disease. An antibody fragment, devoid of oligosaccharides, with affinity for the hormone-specific β subunit was coated onto polystyrene 96-well plates in order to capture the hormone from the cell media. The glycosylation pattern of the hormone was then probed by a series of 11 biotinylated lectins. Lectin binding was indirectly quantified by subsequently binding sptrepavidin-HRP and measuring colored substrate production on a plate reader. It was determined in 3 independent experiments that hCG from a human choriocarcinoma cell line (JAR) contains increased fucosylation based upon increased binding of an *Aleuria aurantia* lectin, as well as the presence of O-linked galactose β(1-3) N-acetyl galactose and triatennary branching determined by the lectins *Amaranthus caudatus* and *Phaseolus vulgaris* leukoagglutinin, respectively. If the glycosylation signatures of hCG derived from transformed cells of many tumors, e.g. reproductive tract, lung, colon, etc., can be determined and distinguished through an easily performed assay, the role of hCG as an early marker of cancer will expand to provide information on the localization of the tumor.

Development of Cognitive Inhibition in Preschool Children

Meenakshi Lambha
Sarah Cummins-Sebree and Dr. Katherine Kipp, Department of Psychology, University of Georgia

Cognitive inhibition is a theoretical construct explaining the suppression of cognitive contents or processes which had been previously activated; in addition, it is thought to develop during early and middle childhood. Cognitive inhibition is important in developing efficient memory skills; being able to inhibit the maintenance of irrelevant information in working memory allows one to use more of the memory store for remembering relevant information and performing other cognitive processes. Previous research indicates that school-aged children (first through fifth graders) are able to inhibit irrelevant information in various memory tasks. However, considerable frontal lobe development occurs during the preschool years, which has been implicated in cognitive inhibition abilities. The purpose of our study is to test 40 preschoolers' (ages 3-6) abilities to inhibit prepotent responses, as well as assess construct validity, in three cognitive inhibition tasks (modified Stroop task, picture naming task, and directed-forgetting task) and one vocabulary test (Peabody Picture Vocabulary Test-Revised). We will also test 20 adults for a comparison control group. We hypothesize that there will be differences in responses among the 3-4.5 year-old group and the 4.5-6 year-old group, such that the older preschoolers will exhibit higher levels of cognitive inhibition than the younger preschoolers. Independent t tests will be used to compare performances of the two preschool groups on our tasks. Findings from this study will enhance our knowledge of cognitive inhibition development in young children. Currently we are beginning data collection on our research.

Motivations of U.S. Southern Homegardeners: Preserving the Past in a Modern World

Crystal Leaver
Dr. Virginia D. Nazarea, Department of Anthropology, University of Georgia

The purpose of this study was to discover the different motivations that homegardeners and farmers in the Southeastern United States have for growing heirloom, or traditional varieties of crops. Through the content analysis of interviews, this paper examines the motivations that prompt gardeners to persist in cultivating heirloom varieties with no institutional support. It compares the motivations of women and men, as well as older and younger growers. My research found that older growers were more likely to grow heirlooms because of tradition and utilitarian reasons, and younger growers grow heirlooms because of personal preferences and as a conscious effort to conserve biodiversity. Since the adoption of industrial agriculture and the Green Revolution, farmers and even homegardeners have replaced their local varieties with high yielding and high input hybrid crops. Local varieties are disappearing at an alarming rate, contributing to the worldwide decrease in crop biodiversity. However, many people in the U.S. among other places refuse to conform to these trends and continue to cultivate heirloom varieties.

The Colorfastness of an Interlock T-shirt Material Laundered with a Detergent Compared to Laundering with a Detergent Plus Enzyme

Shelley Ledford
Dr. Nolan Etters, Department of Textiles, Merchandising, and Interiors, University of Georgia

The purpose of this study was to see if adding enzymes to the home laundering would prevent the color loss on T-shirts. I used AATCC Test Method 124-2001 Appearance of Fabrics after Repeated Home Launderings, Standardization of Home Laundry Test Conditions developed by AATCC Committee RA88, 1993 AATCC Standard Reference Detergent and Laundry Detergents in General developed by AATCC Committee RA88, Instrumental Color Measurement developed by AATCC Committee RA36, Instrumental Assessment of the Change in Color of a Test Specimen developed by AATCC Committee RA36. I bought six yards of purple, red and orange t-shirt material. I cut a swatch out of each of the original materials as a controlled sample. Then I cut the purple fabric into two equal sized pieces and labeled the left piece A and the right piece B. Piece A was only laundered in the detergent while piece B was laundered in the detergent plus 1g of cellulase enzyme. I used cellulase because it is a natural catalyst that accelerates the hydrolysis. I dried the fabric and then cut a swatch and took a reflectance reading on the spectrophotometer. I measured the color range for piece A and for piece B after the first, the fifth, the tenth, the fifteenth, and the twentieth washings. The expected results should reveal that the material washed with detergent plus cellulase will appear vivid, while the material washed with just detergent will have pills. The pills will make the light scatter rather than absorbed, making the color dull and shaded. Many Americans use t-shirts as their own personal billboard to the world. I want my t-shirt's color to be as brilliant as my message. This project has taught me how to preserve the color quality of new t-shirts.

Neuropeptide Y as a Factor in Ethanol Consumption in Zucher Rats

Rachel Lewis
Dr. Gaylen Edwards, Department of Physiology and Pharmacology, University of Georgia

Past studies have shown that neuropeptide Y (NPY) injected intracerebroventricularly (ICV) increases feeding behavior while decreasing measures of anxiety. One study found that consumption of a sucrose solution increased while the amount of ethanol solution consumed did not change following ICV injections of NPY. It was hypothesized that ICV injections of NPY could be affecting receptors in both the hypothalamus (increasing feeding behavior) and the amygdala (resulting in decreased anxiety). Additionally, NPY and ethanol have similar anxiolytic effects. The present study hypothesized that NPY or NPY antagonists injected into the amygdala of Zucker Lean (ZL) or Zucker Obese (ZO) rats would decrease or increase consumption of a 5% ethanol solution (5%EtOH) respectively. The ZL (N=3) and ZO (N=5) rats were housed in separate cages with ad libitum access to 5%EtOH and water. The amount of 5%EtOH consumed was recorded daily prior to injections, during vehicle injections, injections of NPY (.5 μg for 3 days), during injections of NPY antagonist (1 μg for the first 3 days and then 2.5 μg for 2 days-day 3 was lost), and for 1 week after injections were complete. All doses were based on doses reported in the literature. Results showed that NPY suppressed intake and NPY antagonist increased intake in both strains when compared to amount of ethanol consumed prior to and during vehicle injections. Therefore, each animal serves as its own control. Future studies will examine methods to alter NPY levels and test whether these are useful in the treatment of alcoholism.

Improvisation in the Choreographic Process

Elizabeth Lide
Dr. Bala Sarasvati, Department of Dance, University of Georgia

This study will explore approaches and use of improvisation in creating contemporary modern dance choreography. An overview of the history of improvisation in the United States since the 1960's will provide a contextual base for this study, which will proceed to examine the choreographic processes of three selected prominent postmodern choreographers who use improvisation as a base for developing movement vocabulary. I will compare and contrast their methods, and through experimentation, develop my own approach. In the process, I will conduct rehearsal labs to develop a choreographic project. This project will be presented in both live and edited film versions at the CURO Symposium.

Ferdinand Warren: Artist, Craftsman, American Aristocrat
Andrew Littlejohn
Dr. William Eiland, Department of Art History, Georgia Museum of Art, University of Georgia

When speaking with Ferdinand Warren's dealer, Ann Jacob, she described him as "an American aristocrat." Perhaps there is no better way to sum up this handsome, humble, hardworking, and creative artist, for he was the epitome of old world American class. Born in Independence, Missouri, in 1899, Ferdinand Earl Warren traveled to New York City on a Tiffany Fellowship in 1926 where he established himself among the likes of the American Eight and other notable expatriate artists. Lamar Dodd brought Warren to the University of Georgia in 1951 as an artist-in-residence. A mature 52-years-old, Warren's works of art were already displayed in notable venues such as the Metropolitan and Brooklyn Museums of Art. After a successful year at the University of Georgia, Warren attained a faculty position at Agnes Scott College as head of the art department. During his eighteen-year tenure at Agnes Scott, Warren settled into a southern groove and continued to develop his disparate style. He never ceased to try any and every artistic method, exemplary in his oeuvre of oil paintings, encaustics, enamels, jigsaw puzzles, and woodblock Christmas cards. The purpose of my research is to resurrect an interest in Ferdinand Warren with a catalogue raisonne and a potential exhibition at the Georgia Museum of Art. However, I believe my research is more important than merely to induce interest in a virtually unknown artist. Little to no research has been conducted on Ferdinand Warren, and this is historically irresponsible and quite unfortunate. During my examination of Warren, I have visited numerous private and public collections, which have taken me as far as Houston, Texas. Additionally, I have consulted the Hargrett Rare Books Library, the Georgia Museum of Art's collection and files, Agnes Scott College's resources, and I have corresponded with various museums and Warren's acquaintances all across the United States and Canada. Ferdinand Warren was a benevolent and loving friend, family man, and teacher, and for these reasons, not to mention his excellence as an artist, it will be an honor to enlighten the public on Ferdinand Warren's art through my efforts and those who have helped me discover this true "American aristocrat."

A Data Envelopment Analysis of the Efficiency of Georgia Politicians
Chandler McClellan
Dr. David Mustard, Department of Economics, University of Georgia

Previous studies have proven that sheer spending in elections is not statistically significant. Therefore, this study examined if the efficiency with which a candidate spends money can affect electoral outcomes. To accomplish this goal, this study used Data Envelopment Analysis to measure the technical efficiency of candidates for the 2000 Georgia House of Representatives. However, there are many factors in an election that a candidate has no influence over but are included in this measure of candidate technical efficiency. Such factors include the candidate's personal characteristics, his opponent's level of spending, and district characteristics. A second stage regression is used to factor out the influences of these variables that a candidate cannot influence, thereby yielding the candidate's pure efficiency. When compared with the technical efficiency scores, these pure efficiency scores show which candidates do well because they are efficient and which do well because they run in a favorable district. Therefore, the pure efficiency measures can be used in allocation of scarce campaign resources or as a proxy for candidate quality in other studies on campaign spending. In nearly all races studied, the candidate with the more efficient scores won. In races in which the less efficient candidate won, the winner significantly outspent his opponent. The results of this study are consistent with the results of a similar study by Dennis Coates, leading to the conclusion that the efficiency with which a candidate spends his campaign money will affect the outcome of the election. Though this study's results are compelling, additional observations and regression variables could improve the accuracy of the pure efficiency scores.

An Analytical Study of Interfacial Stresses in Bonded Materials
Cliff McLeroy
Dr. Guigen Zhang, Department of Agricultural and Biological Engineering, University of Georgia

The goal of this project was to develop an analytical solution for the interfacial stress distribution of bonded materials as a function of force, deflection, and material properties. Currently the evaluation of the bonding strength of adhesives for possible dental crown applications is performed with a three point bending test. The specimen consists of a thin metal strip supported on its ends with a ceramic material bonded to the bottom. The two quantities obtained through this type of experiment are the deflection of the strip and the load applied. The difficulty was to obtain an accurate measurement of the bonding strength based on the load-deflection curve without knowing the interfacial stress distribution. Since the stress incurred by the bond is due to the tendency of the strip to bend and change shape, it is not constant. There are normal and shear stresses that occur at the bond which both vary along the length of the bond. In this study, solutions of the interfacial stress distributions were developed through the use of an advanced engineering technique called the Theory of Elasticity. This technique provides a high level of accuracy that is not obtainable through other methods such as Mechanics of Materials. Following this, parametric studies were performed which provided graphs, charts, and computer code for the stress distribution along the bond interface. The uniqueness of this study is that it allows dentists and non-engineers to accurately interpret test results based on the load-deflection curve.

Synthesis and Use of Caged Compounds to Explore Cellular Processes
Kenneth Miller, CURO Summer Research Fellow
Dr. Timothy Dore, Department of Chemistry, University of Georgia

Caged compounds are drugs or other biological effectors that are rendered biologically inactive through coupling to a light sensitive molecule known as a caging group. The caged compound can easily be converted to the biologically active, uncaged form by pulsing the caged molecule with either IR or UV radiation. Such a drug delivery system is advantageous in that a dramatic increase in drug concentration can be achieved in the very short time period of a light pulse. However, in order to obtain tight spatial as well as temporal control of drug release, multi-photon excitation can be employed. Multi-photon excitation occurs when a molecular cage absorbs two or more photons simultaneously and subsequently releases the effector; the process is limited to the focus of a pulsed IR laser due to the necessity of a large photon flux. Therefore, one can achieve an excellent level of three-dimensional selectivity of the release of a biological effector by focusing the laser on an area of interest such a dendrite in a single neuron. Bromohydroxycoumarin (Bhc) is a biologically useful caging group that undergoes two-photon excitation using a 740 nm laser, and others have used Bhc caged glutamate to study glutamate sensitivity in neurons. Utilizing a Pechman condensation of 2,7-dihydroxynaphthalene and ethyl acetoactetate and a number of other synthetic steps, a new series of caging groups were synthesized, which absorb higher wavelengths of light compared to Bhc. Such “extended coumarins” contain an additional conjugated ring facilitating the absorption of longer wavelengths of light, which are less energetic and cause less damage to living cells. Tribromo-, dinitro-, and monofluoro- extended coumarins were synthesized, and the tribromo product shows two photon uncaging at 800 nm.

Transgenic Study of a Conserved Neuropeptide Network for Feeding Regulation in *Drosophila*
Eric Morishige
Dr. Ping Shen, Department of Cellular Biology, University of Georgia

Hypothalamic neuropeptide Y (NPY) stimulates the appetite. Leptin-deficient mice, which are obese due to excessive appetite, show over-expression of NPY in the hypothalamus. Furthermore, mice deficient in both leptin and NPY show attenuated obesity symptoms, indicating a role of NPY in body weight control. Neuropeptide F (dNPF), the *Drosophila* homologue of NPY, has been identified. This study aims to use dNPF as a model to understand the mechanism and role of NPY signaling in regulating feeding behavior. Transgenic flies were used to analyze the effects of over-expression of dNPF on the nutritional levels of the flies. Glucose, glycogen, and lipid levels of the individual flies were analyzed according to the protocol described by Van Handel and Day (1988, J.Am. Mosquito Control Association, pp549-550). Each Fly was homogenized and the Glycogen was precipitated into a pellet, while the glucose, and lipids were dissolved into solution. Colored reactions were then carried out, and a spectrophotometer quantified the results. Preliminary experiments tested male and female flies of wild type, and over-expression lines (between 6 to 12 flies each). Initial results suggest that flies with an excess of dNPF may contain significantly more fat than their wild type counterparts, and appear to convert glucose into glycogen at a much slower rate. These results suggest that *Drosophila* can be a good model for studying the molecular mechanism of the signaling pathways involved in obesity and diabetes. Verification of the results is currently being carried out.

Fish Oil: The Effect on Insulin Sensitivity When Incorporated into a High-fat Diet
Sara Morris
Dr. Dorothy B. Hausman, Department of Foods and Nutrition, University of Georgia

This research project tests the hypothesis that the inclusion of fish oil in a high-fat diet will increase insulin sensitivity and lower insulin resistance. Three groups of 10 male Swiss mice have been assigned either to a low-fat control diet (10% calories from fat) or to one of two high-fat diets. The high-fat control diet consists of 39.39% lard and 5.54% soybean oil; the high-fat experimental diet consists of 29.40% lard, 5.54% soybean oil, and 9.98% fish oil. The mice are being fed ad libitum for approximately eight weeks with food intake and body weight measured weekly. At four weeks the effectiveness of these diets on inducing insulin resistance was assessed *in vivo* using insulin sensitivity tests by fasting the mice for five-seven hours and collecting tail blood samples prior to and at 15, 30, 45 and 60 minutes after administration of insulin (0.75 U per kg). Blood glucose concentration was analyzed at all time points and serum insulin at 0 and 15 minutes only. The data were analyzed one-way by ANOVA with post hoc Duncan's multiple range test. Results after four weeks indicate a significant increase ($P<0.05$) in food intake and body weight in the fish oil group as compared to both control groups. Insulin sensitivity tended to be decreased in the control high-fat group but not in the fish oil high-fat group, although the difference was not statistically significant ($P=0.058$ vs. low fat). Thus, inclusion of fish oil in a high fat diet may have a protective effect against the development of insulin resistance.

“each morning I get up with one word in mind: plastik…”
Lorina Naci, CURO Summer Research Fellow
Professor William Paul, Jr., School of Art, University of Georgia

From 1945-1989 Central and Eastern European countries adopted Communism as an economic, political, and social system. The Communist radical ideological and physical culture, characterized by the lack of material goods, changed the cultural traditions of the Eastern European countries, as it was superimposed on all facets of human life. After twelve years of shifting towards democratic systems, the citizens of these countries are feverishly anticipating the harvest of this transition: full integration into the capitalistic global village. Homogenization with Western European structures affords these countries unprecedented opportunities. Scholars perceive that the political-economical phenomena of multiculturalism and globalization are manifestations of the dominance of the western cultures, and that by colonizing the rest of the world equally as its place of origin, globalization causes social and cultural uniformity. The cultural threats and the ethical dilemmas caused by globalization, such as the suspension of the personal and the native in the face of the industrially and technologically advanced other, are the focus of my current research and artistic work.

Chinese Classical Dance
Lynn Nguyen, CURO Summer Research Fellow
Dr. Mark Wheeler, Department of Dance, University of Georgia

As it is understood in the field of dance research, ethnography is the writing of people to discover the cultural knowledge they are using to organize their behavior and interpret their experience. This research uses an ethnographic approach to study the culture of the Chinese-Americans through the understanding and knowledge of Chinese dance. The approach relies on the method of participant observation, which included thirty-two hours of Chinese classical dance instruction over an eight-week period plus interviews with students, teachers, and choreographers, and observations of classical, folk, minority, and contemporary Chinese dance performances. The research gives not only an introduction to the role of Chinese dance within the Chinese-American culture, but it also makes connections between Chinese classical dance elements and Chinese contemporary dance themes. Three individual classical dances—the feather fan, long sleeve, and sword—will be demonstrated, followed by a short oral report presenting the conclusions drawn from this research.

Factors Affecting Male Longevity in a Parasitoid Wasp
Matthew David Oliver
Dr. Robert W. Matthews, Department of Entomology, University of Georgia

Melittobia digitata parasitoid wasps develop gregariously in groups of 100 to 800 (depending on host size). They are unusual among insects in that the sex ratio is extremely female biased (95:5). Furthermore, males engage in lethal combat and survivors mate only with their sisters, never leaving their host's cocoon. Because fighting, courtship, and mating are energetically costly, males may exhaust their energy reserves before mating with all their sisters, potentially reducing their fitness. Some previous researchers have claimed that males obtain all their nourishment as larvae and do not feed as adults. Others suggest that males opportunistically feed on defeated males or other females. This study used male longevity as an indirect measure to assess whether males may obtain supplemental nutrition. The overall hypothesis was that if males are provided opportunity to obtain food, then they will live longer than controls. Potential food variables present in nature include hosts, other adults, and pupae of both sexes. These variables were experimentally manipulated in the laboratory. Ten Experimental treatments in which individual males were given direct or indirect access to various combinations of potential food were replicated 20 times at 25^{o}C and male longevity was recorded. Results are still incomplete but will be analyzed in time for presentation. They will be interpreted in the context of the natural history of this unusual insect.

In the Room: a Performative Text of Story, Poetics, and Criticism
Julie Orlemanski
Dr. Richard Menke, Department of English, University of Georgia

This project will demonstrate some of the ways language performs narrative, narrative not limited to a single identifiable plot but working in a number of intersecting discourses. In this text, an original short story entitled "In the Room," the aleatory, the temporal, the spatial, and the visual emerge from a place formerly perceived as static and transparent – the page. The text literally becomes multi-dimensional and interactive. "In the Room" contains three distinct but codependent narratives – the subject of the story, an account of its structuring, and the response of the reader. The narrative plotline will thus give rise to the two meta-narratives, one of the writer's creation and one of the readers' experiences. How one balances all these in the making of and responding to literature will be the synthesis of the three elements of the project. Each time another reader enters the room of the text, another performance begins. This is your invitation to come in.

Music Therapy with Premature Infants

Cori Pelletier, CURO Summer Research Fellow
Dr. Roy Grant, Music Therapy, School of Music, University of Georgia

Premature infants experience many complications after birth, including, but not limited to, low oxygen saturation levels, low birth weight, apnea or bradycardia episodes, and a lack of nutritive sucking skills, all of which may increase the length of hospitalization. Researchers have shown that music, contingent on nonnutritive sucking, may help develop nutritive sucking skills resulting in increased weight gain and oxygen saturation levels, decreased apnea or bradycardia episodes, and shortened length of hospital stay. Still data are inconclusive as to when to administer music therapy, such as the time of day, time in relationship to infant's feeding schedule, consecutive versus nonconsecutive days of music, and the best gestational age at which to begin. As part of my summer research fellowship I participated in studies addressing some of these concerns. The first involved 69 trials by 10 randomly selected premature infants to determine the effect of time of day, morning vs. afternoon (8:00am and 2:00pm), on the amount of time engaged in nonnutritive sucking during contingent music. Our hypothesis was that there would be no significant difference due to the controlled environment of the Special Care Nursery. The results of a t-test approached .10 so the hypothesis was accepted. Next we analyzed the relationship of the infants' feeding schedules on the amount of time spent in nonnutritive sucking during the contingent music, as some researchers have suggested that music therapy best occur during the hour post feeding during a typical three-hour feeding schedule. We divided the three-hour feeding schedule into five blocks: 30 minutes during feeding, 31 to 60 minutes post feeding, 61 to 120 minutes post feeding (deep sleep), 121 to 150 minutes, and the fifth block 151 to 180 minutes. Results were: Block One -78%, Block Two -57%, Block Three -54%, Block Four -73%, and Block Five -71 %. Contrary to previous research those babies in Block One produced 78% music during feeding, but our nurses frown on this time because of the frequency of reflux. Block Four produced 73%, Block Five 71 %, Block Two 57%, and Block Three 54%. Therefore, results indicate that more babies suck longer without ill effects during nonnutritive sucking with contingent music prior to feeding. At a later date attention will be given to the effects of the feeding schedule as the number of subjects increase. In the third statistical analysis we measured the percent of music and the average segment of music on the third consecutive day vs. the third nonconsecutive day of music therapy for 26 and 20 infants, respectively. Our hypotheses were that infants with a third consecutive day of music would have higher scores; the hypotheses were accepted. Infants with three consecutive days of music averaged two and one half times larger segments of music, $p < .05$. Those infants having music three consecutive days had significantly greater overall percentage of music, $p < .01$. Data are still being compiled as part of a regional study to determine the best gestational age to begin music therapy, the length of stay in the Special Care Nursery, days until first successful bottle feeding (PO), and weight gain, all with control and experimental groups.

Chimpanzees' Manipulation of Objects within the Hand

Linda Pierce and Christine Oshansky
Dr. Dorothy M. Fragaszy, Department of Psychology, University of Georgia

Are humans unique in how we use our hands to manipulate objects? To move an object held in one hand, humans use individuated movements of the digits in simple synergies, reciprocal synergies, sequential patterns, and palmar combinations. Simple synergies are movements in which all the digits are converging simultaneously. Reciprocal synergies include digit flexion and extension. Movements that involve multiple digits performing the same pattern at different times are termed sequential patterns. Palmar combinations are hand movements in which the object is held stationary in the palm while manipulated with the digits. To determine if chimpanzees could use their hands in the same way as humans, we analyzed three adult female chimpanzees' actions with objects held in one hand. Each subject inserted five differently shaped objects through corresponding holes in a vertical panel. The chimpanzees were encouraged to complete three insertions with each shape on each of three observation sessions. We scored the seven to 36 actions per individual that were clearly visible on videotape. We identified every class of movement described for humans at least once in our sample from the chimpanzees. Chimpanzees evidently have the ability to move objects held in one hand using individuated digital movements in the same way as humans. The next challenge is to determine if any species of monkey has similar abilities to control the digits of the hand while manipulating an object.

Supported by an award from the Japan Society for the Promotion of Science. Thanks to T. Matsuzawa, M. Tomonaga, and M. Tanaka of the Primate Research Institute of Kyoto University for their assistance.

Georgian Computer Usage

Charlie Pitts, CURO Apprentice
Dr. James Bason, Survey Research Center, University of Georgia

This research will examine the relationship between computer usages, choice of computer operating system, and demographic characteristics (age, income, education, and gender) of Georgia residents. Previous research has indicated that increasing levels of education and income are positively associated with computer usage. The present study will examine those relationships among Georgians. Additionally, this research will examine the incidence of operating systems and office software packages. Both Microsoft's Office suite and Windows operating system command a substantial portion of the world's share in their respective markets. This research will examine these findings in the context of Georgia residents. Data for the study was collected utilizing the annual Georgia Poll survey done by the Survey Research Center of the University of Georgia. For the Georgia Poll, 400 randomly selected Georgia households were contacted and interviewed about a variety of questions including those related to the research. Descriptive statistics univariate frequency distributions will be presented and bivariate analyses will be conducted to test for statistically significant differences among sub-groups in the population. Findings from the present study will be compared and contrasted with national and international data.

Public Perception of "FONAG:" An Ecuadorian Watershed Sustainability Program Case Study
Jeffrey Pugh
Dr. Fausto Sarmiento, Center for Latin American and Caribbean Studies, University of Georgia

In 2000, the city of Quito, Ecuador began working toward protecting the ecologically fragile watershed area from which its drinking water was drawn. In order to do this, the independent Fund for the Conservation of Watersheds (FONAG) was launched to finance sustainability projects designed to ensure that the Papallacta watershed could remain a long-term source of drinking water for Quito. FONAG is funded in part through startup grants from several organizations and a 1% fee on all Quito water bills, but it has been unable to build an endowment comfortable enough to begin implementing projects. The present research measures perceptions of the fund by 41 Quito citizens from two universities. It also evaluates the quality of the fund's proposed communication campaign based on existing communication theory and attempts to explain the findings in terms of an adapted environmental education model. Hydrological protection measures, such as erosion controls in the watershed, should be implemented quickly as they were supported by 76 percent of those surveyed. Indeed, their absence was cited as a reason for the U.S. Agency for International Development (USAID) withholding assistance from the project. These measures would result in tangible improvements in watershed quality and would be useful in attaining international funding, which FONAG desperately needs to build its endowment. In order to motivate Ecuadorians and foreigners to support the FONAG project politically and financially, communication theory suggests that the communication plan must be more focused on showing direct economic benefits of the proposed projects.

The Relationship between Critical Flicker Fusion Thresholds and Resting Systolic Blood Pressure
Jennifer Reingold
Dr. Billy R. Hammond, Vision Sciences Laboratory, Department of Psychology, University of Georgia

Many visual diseases involve vascular complications. Consequently, understanding the interactions between the visual and cardiovascular system is important. In the present study, the relationship between critical flicker fusion thresholds (CFF) and resting systolic blood pressure (SBP) in 82 males and 113 females recruited from the UGA student population was assessed. CFF was measured as a holistic index of visual function using a 1-deg, 570 nm test stimulus. Flicker thresholds were determined using an ascending method of limits (beginning supra-threshold at approximately 12 Hz). Fusion thresholds were determined using a descending method of limits (beginning at around 30 Hz for most subjects). Critical flicker fusion thresholds were calculated as the average of the flicker and fusion thresholds. SBP was measured using an automated sphygmomanometer. The overall relationship between SBP and CFF was highly significant ($Y = 18.0 + 0.04X$, $r = 0.26$ $p<0.0002$). A positive relationship between SBP and CFF indicated that changes in cardiovascular function are directly related to changes in visual function in normal, non-diseased individuals.

Cozaar Fails to Block Pressor Response in Cats

Vanessa Reynolds (with Sheerin Mathur, Su Sheldon, and Leslie Cartier)
Dr. Scott Brown, Department of Physiology and Pharmacology, University of Georgia

Systemic hypertension is a problem that occurs in one of five cats over the age of fifteen. Cozaar, a human antihypertensive drug, contains losartan, the active ingredient that serves as a competitive antagonist for the Angiotensin II type-1 (AT-1) receptor. By blocking this receptor, Angiotensin II (AII) mediated hypertensive effects such as vasoconstriction and increased blood volume are lessened – thereby decreasing blood pressure. We evaluated the efficacy of this competitive antagonist as an antihypertensive agent in cats. Angiotensin I (AI) is converted to AII in the body. In preliminary studies, we determined the optimum dosage of AI that produced a pressor response of an approximate 50 mmHg rise in systolic blood pressure. Subsequently, AI was delivered intravenously following varying dosages of Cozaar (0 mg, 5 mg, 10 mg, 50 mg, 75 mg, and 125 mg) to five cats implanted with radio telemetry blood pressure monitoring devices to determine if Cozaar could effectively block the pressor response. Conscious cats were dosed orally with Cozaar daily and then given a 1μg intravenous injection of AI four to six hours after dosing. In conscious, restrained cats given 0 mg of Cozaar, the AI injection resulted in an average 36.7 mmHg rise in systolic blood pressure. Cats dosed with 5 mg Cozaar and injected with AI averaged a 39 mmHg rise in blood pressure. Cats dosed at 10 mg, 50 mg, 75 mg, and 125 mg of Cozaar demonstrated a similar average increase in systolic blood pressure. The standard human daily dose of Cozaar is 50 mg. Even when the cats were dosed at 250% human dose and experienced the additive effect of high Cozaar dosages delivered on successive days, their baseline blood pressure and pressor response to AI administration did not significantly change. The results indicate that Cozaar does not hold potential as an antihypertensive treatment for felines. Future studies may determine why Cozaar / losartan is not metabolized by cats.

Amphibian Declines and the Frog Fungus Disease: Effects of Infection of Frog Eggs and Tadpoles

Tricia Rodriguez
Dr. Peter Daszak, Consortium for Conservation Medicine, Palisades, NY, Dr. Joyce Longcore, Department of Biology, University of Maine, and Dr. David Porter, Department of Botany, University of Georgia

Chytridiomycosis is a recently emerged fungal disease causing mass mortality and population declines in amphibians on a global scale. The disease is fatal to post-metamorphic frogs, although it does not cause mortality in tadpoles. Little else is known of its effect on these anuran larvae. The fungus infects only the keratinized mouthparts of tadpoles, but can result in the loss of a large proportion of their "teeth." Because tadpoles feed by scraping algae from a substrate with their teeth, tooth loss may inhibit their growth and development. I tested the hypothesis that infection with chytridiomycosis affects tadpole feeding abilities. I inoculated 25 *Rana pipiens* tadpoles with the fungal pathogen *Batrachochytrium dendrobatidis*; another 25 tadpoles served as controls. Tadpoles were weighed, measured and their developmental stage determined twice weekly. Growth parameters over five weeks showed no significant differences between infected and control groups. These data demonstrate that chytridiomycosis does not affect the feeding efficiency of tadpoles in early stages of development. Currently I am testing the role of amphibian eggs as a substrate for chytrid growth and means by which the disease increases its impact through different infection strategies. In addition, I am looking into possible mechanisms of disease transmission between life stages (vertical transmission) as well as infection from outside sources (horizontal transmission). These studies will aid our understanding of the ecology of this disease and help predict future patterns of disease outbreak.

Polar Endemism in Archaea: A Comparison of Archael 16S rDNA Sequences from the Arctic and Southern Oceans

Shomari Ruffin, CURO Apprentice
Dr. James T. Hollibaugh and Dr. Nasreen Bano, Department of Marine Sciences, University of Georgia

Cold polar oceans are relatively new features of the Earth, originating about 25 million years ago when the continents of Antarctica and Australia separated on the one hand, and the mid-Atlantic Ridge propagated into the Arctic Ocean basin, connecting it to the Atlantic Ocean. This was accompanied by a shift in global climate and both oceans cooled rapidly, forcing Arctic and Antarctic organisms to adapt independently to the new conditions. This led to the evolution of endemic species in the two oceans, for instance Polar Bears are endemic to the Arctic Ocean while penguins are endemic to the Southern Ocean. This study focuses on determining whether endemism applied to members of the Archaea Domain. To address this question we constructed a clone library of Archaea 16S rDNA sequences from five samples collected at a depth of 55m, 133m, and 235m during 1995, 96, 97 from the Central Artic Ocean. Each library was screened with denaturing gradient gel electrophoresis. The sequences of 25 clones with unique inserts were determined. All sequences were grouped within Euryarchaeota (Group II) and Crenarchaeota (Group I), the two major phylogenetic archeal groups. Within the Euryarchaeota there were two main clusters: one representing most of the 55m samples and the other was mostly composed of the deeper water samples. With a few exceptions, most of the sequences were distinct from southern ocean sequences. We concluded that polar Archael populations were composed primarily of endemic species. This study will provide information about the biogeography and biogeochemistry.

Cellular Tropism of an Undescribed Ehrlichia from White-Tailed Deer

Alexandra Isabel Sahora
Dr. William R. Davidson, Southeastern Cooperative Wildlife Disease Study (SCWDS),
Dr. Elizabeth W. Howerth, Department of Pathology, Dr. David E. Stallknecht, Department of Medical Microbiology and Parasitology, Vivien Dugan, Southeastern Cooperative Wildlife Disease Study (SCWDS), and Dr. Danny Mead, Southeastern Cooperative Wildlife Disease Study (SCWDS), University of Georgia

Prior studies on white-tailed deer have confirmed the presence of infection with at least three zoonotic *Ehrlichia* in the blood. An additional undescribed *Ehrlichia* was found to be common in white-tailed deer and the 16S DNA sequence of this organism was closest to *Ehrlichia platys*, a canine *Ehrlichia* that infects platelets. The objectives of this study were to visualize and determine the cellular tropism of this undescribed *Ehrlichia* agent. Antibody-coated magnetic beads were used to obtain high purity preparations of platelets free from other cellular components of blood, which were tested through polymerase chain reaction (PCR) and electron microscopy (EM) for ehrlichial infection. Blood from both naturally wild white-tailed deer and experimental wild deer was processed using two sets of Dynabeads® coated with either CD62P antibodies or M-M9 antibodies to obtain pure platelet and monocyte preparations, respectively. These preparations were then subjected to nested PCR using primers specific for this *Ehrlichia* and processed for transmission electron microscopy (TEM). PCR assays on platelet preparations consistently gave a strong, definite band correlating with the expected product size for this *Ehrlichia*. Positive PCR results were also produced for the monocyte preparations. Electron microscopy revealed characteristic *Ehrlichia*-like morula within platelets. These results strongly suggest that this undescribed *Ehrlichia* infects platelets. *In situ* hybridization assays to confirm the genetic identity of the morula in the platelets are in progress.

Children's Friendship Groups: The Wannabes in the Clique Hierarchy

Katrice Saudargas
Dr. Michele Lease, Department of Educational Psychology, University of Georgia

Friendship and peer acceptance are important for social development and self-esteem in children. According to the ethnographic research of Adler and Adler (1998), children's peer groups are organized along a continuum of popularity (i.e. visibility, social power, and control) into distinct groups including the popular clique, the wannabes, the middle group, and the social isolates. The "wannabes" were the focus of the current study. These children long to be friends with those in the popular clique but are denied inclusion. Adler and Adler (1998) describe the wannabes as being higher in popularity than the middle friendship children but having few, if any, friends. Adler and Adler (1998) hypothesize that due to a lack of secure friendships the wannabes have lower self-esteems and self-perceptions than those in the middle friendship groups despite their second highest ranking in the clique hierarchy. The current study tested this by comparing the number of best friend reciprocations of wannabes to those in other cliques as well as comparing scores on self-reported measures of self-esteem and self-perceptions. Participants were 222 students from four 4th, four 5th, and two 6th grade classrooms (51% female; 73% "white"/25% "black"). These children completed questionnaires in which they nominated peers for various descriptors and nominated three children who were their friends. The children also completed a range of self-report scales. A coding system was developed to classify children as belonging to the popular leader, popular, popular follower, wannabe, top middle friendship, middle friendship, bottom middle friendship, or social isolate level of the popularity hierarchy, as described in the ethnographic research reported by Adler and Adler (1998). The coding system used the following information: (a) perceived popularity (Parkhurst & Hopmeyer, 1998) and social preference (Coie et al, 1982) scores, (b) mutual friendship nominations as well as one-way nomination patterns, and (c) number of social influence nominations from peers (i.e., leadership, social control, admiration, and influence; Lease et al, in press). Interrater reliability was adequate (Kappa = .88). Because all children needed to be classified, all disagreements between the two coders were discussed and resolved. Children at the eight levels of the popularity hierarchy were compared on self-reported measures of loneliness and social dissatisfaction (Asher & Wheeler, 1985), social self-concept and self-esteem (Dubois et al, 1996), self-perception (Harter, 1985) and 3 BASC-SRP (Reynolds & Kamphaus, 1992) scales (i.e., social stress, interpersonal relations, and self-esteem). Preliminary findings show that wannabes do have fewer best friend reciprocations than those in middle friendship groups. Planned contrasts (wannabes vs. top middle friendship) revealed no significant differences in the self-report measures between these two groups, contrary to expectations.

New Balance Athens: "Endorsed by No One but Our Valued Customers"

Robin Seagraves
Dr. Michael Lomax, Department of Physical Education and Sports Studies, University of Georgia

The New Balance Athletic Shoe Corporation began a new retailing idea in 1996 with the opening of the first New Balance Concept Store. In an effort to increase distribution, the corporation began entering into agreements with local independent retailers, granting them the right to sell New Balance products exclusively. These stores are based on the concepts of "brand equity," the value added to a product by virtue of its name, and "brand loyalty," the ability of a particular brand to attract and retain customers, and they stock only New Balance footwear, apparel, and accessories. To date, there have been forty-one stores opened across North America. These stores have proved to be very profitable for both the retailer and the New Balance Corporation, with each store averaging between $600,000 and $800,000 in sales per year and showing an annual growth of approximately 40% (Wheeler, 2001). Therefore, it is my intention to capitalize on this market niche for the New Balance brand and open my own concept store, New Balance Athens. This paper will outline my proposal for the store's opening in four sections. First, the operations plan will provide a brief overview of the New Balance Corporation and will describe the basic interior and exterior set-up of the store, as well as the store location. Second, the marketing plan will identify the store's three target consumer groups. This section will also outline the store's first year marketing plan and budget. Third, the organizational plan will describe the managerial set-up and provide information regarding the tentative employee training program. Finally, the financial plan will analyze the total capital required for the store's opening.

Nitric Oxide Synthase mRNA Levels in *Trypanosoma cruzi* Infected iNOS Knockout and Wild Type Mice

Julie Seale
Kara L. Cummings and Dr. Rick Tarleton, Department of Cellular Biology and Center for Tropical and Emerging Global Diseases, University of Georgia

In vitro studies suggest that nitric oxide (NO) is an important killing mechanism of the intracellular pathogen *Trypanosoma cruzi*, the causative agent of human Chagas disease. Better understanding of the role of NO in immune control of *T. cruzi* has been obtained through the study of knockout mice lacking the enzyme nitric oxide synthase (NOS) needed for NO synthesis. Of the three NOS isoforms; inducible NOS (iNOS), endothelial NOS (eNOS) and neuronal NOS (nNOS), iNOS is thought to be most important for production of NO in response to pathogens. However, our lab has observed that wild type mice and mice with induced genetic defects in iNOS production (iNOS knockout mice) are equally resistant to *T. cruzi* infection. We hypothesize that mice lacking iNOS may compensate through higher production of eNOS and nNOS, explaining their resistance to *T. cruzi*. To address this question the levels of nNOS and eNOS mRNA in iNOS knockout mice infected with *T. cruzi* will be determined using a quantitative real-time PCR. The results will lead to a better understanding of the role of NOS in immune control of *T. cruzi*.

The Construction of the Lesbian Identity in the Undergraduate Classroom

Lotus Seeley
Dr. Bonnie Dow, Women's Studies, University of Georgia

As the gay and lesbian rights movement has worked to increase the civil rights of sexual minorities, within the academy there has been a parallel rise of the field of gay and lesbian studies, which has sought to understand and theorize the experience of sexual minorities. Some researchers have concerned themselves with the experience of sexual minorities in schools, predominantly heteronormative institutions. Little attention, however, has been paid to the experiences of undergraduate sexual minorities. My project is concerned with elucidating the classroom experiences of undergraduate lesbians. Specifically, I focus on how women's construction and performance of a recognizable lesbian identity is constrained by how comfortable they feel in disclosing their sexual identity with in a classroom setting. Special attention is paid to the multiple ways, including more and less overt verbal statements and nonverbal means, women attempt to communicate their sexual identity to other individuals in the classroom. Variables such as class size, subject matter, discipline, gender/sexuality of the teacher, and class level are also examined to understand how each may constrain or permit disclosure in their own way. The data for this project comes from open-ended interviews conducted with twenty-two undergraduate women at the University of Georgia who self-identify as lesbian. The women are aged 18-24 and 28.5% of the sample are minorities. Hopefully, the knowledge gained from this project will serve to better the experiences of sexual minorities by allowing a greater understanding of the factors that allow individuals the greatest control in revelation of sexual identity.

Immunohistochemical Detection of Newcastle Disease Virus in Chickens Inoculated with Wild-Type and Infectious-Clone-Derived Newcastle Disease Virus

Amy Sexauer,
Daniel J. King, Bruce Seal, Dr. James Stanton, and Dr. Corrie Brown, Department of Pathology, University of Georgia

The U.S. poultry industry is a thriving economic entity, thanks in part to the exclusion of devastating diseases. Velogenic Newcastle disease is a viral problem causing significant mortality for chickens. The Newcastle disease virus (NDV) circulates in many parts of the world, and incursion into the U.S. would have serious consequences. Understanding what makes these velogenic strains of Newcastle disease virulent would help greatly in devising control methodologies. In this study, four groups of White Leghorn chickens (eight per group) were inoculated with four different viruses – E13-1 (nonpathogenic strain), NDFL+ (infectious clone made from E13-1), NDFL+F (NDFL with fusion virulence gene inserted), and KRC 139 (virulent strain). The birds were monitored clinically and two birds euthanized, with tissues collected at two, five, 10, and 14 days post infection (dpi). Those given the virulent strain succumbed rapidly, dying by 4 dpi. Mild depression was noted in the NDFL+ group. Immunohistochemistry, using an antibody specific for NDV, was employed to follow the path of the virus throughout the body. With the virulent KRC 139 strain, there was extensive viral replication throughout the body. With the other three strains, presence of the virus was very limited. The "F" gene may not play a big role in virulence.

Induction of Apoptosis by Rabies Virus Proteins

Parul Shah
Dr. Zhen F. Fu, Department of Pathology, University of Georgia

Although rabies is one of the oldest recorded infections, it still causes more than 70,000 human deaths each year. The mechanisms by which rabies virus infection causes diseases and death are not completely understood, particularly with regard to the scarcity of neuronal damage associated with rabies virus infection. Recently, apoptosis was reported in experimentally infected animals. To further investigate if apoptosis is a pathogenic mechanism for rabies, we have compared the induction of apoptosis in animals infected with different rabies virus. Groups (10) of mice were infected with 10^6 focus-forming unit (ffu) of either laboratory-adapted or wild type rabies virus. Brains from four mice in each group were used histopathology, and brains from other mice were used for detection of apoptosis using terminal deoxynucleotidyl transferase-mediated dUTP-digoxigenin nick end-labeling (TENEL) assay. Surprisingly, only laboratory-adapted virus induced apoptosis in the brains of infected animals whereas the wild type rabies virus did not, indicating that apoptosis may not be a pathogenic mechanism for rabies, particularly for wild type rabies virus infections. To further investigate the mechanism by which rabies virus infection induces apoptosis, we expressed rabies virus nucleoprotein (N), phosphoprotein (P), and glycoprotein (G) proteins from laboratory-adapted virus individually in insect cells via recombinant baculoviruses and monitored for the induction of apoptosis in insect cells by DNA laddering. Preliminary studies revealed that apoptosis is induced only in cells infected with recombinant baculovirus expressing rabies virus G, indicating that rabies virus G is capable of inducing apoptosis.

Purification of Hirano Bodies from *Dictyostelium discoideum*

Sonbol Alexandria Shahid-Salles
Dr. Marcus Fechheimer and Dr. Ruth Furukawa, Department of Cellular Biology, University of Georgia

During the past three decades, Hirano bodies have been described in post mortem examination of brain tissue from patients with neurodegenerative diseases, muscle diseases, diabetes, alcoholism, and cancer. The Hirano body is composed of highly ordered paracrystalline actin filaments, actin binding proteins, and other components that have not been definitively elucidated. Recent studies demonstrate that Hirano bodies similar to those described in humans can form in the model organism *Dictyostelium discoideum.* The goal of this project is the biochemical purification of Hirano bodies to define their primary constituents. First, an assay to detect the presence and stability of Hirano bodies was developed using fluorescence microscopy. Second, it was found that Hirano bodies were stabilized in solutions containing 5 mM EGTA, 1 mM $MgCl_2$, 1 mM ATP, at pH 6.5 at room temperature. Third, release of intact Hirano bodies was observed to be optimal with lysis of *Dictyostelium* cells by Dounce homogenization in the presence of 0.5% Brij detergent. Fourth, Hirano bodies were collected by low speed sedimentation following cell lysis, and further enriched by density gradient fractionation in step gradients of iodixanol to remove nuclei. Protein separation by two dimensional gel electrophoresis with subsequent identification utilizing mass spectroscopy will be performed to identify the primary constituents of Hirano bodies. Future studies will also assess the role of these proteins in the formation of Hirano bodies by creating *Dictyostelium* cells lacking specific components. In addition, the presence of these proteins in Hirano bodies in autopsy specimens will be assessed.

Developing a Sensor for Measuring Suspended-Sediment Concentrations

Jai Sikes
Dr. Bruce L. Upchurch, Department of Biological and Agricultural Engineering, University of Georgia

Stream sediment degrades water supplies for human use, acts as a carrier for pollutants, and may adversely affect fluvial ecosystems. Recently, a densimetric instrument or "densimeter" for *in situ* monitoring of suspended sediments was developed. This densimeter offers advantages over commonly used samplers by continuously measuring suspended-sediment concentrations on site and allowing for longer sampling periods. Laboratory tests provided accurate results for concentrations from 10mg/L to 1000mg/L; however, field measurements contained several artifacts in the output signal. There was a ±30mV ($0.0024 in H_20$) fluctuation in the output signal when the transducer was placed in the field that corresponded to an 88mg/L (8.8% error F.S.) change in sediment concentration. Variations in the measurement could be caused by noise or dynamics of fluid flow around the ports. The objective of this project was to investigate the effects of port vibrations on the pressure measurements. A scaled version of the densimeter was constructed and tested by mounting a differential pressure transducer to an inverted pendulum and inducing vibration through a rotating cam. During three repetitions, differential pressure changes were monitored for a vibration range of 2-6 Hz and displacement angle range of 0.52-4.2 degrees in standing water. Generally, the differential pressure increased as displacement and frequency increased. A linear offset in the data was observed and contributed to a 50%-300% error; however, after subtracting the offsets, the results closely tracked the theoretical model. Further study will use these initial findings to develop an accurate measuring protocol for application of the densimeter in the field.

Immunohistochemical (IHC) Detection of Natural Killer Cells in Fish

Kate Smith, CURO Summer Research Fellow
Dr. Kenneth S. Latimer, Department of Pathology, University of Georgia

Immunohistochemistry (IHC) is the use of antibodies to detect specific antigens in cells of various tissues and organs. Sections of paraffin embedded tissues are cut at 3µm thickness and placed on glass slides. Following dewaxing, application of the IHC technique, and appropriate counterstaining, specific cells can be identified microscopically based upon their surface antigen expression. In this study, an IgM primary monoclonal antibody was used to identify natural killer (NK) cells in tissues of black sea bass (*Centropristis striata*). The specific IHC procedure was the avidin-biotin immunoperoxidase complex method. Sites of primary IgM antibody binding were identified using a biotinylated secondary antibody, an avidin-biotin peroxidase complex, and a diaminobenzidine chromagen. The slides subsequently were counterstained with hematoxylin, dehydrated, coverslipped, and examined microscopically. Natural killer cells are critical for effective innate and adaptive immunity in teleost fishes. The purpose of this study was to develop the IHC procedure to detect natural killer (NK) cells in formalin-fixed, paraffin embedded tissue sections from black sea bass, an important marine fish species along the Georgia Atlantic Coast. The significance of this initial research accomplishment is that the IHC staining protocol that was developed developed can now be applied to investigations of specific facets of cell-mediated immunity in fish. The technique will be used to investigate NK cell populations in histologic sections of lymphoreticular tissues from clinically normal black sea bass to understand the dynamics of this cell population in the constitution of the cell-mediated immune system. Expectations are that this technique will be used to expand basic knowledge of an important facet of immunity in black sea bass and other telost fishes. The information obtained will be useful in evaluating the health status of cultured black sea bass stocks before costly mortality events occur.

Optimization of Textural and Structural Properties of a Refrigerated Soy Based Dessert

Sara Smith, CURO Apprentice
Dr. Milena Corredig, Department of Food Science and Technology, University of Georgia

Soybeans have been used for many years in the production of soybean products and soy enriched products. In recent years scientist have found more nutritional value in the soybean. Due to these new discoveries industries have begun to increase the amount of and invent new soybean or soy-enriched products. Products ranging from soymilk to soy-enriched cereal have flooded the health food market. With the U.S. focusing more on health issues a demand for new soy products is growing. The objective of this project was to develop a sugar free soy based refrigerated dessert with the texture, taste, and feel of a mousse- type product. The texture was fundamental to the quality and the challenge is to maintain the textures at refrigeration temperatures. Grittiness was a characteristic typical of soy-based products. These textual properties were the focus of the formulation development. These textual properties derive mainly by fat globules, ice crystals, and air bubbles all in a protein network. All of these in an optimal equilibrium will result in acceptable physiochemical and organoleptic qualities. Preliminary work on a small scale (1 kg batches) and then larger batches (2 kg batches) were prepared in the pilot plant. Each of the eleven batches were characterized by a different formulation and were prepared by mixing, pasteurization, homogenization, freezing, and refrigeration. Formulations were optimized in the pilot plant and the best combinations were tested for texture and the microstructure was observed. Texture was tested with the TA-XT2 texture analyzer. The effect of various concentrations of soy protein and the ratio of soy to milk protein (used because of its functional properties) was studied. If starch was added to the formulation the texture was highly creamy but not stable enough to hold its structure in refrigerated temperatures and therefore not acceptable. The addition of soy protein strengthened the texture and stability but added to its grittiness. The grittiness increased when the amount of soy protein increased. To improve stability at refrigeration temperatures a stabilizer was added. Two types of stabilizers were tested. Stabilizer one contained gelatin (Degussa) and the other did not contain gelatin (Cpkelco). The gelatin-containing stabilizer was used successfully in many different formulations and resulted in acceptable texture. The non-gelatin stabilizer was successful in only a few formulations.

The Effect of Light Intensity on the Transformation Frequency of Soybean Somatic Embryos

Lauren Stanchek
Dr. Wayne Parrott, Department of Crop and Soil Sciences, University of Georgia

The effects of light intensity on the embryogenesis of numerous plant species have been well-characterized. However, the effects of varied light intensities on the transformation frequency of embryos have been largely unexplored. This experiment sought to determine the influence of light intensity on the frequency and efficiency of soybean somatic embryo transformation. Embryos were generated from immature cotyledons under either high light [46 $\mu E/m^2$ /s] or low light [10 $\mu E/m^2/s$] and bombarded with the pCAMBIA 1305.2 construct, which contains two genes—one that confers resistance to the antibiotic hygromycin and the other the GUS Plus reporter gene. Both treatments consisted of four replicates of approximately 100 mg of tissue/replicate. After bombardment all embryos were placed into liquid 25 μg/ml hygromycin selection for two months. The resultant hygromycin resistant embryos were tested for expression of the GUS Plus gene. PCR was performed to determine the presence of the hygromycin resistance gene and to exclude the possibility of "escapes." Stable transformants and copy number of the lines were assessed by Southern blot hybridization analysis. The total transformation frequency, based on hygromycin positive PCR results, was 5 lines/bombardment for the low light treatment and 1.1 lines/bombardment for the high light treatment. Therefore embryos grown under the low light treatment appear to be more amenable to transformation than those generated under high light. The expression transformation frequency was based on the expression of the GUS Plus reporter gene. In general the expression transformation frequency was approximately half of the total transformation frequency for both treatments. Student's t-test showed the results to be significant at the one percent level.

Friendship in the Age of Sensitivity: The Correspondence between Johann Wilhelm Ludwig Gleim and Johann Georg Jacobi

John Stark
Dr. Mark Kagel, Department of Germanic and Slavic Languages, University of Georgia

Sensitivity, or *Empfindsamkeit* in German, is a term that refers to a period of the German Enlightenment and is characterized by the frequent and often excessive expression of emotion. Sensitivity writing often examines the relationship between the head and heart as well as those things that disrupt this balance, such as enthusiasm and melancholy. Letter writing as a medium for communicating emotions is an integral part of the literary writing during the Age of Sensitivity. The letters help to establish a community of minds, serving not only as a medium between friends, but also as a form of introspection, by which writers could better discover themselves. An examination of an extended correspondence between Johann Wilhelm Ludwig Gleim and Johann Georg Jacobi, published in 1768, offers insight into the fashion of the period: to express oneself emotionally and not to veil or rationalize one's feelings. It also shows how friendship is established and expressed between two educated men in the middle of the eighteenth century. The language of the correspondence shows that Gleim and Jacobi prefer a language of emotion to a language of reason in their friendship correspondences with one another. Gleim and Jacobi's correspondence reflects the deep labyrinth-like intricacies of their complex friendship. The correspondence between Gleim and Jacobi reflects the feelings of many members in the educated population of Germany during the period of Sensitivity.

Time and Myth: Literary/Philosophical Accounts/Representations

Joshua Striker
Dr. Thomas Cerbu, Department of Comparative Literature, University of Georgia

In the research paper, "Time and Myth: Literary/Philosophical Accounts/Representations", I investigate the anthropological significance of time and myth within, broadly speaking, the contexts of philosophy as well as of literature. Concentrating primarily on Frank Kermode's *The Sense of an Ending*, Jean-Paul Sartre's *Nausea*, and Robert Musil's *The Man Without Qualities*, the essay also discusses Augustine's definition of time, the way in which Paul Ricoeur understands the relationship between literature and the self's temporality, and Michel Tournier's mythical, timeless Abel Tiffauges. While to some degree a work connected inextricably to particular texts, this paper attempts as well to summarize and consolidate the fundamental, or perennial, aspects of those texts' theses in order to present a relatively independent construal of myth and time. Balancing delicately basic categories like philosophy and literature, time and myth, the essay follows the lead of many of its textual foci in retaining categorical distinctions without indiscriminately accepting their accuracy. In this vein, the essay will explore those ontological and epistemological commitments that myth-making entails, such as the commitment to personhood, or interpersonal communication, as well as the communicative form(s) and presentations of the self that mythologizing contains. Ultimately, "Time and Myth: Literary/Philosophical Accounts/Representations" construes myth as an extreme form of man's endeavor to explain and portray himself within time.

Biometric Differences between Otoliths of Two Species of Sea Catfish

Kathleen Teeples
Dr. Elizabeth Reitz, Georgia Museum of Natural History, University of Georgia

This study defined differences between the otoliths of two species of sea catfish using biometric analyses. Vertebrate remains from archaeological sites are identified using a comparative skeletal collection. The results are interpreted in terms of human/environmental relationships. Otoliths, the inner ear stones of fish, are commonly found in coastal assemblages dominated by sharks, rays, and bony fishes. The morphology of these skeletal elements are species-specific. However, it is difficult to distinguish between two species in the family Ariidae (sea catfishes) based solely on otolith morphology. Distinguishing between the hardhead catfish *(Arius felis)* and the gafftopsail catfish *(Bagre marinus)* is critical to a broad range of zooarchaeological research problems, especially those based on habitat differences, such as stable isotope analysis. Members of these two genera once grew to a much larger size, and stable isotopes may identify the causes for this, but first we must be able to distinguish between the otoliths of the two species. The length, width, and thickness of 80 otoliths from the two species were measured and mathematical equations applied to define differences between them. These otoliths were from the comparative collection at the zooarchaeologicallab, Georgia Museum of Natural History. The results of this study are significantly different from those of previous studies whose results could not be duplicated. Stable isotope protocols will be adjusted to take the difficulty of distinguishing between these species into account.

Parameter Development and Application of the Glycam Force Field for Sialic Acid Derivatives

Buudoan V. Tran, CURO Summer Research Fellow
Dr. Karl N. Kirschner and Dr. Robert J. Woods, Complex Carbohydrate Research Center, University of Georgia

Glycerol and glycerol derivatives are ubiquitous in biological systems, from fatty acids to polysaccharides. Understanding the interplay of intra- and inter-molecular forces in glycerol and the effect these forces have on the conformation is critical in understanding the role and behavior of compounds that contain glycerol. Molecular modeling systems can provide valuable insight into the behavior of complicated systems. The GLYCAM parameters for molecular mechanics (MM) and dynamics simulations of carbohydrates with the AMBER force field have been extended to include parameters for acyclic polyhydroxy compounds. The parameters were developed for 1,2-ethanediol using quantum mechanical (QM) calculations of its potential energy using HF/6-31 G* and B3LYP/6-31++G(2d,2p) levels of theory in the Gaussian98 program suite. The conformational energies for the various rotamer populations of 1,2-ethanediol were compared to energies given by MM calculations in the GLYCAM force field, yielding parameters for the OCCO torsion angle based on an analysis of the effect of non-bonded interactions. Once parameterized, the QM and MM results were in good agreement. These parameters are particularly relevant for simulations of sialic acids, which contain glycerol sidechains. The behavior of these sidechains and, consequently, the conformation of sialic acid depend directly on the influence of the OCCO torsion system. Molecular dynamics simulations were performed on 5-N-acetylneuraminic acid and glycerol and the results compared to solution-phase NMR data. The computed solution structures and rotamer populations are in good agreement with the experimental data. The conformational properties are discussed in terms of internal hydrogen bonding versus solute-solvent interactions.

The Use of Immunohistochemistry to Diagnose Chytridiomycosis in Frogs

Tracy K. Van Ells
Dr. Corrie Brown, Department of Pathology, University of Georgia

Chytridiomycosis, caused by *Batrochochytrium dendrobatidis*, is an emerging disease of frogs, posing a threat to their survival in many parts of the world. Because the disease can be difficult to diagnose on routine pathologic sections, the purpose of this study was to develop a standardized method for identification. To accomplish this, immunohistochemical staining was applied to histologic skin sections from four experimentally infected frogs of the species *Dendrobates tinctorius*. The primary antibody was anti-chytrid, made in rabbit, followed by biotinylated anti-rabbit, made in goat. The detection system was avidin-biotin alkaline phosphatase and the substrate used was Vector Red. Antibody dilutions were titrated to optimize the signal. A dilution factor of 1:2500 for the primary antibody was found to maximize visualization of the fungus while producing very little background staining. Negative serum and tissue samples were also included, as were four non-chytrid fungal controls, to ensure the specificity of the primary antibody. Staining of the positive tissue sections was distinct and readily visualized, making this technique a valuable ancillary diagnostic test for the presence of this important disease.

The Genomic Study of Multigene Families of *Pneumocystis carinii* for Potential Drug Targets

Claudia Vargas
Dr. Jonathan Arnold, Department of Genetics, University of Georgia

Pneumocystis, a genus of opportunistic fungi, is a serious threat to immune deficient patients, particularly those who are HIV positive. *Pneumocystis* causes thousands of deaths each year by infecting the lungs of immunocompromised individuals, leading to acute pneumonia. An estimated eighty-five percent of patients diagnosed with AIDS will develop pneumonia caused by *Pneumocystis*. Efforts to expand therapeutic options against this pathogen are essential, as increased use of antibiotics has lead to drug resistant fungal strains. Due to the obligate parasitic nature of *Pneumocystis*, it has been difficult to traditionally culture and study this organism; thus, genomic methods have been utilized to produce the most informative research. This multi-institutional research project among the University of Cincinnati College of Medicine, University of Kentucky, Indiana University Medical School, and University of Georgia aims to produce a genomic map of *Pneumocystis carinii f. sp. carinii*. Several genetic methods have been employed including generation of multiple *Pneumocystis* libraries, sequencing through subcloning of related contig DNA, and hybridization by P-dCTP pWEB DNAs against a known *Pneumocystis* cDNA library. Presently, over fifty percent of the genome map has been constructed with an average of thirteen contigs per chromosome. Several significant protein-coding sequences were identified, such as the major surface glycoprotein family (MSG), which is hypothesized to be responsible for the pathogenic nature of *Pneumocystis*. Other findings include the discovery of only a single copy of rDNA in *Pneumocystis*, which is a possible genome conservation strategy.

Joan of Arc: History's Conflicted Warrior

Karen Viars
Dr. Katharina Wilson, Department of Comparative Literature, University of Georgia

Since before her death in 1431, Joan of Arc has been a fascinating subject for writers. The first of these was Christine de Pizan in 1429 and they continue into the present day. Each author, while usually expressing great respect for Joan and her accomplishments, almost always uses her as a historical example to influence contemporary politics. Because Joan was a political figure inextricably part of France's role in the Hundred Years War, it is not surprising that authors and propagandists use her in this way. Politics is not the only arena in which Joan's story appears as a didactic tale; portrayals of her vary as widely as the causes writers cite her to support. These different and often conflicting images have much to do with Joan's rehabilitation trial and canonization as a saint in 1920, with her usefulness as a propaganda figure, and with modern ideas of her nature. Using various texts spanning from the original trial documents to modern works, I intend to assess images of Joan of Arc in literature and culture, and discern how authors use her as an icon to further their own agendas.

Cytoskeleton Induced Apoptosis of HeLa Cells

Heidi Woessner
Rich Davis, Dr. Ruth Furukawa, and Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia

Cells die from diverse processes such as senescence (old age), necrosis (disease), and apoptosis (programmed cell death). Apoptosis is characterized by a series of cellular events including activation of caspases, mitochondrial membrane depolarization, blebbing at the plasma membrane, and fragmentation of DNA in the nucleus. Apoptosis occurs in association with a variety of normal and pathological conditions. The initial goal of this project was to study formation of Hirano bodies in HeLa cells, an immortalized epithelial cell line, following expression of an altered form of the *Dictyostelium discoideum* 34 kDa actin bundling protein. Hirano bodies are paracrystalline actin structures associated with a variety of diseases. Formation of Hirano bodies in HeLa cells was not observed. Surprisingly, HeLa cells were stimulated to undergo apoptosis. The following evidence supports this conclusion: 1) an increase in cell death was observed by staining the cells with trypan blue; 2) membrane blebbing was detected by light and scanning electron microscopy; 3) DNA fragmentation was demonstrated using a TUNEL assay that detects free ends on DNA; and 4) loss of energized mitochondria was demonstrated using a fluorescence assay. These findings were unexpected, since the actin cytoskeleton in not known to participate in initiation of apoptotic signaling. Future studies will attempt to unravel the pathways of apoptosis initiated by perturbation of the actin cytoskeleton. Moreover, additional investigation is needed to elucidate the relationship between formation of Hirano bodies and initiation of apoptosis in different cell types.

The Generation of Mutations in the N-Terminal Region of the Protoporphyrinogen Oxidase of *Bacillus subtilis* to Create a Protein Capable of Mitochondrial Targeting in Mammalian Cells

John Woodruff, CURO Summer Research Fellow
Dr. Harry Dailey, Department of Microbiology, University of Georgia

Protoporphyrinogen oxidase (E.C.1.3.3.4) (PPO) is the penultimate enzyme of the heme biosynthesis pathway. Given the mitochondrial location of both its substrate and the subsequent enzyme of the eukaryotic heme biosynthesis pathway, PPO must be effectively targeted to the mitochondria to function properly. Human PPO contains a N-terminal mitochondrial targeting sequence that is atypical in a number of its characteristics, including the fact that this leader is not cleaved following its import into mitochondria. This is significant because the leader sequence is also involved in PPO functionality. Because the leader is required for PPO to function, it has been highly conserved throughout evolution, and a homologous region occurs in the PPO of *Bacillus subtilis*. The current study demonstrates that the prokaryotic *B. subtilis* leader does not target Green Fluorescent Protein (GFP) fusions to the mitochondria of hepatoma cells. It is shown that it is possible to introduce mutations to the *B. subtilis* leader that confer certain putative characteristics of the human PPO N-terminal targeting sequence, including its hydrophobic-hydrophilic amphiphilic alpha helix with a basic region at its far end, transforming it into a leader that induces translocation. In doing so, this study has identified the characteristics of the N-terminal region of PPO that are responsible for its ability to function as a leader sequence.

The Effect of Genetic Background on Stress Resistance in Transgenic Fruit Flies
Amber Wright
Dr. Daniel Promislow, Department of Genetics, University of Georgia

Attempts to identify genes that extend life span in fruit flies have used short-lived lab strains. We hypothesize that these 'longevity' genes may simply cure short-lived flies. The experiment described below attempts to determine if longevity genes also increase fitness in longer-lived wild-caught flies. Previous research has demonstrated that resistance to oxidative stress plays an important role in the aging process. Antioxidant genes such as superoxide dismutase (SOD) fight aging scavenging free radicals. In the fruit fly, *Drosophila melanogaster*, mutants that over-express SOD live substantially longer than control flies. Unfortunately, these mutants, and others like them, are produced by inserting novel genes into relatively short-lived laboratory strains. To determine whether SOD can extend life span in natural genetic backgrounds, we crossed SOD males with strains of fruit fly recently derived from wild populations. Previous studies have shown that longevity is genetically correlated with stress resistance. Accordingly, offspring from each SOD x wild line cross were tested for resistance to the paraquat, which generates oxygen radicals, and to a 38° C heat shock, which denatures proteins and increases mortality rates. We found that over-expression of SOD generally increased stress resistance, though in some genotypes SOD had no effect, or even decreased stress resistance. These results indicate that while mutant genes identified in the lab might be important in natural populations, not all genotypes will respond to such genetic manipulations. Future studies will attempt to identify specific genes that interact with SOD to modify its effect on longevity.

Isolation and Characterization of Novel Anaerobic Thermophilic Iron(III)-Reducing Bacteria
Eric Wright, CURO Apprentice
Dr. Juergen Wiegel, Department of Microbiology, University of Georgia

This research focused on discovering and studying novel species of anaerobic, thermophilic, iron(III)-reducing bacteria from volcanic areas and hot springs in Russia and the United States. Iron-reducing bacteria are important to several geochemical processes around the globe. Isolation of the bacteria involved anaerobic techniques using sophisticated gassing equipment and atmospheric controls to produce pure, single-species colonies in media incubated under high temperatures. Two samples were used in the isolation process and were transferred to cultures containing differing media and concentrations of gases. From there, single strains were isolated. Characterization of the isolated specimens will be accomplished through RNA sequencing. Since anaerobic, thermophilic iron-reducers survive under conditions similar to those of the early earth, the study of these bacteria will shed light on the biological and chemical processes and pathways that were probably present in early unicellular life, and perhaps on the evolutionary process itself.

Adintern.com: A Website to Assist Advertising Focused Students in Finding, Getting, Keeping, and Leaving an Internship
Margaret Young
Dr. Kirsten L. Strausbaugh, Department of Advertising/Public Relations, University of Georgia

Adintern.com is a website to assist advertising & design focused students in finding, getting, keeping, and leaving an internship. Adintern is a practical application of research while at the same time a new medium to fill a niche in the online and career services arena that has in the past been overlooked in the field of advertising. Internships are a vital part of the advertising curriculum and are an essential prerequisite to an entry-level position in the competitive field of advertising. Advertising agencies do not recruit like many business corporations; it is therefore upon the advertising students to create opportunity. Adintern creates this opportunity. The site consists of various facets helpful to the advertising student, the main of which are advertising focused career advice, advertising industry information and trends, agency profiles, internship postings, advice from advertising experts, access to previous interns for advice, and links to industry publications and relevant information. Aside from the site itself, the written thesis examines the motivations and reasoning behind the site, influences of the site, methods used to prepare the site, and a formative evaluation of the site's design and usability. Adintern.com is proactive, prolific, and progressive. The site is viewable from the World Wide Web at http://www.adintern.com.

Artist Statements
Visual Arts
Creative Writing

Stephanie Anderson
Professor Edward Lambert, Fabric Design, Lamar Dodd School of Art, University of Georgia

"The body is not a thing; it is a situation." – Simone De Beauvoir
In this body of work the subjects are the keys. They are first but not primary. Their forms are constructed only of shadows yet they embody their surroundings. The shadows act as boundaries in a state of flux as there are no true borders beyond one's own construction. My interest is in the relationship between the subject and its environment. Does the environment act upon the individual or is it the individual's perspective which shapes their surroundings? Which shapes their surroundings? These works allow insight into the mutability of perspective. The subjects are not symbols but are symptoms of the intermixing of place and sensation. Color is that language by which the situations are told. Transparent pigments are applied in layers on loose woven linen to build perceptual depth of hue. The additive process allows many colors to be present at once within each area.

Antibiotic Art
Jeff Edwards
Professor Robert Stackhouse, Lamar Dodd Professorial Chair, Lamar Dodd School of Art, University of Georgia

I am not a troublemaker, I swear! My recent sculpture has been about creating staged social conflict within the viewer. My goal is to allow the viewer to interpret her or his reaction as psycho-visual incongruities in her or his social thought. Each piece is designed to create emotional action or reaction. Over time, I hope to develop a catalog of human emotional experience, with each sculpture cataloging the greater metaphors of existence. I wish to inspire dialog about creating experience-based social change. Being a professional artist is one of the most self-glorifying careers one could choose. It stands to reason that an artist should cultivate her or his true understanding of the self. "One is never more attractive than when one is being one's true self." Note to self – Rent costume! Never should it be said that an artist "does not know what her or his work means." Neither should it be said that the artist created a work "for no reason." Wasting opportunity makes your work not worth a footnote. The artist has the responsibility to defend and promote her or his work. Talking about projects is an opportunity – a platform. This movement will likely be bisected by a hypocrite movement with "similar principals," likely from advertising or insurance interests, unless YOU, as artists defend, promote, and explain your work. Ancient Egyptians used pictures to represent words. Modern Americans use words to create pictures, metaphors. My art uses visual metaphors to create emotion.

Caitlin Martell
Professor Melissa Harshman, Printmaking, Lamar Dodd School of Art, University of Georgia

My current body of work stems from an exploration of the beauty of repetition and the language of the body. Working in an unmediated and ritualistic method, I make prints of my body, building up the surface through repetition, documenting the texture and markmaking of my own skin. I seek to visually communicate the experience of the soul by developing a language through the repetition of my own bodily forms. The work is both simple in execution and yet visceral. It draws from the influence of artists such as Kiki Smith and Leslie Dill as well as more direct studio exposure to the etchings of Jennifer Anderson.

Amanda Gary
Professor Edward Lambert, Fabric Design, Lamar Dodd School of Art, University of Georgia

Utilizing the designs of primitive artists as a point of departure, my work revolves around the simple, contemporary processes that reflect a combination of primal and modern sensibilities. Creating layer fabric allows for the exploration of shape, color, and line in a very direct and innovative manner. From simplistic design and technique, I attempt to show complex and multi-layered images with fabric.

"each morning I get up with one word in mind: plastik…"
Lorina Naci, CURO Summer Research Fellow
Professor William Paul, Jr. Drawing and Painting, Lamar Dodd School of Art, University of Georgia

My artistic work is concerned with two encroaching phenomena that address the legitimacy of my Albanian heritage: Post Communism and globalization. I am interested in the quintessential values of Albanian natives and how some of these values are threatened by the advent of better technologies, faster information flow, and faster lifestyles brought by globalization in my country as well as elsewhere in the world.

By focusing on facial close-ups and on the physiognomy of natives of Albania and of Western Europeans in painting, in film, and in sculptural work, I seek to investigate the identities produced by the different economical, political, and social systems expressed visually in the body as the physical site of the human interaction with the governing system.

Theresa Marie Sporer
Professor Larry Millard, Sculpture, Lamar Dodd School of Art, University of Georgia

Using a dichotomy of materials, my sculptures express experiences from my life. I am really attracted to the interaction of contrasting materials (such as fibers, steel, and ceramics) inter-laced and working together to create an overall mood. I incorporate my ceramics background into my sculpture by utilizing techniques from both disciplines. The endless capabilities of sculpture enable me to develop themes in my work, which I was unable to accomplish with just ceramics. Reoccurring themes in my work include marriage, anticipation of becoming pregnant, and the trauma I experienced after being bitten by a venomous snake. These ideas and experiences are expressed conceptually rather than through direct imagery.

Jennifer Srygley
Professor Judson Mitcham, Department of English, University of Georgia

In writing poetry for my Honor's thesis this semester, I am exploring the effect of sounds and rhythm on the writing of the lyric. Perhaps this exploration can best be explained in the words of poet Richard Hugo, "all truth must conform to music." My thesis is comprised of a collection of poems written in various workshops. In writing poetry, I have found that it is impossible to completely separate my work from the rich tradition of American poetry. Poets whose work has influenced my own include Frank O'Hara, Richard Hugo, Kenneth Koch and Ellen Bryant Voight. If one thinks about poetry as a kind of music, it is possible to gain a new level of understanding of poems that is based on aural expression and often belies the content of the words. In writing and reading my poems, I hope that I am able to convey a sense of sounds and the musical quality of language.

Are Deer Mice the Reservoir of Vesicular Stomatitis Virus?

Despite extensive research efforts to clarify the transmission cycle of vesicular stomatitis virus (VSV), the causative agent of an important arboviral disease of livestock in the western United States, several aspects remain unclear, including the involvement of insects in virus transmission. Experimental infections of natural livestock hosts with the New Jersey serotype (VSV-NJ) have failed to produce sustainable viremia. In studies with deer mice (Peromyscus maniculatus), juvenile deer mice developed viremia following intranasal and intradermal VSV-NJ inoculation. However, it was not determined if the level of viremia was sufficient to infect insects. The objectives of this project are to determine if viremia is present in juvenile deer mice after being fed upon by black flies infected with VSV-NJ, and to determine if black flies can be infected with VSV-NJ by

feeding on viremic deer mice.

Laboratory-reared female black flies (Simulium vittatum) were infected with VSV-NJ by intrathoracic inoculation and allowed to feed on susceptible juvenile deer mice. On post-infection day 3, blood samples were collected from each mouse and tested for presence of VSV-NJ by cell culture inoculation. Additionally, non-infected black flies were fed on mice at the same time period. Viremia had not been detected in any of the mice as of day 6. As of day 7, 4 of 15 mice developed severe posterior paralysis, indicating transmission of VSV-NJ through fly bite. Transmission in the remaining mice will be confirmed by virus isolation from brain samples and serum neutralization assay.

Zoroastrian Influences on Abrahamic Religions

When people from varying geographic regions interact with one another, certain characteristics cross borders. These characteristics can come in the form of different ideas based on religious beliefs. As these beliefs cross borders, they may be more directly based on cultural characteristics instead of religious principles. One may not realize that a belief that they thought originated with their religion actually originated with another. Within the Abrahamic religions of Judaism, Christianity, and Islam there are specific there are specific religious principles that are viewed to have originated from within, when actually they originated elsewhere. The followers of the Abrahamic religions have come into contact with people from various faiths. Through extensive research I was able to conclude that one of the most influential contacts was with the Zoroastrians of ancient Iran.

The first thing that will be presented is a basic history of the Zoroastrian faith, followed by its influences on the Abrahamic religions. In determining how Zoroastrianism influenced Judaism, Christianity, and Islam I compared the Zoroastrian religious texts with the other religion's texts, drawing specific examples in which Zoroastrian influence is most evident. The sources of my research not only include specific quotes from the Torah, Bible, and Quran, but also from field research in an Atlanta Zoroastrian community, books about ancient Persian history, and travel to Iran.

MODELING AND ANALYSIS OF THE BIOLOGICAL CLOCK IN *NEUROSPORA CRASSA*.
Dr. Jonathan Arnold, Dr. H. Bernt Schuttler Department of Genetics, University of Georgia, Athens, GA 30602

A biological clock is a recurring set of reactions within a system that produces an oscillating pattern. Unlike a traditional “clock,” a biological clock can run continuously so long as all reaction components are present. Reaction rates are the main variants.

Genetic networks are used to understand the relationships between genes, RNA, and proteins. These models show which genes are active, how they become active, what their products do, and their relationships with other genes and their products in the circuit. Then an ensemble of genetic networks for the biological clock was identified, fitting available RNA and protein profiling data. The fitted ensemble was used to identify essential features of the genetic network needed to sustain oscillations. Two features that appear necessary for oscillations are: (1) cooperativity in the action of two clock components, the White Collar (WCC) protein and Frequency (FRQ), and (2) a closed feedback loop in clock components. Along side the ensemble experiments, local stability analysis was done to examine equilibrium properties of the genetic network. Oscillations will only occur if the system does not have a stable fix point. Analytical conditions for instability are derived, permitting

oscillations. In short, the clock needs several interacting proteins, a negative feedback loop, some cooperativity and the absence of a stable fix point to which the system would otherwise equilibrate.

Identification and partial characterization of insertional mutants in a family of putative glycosyltransferases that may be involved in plant pectin biosynthesis.
Xiaogang Gu and Michael G. Hahn; University of Georgia, Complex Carbohydrate Research Center and Department of Plant Biology.

All plant cells are surrounded by a cell wall that not only provides form and structure to the plant, but is also the interface where plant cells interact with each other. The cell wall is predominantly made up of polysaccharides. Significant advances have been made in our knowledge of the structures of many polysaccharides, but little is known about their function and biosynthesis. We are studying the biosynthesis of pectins, a group of polysaccharides that form one of the macromolecular networks within plant cell walls. We have identified a small gene family thought to encode a group of glycosyltransferases involved in pectin biosynthesis. We are trying to determine the function of the genes in this family by isolating and characterizing plants carrying insertional mutations in these genes. Arabidopsis thaliana seeds with T-DNA inserts within the genes of this glycosyltransferase family were obtained from the Salk Institute. Seeds from the Salk Institute were planted and allowed to grow into mature plants and set seed. Healthy leaves were harvested from individual plants. DNA was extracted from the leaves using rapid DNA extraction techniques. PCR was then used to amplify the part of genes thought to contain the insert. Finally, gel electrophoresis was used to identify the insertional mutants. So far, we have identified Arabidopsis plants that are homozygous for mutations in two of the genes in the gene family. Seed from these plants are being grown to obtain sufficient tissue to analyze their cell walls for compositional changes resulting from the mutations.

Generating Expressed Sequence Tags from Sorghum bicolor
Dr. Lee H. Pratt and Ms. Shana Seamans

Expressed Sequence Tag (EST) sequencing is a process that allows expressed genes in particular tissues or cell types to be identified through the utilization of complementary DNA (cDNA) libraries. These cDNA libraries are compiled through the reverse transcription of mRNA in an organism's cells. For this project, the organism is Sorghum bicolor, or sorghum, a plant similar to maize. Unlike maize, however, sorghum is capable of withstanding many harsh conditions such as drought, surplus hydration, surplus salinity, and a variety of chemical compositions in its soil. The purpose of this project is to use EST sequencing to identify sorghum's expressed genes. This process begins by inserting cDNA into a plasmid vector of known sequence. The plasmids, all containing different cDNA sequences, are inserted into separate Escherichia coli cells, which are then allowed to multiply. The plasmids were then isolated from the bacterial cells and purified in a three-day process after which each unidentified cDNA sequence was sequenced from both the 3' and 5' ends and analyzed for quality. The sequences will be inserted into a computer database to be compared with other EST data in order to separate highly expressed genes, which are transcribed frequently, from genes that are unique to a particular environmental stress. The discovery of the genes in sorghum used for resistance to environmental stress will contribute not only to the understanding of sorghum's endurance, but will hopefully lead to methods of improving crop plants, which may prove less durable.

Developing a Fast Plant Expression System to Identify Biosynthetic Genes Involved in Pectin Synthesis
Dr. Maor Bar-Peled

Pectin, the most structurally complex wall polysaccharide, is involved in many plant cellular processes such as cell-cell adhesion, cell-cell recognition, and pathogen recognition. Recent studies provide evidence that pectin may have important health benefits, most notably in the treatment of cancer. In one study, citrus pectin was found to inhibit tumor growth, angiogenesis, and metastasis in mice injected with human breast carcinoma cells. In order to build upon the initial findings, greater understanding of this complicated polysaccharide is essential. While there has been much progress in determining the structure of pectin in recent years, its synthesis remains poorly understood. A crucial step in pectin synthesis is the synthesis of 16 distinct nucleotide-sugars. These activated sugars serve as the immediate substrates for the enzymes that construct pectin. This project's purpose is to design an expression system to identify biosynthetic genes involved in nucleotide-sugar synthesis. Expression of the putative biosynthetic genes in E. coli has been a successful and fast system with previous genes, but has been unsuccessful with the putative UDP-apiose synthase gene as well as other putative genes in past attempts. In this experiment, a stable GST protein was tagged to the protein encoded by the putative UDP-apiose synthase gene, enhancing protein stability and therefore protein expression. Using this GST-fusion method, the alleged UDP-apiose synthase gene is one step closer to being confirmed, making this a promising and fast method for identifying putative genes encoding unstable proteins.

Apoptosis of pancreatic exocrine cells in birds infected with Newcastle disease viruses

Newcastle disease virus (NDV) is a highly infectious viral disease of many species of birds, including poultry. In this experiment, two virulent strains of NDV were introduced into chickens, turkeys, and pigeons. The pancreatic tissues were harvested for immunohistochemistry (IHC) for viral nucleoprotein to demonstrate viral distribution, and IHC for active caspase-3 and TUNEL assay to detect apoptosis. The pancreatic lesions of each protocol were then compared, demonstrating the correlation between NDV and apoptotic cells in the pancreas.

Malleability Of Interpretation Bias In Social Anxiety And General Anxiety
University of Georgia

Individuals with anxiety tend to interpret ambiguous cues as negative (e.g., Amir et al., 1998, Constans, Penn, Ihen & Hope, 1999; Stopa & Clark; 2000). Although one goal of cognitive behavioral therapy is to change the cognitions of individuals with SA and generalized anxiety disorder, it would be more efficient if these biases could be changed experimentally. Recent studies suggest it may be possible to change information processing biases in anxious individuals (e.g., Mathews & Mackintosh, 2000). In the current study, we attempted to change interpretation bias for threat in individuals and examined the effect of these changes on self-report of anxiety. Participants were individuals who reported either high levels of social anxiety or general anxiety. Participants first saw either a positive or a negative prime (e.g., graceful or clumsy) on the computer screen. They then saw an ambiguous sentence (e.g., You dance at the party) and were asked to decide if the word and sentence were related. The computer then provided feedback as to whether their answer was "correct" or "incorrect". Participants were assigned to either a positive training condition or a placebo condition. In the positive training condition, feedback was contingent on their response, (e.g., when the first word was positive, the correct answer was 'yes, they are related.' When the word was negative, the correct answer was 'no, they are not related.').

Therefore, the feedback trained participants to interpret ambiguous information in a positive manner. In the placebo condition, participants received random feedback that was unrelated to their responses. Preliminary results suggest that participants in the positive training condition were faster at deciding an ambiguous sentence had a positive interpretation than were those in the placebo condition. Moreover, they chose more positive interpretations of ambiguous test sentences after positive training than after the placebo. These results suggest that speed and direction of interpretation can be changed using this paradigm. Thus, this training shows promise as an adjunct to traditional cognitive behavioral treatments of anxiety.

Characterization of Microorganisms from Deep Sea Sediment Samples
Mr. Kevin Lee, Mr. Isaac Wagner, Dr. Juergen Wiegel, Department of Microbiology, University of Georgia.

During the Ocean Drilling Cruise (Leg 201) from January, 2002 to March, 2002 in the Eastern Equatorial Pacific Margin samples were obtained to study the presence of anaerobic thermophilic microorganism in various depths of marine deep sea sediments. Four pure cultures were obtained through enrichments performed during the cruise and subsequently purified. Three of the samples came from Leg 201 Site 1227 (Peru Margin) with an ocean floor temperature of 9.0oC (450m below sea level). The other isolate came from Site 1228 (Peru Margin) with an ocean floor temperature of 12.0oC (252m below sea level). All of the isolates came from samples of cores ranging from 1-9m in the upper sediment depth. Preliminary analyses based on 16S rRNA sequence analysis suggest these isolates represent a novel genus in the vicinity of Thermovenabulum or Thermoanaaerobacter. Characterizations includes determination of substrate spectra, NaCl requirement, yeast extract, pH, and temperature profiles of two of the isolates is underway. Preliminary results show an optimal yeast extract concentration of 2% and an optimal pH of 8.0 and 7.0 for the isolate 201-1228P and 201-1227G, respectively. The isolation and characterizations of these novel thermophilic microorganisms gives insight into the distribution of thermophiles in marine sediments as well as the fact that thermophiles can survive for decades at suboptimal temperatures in these sediments.

Examination of peptide specific antibodies for detection of Infectious laryngotracheitis virus (ILTV)

ILTV causes an acute respiratory infection of chickens with moderate mortality, and a decline in egg production. The disease can be easily spread among large poultry production areas if not detected rapidly. Therefore rapid and specific tests for the detection of infected poultry are fundamental to control the disease.

Antibodies against glycoprotein E peptides had been raised in rabbits. We are in the processes to characterize the specificity and reactivity of these antibodies, and their potential use as a tool as a rapid diagnostic test for detection of ILTV infected poultry.

Operational Characteristics of a Mobile Spectral Imaging System
Dr. Chi N. Thai, Biological & Agricultural Engineering Department

Background:

Our research involves the characteristics of vehicle mounted spectral imaging systems for plant health detection.

Proposed Project:
Our method of gathering spatial crop health data involves collecting spectral images via a camera mounted on a tractor to maximize spatial information while minimizing problems of weather and timeliness (as compared to satellite operations). To increase the sampling rate, our camera takes a series of strip-images as they move down a row of crops (push-broom technique). These images must be compiled into a coherent mosaic image with minimal loss in quality and information. The goal of the first phase of the project is to find an optimum strip-image width to minimize final image distortion.

This vehicle-mounted imaging model was simulated in a laboratory setting using a fixed camera mounted above a mobile translation stage. The stage was moved at discrete intervals, and images were taken at each interval to simulate motion. This experiment was performed at various camera angles, as was a second experiment involving rapid image capture as the stage moved continuously below the camera.

Outcome:
The data reflected a linear trend in optimum strip width versus camera velocity, as well as strip width versus viewing angle. These results were consistent with known imaging phenomenon; smaller strip widths minimized distortion and high velocities and oblique camera angles. The linear regressions developed during this experiment could be used in the next phases of the project to predict optimum camera setting for given imaging situations.

Characterization of Cell Lines Derived from Feline Injection-Site Sarcomas
Karen K. Cornell, DVM, Ph.D., Department of Small Animal Medicine and Surgery, College of Veterinary Medicine, University of Georgia

An injection-site sarcoma is a malignant tumor of cats that arises at the location of a previous injection, commonly a vaccination. These occur in approximately 5 of every 10,000 cats vaccinated, are locally aggressive, and spread to other organs in 25% of cats. Complete removal of the tumor is often impossible and cure is rare. We established cell lines derived from 1) a primary injection-site sarcoma, 2) a metastatic lung tumor, and 3) tumors that developed after intact tissue transfer to athymic mice. The growth characteristics and invasive capabilities of the cell lines were determined in vitro in addition to elucidating the in vivo biological behavior of the tumor in athymic mice. Proliferation rates were measured using the CyQuantTM Cell Proliferation Assay yielding population doubling times. Tumor cell invasiveness was assessed using gelatin zymography to evaluate matrix metalloproteinase activity. Tumorigenesis and metastatic potential were studied by injecting tumor cells subcutaneously in athymic mice. Mice were sacrificed and complete necropsy and histopathologic examination performed. Currently, there is no model of this feline cancer. Through the characterization of cell lines derived from injection-site sarcomas, our goal is to develop a rodent model of this tumor in order to study potential genetic markers of prognostic value and possible therapeutic options.

Emotion Socialization and Regulation in African American Parent-Child Dyads

This study investigates maternal socialization of children's emotion in a sample of 70 African American parents living in poverty. Of particular interest is the extent to which negative emotional expression (i.e., the expression

of anger, sadness, and fear) is inhibited in the parent-child dyads and what unique environmental factors (e.g., poverty and discrimination) account for making such inhibition functionally adaptive. Parents and their children participated in a video-taped interaction task (Shipman & Zeman, 2002) that was coded for emotion validation/support and invalidation of children's emotion (Schneider & Shipman, 2003). Maternal socialization will be investigated as a function of emotion type and child gender. Further, relationships between parental emotion socialization and children's psychological adjustment (i.e., internalizing, ex! ternalizing difficulties) will be examined. Findings will be discussed with regard to how maternal socialization strategies may facilitate adaptation within their family and neighborhood context.

Cloning Genes from the *T. cruzi* Genome and Observing Infectivity of Wild Type *T. cruzi* Compared to the Cloned Gene Products

Trypanosoma cruzi, a protozoan parasite, causes Chagas disease, a potentially fatal disease involving heart and gut tissue in humans. T. cruzi expresses cysteine proteases (cp), enzymes that aid in invasion of mammalian cells and replication of the parasite within cells. The important role of cp in parasite survival in mammals suggests that these proteins may be good vaccine candidates. The cp are encoded by an estimated 131 genes in T. cruzi. To investigate if the cp could be an effective vaccine, we will inject mice with different sets of cp genes and assess the ability of the cp genes to protect against lethal challenge with T. cruzi. The first step toward generating cp vaccines was to design primer combinations to amplify the various cp gene variants. Using these primers we then used polymerase chain reactions to amplify the target sequences from T. cruzi DNA. Adaptamer reactions were then performed to attach sequences needed for cloning into Gateway (invitrogen) adapted vectors. Currently, two cp clones are ready to be shuttled into a vaccination plasmid, 2 cp clones are ready to undergo transformation in an E. coli medium, and 11 cp clones are undergoing the adaptamer reaction. Once all clone products are obtained, these will be shuttled into a vaccination plasmid and injected into mice as DNA vaccines. The ability of different cp clones to protect the mice against lethal infection with T. cruzi will then be assessed.

Cytoxic Effects of A?42, RAGE, and A?42 & RAGE Complex of PC12 Cells and the Formation of of Senile Plaques in the Brains of Alzheimer's Patients

Alzheimer’s disease (AD) is a neurodegenerative dementing disorder affecting half of our elderly population of ages 85 and above. Senile plaques (SPs) composed of a 42 amino acid beta amyloid (A???peptide fragment have been recognized as the hall mark of AD-patahogenesis; though the contributory factors for SPs are not known yet. Autoimmunity seems to play a promient role in disease progression. We hypothesize that age is one of the crucial factors in AD initiation and an important aging process to form advanced glycation end products (AGEs) and their receptors (RAGEs) to complex with A?42 might play a major role in AD. To test our hypothesis, we conducted in-vitro and in-vivo experiments. Differentiated PC12 cells treated with 10-100?M concentrations of in-vitro incubated A?42??RAGE, and A?-RAGE complex showed that the A?42?RAGE complex produced a much greater cytotoxic affect on PC-12 cells compared to cells incubated with either RAGE or A???? alone. In another series of experiments, plasma and autopsy brain tissue extracts derived from individuals with AD and normal elderly control individuals revealed a 2-3 fold increase in RAGE and A?42 IgG levels in the AD samples relative to the control samples. These samples also exhibited a near 1:1 ratio between RAGE and A?42 IgG levels indicating that the auto-antibodies were binding to the same protein or protein complex. These experimental results suggests that RAGE and A?42 complex in vivo, and that the complex is a highly potent immunogen capable of provoking auto-immune and cytotoxic responses in both the

peripheral blood and within the brain.

The Identification of *Trypanosoma cruzi* Surface Proteins Using Bioanalytical Mass Spectrometry

The protozoan *Trypanosoma cruzi* is the causative agent of Chagas disease, a major ailment of millions of people in the rural areas of South America. Humans represent an intermediate host for this parasite while the reduviid bug, *Triatoma infestans*, is the definitive host. The life cycle of this organism cycles between these two hosts and involves four life stages: metacyclic trypomastigotes, epimastigotes, amastigotes, and trypomastigotes. The surface proteins expressed during these life stages represent the majority of what is displayed to the immune system, and thus are critical to the subsequent immune evasion. This surface includes transmembrane and glycophosphatidylinositol (GPI) anchored proteins with functions ranging from invasion to control of morphological transitions. In our study we attempted to isolate the membrane and strip the glycosylation from mucins using a process known as ß-elimination. Following purification and digestion, we sequenced the resulting peptides using tandem mass spectrometry and identified them by searching the spectra against the newly annotated *Trypanosoma cruzi* genome. The identification of these surface proteins and further investigation into their role during infection may lead to their future use as vaccine targets.

Uncovering the structural function of an additional amino acid sequence in the long form of augmenter of liver regeneration (ALR) through biochemical and structural comparisons of long and short ALR

Though much data has contributed towards understanding the role of augmenter of liver regeneration (ALR) in regeneration, little is known about the biochemical and functional properties of the protein. A sulfhydryl oxidase hepatotrophic factor originally identified through bioassays of regenerating rat and canine livers following partial hepatectomy, ALRp is a cone-shaped helical bundle containing a bound FAD molecule at the mouth of its cone. The presence of FAD is of particular interest for two reasons. One, the high stability of FAD in the absence of an identifiable dinucleotide binding motif suggests a unique FAD binding motif. Secondly, ALR is the first FAD containing growth factor ever identified, implying the possibility that ALR is a redox-sensitive cellular regulator. This study uncovers the role ALR's structure plays in FAD reduction by focusing on two forms of ALR: a long and a short form, Caenorhabditis elegans ALR and rat ALR, respectively. C. elegans ALR contains an additional disulfide bridge (C9-C13) in a 35 aa sequence preceding the N-terminal of the 125 aa sequence characteristic of rALR. It is believed that these additional cysteines in C. elegans may play a role in the stability of FAD. Therefore, recombinant forms of short C. elegans ALRp without the additional 35 aa sequence as well as a long rALRp containing the 35 aa's were synthesized and compared to their respective counterparts through examination of crystal structures and reduction kinetics in the presence of dithiothreitol (DTT). Conclusions are made about the function of the additional amino acid sequence.

The PATRIOT Act: Amending the Foreign Intelligence Surveillance Act and Diminishing Civil Liberties
Dr. Loch Johnson, Department of Political Science, University of Georgia

Under the guise of national security and September 11th, the PATRIOT Act repeats a pattern in which the U.S. government has relaxed the protection of civil liberties and fundamental rights. A history of Executive Branch

agencies neglecting fundamental rights led to the Foreign Intelligence Surveillance Act (FISA) and the Church Committee. Reforms, recommended by the Church committee and implemented through FISA were put in place to protect the American people from an overzealous government or intelligence agency blinded by its pursuit of national security. The PATRIOT Act's amendments weaken the protection of civil liberties and effective accountability. The Act expands governmental powers and removes many of the existent safeguards, leaving Americans open to an empowered executive branch unrestrained by effective oversight. Since its inception, actions taken under the provisions of the PATRIOT Act have been shrouded in secrecy, even from Congressional oversight committees. In order to prevent violations mirroring those prior to FISA and the Church Committee, reforms must be made to the Act. What is needed is more consensus, more intense oversight which does not only include a reactive judiciary but also a constructive, proactive Congress, and more candidness about what freedoms are being sacrificed in order to protect the United States from terror. Only after a nation weighs the costs of a domestic war on terror can it strike the proper balance between freedom and safety.

Wealth Creation in America
Dr. Charles Hofer, Department of Strategy & Entrepreneurship, Terry College of Business, University of Georgia

How do most Americans generate personal wealth? Fred J. Young, former Vice President of the Harris Trust & Savings Bank of Chicago, analyzed, over a 40 year period, the sources of wealth of Harris clients who provided the bank with over $1 million in capital for investment. His study concluded that the two most prevalent ways of accumulating wealth were through starting and selling a business and real estate investments. In this research, we apply Young's research principles to a new business climate. Data will be collected from local trust departments in the Athens-Atlanta area through interviews and questionnaires. The information gathered will describe the basic strategies used by Americans today to accumulate/earn significant wealth. We will also review Young's How to Get Rich and Stay Rich and perform a comparative analysis of our data versus his observations. With these results, we will be able to determine what factors drive the greatest creation of wealth in America, and explain the role of entrepreneurship and small business creation in the modern economy.

Variability in the OGLE Sky Survey
Dr. Scott Shaw

Eclipsing binary systems in which both stars are cool M stars are exceedingly rare. Fewer than ten are currently known. Searching large sky surveys, such as OGLE II, holds the promise of doubling or tripling the number of known M-type eclipsing binaries stars. Multiple computer programs run on data sets taken by the OGLE Sky Survey group has carefully selected variable stars out of forty nine fields of the Galactic Bulge. Each field contains about 2000 to 8000 variable stars. Currently, computer programs have not been able to classify all the various types of variable stars nor have the programs been able to identify which stars are M-type eclipsing binaries. Using Excel's spreadsheet, AVE's light curve graphing and phasing program, and standards set in rejecting period aliases, we are now closer to our goal of automatic selection through the use of computers.

Effects of nutrients on leaf decay and detritivores in a headwater stream.
Wyatt Cross, Jennifer Greenwood, Roger Hilton, Dr. Amy Rosemond, Institute of Ecology, University of Georgia

Nutrient enrichment of stream ecosystems is a widespread problem caused by non-point source pollution. Excess nutrients profoundly affect aquatic ecosystems and are an important cause of declining water quality world-wide. The effects of nutrient enrichment are known for primary producer based systems, but are less well-known for detritus-based systems. To test the effects of nutrients in a detritus-based system, UGA researchers have continuously added nitrogen and phosphorus to a headwater stream at the Coweeta Hydrology laboratory in North Carolina and compared effects to a reference stream. This study examines effects of the continuation of that enrichment from year 2 to year 3. Decay rates of leaves were measured as an indication of effects of nutrients on invertebrate and microbial processing of organic matter, which is an important ecosystem process. The decay rate and invertebrate biomass and composition will be determined from litter bags that were placed in the enriched stream and reference stream and compared to values determined from previous years of enrichment. The leaf packs were assembled using rhododendron leaves from the fall. The packs were collected at 14, 30, 55, 70, and 118 days. Invertebrates will be sorted from leaves, preserved in formalin and keyed to species. Invertebrate biomass will be determined from measuring individuals to the nearest 0.5 mm and using length-weight regressions. These data will add to our understanding of nutrient effects in detritus-based aquatic ecosystems and help to predict the effects of enrichment on higher trophic levels in detritus-based food webs.

***Mycobacterium marinum* Promoter Library**

Mycobacterium tuberculosis is responsible for the deaths of three million people annually, and it has been estimated that possibly 1/3 of the world's population is infected. In addition, *M. tuberculosis* is the second leading killer of those afflicted by AIDS. For these reasons, the study of*M. tuberculosis* is of vital importance. However, due to the technical difficulties associated with research on this pathogen, a surrogate organism, the marine relative, *M. marinum*, has emerged as a popular alternative. *M. marinum* is a close genetic relative of *M. tuberculosis*, possesses a faster growth rate, does not cause serious human infections, and is more susceptible to genetic manipulation. Similarities in the initial host-pathogen interactions between *M. marinum* and *M. tuberculosis* have been observed suggesting that these bacteria may possess common virulence mechanisms. In this study, we will identify *M. marinum* virulence genes using promoter trap technology. An *M. marinum* promoter library possessing a green fluorescent protein reporter has been created. Once these constructs are transformed into *M. marinum*, fish macrophages will be infected, and the clones of interest that fluoresce green will be isolated. The promoter sequences will be identified, and the *M. tuberculosis* homologues of these genes will be studied.

Functional Analysis of CD8+ T cell Epitopes in Experimental Trypanosoma cruzi Infection Using ELISPOT and In Vivo Cytotoxicity Assays

Trypanosoma cruzi is the etiologic agent of Chagas disease, a condition affecting sixteen to eighteen million people and causing fifty thousand deaths each year in Central and South America. A murine model mimics human infection as parasite persistence in muscle tissue is common in both mice and humans. Studies in gene-knockout mice have demonstrated the importance of CD8+ T lymphocytes in the concerted immune response to combat infection. However, little is known about the antigen specificity of the CD8+ T cells activated by this infection. The first identified epitope of the CD8+ T cell response to T. cruzi was peptide 77.2 (VDYNFTIV), a

member of the transialidase gene family consisting of over 600 genes. A BLAST search of the transialidase gene family in the TIGR database revealed over 400 peptides with homology to peptide 77.2. The ability of these peptides to stimulate a CD8+ T cell response was examined utilizing an in vivo cytotoxic T lymphocyte assay and an ELISPOT assay of cytokine production. Four peptides were identified that elicited both specific cytolytic activity and interferon gamma production by CD8+ T cells. Peptides were also identified that induced interferon gamma production without corresponding cytotoxicity. Current work is focusing on the question of whether the homologues of the peptide 77.2 epitope can antagonize the response to each other through altered peptide ligand effects. We are examining the hypothesis that peptides derived from transialidase gene family members that do not fully activate the CD8+ T cells are involved in parasite evasion of the host immune response.

Estrogen Signaling in Coronary Artery Smooth Muscle
Dr. Richard E. White, Ph.D., Pharmacology, Medical College of Georgia, Augusta GA 30912

Estrogen has been known to be beneficial in reducing cardiovascular dysfunction by acting as a vasodilator. Recent studies have suggested that restoration of estrogen through hormone replacement therapy actually hinders the prevention of cardiovascular dysfunction. The purpose of this study has been to explore the possible dual role of estrogen. Through pharmacological techniques such as patch-clamp and tension studies; and biochemical techniques such as immunoblotting we have been able to study whether estrogen stimulates the generation of nitric oxide (NO), a vasodilator or superoxide (O2-), a vasoconstrictor. Single cell-attached patch clamp studies showed that estrogen opens the large conductance voltage-and-calcium dependent potassium channels (BKCa) in porcine coronary artery smooth muscle cells. Fluorescent studies showed that estrogen stimulated the generation of NO through NOS. The present study suggests estrogen stimulates neuronal nitric oxide synthase (nNOS), in particular, to generate NO. Immunoblotts of denuded coronary arteries showed a greater expression of nNOS in comparison to the other two isoforms. Patch-clamp studies showed that inhibition of the ability of nNOS to produce NO by using N?-propyl-L-arginine (L-NPA), blocked the ability of estrogen to stimulate the opening of BKCa channels. Tension studies showed that when the ability of NOS to produce NO was inhibited, estrogen, caused a contraction

Environmental regulation of extracellular protein synthesis in *Staphylococcus aureus*.

A number of previous studies have shown that variation of environmental conditions can greatly affect the growth and behavior of the major human pathogen *Staphylococcus aureus*. In this study we have characterized the specific effect of alterations in environmental conditions on the production of two major virulence determinants implicated in the pathogenesis of *S. aureus*, aureolysin (*aur*, a zinc-dependant metalloprotease) and the V8 serine protease (*ssp*). Introduction of 1M NaCl into growth media of S. aureus results in a complete lack of transcription proceeding from both the *aur* and *ssp* operons in all strains studied with the exception of the protease hyper accumulating strain PC1839. Indeed even in PC1839 an approximately 5-fold reduction in transcription was observed for both of these loci in the presence of NaCl. Not only did 1M NaCl abolish production of these protease but more profoundly the secretion of all other major extracellular proteins was almost entirely absent. Growth of studies of *S. aureus* at both 25C and 30C also revealed a similar decrease in protease synthesis, without significant variations in final growth yields. Interestingly these conditions did not produce the total lack of extracellular virulence determinants observed in the presence of supplemental NaCl, indicating an alternative mechanism of transcriptional repression. This information has important implications in the ongoing study of the mechanism by which this organism can exist both as a harmless commensal and a potential fatal infective pathogen, and how it alternates between these states.

Actin Rearrangement and Hirano Body Formation as Modulators of Apoptosis
Marcus Fechheimer and Ruth Furukawa

Hirano bodies, paracrystalline cytoplasmic inclusions enriched for the cytoskeletal protein actin, have been noted in post mortem analysis of neuronal tissue in patients suffering from a wide variety of neuropathological conditions, including Alzheimer's disease, Parkinson's disease, and amyotrophic lateral sclerosis. The basic physiological role that Hirano bodies play in cells is unknown. Formation of model Hirano bodies can be induced in a variety of cell types by introduction and expression of mutated forms of the *Dictyostelium* 34 kDa actin-bundling protein. Evidence indicates that mouse fibroblast L cells stably expressing a truncated C-terminal fragment (CT, amino acids 124-295) of this protein are less susceptible than wild type cells to programmed cell death (apoptosis) induced by oxidative stress. My research has focused on further exploring the possible relationship between Hirano bodies and apoptosis. Fibroblasts stably expressing the CT protein and exposed to the DNA-damaging drug etoposide, an inducer of p53-dependent apoptosis, were not significantly more viable than wild type cells. Thus, Hirano bodies do not protect cells from apoptosis mediated by the tumor suppressor protein p53. By contrast, in transfected human cervical cancer HeLa cells, the CT protein itself seems to act as an apoptotic trigger. I have experimentally determined by treatment with pharmacological and genetic p53 inhibitors that CT-induced apoptosis in HeLa cells is p53-independent. Thus, the presence of Hirano bodies can modulate apoptosis in a positive or negative way, depending on the cellular context. In all cases studied, the effects of Hirano bodies on apoptosis do not appear to involve p53. These studies of the relationship between model Hirano bodies and apoptosis may contribute to our understanding of the role these inclusions play in disease processes.

Energy Dissipation in Nanomechanical Resonators
Dr. Guigen Zhang, Department of Agricultural and Biological Engineering, The University of Georgia
Dr. Michael Geller, Department of Physics and Astronomy, The University of Georgia

Nanomechanical resonators are miniscule pieces of solid that are now being recognized as contenders to replace bulk quartz crystals and surface-acoustic wave resonators to provide more accurate timing in precision measurement equipment. A good resonator exhibits an extremely long resonating lifetime when compared to its period of oscillation, or a high quality factor (Q factor). At present, the combination of mechanical devices and modern electronics has been very successful, but their speeds of operation are much too slow to compete with the speed of today's technology. Small nano-sized materials would make much higher operating frequencies possible; yet, Q factor has been shown to decrease with the decreasing sizes of these materials. Mechanical radiation of energy by the resonating structure into its support and the non-linearity between the different sized resonators are two possible causes for this extra energy loss. There have been studies evaluating the radiation of energy; however, there have not been many studies assessing the non-linearity issue. We have performed non-linear analyses using finite element analysis (FEA) to investigate both possibilities. For this investigation, we developed two dimensional models consisting of cantilever beams with small visco-elastic sections at the fixed ends. Our results using inch sized models suggest that the energy loss through the supports may play a larger role than non-linearity. We are working to overcome hardware difficulties found while creating smaller models to further study these issues at the micro and nano sizes.

New Shapes in Knot Theory: nth Hulls of Knotted Curves

Recruiting posters and advertisements for graduate math programs, mathematics conferences, and think tanks try to capture the viewer's eye, using beautiful shapes discovered in new research to arouse curiosity. Certainly this is a more effective means catching attention than a drab photograph of numbers and symbols on a chalkboard. A substantial number of these shapes have come from knot theory: a branch of mathematics that has proved valuable both for its applications in genetics, physics, and coding and for the remarkable images that come from its objects of study. One new source of beautiful shapes comes from the nth hulls of knotted curves, which only recently have been modeled on the computer.

The convex hull of a knot is the set of points such that any plane that intersects the set must cut the knot twice. Similarly, the nth hull of a knot is the set of points through which every plane cuts the knot 2n times. The author with the help of advisor Dr. Jason Cantarella has developed a computer program, TwoHull, which given a knot is capable of modeling any associated nth hull. Essentially, TwoHull "carves" the nth hull by cutting along a subset of the planes mentioned above. The 3-dimensional forms produced by TwoHull beautifully represent intriguing properties of ordinary knots and are valuable both aesthetically and mathematically. A short film will be shown of nth hulls as they are carved and rotated.

Modeling Contributing Factors of Alzheimer's Disease: Expression Studies of Yeast Ste23p

STE23 is a gene of *Saccharomyces cerevisiae* (yeast) that encodes the STE23p protease. Proteases are proteins that cleave other proteins at specific sites. In the case of *S. cerevisiae* , Ste23p is known to be one of two proteases involved in the cleavage of a precursor to the pheromone " **a** -factor," which is a key signaling molecule in the process of yeast mating. Currently, there are no significant publications about Ste23p despite its extensive similarity to human Insulin Degrading Enzyme (IDE), a protease involved with the prevention of Alzheimer's disease. Our lab has found that epitope tagging Ste23p does not affect its function, and this finding has allowed further cellular and biochemical experimentation of this enzyme. In particular, we have found that *STE23* is expressed in all yeast cell types unlike Ax11p (a closely related enzyme). Ste23p is also over-produced compared to Ax11p. Finally, we have found that the presence of a gene named *YDJ1* is needed for optimal expression of Ste23p. We will discuss these findings in more detail and present new data for using yeast as an expression system for IDE. We expect that our finding on STE23 will lead to new insight concerning the life of *S. cerevisiae* and also provide a simple model for understanding more about human IDE.

An inventory and assessment of medicinal plants and animals used by traditional healers in Limpopo Province, South Africa
John P. Carroll, Warnell School of Forest Resources, University of Georgia, Athens, GA

Traditional healers play a role in an estimated 80% of the South African population. Harvesting plants to meet this urban demand has become environmentally destructive in some areas. Considerable strain is also placed on several animal species used in traditional healing, many of which are already protected. The origin and accessibility of these natural resources are unknown; therefore, the impacts on the environment have not yet been determined. This study identifies plant and animal species used by a traditional healer in the Limpopo Province, South Africa. Verbal data was collected from the chief traditional healer with the help of a Tsonga

translator. Additional information on species identification, harvest site, cost, parts of species used, ease of getting, and medicinal usage of the species were summarized. Each species' statuses according to The World Conservation Union (IUCN) Red Data List of Threatened Species and the Convention on International Trade in Endangered Species (CITES) appendices were obtained. We identified 69 species, 34 animals and 35 plants. These animals were harvested from Mozambique, 35%, Zimbabwe, 21%, and locally around the village, 21%. At least 35% of the animals are protected under CITES, either under Appendix I, 12%, Appendix II, 15%, or Appendix III, 9%. One animal species is also considered endangered and 3 vulnerable in the Red Data List. We assessed habitat preference of each species and found most animals, 75%, to be savanna/grassland species. Most plants, 86%, were harvested locally around the village. Our data suggests the presence of a large network in trade of animal and plant parts, which includes international boundary issues.

The Effects of Benthic Particle Size on Relative Abundances of Stream Fishes
Dr. Gene Helfman, Institute of Ecology, University of Georgia

I investigated possible correlations between benthic particle size and fish assemblages. Particle size is ultimately affected by land use practices, where more land disturbance (=less forest cover) often leads to a smaller average particle size. Widely dispersed, generalist fish species were designated "cosmopolitan," whereas those species restricted to more undisturbed, highland habitats were designated "endemic." Fish were collected in streams in the Little Tennessee River drainage and relative abundances of these two groups were determined. Mean benthic particle size was measured at several points in each reach. Streams with higher average particle sizes had apparently higher endemic to cosmopolitan ratios, but the relationship was relatively weak, indicating that other factors must be involved.

Identifying Expressed Sequence Tags involved in wound response from Sorghum bicolor.
Dr. Lee Pratt and Ms. Shana Seamans

An Expressed Sequence Tag (EST) project utilizes complementary DNA (cDNA) reverse transcribed from mRNA to identify genes expressed in tissues, cell types, or a whole organism under a desired environmental condition. *Sorghum bicolor* is a plant similar to maize that can withstand harsh environmental conditions such as drought and excess salinity (National Grain Sorghum Producers: http://www.sorghumgrowers.com). The purpose of our project is to generate and analyze ESTs from sorghum seedlings that were wounded by crushing one-half of their second leaf and seedlings that were grown on methyl jasmonate media. Methyl jasmonate induces a stress response similar to wounding (Hudgins *et al*., 2004). After reverse transcribing the mRNAs into cDNAs, the cDNAs were inserted into plasmids, which were transformed into *Escherichia coli* bacterial cells. The *E. coli* cells were amplified and the cDNA-containing plasmids were purified. The ends of the cDNAs were sequenced to generate the ESTs. To date, 3702 cDNA-containing plasmids have been isolated, the ends of which are currently being sequenced to produce 7404 ESTs. These sequences are being analyzed for quality and contamination The "good" sequences will be grouped into contigs to eliminate the redundancy observed for highly expressed genes, which are transcribed more frequently than others are and thus likely to be sequenced more often. The numbers of sequences present in each contig will also reveal the relative level of expression of each gene expressed during wounding response. The contig sequences will be compared to a database of known protein sequences via BLAST (Altschul *et al.*, 1990) to identify novel genes and those genes most actively transcribed following wounding.

12th Century Medical Treatments Described in Hildegard's Cause et Cure and the Success of 21st Century Pharmaceutical and Medical Research
Dr. Katharina Wilson

Hildegard of Bingen was a twelfth-century nun, writer, theologian, natural philosopher, medical practitioner, political activist and playwright among other tittles. She is also the presumed author of the original medical text Liber simplicis medicinae, more commonly known as Physica, originally presented in a set of five manuscripts. One of the documents, Cause et cure (Causes and Cures) contains twelfth century medical principles and has been preserved in a thirteenth century manuscript. The concepts discussed in Cause et Cure incorporate the Empedoclectic doctrine: four distinct elements- fire, air, water, and earth-which are essential to all life. These four basic elements are also an integral part of the ideas illustrated in the Corpus Hippocraticum, one of the most well-known medical documents of Antiquity. Each of the Empedoclectic factors corresponds to the four fundamental bodily fluids: yellow bile, blood, phlegm, and black bile. In Cause et Cure, Hildegard describes a healthy person as having a balance of these four bodily fluids; therefore, a diseased person would have an imbalance of any of the four bodily substances also known as "humors." In Cause et Cure, Hildegard prescribes treatments that essentially readjust the imbalance of the humors via diet, medication, lifestyle, as well as the elimination of waste matter via sweating, sneezing, crying, vomiting and bloodletting. Many of Hildegard's proposed medical treatments stem from the Hippocratic tenet "cure opposites with opposites." Hildegard also prescribes many natural remedies such as the use of bear fat and wheat for treating hair loss, as well as a sage and vinegar concoction that is used to treat migraine headaches. Between 1983 and 1994, over forty percent of the drugs approved by the FDA were derived from natural compounds. Furthermore, natural compounds often provide a lead to the development of new synthetic drugs. In intend to deconstruct particular natural remedies described in Cause et Cure, and through contemporary scientific analysis, reveal any similarities in the chemical basis of various medications used today. I would also like to examine the possibility of additional research surrounding the natural remedies described in Hildegard's Cause et Cure in the context of future drug discovery.

Chronic Illness and the Benefits of Therapeutic Summer Camp
Mentor: Dr. Ronald Blount

Children with chronic medical conditions are often subjected to greater stressors and less socialization and independence than are healthy children. The main concentration of my research has been a therapeutic summer camp for children with cardiac disorders. Attending this camp provides these children with an opportunity to be in the presence of other children with similar cardiac conditions, fostering a sense of likeness and support as they participate in the camp activities, which often reach far beyond the scope of the activities they are able to engage in elsewhere. Parents are given a respite during which time they are not primarily responsible for providing their child's care. The study's purpose is to evaluate the effects of the summer camp on these children and their overall functioning. Measures have been gathered at three stages: pre-camp, at-camp, and post-camp. Both the children and parents fill out measures, allowing the collection of data on aspects such as prior camp experience, maternal separation anxiety, camp expectations, and psychosocial functioning. The data that has been gathered from this study provides insight into the psychology of pediatric chronic illness and will allow for improvement in approaches used to treat these children beyond their illnesses. We hope to continue gaining insight into the effects that cardiac disorders have on children's lives and to evaluate whether therapeutic summer camp can provide a normalizing experience for children whose lives are often far from "normal."

The Beautiful and the Absurd
(Under the direction of Prof. Ben Reynolds)

Beauty is all around us. At least, that is the goal of every advertising agency and marketing executive in America. Every day we are bombarded with a multitude of images, all of which are designed to "educate" the public as to what Beauty truly is. However, most of us know the bitter truth: the marketed glamour image is simply a perversion of reality. Attempting to achieve this image is hopeless at worst, absurd at best.

My photographs turn the tables on the glitz and glamour of the fashion world by showing that there is nothing very pretty about it at all. Many aspects of this industry can be considered slightly insane – from the painful contortions the models must perform, to the outrageous clothing that nobody actually wears in real life. I create images that subvert that which is beautiful by adding elements such as gore, excess, and the bizarre. My goal in highlighting the "dark side of beauty" is for the public to lighten up and to take themselves, and how they are expected to look, a little less seriously.

Conspecific Sperm Precedence and Speciation in *Drosophila pseudoobscura*

In nature many species coexist sympatrically without interbreeding which is prevented by strong reproductive isolating mechanisms, i.e., pre-mating isolation and post-mating isolation (Dobzhansky,1951). We have studied possible reproductive isolating mechanisms utilizing 1) two races of *D. pseudoobscura*, Mainbody (M) and Bogota (B), that are in the process of diverging and 2) two sibling species, *Drosophila pseudoobscura* (O) and *D. persimilis* (S), that diverged 500,000 years ago. We compared the amount of sperm transferred and the number of progeny after mating females with conspecifics and heterospecifics. There was a significant difference in sperm transfer between conspecific matings and heterospecific matings: Bogota female accepted more sperm when mating with Bogota male than when mating with Mainbody male (P=0.0477). The same trend, though statistically insignificant, was observed for Mainbody female (P=0.1435). Tests between *D. pseudoobscura* and *D. persimilis* are still ongoing. When females subsequently mated with conspecific and heterospecific males or vice versa, the conspecific matings produced more progeny than heterospecific matings regardless of order of mating, except for Bogota females (P=0.0145 for M?M?B?; P<0.001 for M♀B♂M♂; P=0.0077 for O♀O♂S♂; P<0.0001 for O♀S♂O♂; P=0.0002 for S♀S♂O♂; P=0.3832 for S♀O♂S♂). In the B♀B♂M♂ the second, heterospecific, male (M) produced more progeny (P=0.0137), and in the B♀M♂B♂ cross there was no difference in the number of progeny by the subsequent matings (P=0.9137). These results suggest a possible role of cytoplasmic incompatibility in hybrids and genes that cause the hybrid inviability we observed in this project.

The effect of behavioral interactions between sexes on mate preference in *Drosophila pseudoobscura*

Natural selection is expected to adjust behavior to increase fitness. We tested this hypothesis with *Drosophila pseudoobscura* while observing the relationships between mate preference and fitness. Mate preference was determined in small arenas where a single fly was allowed to choose between two flies of the opposite sex eliminating all possibilities for male-male competition, female-female competition and male coercion or

manipulation of females. Matings were arranged with preferred (P) and non-preferred (NP) partners. Our early studies (Anderson *et al.* , in press) have demonstrated that fecundity was higher in NP matings but not statistically significantly different from in P matings. However, offspring viability was significantly higher in P matings. Subsequently, we measured fitness of males while counting number of sperm delivered to females during copulation. In both male and female choice situations, NP matings delivered significantly more sperm to females than P matings. These results suggest that 1) freely expressed mate preference affects the fitness of offspring; and 2) the increase in fecundity and sperm observed in NP matings may be compensatory behavior for a low viability of offspring from these matings. In attempts to investigate associations between mate preference and mate choice, flies collected from the mate preference tests were observed in mating chambers while measuring courtship and mating behavior. When ecological interaction among individuals was reinstated in the mating chambers, there were no significant differences in number of matings with P and NP partners that we observed in mate preference tests. Males did not discriminate between P and NP females but they significantly more mated with first encountered-females (? 2 = 5.12, p <0.05). However, females did not show significance in matings (? 2 = 3.10, ns) between first courting males and second males. Under ecological and social constraints, we did not find significant differences in copulation latency and duration as well as in number of sperm delivered to P and NP partners. These results support our early observation that individual males and females facultatively vary behavior.

Rodent Vectors in the Transmission of Multi-drug Resistant Pathogens in a Small Animal Teaching Hospital
Athens Diagnostic Laboratory, College of Veterinary Medicine Athens , GA

Previous research has shown the presence and spread of nosocomial *Escherichia coli* and *Enterococcus* strains resistant to several antibiotics in the University of Georgia Small Animal Teaching Hospital . The past work focused on isolates from the environment as well as from animal wounds. Soon after drug-resistant characterizations of these isolates were completed, rodent nests were discovered under rehabilitation cages in the surgery ward. Common house mice (*Mus musculus*) feces contain large numbers of enteric bacteria. This research investigates the possibility that these mice act as a reservoir of previously described isolates. E *scherichia. coli* and *Enterococcus* sp. were cultured on selective media from feces, bedding material, and desiccated rodent bodies found in the nests. At least two strains of *E. coli* resistant to Ceftiofur, Chloramphenicol, Enroflaxin, Ampicillin, and Tetracycline were detected. These two strains were identical by ERIC PCR to strains detected by the past work. *Enterococcus* strains resistant to Gentamycin, Ceftiofur and Ampicillin were also cultured. Total nucleic acid was extracted from strains of both species. A resistant *E. coli* culture was positive for class 1 integrase gene and a florfenicol resistance gene, *flo,* by PCR. Total nucleic acid extracted from fecal pellets were tested by PCR for the presence of *Salmonella* sp., *Campylobacter* sp. and *Leptospira* sp. The implication that rodents may be a vector in spreading, and a reservoir for multi-drug resistant bacteria validates rodent control as a method to help prevent nosocomial infections in the hospital setting.

HOW HAS HIV/AIDS IMPACTED THE SUPPLY AND DEMAND OF EDUCATION IN KENYA?

Case Study: Rift Valley Province

Within one decade AIDS/HIV prevalence in Kenya tripled from 4.8% in 1989 to 13.5% in 1999. During this period another alarming trend occurred, the enrollment rate of primary school students began a steep decline. Sparked by a UNAIDS ambassador's comment that related the hazardous effects of HIV/AIDS on education, I wanted to discover if there was a relationship between the rising infection rate and the reversal of education trends in Kenya. I use both primary and secondary data to determine what impact HIV/AIDS has had on the supply and demand of education in Kenya. Within the secondary data, I examine the role of school fees, the perceived benefits of education, the orphan crisis, family income, HIV status of education professionals, and emotional stress. By using regression analysis on primary data collected in May-June 2003 from three primary schools in Rift Valley Province in Kenya, I can present case studies that highlight certain aspects of the complicated relationship. In particular, I consider the function of ethnicity, gender, number of siblings, type of school, and method of HIV/AIDS-education on the students' knowledge and perception of the virus and its spread. The rate at which young people are infected with HIV/AIDS has soared, a 300% increase in the past ten years. Meanwhile, enrollment and teacher participation rates have steadily fallen from 92% to 86%. These numbers are more than likely uner-reported. The paper concludes by identifying the most effective policy changes that are working to alter these disturbing trends.

The Effects of a High Fat Diet and Warm Environment on Leptin in Mice
Ruth B.S. Harris and Tiffany D. Mitchell, Department of Foods and Nutrition, University of Georgia

Mice adapted to a high-fat diet are reported to be leptin resistant but we previously found that young mice fed a high-fat (HF) diet and housed at 23o C remained sensitive to peripheral leptin and lost body fat. This study tested whether increasing environmental temperature combined with a HF diet impaired leptin action by inhibiting thermogenesis. Male C57BL mice were adapted to low-fat (LF) or HF diet from 10 days of age and were housed at 27o C from 28 days of age. From 35 days of age baseline food intake and body weight were recorded for one week and then mice on each diet were infused with 10 ug leptin/day or PBS from an intraperitoneal miniosmotic pump for 13 days. HF-fed mice had a higher energy intake than LF-fed mice and were heavier and fatter. In contrast, serum leptin was lower in PBS-infused HF-fed than LF-fed mice. Leptin significantly inhibited energy intake of both LF-fed and HF-fed mice and this was associated with a significant increase in hypothalamic long-form leptin receptors with no change in short-form leptin receptor. Leptin significantly reduced body fat mass in LF-fed mice but not HF-fed mice. These results suggest that an ability to increase thermogenesis is more important in mediating the reduction in adipose tissue of HF-fed than LF-fed leptin-treated mice and that dietary fat modifies mechanisms responsible for leptin-induced changes in body composition.

A Pragmatic Analysis of the Variable Forms and Functions of Noun Phrases in Modern Written French

Modern French grammars tend to mention only one basic sentence structure: a transitive verb surrounded by a subject and a direct object which are encoded as lexical noun phrases. In a study of spoken French, however, Ashby (1999) found that several factors unconsciously influence a native speaker's choice as to how information in spontaneous dialogue is encoded- including its state of animation and its accessibility- and that lexical noun phrases generally do not function as subjects. In this project, I wanted to discover whether the same factors and tendencies existed in written French as well.

In order to do so, I looked to four representative pieces of literature. For each work, I recorded the first fifty lexical noun phrases, their state of activation, their possession or lack of animation, and their syntactic function. The results were surprisingly comparable with those of Ashby's study, implying that the factors that influence a native speaker's choice of sentence structure are based on an intrinsic knowledge that extends to writing as well as speech. The form, and consequently the function, of a noun phrase depends on the accessibility of the information contained therein. Frequently, noun phrases that function as subjects do not introduce new ideas, but rather given ideas; therefore they are often encoded as pronouns. Lexical noun phrases serve other functions such as direct objects and objects of presentative expressions. This proves that overly simplified constructions presented in grammars give an inaccurate impression of the way that French sentences are actually formed.

Genetic Investigation of Nosocomial Infections in the Small Animal Teaching Hospital
Athens Diagnostics Laboratory; College of Veterinary Medicine, Athens Georgia, 30602

Research was conducted at the University of Georgia College of Veterinary Medicine to investigate possible opportunistic organisms and test their susceptibility to clinical antibiotics, in an attempt to quantify and localize the origin of these hospital infections. Selective screening revealed 64% of tested locations produced *Escherichia coli* and 43% resulted in *Enterococcus* sp. growth. Exposure to five antibiotics revealed 25.6% of *E.coli* were resistant to all five drugs, and 32.6% of the *Enterococcus* strains were resistant to three antibiotics. The majority of resistant *E.coli* occurred in the Surgery Ward (SW) and Radiology, with *Enterococcus* growing in the SW, ICU, and computer hallway. Resistant samples were analyzed by PCR, producing genetic fingerprints for individual *E.coli* and *Enterococcus* isolates. For *E.coli* , all locations producing multiple isolate growth had at least two or more genetically different forms. Areas producing the most diversity included Radiology, SW, and ICU, while isolates of similar or the same genetic profiles occurred between several locations, including the SW and Anesthesia floor in front of Surgery. For *Enterococcus* , 78% of locations producing multiple bacterial colonies had at least two genetically different isolates. Areas with the most diversity included the computer hallway, SW and ICU. An abundance of genetically similar profiles were found throughout the hospital and included the computer hallway and SW, and areas between SW and ICU. Resistance profiles for tested *E.coli* show 87% were positive for the *int1* gene, and 50% contained the *flo* or *ampC* gene. Data from previous screenings shows no decrease in the presence of resistant forms of *E.coli* and *Enterococcus* .

The Role of Myosin II in Hirano Body Formation and the Impact of Hirano Bodies on Cell Viability
Marcus Fechheimer and Ruth Furukawa

Neurodegenerative diseases such as Alzheimer's disease are an increasing problem in our society, and are pathologically diagnosed by distinctive brain inclusions. Little is understood about actin-rich paracrystalline inclusions known as Hirano bodies. The goal of this project is to contribute to our understanding of Hirano bodies by studies of the mechanism of their formation, and their role in cell physiology. Expression of ?EF1, a gene encoding a mutant form of an acting binding protein, induces formation of Hirano Bodies in wild type cells. By contrast, no cell growth is observed if the ?EF1 protein is expressed in mutants lacking myosin II. These results suggest that myosin II is necessary for Hirano body formation, and that Hirano bodies may be adaptive structures that promote cell survival and growth. Dictyostelium cells with a temperature sensitive myosin II gene mutation will be used to test the role of myosin II in Hirano Body formation and cell physiology. At the permissive temperature, myosin II is fully functional, and these cells should grow normally and form Hirano bodies while expressing the ?EF1 protein. These cells exhibit all of the hallmarks of the

absence of functional myosin II when at the nonpermissive temperature. The myosin II protein function can be halted by simply lowering the temperature, enabling me to observe the effects of the ?EF1 protein on the cells in the absence of myosin II. Cells were transformed with plasmids to drive expression of the ?EF1 protein, and either wild type or temperature sensitive myosin II. Over one hundred clones were obtained, and they are being analyzed for growth at the permissive and non-permissive temperatures, and by electron microscopy. The prospective results of this research may elucidate the mechanism of formation of Hirano bodies, and their role in cell physiology. If the current working model that Hirano bodies are adaptive structures turns out to be correct, then Hirano bodies will be shown to promote survival of cells exposed to physiological stress. If Hirano bodies actually have a positive effect on cell survival, then these results may offer insight into the treatment of patients with neurodegenerative diseases.

KIT HUGHES
TAGGING *
Faculty Sponsor: Mark Callahan

Since WiFi (wireless internet access) was introduced to consumers in 1999 it has rapidly grown into an experimental medium. In the same manner street graffiti gained mainstream attention in the 1980s and 1990s when introduced into art and design. Both WiFi and graffiti are also linked by their site-specific nature; one enters into a WiFi zone to access the internet and one experiences graffiti on buildings, sidewalks, etc. Tagging is a wireless application that fuses WiFi and graffiti by allowing Internet users to cover downtown Athens with virtual graffiti.

The project allows anyone using a wireless Internet-capable (WiFi) handheld device with a Web browser to select his or her location from an online map and use a stylus to "tag" images of surrounding buildings on a handheld computer screen. The graffiti is then stored in a database and becomes part of the virtual cityscape of downtown Athens. As with traditional graffiti, each person may add to previous graffiti or create his or her own. The results are available for immediate viewing on the device and on the project's website, www.tagging.us.

Tagging is an art project straddling the genres of technophile net.art and visceral street graffiti; likewise, the technological underpinnings serve as entertainment and research. The project integrates dynamic content with motion graphics on a foundation of database technology. These three areas are reaching conventional use on the Internet but have not been fully explored in a wireless environment. While the primary objective of Tagging has been to serve as a work of art, the users of project will provide useful feedback regarding user interface preferences, bandwidth limitations, and the potential of location-based wireless technology.

Virtual vandals will have their chance at tagging Athens throughout April with handheld devices available for loan through Ideas for Creative Exploration (ICE). The month long interactive exhibition coincides with the CURO symposium.

*Tagging is a word used by graffiti artists to describe writing.

Temporal requirement for the amontillado (amon) gene during development in Drosophila melanogaster

We report here the developmental requirements of the homologue of mammalian prohormone convertase 2 (PC2), amon. Animals with mutations in amon die during embryogenesis and early larval development. We have used a conditional expression system to rescue amon mutants past these early stages and to determine the

effects of amon deficiency on later developmental transitions. We show that amon mutants arrest during pupal development and fail to eclose due to defects during metamorphosis. amon mutant pupae fail to evert the head sac, to fully extend the thoracic appendages, and to develop abdominal bristles. The abdominal mutant phenotype is similar to that seen in animals treated with juvenile hormone (JH), suggesting that amon may function to process peptide hormones that regulate JH release. Currently, we are completing our analysis of amon mutant phenotypes. In addition, we are using antibodies directed against the amon protein to determine if AMON is present in neurons innervating the corpus allatum, the juvenile hormone-producing region of the ring gland.

Rocking Out the USSR: A Study of Anti-Soviet Themes in the Lyrics of the Late 1980's Soviet Underground Rock Movement in Leningrad (St. Petersburg)
Dr. Keith Langston, Department of Germanic and Slavic Languages, University of Georgia

In the late 1980's, the Soviet Union experienced rapid currents of social, economic and political change as it approached its collapse. Although glasnost' and perestroika allowed for some discussion of change, a large portion of anti-Soviet dialog remained underground. An underground culture flourished in large cities across the Soviet Union. One of the most popular vehicles of sociopolitical commentary for the underground was avant-garde rock music. Although several scholars recognize the significance of the underground movement, few have discussed the actual texts, subtexts and themes of the movement. The purpose of this paper is to uncover, explore, and analyze subversive anti-Soviet lyrical themes of the underground rock movement in Leningrad (St. Petersburg) during the last years of the Soviet Union. Primarily focusing on the works of the groups Kino, Akvarium (Aquarium), and DDT, this paper develops a dialog between underground avant-garde rock and the sociopolitical change of the time. This paper also explores the significance of Soviet underground youth culture in Leningrad with respect to the role of rock music in the making of the demise of the Soviet Union.

The Rise of Private Corporations in China: An Analysis of the Evolving Chinese Political Economy
Dr. Clifton W. Pannell, Department of Geography, University of Georgia

The goal of this paper is to determine the extent to which China is transforming from a centrally-directed, state-run economy into an open-market economy with a growing number of privatized businesses. The cultural and economic ties between private businesses and the local government officials are explored to determine if private businesses are truly independent of state control. Primary sources from official Chinese agencies, books, and articles from academic journals pertaining to the contemporary Chinese political economy are used for quantitative data. Discursive explanations from a variety of secondary and primary sources are examined and assessed to determine the extent of control communist party officials (cadres) exert over private businesses. My findings are based on descriptive quantitative data on the number and types of private enterprises in China seen and graphed over time as well as analysis and interpretation of narrative explanatory information from official and secondary sources. These findings suggest that in most cases private businesses thrive only if personal relationships are established with local cadres, although the specific form(s) of this state "corporatism" may vary by location. These personal relationships normally involve the private corporations making gifts to the cadres. This research indicates the emerging form of market capitalism in China differs from the western form and may also vary internally within China by region.

Natural Selection for Adaptive Leaf Syndromes across a Severe Environment Gradient

Severe environmental gradients found in nature are often characterized by abrupt transitions between plant communities. These transitions represent an opportunity to understand how natural selection can lead to local adaptation and subsequent genetic differentiation and speciation. However, the presence of strong gene flow can counteract natural selection. The transition between the deciduous forest community of southeastern Lake Michigan and the dune community is especially abrupt. Although very few plants are able to grow across such a severe environmental gradient, the herbaceous plant Arabidopsis lyrata is found growing on the dune and in the adjacent forest. Given the stark contrast of these neighboring environments, there are many traits that would be expected to differ phenotypically. In order to examine this assumption, I measured flower size, glucosinolates, tissue water content, specific leaf area, date of first flower, leaf shape, leaf area, and anthocyanins. However, in a common garden experiment, only two out of the eight traits measured, leaf shape and date of first flower, showed phenotypic differentiation across the environmental gradient. This lack of differentiation in the other six traits is not surprising given previous findings of strong gene flow occurring across the gradient. The phenotypic differentiation that was found in the face of such strong gene flow strongly implicates the action of natural selection.

Isolation and Characterization of Anaerobic Thermophiles from Uzon Caldera
Dr. Juergen Wiegel, Department of Microbiology, University of Georgia.

The National Science Foundation funded an international, interdisciplinary Microbial Observatory Project to elucidate the microbial diversity and the dynamic relationship between thermophilic microorganisms and the biogeochemistry of selected hot springs. The research includes characterizing novel glycolytic anaerobic thermophiles. Five enrichments from samples taken from two springs (with different pH values) in the North Thermal Field were chosen for the isolation of pure cultures. Enrichments and sub-cultures were incubated under an atmosphere of Nitrogen gas at a temperature of 60°C in media with two different pH values (6.3 and 8.0); glucose, starch, fructose, inulin and maltose were used as carbon and energy sources. Microscopic analysis revealed that four of the five cultures contained multiple spore-forming, rod-shaped bacteria of varying length and diameter. The spores varied in location (center, subterminal, and terminal) and in shape (large and oval; small and round). Isolation of single-cell derived cultures is underway. The cultures did not grow well in agar solidified media suggesting that the bacteria are sensitive to conditions of lower water activity. Isolated cultures will be identified using 16s rDNA sequence analysis. Presently, observed growth behavior suggests that the cultures contain novel glycolytic anaerobic thermophiles. This research can lead to a greater appreciation for the biodiversity that exists in our world and the importance of microorganisms in geochemical and mineralogical processes.

Camp Counselor Interactions during Program Activity Leadership: Guiding Staff Supervision

Administrators seek tools to help staff improve skills with campers. Interactions have been documented between elementary-school teachers and students (Stuhlman & Pianta, 2002; Pianta, Cox, Taylor & Early, 1999). Yet, little is known, and less is documented, about what interactions occur during program activity leadership at camp. The purpose of this study was to document verbal and non-verbal interactions while counselors led camp program activities to gain insight into potential staff supervision tools. Four counselors were observed leading

camp program activities at pre-selected intervals during the seven-week season at a non-profit summer camp located in the Southeastern United States. Content of the interactions between counselors and campers was subdivided as primarily instructional, group management, participatory, or social, while level of interaction was documented as non-verbal, directive/imperative, monologue, discussion, or questions (Hamilton, in review). Data was plotted within categories of interaction, activity-days, and across participants. Trends associated with activity-days hold true across participants, as well as, changes in the types of instruction used as the activity progressed during the season. This information was useful on two levels. First, developing categories of behaviors and separating them into desired/undesired behaviors served to more clearly define for the administrator acceptable performance. Second, by collecting observations the administrator has specific information for targeted performance-review with employees. Future steps in this line of research would include the expansion of the project to include multiple raters that documented both the staff interaction and camper response to that interaction.

ASSESSING THE POSSIBLE LOCAL COMMUNITY BENEFITS FROM ECOTOURISM OPERATIONS IN KENYA
Advisor: Michael Tarrant

The purpose of this research is to identify ways in which ecotourism operations can benefit local communities in Kenya. In recent years, sustainable development and ecotourism in developing nations have become the new focus of these nations' attempts to preserve their resources and increase their economic stability. However, when promoting the preservation of lands in developing nations, planners must take into account the local communities who base their livelihoods and economies on natural resources. Kenya has had the longest running ecotourism operations in all of Africa, but its past is riddled with government corruption and acquisition of indigenous land, which has hurt the amount of benefits that communities can derive from wildlife protection. This paper will illustrate the range of Kenyan ecotourism operations (government, non-government, and private) and the nature of their relationship with the local people. It will also show how these local communities currently benefit from ecotourism. Considering that Kenya has several setbacks to local community benefits because it is a developing nation, a comparison with a strong ecotourism organization in a developed nation is necessary to discuss how Kenyan ecotourism can improve its local community benefits.

"Bad" Girls: The Striking Epidemic of Female Juvenile Offenders
Professor Dean Rojek

Over the past decade, crime statistics for female juvenile offenders has increased dramatically, -- receiving the attention of numerous political officials, -as well as the public and media. The purpose of this study is to delve into the growing phenomena of females offenders in the juvenile justice system; address case studies; and the bias view of the 'typical' juvenile offender. After exploring a variety of studies and journal entries concerning female juvenile offenders, it is my hope to provide statistical information along with an analysis of the various types of crimes and offenses committed by youth, and draw on the increasing correlation between male and female delinquents. The purpose of the analogy is to communicate the need for more in-depth research and preventive crime programs that will education the public, and hopefully, decrease the number of girls entering into the juvenile justice system.

Buddhism and the Beats : « Dharma bums » or bumming around ?
Dr. Glen Wallis

How did Buddhism affect the counter-culture movement of the Beat Generation in 1950's America? This paper will analyze the works of Jack Kerouac, Allen Ginsberg, and William S. Burroughs, tracing the effects of Buddhism upon literary form, character, and theme. Through literature, I will investigate the transplanting of Eastern thought to Western philosophy, questioning whether the Beats can indeed cultivate Buddhist ideals with a Western lifestyle or if their actions assume only surface Eastern spirituality. Furthermore, if Buddhism does have a meaningful place in the movement, can the revelation and translation of a history with Eastern thought give the Beat work and lifestyle more credibility in the opinion of mainstream America? Can Eastern thought penetrate mainstream American culture through literature?

The Personal and Professional Life of a Rural Mexican Primary School Teacher

This study chronicles the daily and weekly activities of Lourdes Spino, teacher of grades one through six in the coffee growing town of Chopan, Mexico. A typical week of work for Lourdes includes walking an hour to visit parents of her students, canceling classes due to unannounced district meetings, and teaching her rural students from agricultural families to think for themselves. Based on visits to the school, interviews with the teacher and all 19 families who have children attending the school, and observations of district meetings and other events, this study was conducted over a period of 5 months in the spring of 2003. A limited amount of research, mostly available only in Spanish, has been published to date on the reality of education in rural Mexico. The purpose of this project is to increase the body of knowledge regarding the lives and work of elementary school teachers in the numerous rural schools of Mexico. The presentation of this study will include photographs of the school and the students, video footage of the teacher performing her daily activities, a review of interviews with families of the community and the teacher, and some anecdotes of classroom observations which personify the teacher's work with her students.

Antibiotic Resistance From Sewage Oxidation Ponds
Oconee County High School. USDA Russell Research Center, Antibiotic Resistance Research Unit (ARRU)

In an extensive, multi-year study of antibiotic resistance from sewage oxidation ponds, a mobile home park sewage oxidation pond was discharging high antibiotic-resistant bacteria levels into the Oconee River . T etracycline resistance genes C and G were detected in the 1 st and 2 nd stages and the discharge of the pond going directly into the environment. These genes are usually found in intestinal bacteria, so it can be inferred that they are from a human source. Antimicrobial residue from the beta-lactam family of antibiotics was found in all oxidation pond stages and in the creek above the pond. Tetracycline residue was found in the first and second stages of the pond. Thus, genes coding for antibiotic-resistant pathogens and the antibiotics themselves were documented to survive oxidation pond treatment.

A model simulating biofilm treatment in oxidation ponds was created using a highly antibiotic-resistant *Salmonella typhimurium 3/97* and pond water. Under optimal conditions, *S. typhimurium 3/97* remained in this *in vitro* system. Thus, the competitive inhibition process that assists in the removal of bacteria in oxidation

ponds did not effectively remove *S. typhimurium* 3/97 in this mock oxidation pond.

This bioreactor model can be used to further investigate oxidation ponds. A public awareness campaign was initiated by the author to encourage proper use and disposal of antibiotics, as flushing them is a common practice in the United States . A cost-effective technique is also needed to inactivate antibiotic-resistant bacteria and remove the antibiotics in oxidation ponds.

The Impact of Indian-Americans in a Georgia Congressional District

Minority politics unarguably play a role in U.S. elections and representation, as evidenced by the courting of African-American and Jewish voters in times of election and the activism of minority interest groups on political issues. The Indian-American community in the U.S. though has only begun to use its political voice or organize a united approach to politics as other minority interest groups have. Obstacles that this minority ethnic group must face in exercising political influence include its small numbers, divided factions within those numbers, and presently a lack of significant historical precedent as to how the group should maneuver to pursue political objectives. Indian-Americans have begun to mobilize, however, and in addition to establishing national-level interest groups and voter education centers many local successes have been attained which Indian-American communities throughout the U.S. can seek to emulate. One such example can be found in the 4th district of Georgia, a majority-minority district in which an incumbent Democratic candidate Cynthia McKinney lost in the primary against Denise Majette, the latter having the support of the Indian-American community in the area. Although other organizations and voting groups are credited for the victory of Congresswoman Majette, Indian-American supporters demonstrated a unified effort and an early, organized response in the competition which indicates the continuing maturation of Indian-American politics. This new activism and organized fundraising within 4th district has caused political actors such as Congresswoman Majette to recognize the importance of this group and represent their interests.

Sociocultural Influences on Healthcare in Kenya

The societal character and the numerous cultural influences that color the citizenry of Kenya make a powerful impact on the structure and efficacy of public healthcare systems in the nation. In dealing with public health issues ranging from family planning to malaria and tuberculosis epidemics, public officials must carefully choose their strategies in order to harmonize with the sociocultural environment while carrying out the task in question. This study observes the impact of various components of the sociocultural atmosphere, including tribal culture and taboos, the influences of colonialism, the arrival of new ethnicities, and religious belief, on the workings of Kenyan public sector health programs. Through participant observation in community medicine and health education programs and via personal interview of health agency officials, medical doctors, and rural health workers, the sociocultural environments throughout Kenya are analyzed and evaluated in terms of the implications for success of various public health initiatives. Continuing to research these influences on the healthcare infrastructure and efficacy will allow Kenyan health officials to better confront the massive public health problems that face the nation today. A better understanding of the sociocultural milieu will allow more effective programs to be designed which do not clash against, but rather fit with and persuasively transform when necessary, the outlook and beliefs of citizens targeted by public health initiatives.

Microarray analysis of 100M and 58M Sorghum bicolor cultivated under variable light stimuli.
Dr. Lee H. Pratt

In plants, the perception of light and shade is mediated by the phytochrome photoreceptor system. Th phytochrome molecule exists in two interconvertible forms, red light absorbing (Pr) and far-red light absorbing (Pfr) (Furya and Song, 1994). Chlorophyll strongly absorbs red photons, and plant subsequently sense this aspect of light quality. Recently, phytochrome deficient mutants have been recognized as powerful tools in the assignment of the individual function of each member of the phytochrome photoreceptor system, as well as genes that are potentially involved in downstream signaling mechanisms and physiological molecular responses (Correll *et al.* , 2003). Our project seeks to characterize the differential gene expression between wild type and phytochrome B-deficient *Sorghum bicolor*. Sorghum strains 100M (wild type) and 58M (phytochrome B-deficient) are nearly isogenic. Both were grown under light and dark conditions to determine if a mutation in the phytochrome B receptor affects a plant's perception and responses to a given light stimulus. RNA microarray technology has been employed to produce gene expression profiles of the mutant and wild-type sorghum. By analyzing this data using bioinformatics software (Spotfire: http://www.spotfire.com/) we hope to determine the effect of mutant phytochrome B, and its associated receptor genes, on a plant's light responses and growth.

Diagnosis of Equine Fungal Keratitis Using Polymerase Chain Reaction
Dr. Susan Sanchez, Department of Medical Microbiology and Parasitology, College of Veterinary Medicine, University of Georgia

Currently cytology, culture, and histopathology are the only diagnostic methods available to identify fungal pathogens associated with keratomycosis (G. *keras* = cornea + *myk e s* = fungus). The purpose of this study was to evaluate polymerase chain reaction (PCR) as a method for early and rapid detection of equine fungal keratitis. The yeasts *Candida albicans* and *Cryptococcus neoformans*, and the filamentous fungi *Aspergillus* , *Cladosporium* , *Fusarium* , and *Penicillium* were used to evaluate universal primers. Genus specific primers were tested against *Candida albicans* (ATCC 10231), and *Aspergillus* and *Fusarium* isolates . PCR using universal fungal primers targeting the conserved regions of ITS1 and ITS2 and genus specific primers were performed on 22 cases of equine keratitis. Fungal PCR (n=22) results were compared to those of corneal cytology (n= 22), fungal cultures (n= 22), and histopathology (n=16). PCR results were positive for universal fungal primers or genus specific primers in 81.8% (n=18/22). Corneal cytology was positive for fungal hyphae in 63.6% (n=14/22). Fungal cultures were positive in 50.0% (n=11/22). Histopathology confirmed the presence of fungi in 43.8 % (n=7/16). Of the 15 cases positively identified with fungal organisms by cytology, fungal culture, or histopathology, 86.7% (n=13/15) were positive by PCR. Of the 7 samples negative for fungal organisms by cytology, fungal culture, and histopathology, 71.4% (n=5/7) were positive by PCR. Of these five cases, four were clinically agreeable with fungal keratitis [stromal abscess (n=3) and deep progressive corneal ulceration (n=1)]. When used in conjunction with cytology, culture, and histopathology, PCR with universal and genus specific fungal primers is a promising tool to aid in the diagnosis of equine fungal keratitis.

Comparing Apoptosis During Different Stages of Limb Development in Chick Embryos
Mary Alice Smith, PhD - Environmental Health Science

Apoptosis, or programmed cell death, is essential in embryonic development and for normal development of

limbs, including deletion of interdigital webs and shaping of limbs. Limb deformities result from too much or too little apoptosis. Using chick embryos as an animal model, our hypotheses were that there is a difference in apoptosis 1) during important stages of limb formation in chick embryos and 2) in the developing fore and hindlimbs. Fertilized eggs were incubated at 37ºC. At the appropriate stage, the embryo was aseptically removed, and fore and hindlimbs were dissected. DNA was extracted using a GeneChoice™ kit. Polymerase Chain Reaction (PCR) was done using a Maxim Biotech TM kit. PCR was used to amplify DNA undergoing apoptosis. PCR results were subjected to gel electrophoresis and the appearance of bands compared to a positive control was used as evidence of apoptosis. The number of PCR cycles was used to quantify the results. The results for stage 25 varied and may reflect differences in populations of cells undergoing apoptosis. More apoptosis occurred at the later stage of development (stage 27) compared to earlier (stage 26), and for stage 27, there was more apoptosis in the hindlimbs than forelimbs. These results suggest that teratogens affecting apoptosis are likely to be more detrimental to the developing limbs during stage 27 and in hindlimbs.

CASTING THE SHUTTER: SURREALISM, POLITICS, PHOTOGRAPHY
Dr. Jed Rasula, English Department, University of Georgia, Athens, Georgia, 30602

This paper will examine the Surrealist use of photography and the political role of the photograph as a form of representation within the Surrealist movement. The Surrealist moment is significant in the history of the theory of the photograph because so many critics have looked back to the Surrealists to interpret their legacy in divergent ways – placing emphasis alternately on the Surrealists' critique of representation and their strategic use of representation in conjunction with a debatably Marxist critique of bourgeois society. The paper will include primary texts, mainly from the Surrealists, including British and American artists such as Man Ray, Lee Miller, and Roland Penrose, as well as read seminal works of photographic theory and criticism and notable accounts of Surrealism. The topic of photography is a subject applicable to any engagement with Modernism and modernity, in that the technology of photographic representation is part of a fundamental break in the means of mimetic representation. In addition to engaging the concerns of literary theory and contributing to an understanding of Surrealism and modernity, this paper will specifically look at American and British surrealists and the relation of their Surrealist conceptions of photography to the documentary trends popular in the USA and UK. By centering my paper on the moment Surrealism and examining photographic theory before, during, and after the Surrealist period, I hope to provide a means for examining the different perspectives on the political role of photographic art.

From whence did Neo-Plasticism Spring?
Supervising faculty: Dr. Thomas Polk, Art History

From the essential planarity of his early naturalistic landscapes to the pure abstractions of his final two decades, the corpus of Dutch Modernist painter Piet Mondrian's work follows such a clear path that traces of his final work can be found in each progression of style. This evolution was primarily propelled by his motto "always forward." The accepted hypothesis seems to be that each transition came about by a revelation in form which enabled him to articulate better the theosophical ideas of Helena Blavatsky which enthralled him from his early years. This gradual development theory seems to be true superficially; however, there is significant evidence, specifically in his own essay "Natural Reality and Abstract Reality", to suggest that major conceptual shifts came about in sudden upward spurts rather than through the gradual evolution espoused by most. If this is true, their will certainly be major events which spurred his push to higher abstraction. I will first attempt to extract explanations from Hans Jaffe's biographical sketch to determine which biographical, intellectual, or artistic

events, if any, led to each change in form. If however the gradual evolution theory proves to be true, this would mean that his conceptual vision of a pervasive spirit was attained early but was simply not able to be articulated. If this is the case, the research will attempt to illuminate what events and influences allowed him to maintain this conceptual rigidity even while the attempts to express himself were frustrated.

Marcus Tullius Cicero's "Pro Archia Poeta": The Poetics of Law in the Roman Republic
Dr. James C. Anderson Jr., Classical Culture, University of Georgia

Reflecting the mounting conflict amidst the militaristic innovation of Cnaeus Pompeius and the oligarchic sentiments of Lucius Licinius Lucullus in 62 B.C.E., the poet Archias, Marcus Tullius Cicero's childhood tutor, faces prosecution based on the tribunal law of Gaius Papius expelling non-Roman citizens. While Cicero's defense of Archias's citizenship depends upon the Lex Julia and the Lex Plautia Papiria, Cicero focuses on Archias's status as a heralded Roman poet. Thus, "Pro Archia Poeta" illuminates Cicero's perceptions regarding the literary foundations of an education and the implications of a political career. By emphasizing notions of glory, honor, and duty in the Roman Republic, "Pro Archia Poeta" establishes the preeminence of literature within a legal education.

Predictors and Outcomes of Networking Behavior Among Recently Laid Off Employees

Networking is a successful job-search method for attaining reemployment (Wanberg, Kanfer, & Banas, 2000). Despite the fact that there have been many studies examining the effectiveness of networking among the unemployed, little attention has focused on how individuals network. To address this gap in the literature 146 recently unemployed individuals completed a survey regarding how intensely they network as well as the quality of their networks. Participants also provided socio-demographic (i.e., age, race, gender) and personality information. Factor analysis of the networking measure indicated that networking is a multidimensional construct represented by networking intensity, networking breadth, and quality of information obtained from networks. In terms of individual difference factors that might be linked to how one networks, significant findings include a positive relationship between proactive personality and networking intensity (ß=.184, p=.025) as well as a positive relationship found between proactive personality and quality of information (ß=.210, p=.010). In addition, age was found to have a significant curvilinear effect on network breadth; younger and older employees reported less breadth in their networks, whereas middle-aged individuals reported high network breadth. Finally, there was a significant interaction found between proactive personality and age when correlated with each of these two dependent measures. Together, these findings will hopefully lead outplacement services and career counselors to a better understanding of how individuals network and what they can do to modify their behavior so that networking will be successful in leading to reemployment.

Mapping of the Yeast Ras Converting Enzyme Active Site
Dr. Walter K. Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia

Rce1p mediates the proteolytic step in the modification of Ras proteins. Because these post translational modifications modulate the biological function of Ras proteins, the inhibition of these modifications has been

viewed as a possible anticancer strategy. The catalytic mechanism of Rce1p is undefined. Protein alignments of Rce1p orthologs from several different species reveal twenty-one conserved residues that are potentially critical to Rce1p catalysis. We hypothesize that residues conserved in the Rce1p family are part of the yet to be identified Rce1p active site and that the active site is on the cytosolic face of Rce1p, which is an endoplasmic reticulum localized membrane protein that is predicted to have multiple membrane spans. Using a site directed mutation approach, we have identified certain invariably conserved histidine and glutamic acid mutations that are essential for Rce1p activity. By contrast, a cysteine and several other conserved residues are not critical for activity. The cysteine mutant in particular challenges a published finding that Rce1p is a cysteine protease. To further support the importance and relevance of the conserved histidine and glutamic acid residues to enzyme function, we have partially mapped the topology of Rce1p. Using a topology reporter, our results support that certain critical amino acids are likely cytosolically disposed and contribute toward the Rce1p active site. We have determined that the first predicted loop and the C-terminus of Rce1p are located in the lumen of the endoplasmic reticulum. We have also determined that the last transmembrane segment and lumenal tail of Rce1p are dispensable for activity.

Effects of endothelin and cyclooxygenase inhibition on canine prostate cancer growth and invasion
Dr. Bruce LeRoy, Pathology, Veterinary Medicine, The University of Georgia

Prostate cancer is very common in American men. Dogs also develop prostate cancer, and are excellent experimental models for studying prostate cancer. Despite research efforts, the growth factors important for canine prostate cancer are still unknown. Dr. LeRoy's laboratory has shown that canine prostate cells produce endothelins, which are critical in the growth of metastatic prostate cancer cells in men. Additionally, other researchers have shown that canine prostate cancer cells produce cyclooxygenases-1 and -2 (COX-1 and COX-2). The goal of this project is to evaluate the effects of an endothelin receptor antagonist (ABT-127) and a cyclooxygenase inhibitor (piroxicam) on the growth and invasion of a canine prostate carcinoma cell line (MAX-1) developed in Dr. LeRoy's laboratory.

Following incubation with vehicle (control) or ABT-127/piroxicam, an MTT assay (Promega) will be used to evaluate the effects on MAX-1 cell proliferation. Effects of inhibitors on cell invasion will be measured using 24-well transwell plates with a polycarbonate membrane (Corning). MAX-1 cells will be loaded in the upper chamber, and vehicle or the inhibitors will be added to the lower chamber of the plate. Cells migrating into the lower chamber will be counted. Each assay will be performed in triplicate. Differences between control and experimental groups will be determined using Student's *t* test (SigmaStat). P values less than 0.05 will be considered significant.

Results of these experiments could demonstrate endothelins and cyclooxygenases are critical for the growth and invasion of canine prostate cancer. This project could also provide valuable insight to the effects of specific growth factor inhibitors and their use as prostate cancer treatments.

Characterization of Chromosomal Integration by Streptomyces Bacteriophages: use in mammalian genetic engineering.
Janet Westpheling, Genetics Department, University of Georgia.

Recombinases (integrases) are enzymes that facilitate exchange between DNA molecules. Integrases derived by *Streptomyces* phages (viruses that infect these bacteria) have been shown to mediate efficient site-specific recombination in mammalian cells. Michele Calos and her colleagues at Stanford University have constructed cloning vectors containing *Streptomyces* bacteriophage integrases and used them to engineer mammalian chromosomes providing a safer nonviral approach to human gene therapy. Vectors containing the attachment sites of phages f C31 and R4 have been shown stably integrate into pseudo attachment sites found on mammalian chromosomes. We have recently isolated and characterized several new temperate phages from *Streptomyces species* and have begun an analysis of the mechanism of phage integration. Putative lysogens were isolated as turbid plaques and tested for the presence of phage by mitomycin C induction. Restriction analysis of released phage confirmed that the lysogens contained the phage used for infection. Libraries of phage DNA are being constructed in non-replicating plasmid vectors to functionally identify the presence of the integrase gene and phage attachment site. Our plans to manipulate these phage components for use in mammalian cell engineering will be discussed.

Kin Recognition in *Drosophila paulistorum*

Kin recognition serves as an inbreeding avoidance mechanism, which is key to maintaining the overall fitness of a species (Hamilton , 1964). It has been demonstrated that *Drosophila paulistorum* , when given a choice, prefer to mate with genetically non-related individuals rather than with siblings (Kim, in press). Further, when non-siblings were raised together, they had reduced sexual activities and consequently avoided mating. In an attempt to further study this kin recognition in *D. paulistorum,* I have investigated 1) whether this recognition is based solely on familiarity with individuals experienced during early development or 2) whether there is a genetic effect on kin recognition utilizing two types of *D. paulistorum,* an old strain maintained in the lab for many generations and a new strain that was recently collected in nature. I raised them in four different treatments; 1) siblings raised apart communally (SRAC), 2) half-siblings raised apart communally (HSRAC), 3) cousins raised apart communally (CRAC), and 4) non-siblings raised apart communally (NSRAC). These groups are only different in their genetic relatedness and they have no prior contact with non-related individuals. In the female choice situations, one female was placed with a sibling male and a half-sibling male (HS tests); one female with a sibling male and a male cousin (C test); one female with a male sibling and a non-sibling male (NS test), respectively, without prior experience of either male. I observed whether the female mated with her sibling or the distantly related male. Current data show that there are no significant differences in mate choice between sibling and individuals who are different in degree of genetic relatedness (c 1 2 =0.03, ns for HS; c 1 2 =0.81, ns for C; c 1 2 =0.00, ns for NS for the old strain; c 1 2 =2.00, ns for HS; c 1 2 =0.76, ns for C; c 1 2 =1.58, ns for NS for the new strain). There were no significant differences in mate choices treatment groups (c 2 2 =0.68 for old strain; c 2 2 =3.97 for new strain). These results support my hypothesis that *Drosophila* kin recognition is based on familiarity acquired during developmental experience rather than genetic relatedness.

Photochemistry of Benzoyl-substituted Ruthenocenes

Photointiators are compounds that intitate chemical reactions upon irradiation with light and are useful in many real-world applications such as optical imaging and light curable coatings or adhesives. Benzoyl-substituted ruthenocene compounds were investigated as anionic photoinitiators for the polymerization of ethyl 2-cyanoacrylate. Placing a benzoyl group on one or both cyclopentadienyl rings of ruthenocene, Ru(?5-C5H5),

causes significant changes in the electronic transitions observed in the uv-vis spectral region. While the parent metallocene displays low-intensity, solvent-insensitive ligand field absorption bands, benzoylruthenocene and 1,1'-dibenzoylruthenocene exhibit bands that are much more intense and sensitive to the solution environment. This behavior has been attributed to the mixing of appreciable metal-to-ligand charge transfer (MLCT) character into the low-energy excited states of the benzoyl-substituted complexes. Resonance Raman spectroscopy was used as an analytical method to probe the nature of the excited state and confirmed this MLCT assignment. Irradiation of 1,1'dibenzoylruthenocene in ethyl 2-cyanoacrylate results in the anionic polymerization of this electrophilic monomer. The kinetics of this photoinitiated process were investigated using total reflectance infrared spectroscopy. Finally, a possible mechanism of this process is proposed and compared with that previously proposed for the analogous ferrocene compounds based on the excited state properties of both compounds.

Globalization and the Process of Inequality

It is readily apparent to anyone who checks a manufacturing tag, watches the nightly news, or listens to a politician, that the world is in the midst of the era of globalization. Even though the term has become somewhat of a buzzword, especially among politicians, businesspeople and journalists, the effects of globalization are still being scrutinized to better understand what they entail and what they imply. One of the most pressing matters concerning the process of globalization involves the creation or perpetuation of inequalities. These inequalities create classes of winners and losers who unfairly benefit or suffer by participating in the process of globalization. The purpose of my research is to assess empirical data that demonstrates a causal relationship between globalization and various forms of inequality. If one considers globalization as a "supraterritorial" process in which actions taken on a local scale have global implications and vice versa, one can identify inequalities that occur at the international, national, and local level due to globalization. While the world today is in the throws of such a sweeping process, it is vital to understand what is going on around us and why, so that people are not, in a sense, thrown off the "train" of globalization, or simply left behind. At the conclusion of my paper I expect to present a clear relationship between globalization and the generation of inequality and what this relationship implies for the future of this global process.

The U.S. Government vs. The National Football League: How the Government Decided to Regulate the League's Television Policy

This paper analyzes the development of the National Football League's (NFL) television policy from 1949 until the Federal Court ruling in 1953 established the parameters for broadcasting NFL games. A central focus will be on investigating why the U. S. government got involved in regulating the NFL's television policy. Four themes will guide the narrative: the NFL's early relationship with television; the factors that led to NFL Commissioner Bert Bell revising the league's television policy; the forces that led to government intervention into the NFL's television policy; and the impact of the 1953 court ruling. Bert Bell's efforts to revise the NFL's television policy coincided with the emergence of the television industry and their attempts to develop their programming niche, and the simultaneous efforts of the US government to regulate the airways. When Bell attempted to regulate NFL broadcasts, the US government viewed this as a violation of the Sherman Antitrust Act. The NFL was found in violation of antitrust laws, but Judge Allan K. Grim allowed the league to blackout home games within a 75-mile radius. Despite this setback, Bell saw this ruling as a victory because the league won its most important point – the blackout of home telecasts.

Purification and Caracterization of *BkdR* Protein in *Streptomyces coelicolor*

One of the biggest problems facing medicine today is increasing bacterial resistance to antibiotics. The solution may be found by manipulating the natural product biochemical pathway of *Streptomyces* , a soil organism that produces most of the known antibiotics. In order to use this pathway to create novel antibiotics, it must be fully analyzed because the antibiotics can only be created *in vivo* . Mutations in genes that control the branched chain keto acid dehydrogenase complex (bkd) eliminate antibiotic synthesis; therefore bkd is the first choice for further experimentation. Based on predicted structure of the protein and the activity of known homologous proteins in other species, bkdR is hypothesized to be the regulator of the gene and would therefore be the first step in the full analysis of the pathway. Starting with this proposed regulator protein, the components of the pathway will be assayed for biochemical activity. This possible regulator gene was cloned into a vector using restriction digestion and amplification in *E. coli* cell cultures. The vector is designed to add an amino acid tag to the protein product that will allow easy purification. After this purification, the protein will be categorized for many different activities, including DNA binding studies. Also a complementation study is underway to show that the tagged version of the protein functions normally in vivo. In addition to testing the biochemical properties of bkdR, analysis of promoter mutants can be used to determine what cell signals are used and what other proteins interact with bkdR. These studies would determine the direction and scope of further experiments.

GIS and Field-Based Analysis of the Impacts of Recreational docks on the Saltmarshes of Georgia
Applied Coastal Research Laboratory, Georgia Southern University, 10 Ocean Science Circle, Savannah, GA 31411 and Clark R. Alexander, Skidaway Institute of Oceanography, 10 Ocean Science Circle, Savannah, GA 31411

Population pressure along the Georgia coast has greatly increased the number of docks that extend across the marsh, impacting marsh ecosystems through shading. To understand the patterns and impacts of dock proliferation, aerial photography and field data were used within a geographic information system (GIS) to quantify salt marsh area directly affected by docks. Maps showing the footprint of docks from 1970 to 2000 on Wilmington Island, GA, were created to quantify changes in dock area. These maps document an 89% increase in total dock area and a 74% increase in number of docks during this period. Indicators of shading impacts (e.g., plant height and stem density) were quantified for salt marsh grasses beneath and adjacent to docks from a range of time periods, dock orientations and dock heights. Average vegetation stem density was 50% lower beneath docks than measurements adjacent to docks. This study provides baseline and trend data regarding dock impact and proliferation, provides guidance on potential impacts of docks on estuarine productivity and will be a valuable tool for coastal managers in assessing the cumulative impact of these activities.

DATING, MATING, AND PROCREATING: DARWIN IN THE VICTORIAN NOVEL
Richard Menke, Department of English, Franklin College of Arts and Sciences, University of Georgia, 254 Park Hall, Athens, Georgia 30602-6205

Nineteenth-century England was a time and place of scientific exploration and literary innovation, both of

which are blended in Victorian fiction. Victorian novelists took a special interest in the ideas of Charles Darwin, a nineteenth-century naturalist whose work The Origin of Species inspired Herbert Spencer to coin the phrase "survival of the fittest." Victorian novelists often examined the bleeding of evolution into the social sphere of fiction and whether organisms compete and adapt to social as well as physical environments. By definition, evolution is successful if an organism's genes will be passed to the next generation. If an organism also evolves socially, the processes of courtship and marriage make humans "not only animals but cultural animals" that use instinct as well as consciousness and cultural ideas in their sexual selection (Dickens 16).

This paper explores the relationship between Darwin's theory of evolution and the evolutionary process and the social realm of the Victorian novel. Characters and events from Jane Austen's Sense and Sensibility through George Eliot's Daniel Deronda portray popular Victorian sentiments. These sentiments range from feelings about the "pre-Darwinian" thought of Lamarck and Erasmus Darwin to Charles Darwin's The Origin of Species and provide a window into how Darwin's subsequent theory of evolution impacted Victorian society.

Dickens, Peter. Social Darwinism: *Linking Evolutionary Thought to Social Theory.*

Development and Improvement of Assays for the Early Detection of Cancer
Dr. J. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

Trophoblastic malignancies such as choriocarcinoma have been associated with the production and secretion of hyperglycosylated isoforms of the pregnancy hormone, human chorionic gonadotropin (hCG). The identification of such glycoproteins is becoming increasingly important in the development and improvement of tumor marker assays and key in the early diagnosis of cancer. Currently, this research project is primarily focusing on the analysis of pregnancy-derived hCG isoforms and their potential discrimination from trophoblastic malignancy-derived hCG. Thirteen pregnancy urine samples were obtained from patients at the Athens Women's Clinic and analyzed on the BIAcore to determine the concentration of hCG in each urine sample, as well as the various hCG glycosylation isoforms. In this assay, hCG is captured by a modified monoclonal antibody and then probed with various lectins, i.e. carbohydrate-binding proteins. The identification of the different hCG isoforms was performed by injecting several types of lectins, including *aleuria aurantia lectin* (AAL), *galanthus nivalis lectin* (GNA), and *sambucus nigra lectin* (SNA), on the BIAcore after every urine injection. The data gathered from these and other experiments with urine from cancer patients will be used in the development of assays for the early detection of cancer. Even though this research project is currently exploring hyperglycosylated hCG isoforms as potential tumor markers, the project will expand to include the investigation of glycoforms of PSA, CEA and CA-125 as tumor markers. Serum and urine samples from patients with a variety of cancers will be analyzed on instruments such as the BIAcore and the Immulite, which use surface plasmon resonance and fluorescence-based assays, respectively, to detect tumor marker proteins with aberrant glycosylation patterns.

Functional analysis of Ubc2, a putative novel adapter protein in *Ustilago maydis*
Dr. Scott E. Gold, Department of Plant Pathology

The fungus *Ustilago maydis* is the causal agent of corn smut. This fungus alternates between a haploid, budding

saprophytic form found in the soil and a pathogenic filamentous form that invades corn tissue. The *ubc2* gene encodes a protein involved in the MAP kinase pathway controlling mating and morphogenesis . *Ubc2* is a critical virulence factor that encodes a protein possessing four protein interaction domains. Site-directed mutagenesis and complementation studies indicated that certain amino acids within the Sterile-Alpha-Motif and Ras association domains are critical for complementation and hence Ubc2 function. The yeast two-hybrid assay was employed with *Ubc2* as bait to identify interactions between Ubc2 and other proteins in the MAP kinase pathway. Targeted two-hybrid studies revealed that Ubc2 interacts with Ubc4 MAPKK Kinase and that SAM domains at the N-termini of the Ubc2 and Ubc4 proteins mediate this interaction. These results contribute to the overall understanding of morphogenesis in Ustilago.

Immunohistochemical detection of various recombinant Newcastle disease virus strains in embryonated chicken eggs

Newcastle disease (ND) is a poultry disease caused by strains of Newcastle disease virus (NDV), a member of the genus Avulavirus, family Paramyxoviridae. The presence of ND must be reported to the Office International des Epizooties, resulting in financially damaging trade embargos. NDV isolates are typically classified on a scale ranging from least virulent (lentogenic) to most virulent (velogenic). In this study, four viral strains were used: rLa Sota (infectious clone of the lentogenic La Sota strain), rBC (infectious clone of velogenic Beaudette C strain), rLa Sota with BC HN (rLa Sota with virulent BC hemagglutinin-neuraminidase (HN) gene insert), and rBC with La Sota HN (rBC with lentogenic La Sota HN gene insert). Four groups of nine-day-old White Leghorn embryonated eggs were inoculated with the four viral strains, and at 24, 48, and 72 hours post infection both embryo tissues and chorioallantoic membrane (CAM) were harvested from each egg. Tissues were examined immunohistochemically using an antibody to a NDV protein. Embryos infected with rLa Sota had viral protein only in epithelial cells of the CAM. Embryos infected with rLa Sota with BC HN had viral protein found in CAM epithelium, subepithelial cells, and some embryonic tissues. Both embryos infected with rBC and rBC with La Sota HN demonstrated viral protein in CAM epithelium, subepithelial cells, and in embryonic tissue. It can be concluded that in the embryo, the presence of the virulent HN gene is not necessary for extensive tissue invasion and dissemination of the virus.

Georgia's Water Wars: Are Permit Transfers Sound Water Policy?

Decades of population and economic growth exaggerated the existing strain on Georgia's water resources. The purpose of this research was to examine legislation in the 2003 legislative session, specifically, the policy of transferring water permits. House Bill 237 included the controversial strategy of legitimizing water permit transfers in which a person or entity that presently has a permit would be allowed to transfer or to sell rights to some, or all, of the capacity under the existing permit.

Qualitative, primary research was conducted predominantly through interviews with the Georgia legislature and involved lobbyists as well as the attendance of Senate Natural Resources Committee meetings during the 2003 legislative session. Interviews provided differing views to assess the potential effects of permit transfers. Through this analysis, conclusions were drawn as to the possible benefits or costs of allowing permit transfers in Georgia.

Even though concerns of possible problems associated with permit transfers sparked much debate, the most significant argument is whether water rights belong to the public or could be marketed as a private commodity.

After thorough analysis of an array of relevant ideas and arguments, I conclude that, in a capitalist society, markets are the key to economic freedom and represent the economic philosophy of the United States. Creating a market for permit transfers would further economic progress while allocating water to those users who could no longer get permits.

Negative Campaigning in the Georgia 2002 Elections: An Analysis of Scholarly Research in the Context of Real Campaigns

Negative campaigning changed the face of Georgia politics throughout the last twenty years. Due to the public policy implications and increasing frequency of negative advertising as an attack vehicle, scholars engaged in research studying different areas of negative advertising. The purpose of this research is to examine selected 2002 Georgia elections and review specific scholarly studies to determine the effects of attack advertising in the context of real campaigns. Although quantitative data such as election results enriched the research, this study is based primarily on qualitative research derived from personal interviews, newspaper sources, relevant scholarly literature, campaign materials, and advertisements. The examined elections included the Governor's race between Roy Barnes and Sonny Perdue, the State Senate race between Doug Haines and Brian Kemp, the State Senate Primary race between Joyce Stevens and Renee Unterman, and the U.S. Senate race between Max Cleland and Saxby Chambliss. Results show that the use of negative campaigning is increasing and that the characteristics of candidates most likely to use attack advertising in Georgia campaigns are consistent in real campaigns. Findings from scholarly research are demonstrated, specifically, negative advertisements are highly effective during campaigns and seem to lead to electoral victories. Likewise, the traditional view that extreme negativity in advertisements could yield negative effects on the sponsor is disproved due to the phenomena of the sleeper effect which depletes any backlash to the source without diminishing the negative message. These findings create interesting positions for future candidates, the public, and the media.

Recovering Self

Recovering Self, written as an undergraduate honors thesis in creative writing, consists of two parts. The first part entitled "Writing to Permeate Cultural Borders: Analysis of *Mango Street*" reviews and analyzes the themes and composition of The House on Mango Street, authored by Sandra Cisneros, and serves as the introduction to the ensuing collection of short stories. It also focuses on multicultural individuals' ability to serve as intercultural mediators, or liaisons among different groups, through writing and rhetoric. The second part of the thesis consists of a collection of short stories, or vignettes that are subdivided into three logical sections: Departure, Arrival, Recovery; the stories are original pieces that focus on a young immigrant's memories and her search for identity. This search for identity delves into the young girl's past and implicitly reconstructs her life through the readers' eyes. Throughout the work, the search for identity is an active process as it presents situations to which readers can relate or empathize with. The stories, while written in a unique style, were inspired by Cisneros's composite novel. Thus, Recovering Self echoes the themes and mimics the format of The House on Mango Street. The overall theme of the entire work lies in its multicultural appeal. Both the critical review and the actual vignette collection deal with the notion of being an intercultural mediator, a role in which one produces work that will increase knowledge and understanding between different ethnic groups through the human ability to relate to similar events in life.

Sulfur Isotope Analysis of Alteration Minerals in Balekasir area, Northwest Turkey
Dr. Paul A. Schroeder, Geology, University of Georgia

Halloysite is an economically important kaolin group clay mineral used widely in the ceramics industry. As part of a study to understand the viable extent of this natural resource in northwest Turkey, samples were collected in March, 2003 near Turplu in the Balekesir region. The purpose of this study is to characterize mineralogical and chemical properties of the deposits using X-ray diffraction and stable isotope analysis. Alunite, halloysite, gypsum, quartz, plagioclase, and pyrite were found to be the dominant phases. Sulfur was extracted from alteration minerals for the isotope analysis using a combustion method. A gas-source mass spectrometer was then used to quantify the ratio of 34 S to 32 S (i.e., d 34 S values) within each sample.

Alunite samples, when compared to coexisting pyrite, were greatly enriched in 34 S while other alteration minerals were only slightly enriched in 34 S. Analysis yielded a d 34 S Pyrite value of 0.64 and alunite, gypsum and jarosite d 34 S values of 7.81, 2.99 and 2.61. When compared to values from other hydrothermal systems around the world, these data suggest a mixed origin of rock altering sulfuric acid in the system. Through study of the alteration minerals the mode of genesis of the deposit is now better defined. This is important because it indicates that the extent of the halloysite deposit has the potential for future economic sustenance in the region.

Microbial Diversity of Sediment in Mono Lake, California
Department of Marine Sciences, University of Georgia, Athens, Georgia 30602

Mono Lake is an alkaline (pH 9.8), hypersaline (salinity >80ppt), closed basin lake located in central California. Extreme environments, such as Mono Lake, contain many unique microbes. Recent studies have shown that 75% of the 16S rRNA sequences recovered from Mono Lake water clone libraries were distinct at the genus level or higher when compared to known sequences. There is not much known about the microbes inhabiting Mono Lake sediment. We analyzed the microbial diversity in a sediment core (2 cm to 45 cm below sediment surface) collected from station 6 at Mono Lake during August 2002. Denaturing Gradient Gel Electrophoresis (DGGE) and 16S rRNA clone libraries were used to examine microbial community diversity. DGGE fingerprinting showed differences in banding patterns between depths. 16S rRNA clone libraries were constructed from samples taken at 15cm and 24cm of the 2002 core. A total of 14 clones from 15cm and 22 clones from 24 cm were analyzed. The 15 cm clone library was dominated (23%) by Picocystis chloroplast sequences, whereas the 24 cm clone library was dominated (50%) by a Synechococcus-like cyanobacteria. The other major group (23 and 18%, respectively) found in both clone libraries was related to low G+C-Gram-positive bacteria which is also found in Mono Lake deep water. Other sequences found were related to ?????? and ?-Proteobacteria, CFB, Verrucomicrobiales, and candidate divisions. Ongoing work is focused on analyzing the microbial diversity of a 2003 sediment core. Our results concluded that Mono Lake sediment contains some unique microbes. Other sediment microbes were similar to those found in the overlying water. This study will provide a better understanding of the structure of microbial communities in salt lake sediment.

Internal Muscle Architecture During Isometric Contractions of the Quadriceps Muscle with Varying Force.

Exercise Science Department, University of Georgia, Athens, GA 30601.

Many explanations of muscle characteristics in humans are explained by external movement; however, a closer look at internal measurements may provide a better understanding of these characteristics. The purpose of this study was to quantify internal movement during isometric contractions at varying force levels.

METHODS: Six healthy young (20 – 28 years old) males were tested on two different days. The subjects preformed voluntary isometric contractions of the quadriceps muscle with 70 degrees flexion. B-mode ultrasound images of the vastus lateralis were taken at 10, 20, 30, 40, and 50 percent of MVC. Images were analyzed for muscle thickness, pennation angles, fascicle length, and excursion of a central tendon during the contraction. **RESULTS:** At rest pennation angle was 14.8 ± 2.2 o , muscle thickness was 2.69 ± 0.39 cm, and calculated fascicle length was 10.6 ± 1.3 cm (mean ± SD). With increasing force, angle increased (R 2 =0.987), muscle thickness decreased (R 2 =0.857), fascicle length decreased (R 2 =0.864), and excursion increased (R 2 =0.987). Excursion of the central tendon varied from 0.63 ± 0.95cm at 10% MVC to 2.25 ± 0.21 cm at 50% MVC. Excursion had the lowest coefficient of variation (on average 15%). **DISCUSSION:** To our knowledge, this study was the first to measure internal architecture responses to isometric contractions. Excursion of the central tendon had the largest effect size and best reproducibility. The coefficients of variation that we measured were higher than similar ultrasound measurements by other investigators. If the coefficient of variation can be reduced, these measurements may be useful for the study of muscle function in age and disease.

Child Mental Health and Academic Achievement

Child mental health is correlated with academic achievement in elementary school, yet the reasons for this relationship are not known (Veldman & Worsham, 2001). Temperament theory suggests that two components of mental health, attentional control and impulsivity are the active ingredients that either promote or interfere with academic achievement. Attentional control is the ability to orient, sustain, and shift attention; attentional control allows children to regulate their internal arousal. Impulsivity refers to the ability to regulate behaviors related to internal arousal and is exemplified by hyperactive behaviors such as interrupting others and excessive talking (Posner & Rothbart, 2000). We investigated these constructs in a sample of 38 first through fifth grade children by forming two groups of children, moderate behavior problems versus few behavior problems, based on teacher ratings from the prior academic year. We then collected detailed classroom observations of attentional control and hyperactivity/impulsivity behaviors for these same children on several occasions during the 2002/2003 academic year. We found that the moderate behavior problem group displayed significantly more attentional control problems in the classroom, a finding that is consistent with predictions that this variable is important for academic achievement in the classroom. There children also had less favorable academic interactions with teachers. We found, however, that children with few behavior problems were actually more hyperactive in the classroom than the moderate behavior problem group. These findings support the proposition that attentional control, and not impulsivity, is more likely to be an active causal ingredient for academic problems for young children.

Gender in Improvisational Comedy
Dr. Allen Partridge, Department of Drama and Theater, University of Georgia

Since Viola Spolin compiled the essentials of games, storytelling, folk dance, and dramatics in her 1963 Improvisation for the Theater , both women and men have actively participated in the humorous art of theatrical improvisational comedy. However, as both a comedic improviser and an audience member myself, I was curious if male and female improvisers experience gender inequality in this unscripted art form that was founded by a woman. Socialization often encourages the feminine gender—the gender from which improvisational theater and comedy initiated—to embrace passivity and a reserved nature whereas it encourages the masculine gender to celebrate aggressiveness and a more intense willingness to take risks. Thus, our culture's socialization standards are more conducive to males taking a on-stage lead in this craft. Through academic research in improvisational theory, interviews with improvisers, participation in improvisation, and observation and data collection of improvised scenes and both player interactions and audience reactions, I have found that both sexes often possess performance styles reflecting their corresponding gender socialization. However, specific gender-inclusive improvisational training, exercises, and games make players conscious of this socialization, allowing for a more gender-friendly playing ground during both practice and performance.

Girls in the System

Historically speaking, females made up just a small part of the total of juvenile crimes. Although juvenile arrests are declining in general, female juvenile arrest rates remain fairly constant. Contrary to the overall declining juvenile crime rate, the adult female crime rate is on the rise. It is evident that these issues must be dealt with before these young women grow into delinquent adults. This project will present a brief historical analysis on female criminals, and also current statistics about females in the juvenile justice system, including how they go through the system of "cops, courts, and corrections." Exploring the inequality of treatment of young women in the justice system will expose a gender bias. The process from arrest to conviction is explained. The pros and cons of the current practices are evaluated and addressed. Suggestions for future changes and improvements in the system are made.

Early Chick Nutrition: Development of Pre-starter diets
Dr. Amy B. Batal

Immediately after hatch the young broiler chick is forced to rapidly switch from nutrients of endogenous sources (mainly from yolk lipids) to nutrients of exogenous sources (diet). The gastrointestinal tract is also increasing in weight faster than the chick's body weight. Thus, optimal nutrition during the first 4 to 7 days posthatching is crucial to ensure that chicks get off to a good start and are able to great their genetic potential. One way to achieve optimum nutritional benefits during this early period is to develop a pre-starter diet that would be fed for the first 4 to 7 days posthatching. The first step to developing an effective pre-starter diet is to determine the optimal nutrient levels required during the first 4 to 7 days posthatching. By studying the requirements of specific nutrients such as lysine and the sulfur amino acids (methionine and cystine) we will be able to formulate diets that provide chicks with the necessary nutritional balance during this crucial period of development. In Experiment 1 five levels of lysine (0.75 to 1.15% of the diet) were fed for the first 5 days posthatching. Growth performance did not plateau or reach a maximum suggesting that the requirement is greater than or near 1.15% lysine. This study suggests that the lysine requirement of chicks during the first 7 week posthatching is much higher than is currently reported. Additionally, preliminary experiments show a significant increase in weight gain from 0-21 days in diets enriched with 15% plasma. To further test the requirements for lysine and the sulfur amino acids two additional experiments are currently being conducted with emphasis placed on requirements for the first 4 days of age.

Immunomodulatory activity of saliva from the lone star tick, Amblyomma americanum

The lone star tick, *Amblyomma americanum,* is the disease vector for human monocytic ehrlichiosis. Previous investigations suggest that ticks down-regulate host hemostatic and immune system components with saliva to obtain an adequate blood meal. Inadvertently, however, the modulation of host responses may facilitate pathogen transmission. Through a series of *in vitro* assays using a mouse as a model for the human, we have found evidence supporting a similar function for *A. americanum* saliva. Proliferation assays revealed significant dose-dependent inhibition in mitogen stimulated T- and B-cells and in antigen (OVA)-stimulated T-cells from a transgenic host. Two trends of cytokine secretion, measured with the Bioplex system, were found in response to OVA peptide. Inflammatory and Th1 cytokines showed dose-dependent inhibition, while Th2 cytokines were stimulated at low levels of salivary gland extract and inhibited as doses increased. This evidence suggests that the host immune system is pushed toward a Th2 response. HPLC analysis and proliferation assays of HPLC fractions have shown evidence of inhibitory proteins. Work to further purify and characterize these proteins is planned. Identification and characterization of inhibitory proteins may lead to the understanding of the mechanisms of disease transmission and possible disease prevention.

Hahaha, : -), * Falling down laughing *: Expression of Amusement in a Computer-Mediated Community of Practice, an Ethnographic Approach

Members of a computer-mediated discourse community are faced with challenges when attempting to supplement conversational cues, especially emotional cues, not readily transmissible through the computer screen. Online speakers have developed methods for compensating that include ideographs of facial expressions, orthographic representations of non-speech sounds, and written notation that represents action. This paper takes an ethnographic approach toa small computer-mediated community that congregates on LiveJournal, an online weblogging program, and explores the community's choices for expressing amusement. The community members — all women — employ a variety of methods for expressing amusement, however they make stylistic choices for which method to use at which time. These stylistic choices, such as the tendency to use asterisk emoting (ex. *laughs*) or orthographic representation (ex. Hahaha) instead of emoticons, hold meaning and status within their community. The women's choices display the inherent variation in human language, both individually and as a community. These choices is emoting can tell researches much, not only about the specific community, but about language and communities of practice in general.

An Examination of Gender and Age factors in relation to Preschoolers' Aggression

Aggressive behavior among children has fueled a great deal of today's academic research. With the prevalence of violence in schools, researchers are asking questions about the source and implications behind the increase of aggressive behaviors in youth. Studies have suggested that the development of aggressive behavior begins at an early age. Gender differences in aggression have also been identified, with males exhibiting more physical

aggression than females. In the present study, ninety-six preschoolers (54 boys) ranging from 38 months to 62 months (Mean age = 48.34 months, SD = 6.9 months) were recruited from a neighborhood day school and the same county's Head Start program. Two age groups (3-year olds and 4-year olds) were further divided based on their classroom compositions. Fifty-seven 3-year olds (31 boys, mean age 46 months and 26 girls, mean age 47 months) provided age and gender comparisons. This study is a part of a larger study by Chiang collected during the year 2000-2003. All children were randomly assigned into a triad group to participate in two structured plays where one standard toy was provided and a free play session. Children's behaviors were video recorded and coded by semi-blind researchers. Teachers and parents were asked to rate children's behaviors using Social Competence Behavioral Check Evaluation (SCBE: LaFreniere & Dumas, 1995). MANOVA results showed more differences in age factor than in gender factor. Four year olds were more apt to display aggressive behaviors through play and teachers' ratings. Implications will be discussed at the conference.

Survey Of public Health-Related Activities at the University of Georgia

The mission of public health as defined by the Institute of Medicine is to "fulfill society's interest in assuring conditions in which people can be healthy." Public health carries out its mission through organized, interdisciplinary efforts that address the physical, mental and environmental health concerns of communities and populations at risk for disease and injury. For this project a survey was carried out to identify public health related courses, research projects and public services and outreach projects at the University of Georgia. The online course description section of the UGA bulletin was read to identify public health related courses. The funded research projects section of The 2002 OVPR Annual Report was used to identify public health related research projects, and the various web sites of the offices of public service and outreach were used to find PS&O projects that were significant to this research. The public health related courses and projects identified through this research will be used to make a database outlining all public health activities ongoing at the University of Georgia. The information from this database will be used to create a framework to support the foundation of a School of Public Health at UGA. With nearly $19 million funding public health related research projects and over eighty public health related courses being offered on campus, the University of Georgia is well on its way to meeting the criteria necessary to open a school of public health.

AN INTEGRATED ANALYSIS OF A CHEMICAL REACTION NETWORK FOR THE METABOLISM OF QUINIC ACID IN *NEUROSPORA CRASSA*

Dr. Jonathan Arnold, Department of Genetics, University of Georgia, Athens, Georgia 30602

A chemical reaction network for the metabolism of Quinic Acid in *Neurospora crassa* has been proposed. In this reaction network two regulatory genes and five structural genes are responsible for the metabolism of Quinic Acid. The protein product of *qa* -1F transcriptionally controls the expression of all seven *qa* genes, including those encoding enzymes which utilize Quinic Acid as a carbon source, and the protein product, QA-1S, represses the activator protein, QA-1F. An ensemble of possible chemical reaction networks is developed with rate constants consistent with RNA and protein profiling data. An alternative network, in which several molecules of QA-1F (i.e. Hill coefficient is greater than one) cooperatively activate *qa* genes, is also developed.

Elliott Daingerfield's *Tanagra* and the Cultural Tension of Fin de Siècle America
Dr. Janice Simon, Department of Art History, Lamar Dodd School of Art, University of Georgia

The American fin de siècle (1876-1913) was an age of decadence, enlightenment, progress, and cultural revolutions; yet, it was also an era of polarities and contradictions with factions of modern culture simultaneously neglecting and appropriating antiquity. Henry James wrote (1888), "we are divided of course between liking to feel the past strange and liking to feel it familiar; the difficulty is, for intensity, to catch it at the moment when the scales of balance hang with the right evenness." Elliott Daingerfield's Tanagra (also called Contemplation, 1901, o/c) demonstrates this amalgam of what James deems "evenness" between the past and the present. In his use of the Tanagra figurine, Daingerfield (1859-1932) not only merges modern culture with classical influences but also combines stylistic elements of Orientalism and Symbolism, as well as introducing thematic notions of introspection, memory, and spirituality. Daingerfield's Tanagra stands out as a painting of pathos, reflecting not only the demeanor of the female subject, but also the atmosphere of turn-of-the-century America. I contend that Daingerfield's Tanagra embodies a culture in crisis, an America struggling to define itself amidst the many facets and fragments of foreign influences and modern trends. Thus, in its synthesis of classical and eastern aesthetics, it attempts to assuage a distinctly American anxiety. As I will demonstrate, Daingerfield's Tanagra, in fact, represents one of the best efforts at national identification and cultural clarity by one of America's most overlooked painters.

Phylogenetic and Functional Analysis of Pax6 Regulatory Elements
Dr. Jim Lauderdale, Department of Cellular Biology, University of Georgia

The Pax6 transcription factor is required for several aspects of brain development, including regionalization of the neural tube and specification of several types of neurons. Mutations in *Pax6* cause a loss of forebrain structures and misspecification of neurons. However, little is known about the regulation of Pax6 and its mechanism of function in the developing brain. To study the function of Pax6 in the developing forebrain, I have taken a comparative approach using mammals and zebrafish. In zebrafish, the control elements have been divided among two similar transcription units. We have shown, in zebrafish, that one *Pax6* gene gives expression in the neuroepithelium throughout the telencephalon while the other *Pax6* gene gives expression in specific neurons. I hypothesized that I can separate these two control elements in the single mammalian *Pax6* gene. We have shown in transgenic mice that the region upstream of the human P 1 promoter contains the control elements responsible for expression in the forebrain, metencephalon, and spinal cord. I analyzed the expression domain of the control elements in this region upstream of the P 1 promoter by microinjecting the promoter region construct into zebrafish embryos, making them transiently transgenic. After 24 hours of development, I analyzed the reporter expression by creating an accumulated expression map and have shown that the region does give expression in both the neuroepithelium and in specific neurons. Finally, I performed a deletion analysis of the fragment to identify the discrete regions responsible for expression in either the neuroepithelium or the developing neurons.

The Italian hill town as a model for United States urban redevelopment

The irregular layout of Italian public space is a poignant example of the adaptability to modern occurrences that is possible with minimal public governance and an increased public respect for the prospect of symbiosis

between human transportation modes within confined urban spaces. The United States and its inhabitants, on the other hand, now face an epidemic of poorly designed and maintained urban spaces that do not reflect the fluidity present in historically pedestrian Italian cities, which prohibits a symbiotic interaction between all street-level modes of human transportation. The observations gathered while monitoring this fluid daily life of the Italian piazza suggests that the wax and wane of pedestrian and mechanized traffic is a result of not only a delineated structure of allowable uses, but also an inherent realization of the importance by the populace that both forms of traffic play a necessary role in the functioning of the modern economy and society. In addition, the extraneous open space in Italian piazzas may be appropriated by a palpitating public forum of cafes and special events that serve as economic incentives to maintaining the multi-functionality of the piazza. The United States can greatly benefit by utilizing the design adaptability of Italian public space that has originated over thousands of years of intuitive and functional building layout, to redevelop a rich and concise fabric of urban public space.

The Role of CaaX Proteolysis in CaaX Protein Function
Dr. Walter K. Schmidt

Post-translational modification can be a very important step to the function of proteins. Certain proteins with a C-terminal amino acid sequence of cysteine (C), any two aliphatic amino acids (AA), and any amino acid (X) undergo a post-translational modification, referred to as CAAX processing. The human protein Ras undergoes CAAX processing. Understanding the CAAX modification pathway may therefore be useful for identifying methods that can regulate Ras hyperactivity that is typically associated with cellular transformation. Two proteases have been identified that are integral to CAAX processing in *Saccharomyces cerevisiae* . However, the specific characteristics of these CAAX proteases, Ste24p and Rce1p, are largely unknown. This study is focused on evaluating the physiological importance of CAAX proteolysis. We are testing the hypothesis that CAAX protein stability is altered in the absence of proper CAAX processing. We have found that the steady state levels of Ydj1p and Pex19p are reduced in yeast backgrounds lacking Ste24p. A prediction of our model is the alteration of the Ydj1p CAAX motif to an Rce1p-specific motif would correspondingly result in decreased levels in the Rce1p-deficient background. When such a Ydj1p mutant is evaluated, we find that levels are not reduced. Moreover, levels of Ras2p and **a** -factor are also not reduced in any protease-deficient background, suggesting that our hypothesis may only be valid for some CAAX proteins. Combined, our data suggests that CAAX proteolysis is essential for proper protein expression of Ydj1p and Pex19p, but that the protein levels of other CAAX proteins are not affected by CAAX proteolysis. This study implies that inhibitors of Rce1p and Ste24p may not affect the function of all CAAX proteins.

Studies on transgenic mice expressing a constitutively active luteinizing hormone receptor
Dr. Prema Narayan, Department of Biochemistry and molecular Giology, University of Georgia

The luteinizing hormone receptor (LHR) is a G protein-coupled receptor whose activity is regulated by luteinizing hormone and human chorionic gonadotropin. This receptor is essential in mammalian reproduction. A number of naturally occurring activating mutations in LHR cause precocious puberty, a disorder characterized by prepubertal increases in testosterone synthesis. To study the effects of chronic LHR activation *in vivo* , transgenic mice expressing a genetically engineered constitutively active yoked hormone receptor (YHR) were previously generated. YHR was constructed by covalently attaching a single chain hetrodimeric hCG to rat

LHR. Previous characterization of the YHR transgenic mice showed developmental alterations in the gonads. Testis sizes were reduced and an apparent decrease in the area of the seminiferous tubules was observed in testicular sections. Degenerative changes including the presence of cysts were observed in the ovaries. The main goals of my present project are 1) to perform a quantitative analysis of seminiferous tubule area to confirm the observed reduction in the testis sections of YHR transgenic mice. A digital image analysis of testicular sections using the NIH Image J software showed that the cross-sectional area of the tubules was significantly reduced in YHR transgenic mice consistent with the decrease in testicular size. 2) to determine the effect of the mouse genetic background on the ovarian phenotype and pathology. For this study, YHR mice will be bred into a CF1 genetic background and a histological analysis of their ovaries will be performed.

CURO
Center for Undergraduate Research Opportunities

Symposium 2006

University of Georgia, Tate Student Center
April 10-11, 2006

CALL FOR ABSTRACTS

The Center for Undergraduate Research Opportunities at the University of Georgia provides a forum for all undergraduates to present original research sponsored by faculty members. Undergraduate students from all disciplines are encouraged to participate. Representatives of public and private higher education institutions in Georgia are encouraged to apply.

Presentations may be in the form of an oral presentation, poster session, exhibition, performance, or work of art. Students can also present a tutorial about a research methodology or new technology. Undergraduate researchers who are at various stages of the research process are encouraged to submit abstracts describing where they are in the research process and the issues they face. Those who wish to present their work should submit an application (available on the CURO web site at www.uga.edu/honors/curo), an abstract of a maximum of 250 words in electronic form, and a brief supporting letter from the sponsoring faculty member (the letter can be uploaded onto the CURO web site for submission) no later than January 13, 2006. Group research projects should be submitted with one application and one letter of faculty support. All abstracts will receive graduate student peer review with faculty guidance. All participants accepted into the symposium will be notified by February 17, 2006, and their abstracts will be published in a book of abstracts. Sponsoring faculty will be invited to preside at their students' sessions.

Best Paper Awards
Papers accepted for presentation at the CURO symposium that are submitted by March 20, 2006 will be considered for "Best Paper" awards in the humanities, the sciences, and the social sciences. Awards will also be given to the best papers with an international focus and with a focus on civic responsibility. Papers must be submitted electronically to curo@uga.edu. Maximum length is 20 pages (not including bibliography or appendices).

Purposes of the Symposium:
- To highlight excellence in research by undergraduate students
- To enrich the undergraduate experience by promoting communication and cooperation between faculty and students
- To provide a forum for undergraduates to communicate and disseminate their research findings and creative works
- To provide an opportunity for undergraduate researchers in the state of Georgia to engage with their peer researchers

Criteria for Selection:
- Originality and quality of research
- Quality of written abstract
- Ethical and responsible research
- Extent of the undergraduate student's involvement in developing the research design and executing the project. Research presented at the symposium should go beyond work completed for a class paper or project.
- Letter of support from supervising faculty

This event is free and open to the public. All interested faculty and students are encouraged to attend the CURO Symposium. For more information, contact Dr. Pamela B. Kleiber, Associate Director, Honors Program, 203 Moore College, Athens, Georgia, 30602, pkleiber@uga.edu, (706) 542-0530.

CURO Symposium 2005 At A Glance

Monday, April 11th, 2005

Concurrent Oral Sessions (three 50 min. sessions) — **12:20 -3:20 p.m.**
Tate Student Center, Conference Rooms 138, 139, 140, 143, 144 — *sessions acc. to MWF class schedule

Welcome and Opening Session — **4:00 p.m.**
Tate Student Center, Georgia Hall A
Dr. David S. Williams
Director, Honors Program
Dr. Gordhan Patel
Vice President for Research and Exec. Director of the University of Georgia Research Foundation

Introduction of Keynote Speaker — **Jeremy Johnson**
Managing Editor, *Journal for Undergraduate Research Opportunities (JURO)*

Keynote Address: "Transposable Elements: Teaching Old Genomes New Tricks" — **Dr. Sue Wessler**
Distinguished Research Professor of Plant Biology

Reception and Poster Presentations — **5:00 p.m. – 7:00 p.m.**
Tate Student Center, Georgia Hall

Art Gallery Opening and Artist Talks — **7:00 p.m. – 8:30 p.m.**
Tate Student Center Gallery
Prof. Carmon Colangelo
Director, Lamar Dodd School of Art
Ms. Robin Dana
Gallery Director, Lamar Dodd School of Art
Daniel Gough
JURO Fine Arts Editor

CURO Apprentice and Alumni Reception — **7:00 p.m. – 8:00 p.m.**
Tate Student Center, Reception Hall
Melissa Cabinian and Melvin Hines, Jr.
CURO Alumni and Senior Peer Advisors
Ms. Catherine Packer
Graduate Assistant

Tuesday, April 12th, 2005

Concurrent Oral Sessions (three 75 min. sessions) — **9:30 a.m. – 1:45 p.m.**
Tate Student Center, Conference Rooms 138, 139, 140, 143, 144 — *sessions acc. to TR class schedule

Vendor Market — **10:00 a.m. – 2:00 p.m.**
Tate Student Center, Georgia Hall

NIF Research Project — **11:30 a.m. – 1:00 p.m.**
Tate Student Center, Conference Room 145 — Jeremy Johnson

Performing Arts Presentations — **2:00 p.m. – 4:15 p.m.**
Tate Student Center, Georgia Hall

JURO: Meet the Editors — **2:30 p.m. – 4:00 p.m.**
Tate Student Center, Reception Hall

Closing Ceremony and Awards — **4:30 p.m. – 5:30 p.m.**
Tate Student Center, Georgia Hall
Dr. Arnett C. Mace, Jr.
Senior Vice President for Academic Affairs and Provost
Professor Jere Morehead
Vice Provost for Academic Affairs

Monday, April 11, 2005

Concurrent Oral Sessions
Tate Student Center Conference Rooms 138, 139, 140, 143, 144

12:20 - 1:10 p.m. First Concurrent Session

Room 138	**Shana Strickland**	The Socialization of Anger among Maltreating and Nonmaltreating Mothers
	Faculty Mentor	Dr. Kimberly Shipman, Department of Psychology, University of Georgia
	Wendy Ballew, Ann Howell, Andrew Anderson	Toy Preferences in Relation to Gender Stereotypes: Comparing Children from Single versus Two-Parent Households
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College and State University
	Christopher Stokes	Child Attentional Control in the Classroom Milieu
	Faculty Mentor	Dr. Randy Kamphaus, Department of Educational Psychology, University of Georgia
Room 140	**Lauren Dominick**	The Artist in Cuba
	Faculty Mentors	Dr. Dana Bultman, Department of Romance Languages, University of Georgia Prof. Judy McWillie, Lamar Dodd School of Art, University of Georgia
	Erika Vinson	Arts Integration in School Curriculum as a Motivator for Student Success
	Faculty Mentor	Dr. Richard Siegesmund, Art Education, University of Georgia
	Jeremy Johnson	*The Journal for Undergraduate Research Opportunities*: Building an Undergraduate E-journal for Research in the Arts and the Humanities
	Faculty Mentor	Dr. Pamela Kleiber, Center for Undergraduate Research Opportunities, Honors Program, University of Georgia
Room 143	**Benjamin Cannon**	Identification of RNA Binding Proteins' Role in Gene Regulation in *T. cruzi*
	Faculty Mentor	Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia
	Kate Connell	Blockade of Cannabinoid Receptors in the Basolateral Nucleus of the Amygdala Suppresses Stress-Induced Analgesia
	Faculty Mentor	Dr. Andrea Hohman, Department of Psychology, University of Georgia
	Edmund Fomunung	Production of Antibodies to Erythrocyte Invasion Proteins of *Plasmodium falciparum* and Their Use to Investigate Erythrocyte Invasion

	Faculty Mentor	Dr. David Peterson, Department of Medical Microbiology and Parasitology, University of Georgia
Room 144	**Kevin Patrick**	Marcus Tullius Cicero: The Foundations of a Legal Education during the Roman Republic
	Faculty Mentor	Dr. James C. Anderson, Department of Classics, University of Georgia
	Rafael Young	Civil Rights Figures Appearing in the Multicultural Archive of Georgia
	Faculty Mentor	Dr. Timothy Powell, Department of English, University of Georgia
	Jora Vaso	The Effect of Communism on Eastern European Literature: With a Focus on Ivo Andric, Wislawa Szymborska, and Ismail Kadare
	Faculty Mentor	Dr. Katarzyna Jerzak, Department of Comparative Literature, University of Georgia

1:25 - 2:15 p.m. Second Concurrent Session

Room 138	**Cara Altimus**	Light Receptors for the Biological Clock in *Neurospora crassa*
	Faculty Mentor	Dr. Jonathan Arnold, Department of Genetics, University of Georgia
	Natalie Jennings, Annie Tran, Ezinne Okwandu	Gene Expression in Human Embryonic Stem Cells
	Faculty Mentor	Dr. Lee Pratt, Department of Plant Biology, University of Georgia
	Charya By	Characterization of the Presence of Integrons and Gene Cassettes in *Salmonella* Isolates by Polymerase Chain Reaction Assays
	Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia
Room 139	**Brunilis Burgos-Rivera**	Actin Depolymerizing Factor Regulates Key Growth Processes in *Arabidopsis*
	Faculty Mentor	Dr. Richard B. Meagher, Department of Genetics, University of Georgia
	Harry G. Butler IV	Three Dimensional Monte Carlo Simulation of Vapor Deposition Polymerization
	Faculty Mentor	Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia
	Namrata Asuri	An Analysis of the Role of Polyadenylation in tRNA Processing in *E. coli*
	Faculty Mentor	Dr. Sidney Kushner, Department of Genetics, University of Georgia

Room 140	**Amanda Dempsey**	Microarray and qRT-PCR Analysis of Gene Expression in CD8+ T Cells from *T. cruzi* Infected Mice
	Faculty Mentor	Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia
	Nicole Warren	Glycopeptide Isolation and Glycosylation Site Identification: A Standardized Procedure
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry, University of Georgia
	Fei Yang	Regulation of Branched-Chain Amino Acid Catabolism in *Streptomyces coelicolor*: Applications for Metabolic Engineering of Polyketide Antibiotic Biosynthesis
	Faculty Mentor	Dr. Janet Westpheling, Department of Genetics, University of Georgia
Room 143	**Megan Leroy**	The All-American Icon: Frank O'Hara and Coca-Cola Advertising in 1950's America
	Faculty Mentor	Dr. Susan Rosenbaum, Department of English, University of Georgia
	Gene Kim	"Comprehensive Responsibility" and Economic Growth
	Faculty Mentor	Dr. Santanu Chatterjee, Department of Economics, University of Georgia
	Grace Anglin	An Artistic Representation of the Post-September 11th Islamic Community
	Faculty Mentor	Prof. Laleh Mehran, Digital Media, School of Art, University of Georgia
Room 144	**Charlie Pitts, Jr.**	An Evaluation of Red Hat Inc.'s Business Practices, as it Relates to the Development and Distribution of Free and Open Source Software
	Faculty Mentor	Dr. Mark Huber, Management Information Systems, University of Georgia
	Natalia Nicholls and Erendira Casas	What is the True Cost Per Minute When Using Prepaid Telephone Calling Cards?
	Faculty Mentor	Dr. Julia Marlowe, Department of Housing and Consumer Economics, University of Georgia
	Mary Gassama	Student Attitudes Concerning Abortion
	Faculty Mentor	Dr. James Bason, Survey Research Center, University of Georgia

2:30 p.m. - 3:20 p.m. Third Concurrent Session

Room 138	**David M. Smith**	Samuel Beckett and the Antinomies of Author and Audience
	Faculty Mentor	Dr. Adam Parkes, Department of English, University of Georgia
	Leslie Wolcott	Georgia's Environmental Literature: A Survey of Contemporary Works
	Faculty Mentor	Dr. Betty Jean Craige, Comparative Literature and Center for Humanities and Arts, University of Georgia

	Lauren MacDonald	History Defeated: The Art of Kara Walker
	Faculty Mentor	Prof. Isabelle Wallace, Art History, Department University of Georgia
Room 139	**Ashley Johnson**	Bilingual Healthcare: Challenges Posed and How they Are Met
	Faculty Mentor	Dr. John Ross, Department of Romance Languages, University of Georgia
	Rebecca Brantley	Mariska Karasz and Hungary: Early Design and Influences
	Faculty Mentors	Dr. Thomas Houser, School of Art, University of Georgia Ms. Ashley Callahan, Georgia Museum of Art, University of Georgia
	Amy Buffington, Erin Klosson, Jessica Zabell	An Age Appropriate Method in Assessing Young Children's Emotional Competence
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College and State University
Room 140	**Erin Bohan**	The Reconciliation of Selves: The Immigrant Experience in America
	Faculty Mentor	Dr. Katarzyna Jerzak, Department of Comparative Literature, University of Georgia
	Josh Marsh	Shakespeare's Words in Moving Images
	Faculty Mentor	Dr. Fran Teague, Department of English, University of Georgia
	Daniel Gough	Ethnomusicology and the Theory of Race: A Brazilian Case Study
	Faculty Mentor	Dr. Jean Kidula, School of Music, University of Georgia
Room 143	**Chris Holland**	Rank, Ritual, and Akbar the Great
	Faculty Mentor	Dr. Farley Richmond, Department of Drama and Theatre, University of Georgia
	Jeremy Johnson	Shahidki: The Black Widows of Chechnya
	Faculty Mentors	Dr. Amy Ross, Department of Geography, University of Georgia Dr. Eve Marie Troutt Powell, Department of History, University of Georgia
	Alexander Skiles	Dispositionalism and the Principle of Least Action: Reply to Katzav
	Faculty Mentor	Dr. Yuri Balashov, Department of Philosophy, University of Georgia

4:00 p.m. Welcome and Opening Session

Tate Student Center, Georgia Hall A

Introductions and Welcome	Dr. David S. Williams, Director of the Honors Program Dr. Gordhan Patel, Vice President for Research and Executive Director of the University of Georgia Research Foundation

Introduction of Dr. Wessler	Jeremy Johnson, Foundation Fellow, Russian Language and History
Keynote Address	Dr. Sue Wessler Distinguished Research Professor of Plant Biology "***Transposable Elements: Teaching Old Genomes New Tricks"***

5:00-7:00 p.m. Reception and Poster Presentations

Tate Student Center, Georgia Hall

Poster Presentations

Julie Ahern, Janet E. Frick, Shannon Looney, Jessica Peters	The Effects of Total Communication on the Comprehension Abilities of First Grade Students
Faculty Mentor	Dr. Janet E. Frick, Department of Psychology, University of Georgia
Westin Amberge	Culture and Differentiation of *Ulex Europaeus* Agglutinin I Binding Human Embryonic Stem Cells with Direction towards an Endothelial Lineage
Faculty Mentor	Dr. Steven Stice, Department of Animal and Dairy Science, University of Georgia
Conrhonda Baker	Creating Inclusive Campuses through Recognizing Linguistic, Geographic, and Socioeconomic Diversity
Faculty Mentor	Dr. Kecia Thomas, Institute for African American Studies, University of Georgia
William Barrow	Identification of *Mycobacterium tuberculosis* Hypoxia-induced Genes Required for Intracellular Survival
Faculty Mentor	Dr. Russ Karls, Department of Infectious Diseases, University of Georgia
Christine Bassett	The Role of Female Choice in Sexual Selection of *Drosophila pseudoobscura*
Faculty Mentors	Dr. Yong-Kyu Kim, Department of Genetics, University of Georgia Dr. Wyatt Anderson, Department of Genetics, University of Georgia
Susan Bennett	Differences in Shell Availability, Hermit Crab Size, and Shell Diversity in Two Costa Rican Beaches
Faculty Mentors	Dr. Diana Lieberman, Institute of Ecology, University of Georgia Dr. Milton Lieberman, School of Marine Programs, University of Georgia
Layne Bradley	Surface Plasmon Resonance from Aligned Ag Nanorod Structures
Faculty Mentor	Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia

Josef Broder	Multivariate Harmonic Analysis
Karen A. Holbrook Academic Support Award	
Faculty Mentor	Dr. Andrew Sornborger, Department of Mathematics, University of Georgia
Harry Galvin Butler IV	Three Dimensional Monte Carlo Simulation of Vapor Deposition Polymerization
Faculty Mentor	Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia
Anjali Chaudhari	Analysis of *Pax6a* Expression Using a BAC Transgene
Faculty Mentor	Dr. James Lauderdale, Department of Cellular Biology, University of Georgia
Christina Chotiwat	Inhibition of Corticotropin-releasing Factor Receptors during Repeated Restraint Reduces Hyperresponsiveness to a Subsequent Stressor
Faculty Mentor	Dr. Ruth Harris, Department of Foods and Nutrition, Medical College of Georgia
Amy Chudgar	The Role of Angiogenic Factors in Vessel Formation
Faculty Mentor	Dr. Brenda Lilly, Vascular Biology Center, Medical College of Georgia
Collin Closek and Sarah Kilgore	Exploration and Manipulation of Objects and Surfaces by Common Chimpanzees (*Pan troglodytes*) and Capuchin Monkeys (*Cebus apella*)
Faculty Mentor	Dr. Dorothy Fragaszy, Department of Psychology, University of Georgia
Paul Courtwright	Effects of Shared Environment during Development on the Adult Behavior of *Drosophila paulistorum*
Faculty Mentor	Dr. Wyatt Anderson, Department of Genetics, University of Georgia
Caelin Cubenas	The Role of Autophagy in Neurodegenerative Disease
Faculty Mentor	Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia
Sita Damaraju	Effect of Different Bifunctional Linkers on Biological Activity of Functionalized Silicon Nanorods for Glucose Sensors
Faculty Mentor	Dr. William Kisaalita, Department of Biological and Agricultural Engineering, University of Georgia
Taylor Deal	A Comparison among Three Methods to Detect Newcastle Disease Virus in Formalin-fixed, Paraffin-embedded Tissues
Faculty Mentor	Dr. Corrie Brown, Department of Veterinary Pathology, University of Georgia

Anjan Deka	Establishing Mammalian Cell Lines that Modulate O-linked N-Acetlyglucosamine, O-GlcNAc, levels to Characterize Its Role in Apoptosis and Insulin Action
Faculty Mentor	Dr. Lance Wells, Department of Biochemistry and Molecular Biology, University of Georgia
John DuVal	Alternatively Spliced Transcripts of Matrix Metalloproteinase-2 in Ovarian Cancer Cells
Faculty Mentors	Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia Dr. Michael Geller, Department of Physics and Astronomy, University of Georgia
Dustin Dyer	Laplace Force During Wetting of Vertically Aligned Nanorod Array
Faculty Mentor	Dr. Guigen Zhang, Department of Biological and Agricultural Engineering, University of Georgia
Tiffany Gartrell	The Substrate Specificity of Rce1p
Faculty Mentor	Dr. Walter K. Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia
Christopher Hale	Adolescent Vulnerability to Nicotine Addiction: A Biological Basis
Faculty Mentor	Dr. Thomas F. Murray, Department of Physiology and Pharmacology, University of Georgia
Phillip Benson Ham III	Gas Phase Synthesis and Time of Flight Mass Analysis of Novel Semiconductor Clusters Containing Sulfur and Group Thirteen Metals
Faculty Mentor	Dr. Michael A. Duncan, Department of Chemistry, University of Georgia
Matthew Hastings	Implications of Unique Mineral Assemblages Associated With Subterranean Coal Fires
Faculty Mentor	Dr. Paul A. Schroeder, Department of Geology, University of Georgia
Catherine Hudson	Creating an Inexpensive and Fast Method for Screening Potential Drug Compounds for Narrow Spectrum Targeting of the Heme Biosynthetic Pathway
Faculty Mentor	Dr. Harry Dailey, Department of Microbiology, University of Georgia
Ashley Jackson, Shauncre Mitchell, Nikkitress Nelson	Research Experience for Undergraduates [REU]: Encouraging Underrepresented Students to Careers in Science via the GA Herbarium Cultivated/Economic Plant Voucher Collection
Faculty Mentor	Dr. Wendy Zomlefer, Department of Plant Biology, University of Georgia

Natalie Jennings, Annie Tran, Ezinne Okwandu	Gene Expression in Human Embryonic Stem Cells
Faculty Mentor	Dr. Lee Pratt, Department of Plant Biology, University of Georgia
Ashley Johnson	*Vibrio fischeri ArcA*- Mutant Sheds New Light on Bioluminescence Regulation
Faculty Mentor	Dr. Eric Stabb, Department of Microbiology, University of Georgia
Jeremy Johnson	*The Journal for Undergraduate Research Opportunities*: Building an Undergraduate E-journal for Research in the Arts and the Humanities
Faculty Mentor	Dr. Pamela B. Kleiber, Center for Undergraduate Research Opportunities, Honors Program, University of Georgia
Brittany R. King	Attributional Style, Spirituality, and Religious Problem-Solving: Implications for Psychological Well-Being in African American College Students
Faculty Mentor	Dr. Rosemary Phelps, Department of Counseling and Human Development Services, University of Georgia
Allison Koch	Quinic Acid Cluster Computational Model Analysis of RNA and Protein Intensities
Faculty Mentor	Dr. Jonathan Arnold, Department of Genetics, University of Georgia
Jessica Laverentz	Multiple Mates Enhance Offspring Viability for Female *Drosophila pseudoobscura*
Faculty Mentor	Dr. Patricia A. Gowaty, Department of Genetics University of Georgia
Anna Lee	Effects of Environmental Contaminant Perchlorate on Rat Thyroid Sodium-Iodide Symporter (NIS) mRNA Expression
Faculty Mentor	Dr. Duncan Ferguson, Department of Physiology and Pharmacology, University of Georgia
Robin Ligler	Using Streptolysin O for Cell Permeabilization to Determine G-Protein Activation
Faculty Mentor	Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia
Jay McCracken	The Effect of Mutations on the Substrate Specificity of RCE1
Faculty Mentor	Dr. Walter K. Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia
Jon McGough	Conspecific Sperm Precedence in *Drosophila pseudoobscura*
Faculty Mentors	Dr. Wyatt Anderson, Department of Genetics, University of Georgia Dr. Yong Kyu Kim, Department of Genetics, University of Georgia

Jonathan McWhorter	Phenotypic Changes in Dendritic Cell and T lymphocyte Subpopulations of Mice Infected with *Schistosoma mansoni* or Exposed to *S. mansoni* Eggs
Faculty Mentor	Dr. Daniel Colley, Department of Microbiology, University of Georgia
Amulya Nagarur	Functional Analysis of Yeast Axl1, Ste23, and IDE Mutants
Faculty Mentor	Dr. Walter K. Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia
Natalie Nicholls and Erendira Casas	What is the True Cost per Minute When Using Prepaid Telephone Calling Cards?
Faculty Mentor	Dr. Julia Marlowe, Department of Housing and Consumer Economics, University of Georgia
Matthew Nicholson	Detecting RSV Virus by Quartz Crystal Microbalance
Faculty Mentor	Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia
Tatyana Nienow	A Novel Assay for Insulin Degrading Enzyme and it Yeast Orthologs Ste23p and Axl1p Are Recently-Discovered Metalloproteases Found in the Yeast
Faculty Mentor	Dr. Walter K. Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia
William Parker	Creation of a Novel Ribonuclease T1 Gene for Protein Folding Studies
Faculty Mentor	Dr. Marly Eidsness, Department of Chemistry, University of Georgia
Gehres Paschal	Constitutively Active Lutropin Receptor Mutants Associated with Familial Male-Limited Precocious Puberty
Faculty Mentor	Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia
Karen Petree	How African Americans Think about the Links Between Disease and Race
Faculty Mentor	Dr. Celeste Condit, Department of Speech Communication, University of Georgia
Matt Rudy	Cloning and Expression of a Trigger Factor Variant for Protein Folding Studies
Faculty Mentor	Dr. Marly Eidsness, Department of Chemistry, University of Georgia
Amy Sexauer	*In Situ* Hybridization Detection of *Babesia microti* in Experimentally Infected Hamster Tissues
Faculty Mentor	Dr. Corrie Brown, Department of Veterinary Pathology, University of Georgia

Adam Singer	Distribution of MMP-2, -9 and -19 Alternative Splice Variants in Pre-Neoplastic Ovarian Surface Epithelium and Ovarian Cancer Cell Lines
Faculty Mentor	Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia
Matthew J. Stewart	Pancreatic Lesions in Chickens Experimentally Infected with Newcastle Disease Viruses of Different Virulence
Faculty Mentor	Dr. Corrie Brown, Department of Veterinary Pathology, University of Georgia
Adam Stroupe	Drug and Nutrient Trafficking in the Human Pathogen *Cryptosporidium parvum*
Faculty Mentor	Dr. Boris Striepen, Department of Cellular Biology, University of Georgia
Teerawit Supakorndej	Recruitment of Human Telomerase RNA to the Telomeres of Human Cancer Cells
Faculty Mentor	Dr. Michael Terns, Department of Genetics, University of Georgia
John Henry Theiss	Isolation of Mutants of *Arabidopsis thaliana* Having Insertions in Genes Thought to Encode Necessary Components of Plant Cell Wall Synthesis
Faculty Mentor	Dr. Michael Hahn, Department of Plant Biology, University of Georgia
Tendoh Timoh	Trigger Factor (TF) Assisted Co-translational Folding Using Fluorophore Modified Nascent Peptides Synthesis and Characterization of Fluorophore-Modified Trigger Factor for Protein Folding Studies
Faculty Mentor	Dr. Marly Eidsness, Department of Chemistry, University of Georgia
Erika Vinson	Arts Integration in School Curriculum as a Motivator for Student Success
Faculty Mentor	Dr. Richard Siegesmund, Art Education, University of Georgia
Nicole Warren	Glycopeptide Isolation and Glycosylation Site Identification: A Standardized Procedure
Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry and Molecular Biology, University of Georgia
Alyson Weber	Creation of an *in vitro* Transcription System for *Mycobacterium tuberculosis*
Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases, University of Georgia
Matthew Weiss	Assessing Correlations between Elite Media Coverage and Movement in Public Opinion Polls During Presidential Elections

Faculty Mentor	Dr. Audrey Haynes, Department of Political Science, University of Georgia
Stephanie Yarnell	Analysis of the Interactions between Chondroitins and Pectins
Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia
Rafael R. Young	Civil Rights Figures Appearing in the Multicultural Archive of Georgia
Faculty Mentor	Dr. Timothy Powell, Department of English, University of Georgia

7:00 p.m. - 8:30 p.m. **Artist Talks**
Tate Student Center Gallery

Introductions	**Daniel Gough,** Foundation Fellow and *JURO* Arts Editor **Prof. Carmon Colangelo,** Director, Lamar Dodd School of Art **Ms. Robin Dana**, Gallery Director, Lamar Dodd School of Art

Visual Arts Presenters

Lauren Dominick	Sculpture
Faculty Mentors	Dr. Dana Bultman, Department of Romance Languages, University of Georgia Professor Judith McWillie, Department of Sculpture, University of Georgia
Jessica Horwitz	Photography
Faculty Mentor	Ms. Robin Dana, Department of Photography, University of Georgia
Adrienne Lynch	Ceramics
Faculty Mentor	Professor Ted Saupe, Department of Ceramics, University of Georgia
Faith Ploener	Photography
Faculty Mentor	Professor Ben Reynolds , Department of Photography, University of Georgia
Richard Brandon Puett	Painting
Faculty Mentor	Professor Joseph Norman, Department of Drawing and Painting, University of Georgia
Richard T. Scott	Painting
Faculty Mentor	Professor Margaret Morrison, Department of Drawing and Painting, University of Georgia

Art Exhibit arranged by Ms. Robin Dana, Gallery Director, Lamar Dodd School of Art

Tuesday, April 12, 2005

Concurrent Oral Sessions

Tate Student Center Conference Rooms 138, 139, 140, 143, 144

9:30 – 10:45 a.m. First Concurrent Session

Room 138	**Layne Bradley**	Surface Plasmon Resonance from Aligned Ag Nanorod Structures
	Faculty Mentor	Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia
	Phillip B. Ham III	Gas Phase Synthesis and Time of Flight Mass Analysis of Novel Semiconductor Clusters Containing Sulfur and Group Thirteen Metals
	Faculty Mentor	Dr. Michael A. Duncan, Department of Chemistry, University of Georgia
	Katherine Price	Characterization of Chromosomal Integration by *Streptomyces* Bacteriophages: Use in Mammalian Genetic Engineering
	Faculty Mentor	Dr. Janet Westpheling, Department of Genetics, University of Georgia
	Javier Valle	Characterization of Transgenic Mice Expressing a Genetically Altered Luteinizing Hormone Receptor
	Faculty Mentor	Dr. Prema Narayan, Department of Biochemistry and Molecular Biology, University of Georgia
Room 139	**Michelle Borden**	The Nature of the Low-Energy Excited State in Benzoyl-Substituted Ferrocenes
	Faculty Mentor	Dr. Charles Kutal, Department of Chemistry, University of Georgia
	Tyson Turner	Establishing a Tumor Marker Database through Chemiluminescent Immunoassay Analyses
	Faculty Mentor	Dr. David Puett, Department of Biochemistry and Molecular Biology, Georgia State University
	Linda Fernekes	Expression of *Magnaporthe grisea* Extracellular Proteins in a Modified *Pichia pastoris* Expression System
	Faculty Mentor	Dr. Sheng-Cheng Wu, Complex Carbohydrate Research Center, University of Georgia
	Seema Patel, Julie Gordon	Analysis of Bmp Signaling during Thymus Organogenesis Using Neural Crest Specific Knockout Mice
	Faculty Mentor	Dr. Nancy Manley, Department of Genetics, University of Georgia
Room 140	**Anjan Deka**	Establishing Mammalian Cell Lines that Modulate O-linked N-Acetlyglucosamine, O-GlcNAc, levels to Characterize Its Role in Apoptosis and Insulin Action

	Faculty Mentor	Dr. Lance Wells, Department of Biochemistry and Molecular Biology, University of Georgia
	Beau Bryan	Cadherin-Mediated Cell-Cell Adhesion Regulated By GnT-V Expression
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry and Molecular Biology, University of Georgia
	Erika Lentini and Elizabeth Kantor	Serogrouping and Serotyping of *Salmonella* using PCR
	Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia
	Douglas Jackson	A Selected Ion Flow Tube Study of the Reactions of a Sequence of Ions with Amines
	Faculty Mentor	Dr. Nigel Adams, Department of Chemistry, University of Georgia
Room 143	**Amy Sexauer**	In Situ Hybridization Detection of *Babesia microti* in Experimentally Infected Hamster Tissues
	Faculty Mentor	Dr. Corrie Brown, Department of Veterinary Pathology, University of Georgia
	Disha Chhabra	Creating Expressed Sequence Tags of Human Embryonic Stem Cells
	Faculty Mentor	Dr. Lee Pratt, Department of Plant Biology, University of Georgia
	Matthew Crim	Role of Interleukin-7 Receptor in the Maintenance of Antigen-Specific CD8+ Memory T Lymphocytes in Experimental *Trypanosoma cruzi* Infection
	Faculty Mentors	Rick L. Tarleton, Department of Cellular Biology, University of Georgia Diana L. Martin, Center for Tropical and Emerging Global Diseases, University of Georgia

11:00 a.m. – 12:15 p.m. Second Concurrent Session

Room 138	**Ashley Johnson**	Vibrio Fischeri ArcA- Mutant Sheds New Light on Bioluminescence Regulation
	Faculty Mentor	Dr. Eric Stabb, Department of Microbiology, University of Georgia
	Matthew Haney	Antibody Depletion of Highly-Abundant Proteins in *T. cruzi* for Fine-Tuning of Proteomic Analysis
	Faculty Mentor	Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia
	Katrin Usifo	Antibiotic Use on Livestock: A Public Health Concern?
	Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia

	Christopher S. Hale	Adolescent Vulnerability to Nicotine Addiction: A Biological Basis
	Faculty Mentor	Dr. Thomas F. Murray, Department of Physiology and Pharmacology, University of Georgia
Room 139	**Matthew Nicholson**	Detecting RSV Virus by Quartz Crystal Microbalance
	Faculty Mentor	Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia
	Kurinji Pandiyan	Fibroblast and Epithelial Cell Interactions in Tropical Pulmonary Eosinophilia
	Faculty Mentor	Dr. Julie Moore, Department of Infectious Diseases, University of Georgia
	Melissa Cabinian	Antimalarial Effects of Cysteine Protease Inhibitors in Preventing Plasmodium
	Faculty Mentor	Dr. Photini Sinnis, Department of Medical and Molecular Parasitology, New York University School of Medicine
	Layne Bradley	Fabrication of Qubit States
	Faculty Mentor	Dr. Mike Geller, Department of Physics and Astronomy, University of Georgia
Room 140	**Stephanie Yarnell**	Analysis of the Interactions between Chondroitins and Pectins
	Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia
	Lindsay Williams	Antimicrobial Resistance in *Salmonella* of Bovine Isolates in Georgia
	Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia
	Hayes Lee	Laboratory Vector Competence of *Aedes aegypti*, *Aedes albopictus*, and *Simulium vittatum* for West Nile Virus
	Faculty Mentor	Dr. Daniel Mead, Southeastern Cooperative Wildlife Disease Study, University of Georgia
Room 143	**Ginnie Bondurant**	Bringing Domestic Violence to Light: An Evaluation of Batterer Intervention Programs
	Faculty Mentor	Dr. Dean Rojek, Department of Sociology, University of Georgia
	Scott Jacques	The Management of Predation among Young, Middle Class Drug Dealers
	Faculty Mentor	Dr. Mark Cooney, Department of Sociology, University of Georgia
	Matthew Evans	In the Beginning: Initial Interests of Undergraduate Psychology Majors
	Faculty Mentor	Dr. Rosemary Phelps, Department of Counseling and Human Development Services, University of Georgia

	Faculty Mentor	Dr. Jean Martin-Williams, School of Music, University of Georgia
3:15 p.m.	**Hariqbal Basi**	*Saaki* CORE Concert Dance Company

4:30 – 5:30 p.m. Closing Session and Awards Ceremony

Tate Student Center, Georgia Hall

Introductions	**Professor Jere Morehead**, Vice Provost for Academic Affairs
Excellence in Undergraduate Research Mentoring Faculty Award	**Dr. Arnett C. Mace, Jr.**, Senior Vice President for Academic Affairs and Provost

Graduate Assistant Awards	**Dr. Maureen Grasso**, Dean of the Graduate School
Presentation of Best Paper Awards	**Professor Jere Morehead**, Associate Provost and Director of the Honors Program
Joshua Laerm Undergraduate Award	**Dr. Betsy Reitz**, Professor of Anthropology

The office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2001. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students. Awards will be presented at the CURO Symposium Awards Ceremony on Tuesday, April 12, 2005 at 4:30 p.m. in the Tate Student Center, Georgia Hall.

2005 Awards
Faculty Awards
Dr. Gary Barnett, Odum Professor of Ecology
Dr. Sidney Kushner, Professor of Genetics
Department Award
Department of Cellular Biology
Dr. Marcus Fechheimer, Interim Department Head
Recognition
Dr. Lee Johnson, Child and Family Development
2005 Selection Committee
Dr. Roxanne Eberle, Associate Professor of English
Dr. Katherine Kipp, Associate Professor of Psychology
Dr. William S. Kisaalita, Associate Professor of Biological & Agricultural Engineering
Dr. Scott Shaw, Professor of Astronomy
Dr. Pamela Kleiber, Chair

2004 Award
Faculty Award
Dr. William S. Kisaalita, Associate Professor of Biological & Agricultural Engineering

2003 Awards
Faculty Award
Dr. Jody Clay-Warner, Assistant Professor of Sociology
Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Tim Hoover, Undergraduate Coordinator
Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Professor
Dr. Marie-Michèle Cordonnier-Pratt, Senior Research Scientist

2002 Awards
Faculty Awards
Professor William D. Paul, Jr., Professor of Art
Dr. Katherine Kipp, Associate Professor of Psychology
Faculty Recognition
Dr. Susan Sanchez, Assistant Professor of Veterinary Medicine
Department Award
Department of Biochemistry and Molecular Biology
Dr. J. David Puett, Department Head
Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program

Dr. Loris Magnani, Principal Investigator, Professor of Physics and Astronomy
Dr. Heinz-Bernd Schuttler, Professor and Department Head of Physics and Astronomy
Dr. Jonathan Arnold, Professor of Genetics
Dr. Susmita Datta, Professor, Georgia State University
Dr. David Logan, Professor, Clark Atlanta University
Dr. William Steffans, Professor, Clark Atlanta University

2001 Awards

Faculty Award

Dr. Marcus Fechheimer, Professor of Cellular Biology

Faculty Recognition

Dr. David MacIntosh, Associate Professor of Environmental Health Sciences
Dr. Dean Rojek, Associate Professor of Sociology

Department Award

Genetics Department
Dr. John MacDonald, Department Head

Program Award

Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

Thanks and Acknowledgements

Graduate Student Reviewers for CURO Symposium 2005

The Effects of Total Communication on the Comprehension Abilities of 1st Grade Students

Julie A. Ahern
Dr. Janet E. Frick, Shannon Looney, Jessica Peters, Department of Psychology, University of Georgia

Research on the production of total communication (speech + sign language) has shown that American Sign Language signs accompanying speech provide spatial referencing/visual demonstrations of ideas that are not available in speech. This experiment examines whether, and to what extent, children who receive total communication (TC) benefit from the additional information presented by the ASL signs. It was predicted that TC would result in superior comprehension, and further, that children with sign language experience would benefit from TC to an even greater extent. To test this hypothesis, a 2 (sign language experience vs. no sign language experience) x 3 (communication condition; see below) ANOVA design exposed 32 1st grade students to videotapes of three different stories communicated through three conditions: A) speech with normal gesture, B) TC and C) speech + reversed ASL (a control condition in which the visual ASL signs were reversed, but the audio track was presented normally). Comprehension was assessed by quantifying details and descriptors of participants' recollections. Results indicated that participants' recollections of stories were no more elaborate in the TC condition than the speech with normal gesture condition ($p = .854$), but recollections in the TC condition were significantly better than those in the reversed ASL condition ($p = .045$). The level of participants' sign experience did not affect their performance in any of the communicative conditions. Further research may help to elucidate the characteristics of TC, the ages of recipients, or the amount of sign experience that would result in the greatest benefit of the enriched communication available via total communication.

Light Receptors for the Biological Clock in *Neurospora crassa*.

Cara Altimus
Dr. Jonathan Arnold, Department of Genetics, Georgia State University

Most organisms run on 24 hour cycles. While it may seem that this is not not purposeful and only run by the sun, it has been shown that the clock is actually entrained in the genes. The genes and proteins interact to create genetic networks that control all the outputs that we are more familiar with. In *N. crassa* the effect of the biological clock is shown in conidation patterns. The conidiation pattern forms because *N. crassa* produce conidia in regular intervals which leaves behind a quantifiable pattern. A blue light receptor has already been shown for this system but recently we have been able to show that there is also a red light receptor similar to the velvet A gene in *Aspergillius Nidulans*. With simple race tube experiments we have been able to show how this receptor connects to the known network. By comparing racetubes from blue and red light, the pathway for gene regulation can be understood.

Culture and Differentiation of Ulex Europaeus Agglutinin I Binding Human Embryonic Stem Cells with Direction Towards an Endothelial Lineage

Westin Amberge
Dr. Steve Stice, R. Rao, Department of Animal and Dairy Science, University of Georgia

The Ulex Europaeus Agglutinin I (UEA1) lectin is found to be expressed in most human embryonic stem cells (ES cells). It was hypothesized that a subpopulation of UEA1 expressing cells could be isolated and be used in further differentiation studies. UEA1 is a lectin previously only found to be expressed in endothelial cells, thus its expression in some ES cells may be important in the selective differentiation of these cells into endothelial cells. Having the ability to selectively differentiate ES cells to endothelial cells will give rise to many medical advances including potential roles in the treatment of heart disease and of damaged vasculature caused by other

conditions. In order to measure the ability of UEA1 expressing ES cells to differentiate into endothelial cells a subpopulation of UEA1 expressing ES cells would prove very helpful. Following this goal, ES cells were manually passaged and expanded, upon which they were magnetically sorted using a biotin-streptavidin antibody conjugation for UEA1 binding ability. The UEA1 positive cells were plated and cultured separately from the negative cells. Upon sorting, a high number of UEA1 positive cells to negative cells were noted. After immunostaining, the cells that arose from the UEA1 positive and negative cells were both positive for UEA1 binding as well as the expression of Oct4 and SSEA4, common pluripotent markers – proving the cells have not yet differentiated. It was thus concluded that the expression of UEA1 binding is not a genetically conserved trait, as its expression varies between genetically identical cells. Consequently an ES cell subpopulation of UEA1 binding cells cannot be isolated. Following this data, ES cells were sorted for UEA1 binding and then immediately plated on collagen IV in endothelial growth media, conditions known to help differentiate ES cells to endothelial cells. Specific cellular morphology differences were noted between the two cell groups, with many areas in the UEA1 positive group resembling endothelial growth.

An Artistic Representation of the Post-September 11th Islamic Community

Grace Anglin
Prof. Laleh Mehran, Digital Media, School of Art, University of Georgia

The press' advertisement of the post-September 11th "War on Terror" and our current presidential administration fail to differentiate between the Islamic fundamentalist views of terrorist groups and moderate Islam's peaceful, mainstream interpretations. The media's incorrect representations of Islamic beliefs, such as Jihad, lead many American citizens to interpret Islam as a hateful, dangerous, and scary religion. As a result, the widespread stereotypes negatively affect many American Muslims who, based on these stereotypes, experience verbal or physical assault. My project consists of a tile mosaic, an art form often used to decorate mosques, spoiled by graffiti images. These drawings embody the media's misrepresentation of Islam. The result of this misrepresentation is displayed through a series of developed blind contour drawings. Blind contour drawings are produced by drawing a subject, in my case members of the Islamic community, without looking at the paper. The resulting distorted images correspond with the distorted view many Americans have of the Islamic faith. Objects viewed as stereotypically Islamic further blind many Americans, who tend to view the individual as a terrorist and not as an American citizen. I developed the parts of the drawings that depict images stereotypical of Islam, and left the rest of the drawing unfinished and distorted, to represent the tendency to only see the stereotypical object and not the individual with which that object is associated. The point of my project is to help Americans view Muslims as people, not terrorists, and retard the growing trend of prejudice towards the Islamic community.

An Analysis of the Role of Polyadenylation in tRNA Processing in *E. coli*

Namrata Asuri
Dr. Sidney Kushner, Department of Genetics, University of Georgia

Polyadenylation is the post transcriptional addition of poly(A) residues on to the 3' termini of RNA molecules. It is known to play an important role in the post transcriptional regulation of gene expression in *Escherichia coli*. The decay of mRNAs in *E. coli* has been shown to be dependent on polyadenylation. In addition, it has been observed that the overproduction of poly(A) polymerase in *E. coli* is very toxic to the cell. One possible explanation for the loss of cell viability in the presence of excess polyadenylation is an alteration in the normal maturation of transfer RNAs (tRNAs), an important component of the cell's protein synthesis machinery. To test this hypothesis, cDNA clones of tRNACys before and after the induction of extra poly(A) polymerase were isolated. DNA sequence analysis of these clones showed a distinct

difference in the location of the poly(A) tails on the tRNA's as a function of the level of poly(A) polymerase. Subsequently, Northern blot analysis was used to examine the half-lives of various tRNAs, including tRNATrp and tRNAPro. In these experiments a series of strains containing mutations in polynucleotide phosphorylase (PNPase) and RNase II as well as a strain that overexpressed poly(A) polymerase I were used. PNPase functions as both a 3'→ 5' exonuclease and can also synthesize polynucleotide tails. RNase II also functions as a 3'→ 5' exonuclease. The results of these experiments suggested that polyadenylation is required for the normal maturation of tRNAPro and tRNATrp. In addition, PNPase also seemed to play a role in tRNA maturation. An unexpected observation from these experiments was that increased levels of polyadenylation seem to affect the half-lives of the mature tRNAHis and tRNACys. I am currently working to confirm this result.

Creating Inclusive Campuses through Recognizing Linguistic, Geographic, and Socioeconomic Diversity

Conrhonda Baker
Dr. Kecia Thomas, Institute for African American Studies, University of Georgia

The increasing globalization of the American economy creates an increased need for citizens to obtain greater education and take advantage of advanced training opportunities, especially as it relates to diversity. Yet barriers to these opportunities exist for some segments of the population, such as new immigrants and members of the working class. Enhancing access to educational opportunities for immigrants and linguistic minorities, lower and middle economic class members, and those from different regions may afford all students with advanced education as well as the opportunity to gain greater cross-cultural experience and competence. This paper begins with an analysis of the impact of Affirmative Action on higher education policies and the lack of attention to language, economic, and regional diversity. Institutional discrimination and social distancing, that is the exclusion and avoidance of the powerless by the powerful, are the lenses through which this analysis is made. Next the paper will argue for increased attention to these important dimensions of diversity for academic environments. Finally, an agenda for research on this topic is offered as are recommendations for how to enhance linguistic, economic, and regional diversity for institutions of higher education.

Toy Preferences in Relation to Gender Stereotypes: Comparing Children from Single versus Two-Parent Households

Andrew Anderson, Wendy Ballew, Ann Howell
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Children begin to display gender stereotypical play behaviors during their fourth year of life. Most of the existing literature tends to examine children's toys preference without addressing how the make up of their family may affect these children's gender socialization. Without the benefit of modeling in the absent parent, and with the necessity of the primary caregivers' taking on nontraditional gender roles, children from single parent households may form gender norms differently than children with two parents. The present study, a part of a larger study by Chiang, is developed to examine children's toy preferences in relation to their parental make up. The data were used to determine whether differences existed in gender stereotyping behavior between two ages (age 3 and age 4) and between two types of households (single parent versus two parents). It will help us in understanding whether a child's home environment may influence children toy selection. Toys were divided into groups of neutral toys, traditionally male toys and traditionally female toys. In the study, 163 children (Age 3 = 78, boys = 39, girls = 36; Age 4 = 87, boys = 48, girls = 39) were assessed, where 116 of the children came from single parent households and 32 of the children came from two parent households. The preliminary data analyses showed interesting patterns of behaviors. The detail results and implications of the children's toy preferences will be discussed at the conference.

The Complex Nature of Helping: Altruism vs. the Struggle for Global Supremacy

Sara C. Barnhart
Dr. Amy Ross, Department of Geography, University of Georgia

Society views helping as pure altruism by those who genuinely desire to aid those who are less fortunate than themselves. However, the American public must look critically at this perception and deconstruct it. Helping is also a way in which the powerful can manipulate others. By fostering a system in which the less powerful become dependent on aid and economic interaction, nations like the United States are able to persuade these countries to adopt policies which most benefit the U.S. rather than themselves. This relationship results in a lack of independence for the less powerful nations, who are then less focused on creating a plan for their own economic independence and sustainable development. Hegemonic nations help just enough to foster dependence but not enough to break free from it, resulting in untenable relationships plagued by the animosity and resentment of the nations receiving aid.

The presentation will analyze how the complex nature of "helping" shapes the public's view of foreign policy, humanitarian aid and military intervention. It will explore the roots of the concept of helping and trace its development to the role it plays in the relationship between great powers, mainly the U.S. and developing nations. The project will be comprised of several parts deconstructing the idea of helping with regards to human rights protection, international financial aid and development and will give readers a new perspective on the motivations behind U.S. foreign policy in these areas.

Identification of *Mycobacterium tuberculosis* Hypoxia-induced Genes Required for Intracellular Survival

William Barrow
Dr. Russ Karls, Department of Infectious Diseases, University of Georgia

Two billion people worldwide are latently infected with *Mycobacterium tuberculosis*, the causative agent of tuberculosis. Two to three million individuals die of the disease each year. *M. tuberculosis*, a strict aerobe, is killed if oxygen is rapidly removed. However, if oxygen is slowly depleted the bacilli enter a dormant state. Such adaptation may facilitate survival inside the host. The protein Acr is not made under log phase growth, but is the dominant protein produced in stationary phase cultures. Expression of the *hsp*X gene encoding Acr is also induced by hypoxia. It was reported that an Acr deletion mutant (Acr-KO) was impaired for survival in macrophages. Determination of the exact nature of the Acr-KO deletion following completion of the *M. tuberculosis* genome sequencing project indicates that the expression of multiple genes was effected by the Acr deletion.

To identify which genes affected by the Acr-KO deletion facilitate macrophage survival, the Acr-KO strain and another *hsp*X deletion mutant will be complemented with the various effected genes. The *hsp*X gene and other hypoxia-induced genes will be obtained via PCR of chromosomal DNA from *M. tuberculosis* strain H37Rv. These genes will then be ligated into a plasmid able to integrate into the *M. tuberculosis* chromosome. The resulting plasmids will be introduced into the Acr deletion strains via electroporation. The complemented and noncomplemented strains will then be tested for survival by quantitating the number of viable bacilli at 0, 1, 3, and 5 days post-infection with a 1:1 ratio of bacilli to human THP-1 macrophages. The complementing regions that restore intracellular survival to the *M. tuberculosis* Acr deletion mutants will indicate the genes required for virulence. Progress toward these goals will be presented.

The Role of Female Choice in Sexual Selection of *Drosophila pseudoobscura*

Christine Bassett
Dr. Yong-Kyu Kim and Dr. Wyatt Anderson, Department of Genetics, University of Georgia

It has been observed that in some *Drosophila* species, single females are surrounded by multiple males in nature. Females perceive and act on cues from males that differ genetically by quantitative trait loci and perhaps select highly

fittest males. Therefore, genes of high fitness and genes to select for traits with high genetic quality will be passed together onto the next generations. Using *D. pseudoobscura* isofemale lines, we tested the null hypothesis that *Drosophila* females randomly mate among males. For each observation, fourteen sexually mature males were individually marked with fine dots of paint on the thorax and were released into a cage (10x10x20 cm3) where they remained together for a 5-day observation period. One virgin female from the same isofemale lines was introduced into the cage. Observations occurred daily, two hours each morning and two hours each afternoon. At copulation, the pair was removed from the cage. After identification from the marked thorax, the male was returned to the cage. This procedure was repeated with new virgin females and the number of matings per male was scored. The current data show that approximately 20% of males (n=300) were not accepted by females, about 30% accepted 1-2 times and about 10% of males mated more than 10 times during the 5-day period. In addition, we found significant differences in cuticular hydrocarbons between the males with multiple matings and the males with no mating. The males who mated multiply produced more male pheromones ($p < 0.05$). These results suggest that 1) there is a variation in mating success among males; 2) cuticular hydrocarbons could be used as indicators of individual vigor and physical status; and 3) D. pseudoobscura females mate non-randomly. Currently we are investigating the effect of multiple matings on adult and offspring fitness in *D. pseudoobscura*.

Differences in Shell Availability, Hermit Crab Size, and Shell Diversity in Two Costa Rican Beaches.

Susan Bennett
Dr. Diana Lieberman, Institute of Ecology, University of Georgia
Dr. Milton Lieberman, School of Marine Programs, University of Georgia

Tourism is a major revenue source for many tropical countries, and the environmental effects of this industry has not been fully examined. This study investigates the impact of a resort on a stretch of beach on Costa Rica's Nicoya Peninsula. In this analysis, differences in shell assemblages and hermit crab populations from two similar, proximate beach environments with varying levels of human activity—a resort and a beach inside an absolute reserve—were studied. Shells randomly selected from each beach were measured and identified to genus. Additionally, hermit crabs were collected and measured from both beach sites. The shells worn by the hermit crabs were also measured and identified to genus. Diversity and size were compared among the assemblages found empty on each beach and those found on each hermit crab population. The Reserve's beach offered larger shells of greater abundance, as hypothesized, although the Resort's shells were more diverse. The crabs collected at the Reserve were significantly larger than those collected at the Resort, perhaps as a result of the larger shells available in the Reserve. Because the most underrepresented shells were among the most colorful, this phenomenon might be caused by resort visitors' collecting of shells as souvenirs. The results of this study suggest that tourism can create the unintended consequence of altering the ecosystems visitors come to see.

The Reconciliation of Selves: The Immigrant Experience in America

Erin Bohan
Dr. Katarzyna Jerzak, Department of Comparative Literature, University of Georgia

As a country of immigrants, our literature reflects the struggle, tears, and joys of the pilgrimage to a new land. Immigrant literature allows those that have not had to face the hostility of a new environment (because our ancestors did that for us) to imagine and live the immigrant experience. The necessity and complexity of language and the confusion of identity that ensues is fascinating, and is worth a closer look.

As an "insider" attempting to understand an "outsider" and their experiences, I simply began reading autobiographies and novels written by American immigrants, looking for similarities in experience. I also looked closely at how the

immigrants spoke of language, as well as the differences of the definition of "home."

Eva Hoffman and Isabelle de Courtivron write extensively of the vacuum that is created when one is between languages, thinking and dreaming in the native, but forced to converse in the new. It seems that immigrant authors often attempt to displace displacement by writing in the new language, describing emotion and thoughts in an adopted tongue. Both Hoffman and de Courtivron suggest that it is only when an immigrant's mind captures the new language completely, that he can begin to rebuild their identity in the new country.

Ultimately, memory and nostalgia are at the root of the immigrant experience. It is through these devices that an immigrant recovers lost aspects of "home" and transposes these onto their new home, in these cases, America.

Bringing Domestic Violence to Light: An Evaluation of Batterer Intervention Programs

Ginnie Bondurant
Dr. Dean Rojek, Department of Sociology,
University of Georgia

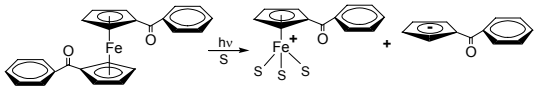
For years domestic violence has been viewed as a family concern in which the police and the courts should not be involved. However, society is now taking a hard look at just how serious a problem relationship violence is in the United States. In an effort to reduce domestic violence: laws have stiffened, police are changing how they handle domestic violence calls, and many states have mandatory prosecution for domestic violence cases. Changes in the judicial system to help victims and punish abusers have already begun; however, more insight and alterations need to occur in order for women and batterers to truly be helped.

Recent researchers have shed some sagaciousness into the limited successes of the newly implemented domestic violence laws such as mandatory arrests and prosecution as well as batterer counseling. While research has shown differing results and conclusions, an overwhelming number of researchers suggest that batterer intervention programs can be extremely successful if used properly. Through examining recent research on batterer counseling programs, numerous problems have been observed and several improvements have been suggested to make the Batterer Intervention Program a more beneficial program for both the batterer and the victim.

The Nature of the Low-Energy Excited State in Benzoyl-Substituted Ferrocenes

Michelle Borden
Dr. Charles Kutal, Department of Chemistry,
University of Georgia

Benzoyl-substituted ferrocenes have been shown to be active photoinitiators for the anionic polymerization of alkyl 2-cyanoacrylates. Irradiation into the low-energy electronic transition of these ferrocenes weakens metal-ring bonding and results in the efficient release of the cyclopentadienide anion in solvents such as methanol or acetonitrile. This process is shown below for dibenzoylferrocene (where 'S' is solvent). Previous work from this laboratory has shown that the lowest energy electronic transition in these compounds contains appreciable metal-to-ligand charge transfer character, and that this redistribution of charge is responsible for the metal-ring bond weakening. Present studies seek a better understanding of the nature of the photochemically active excited state in these compounds. The wavelength and temperature dependence of ring loss has been examined upon irradiation into the low-energy absorption band of dibenzoylferrocene. The results will allow us to decide whether (1) the initially populated Franck-Condon excited state is dissociative in nature, and therefore leads directly to ring loss in a prompt photochemical reaction, or (2) the Franck-Condon state relaxes to a thermally equilibrated excited state from which delayed reaction occurs.



Fabrication of Qubit States

Layne Bradley
Dr. Mike Geller, Department of Physics and Astronomy, University of Georgia

Quantum computing is a rapidly developing field due to the amazing goals that it hopes to achieve. As the theoretical work around the development of the first quantum computer continues to progress, scientists in the field continue to marvel at its possibilities in encryption, information processing, and pure scientific discovery in quantum mechanics. One of the most basic concepts involved in quantum computing is the very concept that provides for its potency – the qubit. While a regular bit of information in a classical computer can exist in only two possible distinct states, a quantum bit (or qubit) can theoretically exist in an infinite number of possible states. This capability would allow a quantum computer to accomplish many more tasks in a smaller amount of time than could be accomplished using a classical computer. In fact, this capability is so pronounced that a quantum computer could accomplish tasks that are, for practical purposes, impossible on a regular computer. The total possible qubit states can be visualized as points on a unit sphere. This sphere is known as the Bloch sphere and is a common idea throughout quantum computing. Implementing the idea of the Bloch sphere and given solutions to the Schrödinger, this project focuses principally on developing a method for producing any desired qubit state. Making use of computer simulations and theoretical calculations certain concepts behind the preparation of qubit states is considered. These reproducible qubit states could later be used within a quantum computer to perform various tasks and calculations.

Surface Plasmon Resonance from Aligned Ag Nanorod Structures

Layne Bradley
Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia

Surface Plasmon Resonance (SPR) has been proven to be a highly sensitive biosensing technique for biomolecular interaction and viral detections. SPR makes use of surface waves created in thin metal films by a laser. These waves are extremely sensitive to changes in the dielectric constant of the surrounding environment. However, practical application of SPR has been very limited outside of pure research. While the optical nature and accuracy of the SPR sensor would make it ideal for detection in a variety of environments, the effect of the SPR sensor has not been as pronounced as it possibly could be due, in part, to limitations in its functionality and in the understanding of some of its basic physical properties. In this presentation, ways of experimentally increasing the sensitivity of the SPR sensor using Ag nanorods are considered, and these experiments are compared to theory in order to help provide greater understanding of the system. Herein, the experimental evidence surrounding the nanorods' capability to increase the sensitivity of the sensor will be given along with the theoretical results. As the sensitivity of the sensor increases, its overall capability for detection and usefulness are increased, and thus an increased implementation in many practical fields extending outside the realm of pure research would be expected.

Mariska Karasz: Fashion, Folk Art, and Modern Design

Rebecca Brantley
Dr. Thomas Houser, School of Art, University of Georgia
Ms. Ashley Callahan, Georgia Museum of Art, University of Georgia

The artist and designer Mariska Karasz (American, b. Hungary-1960) began her career as a fashion designer in New York during the teens. After her arrival in New York in 1914, Karasz was educated under the renowned costume designer and teacher, Ethel Traphagen, and subsequently involved in the "Designed in America" program contests and events headed by fashion industry writer and leader, M.D.C. Crawford. Bringing to America knowledge of Hungarian folk art and part of an era of modern design that paralleled the interest in "primitivism" in the fine arts, Karasz's designs reveal a strong influence of her native Hungary. Research for this paper relies on Karasz's childhood and education in Hungary, where she

was exposed to traditional peasant costume and art, her involvement and education in American art and fashion industry programs, contemporaneous articles that mention her work, and Karasz's own records. As a participant in the "Designed in America" program, Karasz was well acquainted with the belief that designers should look to Central and East European folk art as well as Native American, Asian, and Middle-Eastern sources for inspiration. Crawford specifically mentions Hungary in his writing for Women's Wear and records in a later book that Stuart Culin, the curator of the Brooklyn Museum of Art, which opened its doors to designers including Karasz, collected and advocated East European folk art. A family historian reports that Karasz imported embroidery from Hungary, and a title for a design cites a Hungarian region known for its folk art, the Mezőkövesd. Magazines and periodicals mention Karasz and often emphasize her Hungarian sources of inspiration, one particular article citing a wrap inspired by the traditional Hungarian men's coat, the szűr. Specific designs and decorations parallel Hungarian sources, for example the appliqué and embroidery used on many of Karasz's designs looks similar to the freeform designs used by peasant women on kerchiefs, aprons, and sheets, yet modified and updated for the modern, American culture for which she designs. Karasz's beautiful and innovative early designs, which range from evening gowns to swimwear, are not merely examples of progressive fashion but are unique in their inspiration and creation, anticipating her lifelong work in fashion, textiles, and the arts.

Multivariate Harmonic Analysis

Josef Broder
Dr. Andrew Sornborger, Department of Mathematics, University of Georgia

Signal noise is a problem inherent to the measurement of biological systems. Microscopic fluorescence imaging produces data that is uninterpretable in its unprocessed state. Our goal is the development of techniques to extract statistically significant signals from such high-noise data sets.

We begin by recording imaging data of a specimen subject to a periodic stimulus. We use a two photon microscope to record fluorescence responses in two bands, NADH and FAD. We then search for a statistically significant harmonic response in each band, occurring at the same frequency as the stimulus. If the nature of the biological fluorescence suggests a simultaneous response in both the NADH and FAD band, we search for correlated harmonic signals in the data sets.

To search for harmonic content, we utilize the multitaper harmonic analysis techniques introduced by Thomson. This method allows us to compute the estimated amplitude and probability of harmonic content in univariate data at a given frequency. In the multivariate case, we use an extension of Thompson's technique introduced by Sornborger. To search for correlated harmonic content in either the univariate or multivariate case, we perform a harmonic analysis of the data in each band, and consider the product of the probabilities of harmonic content as a function of frequency. In practice, this technique has the desired effect of identifying a jointly significant signal, when the significance of the signal in either band is sub-threshold. This technique also tends to reduce the detection of spurious harmonic content.

Cadherin-Mediated Cell-Cell Adhesion Regulated By GnT-V Expression

Beau Bryan
Dr. Michael Pierce, Department of Biochemistry and Molecular Biology, University of Georgia

The Pierce laboratory focuses on a particular glycosyltransferase called GnT-V (N-acetylglucosaminyltransferase-V) which has been shown to be up-regulated during oncogenic transformation. With the modulation of cell-cell adhesion and migration as the result, this enzyme (progressively stimulated as cancer develops) adds a specific β(1-6)-glycan branch to N-linked glycans as they are processed in the Golgi, implicating the involvement of GnT-V with the metastatic effects of invasive cancer. This laboratory has shown that aberrant N-linked glycoprotein glycosylation due to GnT-V

and the β(1,6) branch modulates integrin cell-matrix adhesion and cadherin calcium-dependent cell-cell adhesion. N-cadherin ("neuronal" cadherin) and E-cadherin ("epithelial" cadherin) are cell-surface glycoproteins mediating homotypic cell-cell adhesion, and aberrant glycosylation of N- and E-cadherin affects levels of cell-cell adhesion, metastasis, and invasion. Several transfections of GnT-V into human cancer cell lines which I have shown to exclusively express E-cadherin have been attempted to study if similar modulation occurs. The cell lines are very difficult to transfect, and after an extended screening process we are now awaiting verification of GnT-V activity in the (putatively) stable-transfected cell lines. We will continue the E-cadherin project if such activity is present. In order to prove that changes in glycan expression at specific glycosylation sites on N-cadherin cause the phenomena we have observed, we have subcloned human N-cadherin cDNA into the pcDNA3.1(+) expression vector. Although further tests are underway, we did not detect N-cadherin protein expression after cellular transfection of this vector, and we therefore suspect problems intrinsic to the N-cadherin cDNA we originally received from an outside laboratory. We are currently troubleshooting the N-cadherin project and are examining possibilities for future research.

An Age Appropriate Method in Assessing Young Children's Emotional Competence

Amy Buffington, Erin Klosson, Jessica Zabell
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Emotional competency is linked to social competency, which serves as a gateway to understanding and preventing aggression. Individuals' emotional competency is currently measured in a variety of ways ranging from questionnaires, interviews, observations, and experiments. In studying emotions, Susanne Denham's puppet vignettes for interviewing preschoolers and school-aged children are the most common adopted method. The puppet vignettes are used to evaluate the child's ability in recognizing appropriate emotions given situational cues. In the present study, a part of the empathy research by Dr. Chiang, a different set of puppet vignettes are used in assessing preschoolers (age 3 and age 4). Due to limitations on young children's cognitive abilities and Denham's context specific scripts, the purpose of the present study is to design simplified interview scripts for younger children. We believe the revised scripts allow for easy randomization of the story sequence. In addition, the script was also rewritten to avoid portraying negative adult figures and to avoid suggesting negative behaviors to the children. Colorful and non-ethnic specific props and puppets were added to help maintain the child's attention. We believe that these adjustments allow for an age-appropriate assessment. In the study, 163 children (Age 3 = 78, boys = 39, girls = 36; Age 4 = 87, boys = 48, girls = 39) were assessed, 79.1% of the participants were African American and 17.2% were Caucasians. The results showed that children were able to match the appropriate emotions with the scripts. The age differences and their implications will be discussed.

Actin Depolymerizing Factor Regulates Key Growth Processes in *Arabidopsis*

Brunilís Burgos-Rivera
Richard B. Meagher, Department of Genetics, University of Georgia

Our laboratory studies the plant actin-based cytoskeleton in the model dicot plant *Arabidopsis thaliana*. The cytoskeleton controls dynamic processes both within cells and in plant development. One of the 16 families of actin binding proteins is comprised of actin depolymerizing factors (ADFs). ADFs modulate rates of actin polymerization and depolymerization by severing actin filaments and enhancing actin filament turnover. Higher plant genomes contain at least four ancient classes of ADF genes, which may be hundreds of millions of years diverged from common ancestral ADF sequences. These ADF genes are differentially expressed in various organs and tissues. To determine the functional role of two ADF genes in Arabidopsis, ADF4 and ADF9, adf4-1 and adf9-1 T-DNA insertional mutants were examined. The adf4-1 mutant plants had smaller organs at all stages of development.

This indicates that ADF4 functions in the regulation of organ size and/or growth rate. Analysis of the adf9-1 mutant plants showed delayed seed germination and many more branches than wild-type plants. This suggests that ADF9 is required for timing of germination and normal development of shoots. These initial genetic studies suggest that different ADF genes are involved in a variety of cellular and developmental processes in plants.

Ethics Law in Georgia: The Interested Parties and Implications of Proposed Reforms

Caroline Burns
Charles Bullock, Department of Political Science, University of Georgia

Ever since Republican Sonny Perdue became elected as Georgia's governor in November of 2002, he has pushed ethics reform as one of the most important items on his legislative agenda. Since that time, the governor's ethics bills have failed in the Georgia State Legislature. In turn, the governor has blamed various parties for the bill's failure, namely the special interest lobby and the Democratic Party. In 2005, the governor once again submitted an ethics bill with expectations for its passing. This is because 2005 marks the first Republican majority in the state House and Senate, a favorable circumstance for items on the governor's agenda. Additionally, as it is the mid-point of Perdue's as-yet uneventful term, he is under tremendous pressure to pass a piece of legislation to distinguish his tenure. Passage of an ethics bill could not only help the governor in this way but also give him a middle-ground issue to talk about in the 2006 gubernatorial campaign. This paper focuses on the various groups who have an interest at stake in the governor's ethics bill, the path of the previous failed ethics bills, and how the 2005 ethics bill could play a role in the 2006 gubernatorial race.

Three Dimensional Monte Carlo Simulation of Vapor Deposition Polymerization

Harry Galvin Butler IV
Dr. Yiping Zhao, Department of Physics and Astronomy, University of Georgia

Organic polymers have many applications, including organic electronics and biotechnology. Vapor deposition polymerization (VDP) is a technique used to create polymer thin films by controlled condensation of organic sources onto a subtrate. By creating an accurate simulated model of VDP with organic dimer molecules, we hope to understand the physical and chemical processes that affect growth, in order to better control the growth process and quality of polymer thin films. This paper analyzes the growth mechanism of VDP using a three-dimensional lattice Monte Carlo simulation. The polymerization model includes the deposition of organic monomers at random deposition angles, dimmer formation by two monomers through diffusion or deposition, and polymer chain propagation through monomer bulk diffusion. The simulational results will be compared to similar inorganic models as well as expiramental results of organic vapor deposition polymerizations.

Characterization of the Presence of Integrons and Gene Cassettes in *Salmonella* Isolates by Polymerase Chain Reaction Assays

Charya C. By
Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia

Bacterial resistance to an increasing number of antimicrobials is a well-established problem. Numerous mechanisms involving mobile genetic elements, such as transposons and plasmids, have been confirmed to contribute to the proliferation of this resistance. In recent years a unique group of DNA mobile elements able to confer antibiotic resistance genes by site-specific recombination have been identified in gram negative bacteria. These mobile elements have been termed integrons and gene cassettes. Integrons are genetic units that include genes of a site-specific recombination system capable of capturing and mobilizing genes contained in mobile elements called gene cassettes. Southern

blot using probes specific for the integrase genes *int1* and *int2* and polymerase chain reaction (PCR) assays using specific primers for the same genes were used to screen 198 *Salmonella* cattle isolates. Cattle isolates were used in this study as it is a part of a larger project that is examining the epidemiology of antibiotic resistance of cattle and livestock of various farms throughout the state of Georgia. *Salmonella* samples were isolated from fecal, water, and feed samples from five different farms from Georgia, the DNA of the *Salmonella* were isolated using a DNA extraction procedure and kit. The isolated *Salmonella* DNA were verified using 16S PCR and InvA PCR. 16S PCR determines the presence of DNA and InvA PCR determines the presence of *Salmonella*. Once the isolates were validated to contain *Salmonella*, *int1* and *int2* PCR were performed on each isolate. In isolates that were found positive to contain *int1* or *int2*, 53 PCRs were performed to determine the size of the integron. From the PCR assays, 41% of the isolates were *int1* positive and 5% were *int2* positive. The prevalence of *int1* in dairy cattle is relatively high, suggesting possible multiple drug resistance in the *Salmonella* by the mobile integrons that can carry resistance genes. Integrons have the capability to disseminate antimicrobial resistance genes, through gene cassettes, among bacteria associated with *Salmonella* in the gastrointestinal environment. By characterizing the integrons associated with pathogenic *Salmonella* we can later characterize and compare the integrons found, if any, in the commensal bacteria of the gastrointestinal environment in order to determine if they can serve as reservoirs for antimicrobial resistance.

Antimalarial Effects of Cysteine Protease Inhibitors in Preventing Plasmodium Sporozoite Invasion of Hepatocytes

Melissa Cabinian
Dr. Photini Sinnis, Department of Medical and Molecular Parasitology, New York University School of Medicine

Widespread drug resistance of malarial parasites has impeded the effective treatment and control of malaria worldwide. The development of novel antimalarial drugs is important to combat the global burden of malaria in the future. Enzymes essential to the parasite life cycle are promising new targets for drug development. Previous research has identified a papain-family cysteine protease as a potential drug target in Plasmodium sporozoites, the infective stage of the parasite. This protease cleaves the major surface protein, circumsporozoite protein, in a process essential to sporozoite invasion of the liver. Inactivation of this enzyme using cysteine protease inhibitors has been shown to prevent invasion and thus, malaria infection. In this study, the antimalarial effects of two cysteine protease inhibitors, K777 and allicin, were evaluated. K777 is an inhibitor specific to cruzain, a cysteine protease of *Trypanosoma cruzi*. Allicin, which is derived from garlic, is an inhibitor of a broad range of cysteine proteases. A double-staining immunofluorescence technique was used to determine if the compounds prevent sporozoites from invading hepatocytes in cell culture. Malaria infection in mice treated with an inhibitor prior to inoculation with sporozoites was quantified using reverse-transcription and real time PCR of parasite rRNA. Results showed K777 and allicin inhibit sporozoite invasion of hepatocytes in vitro. K777 appeared to have no antimalarial effects while allicin reduced the infectivity of sporozoites in treated mice. These results provide further support for the novel concept of using cysteine protease inhibitors as chemotherapeutic agents for the treatment of parasitic infections.

Identification of RNA Binding Proteins' Role in Gene Regulation in *T. cruzi*

Ben Cannon
Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia

Trypanosoma cruzi, the protozoan parasite that causes Chagas' Disease, is responsible for approximately 50,000 deaths each year. Currently, there is no effective treatment for *T. cruzi* infection. Evidence suggests that gene expression is regulated almost exclusively at the post-transcriptional level. RNA binding proteins (RBP's) are thought to play a major role in gene expression by stabilizing, or not, transcripts produced by polycistronic transcription. Unfortunately, very few RBP's have been

identified and studied for their roles in regulating gene expression. The Tarleton lab has been engaged in a high-throughput gene cloning project in order to screen *T. cruzi* genes as viable vaccine candidates. This project aims to further characterize probable RBP's encoded in the *T. cruzi* genome identified as containing RNA-recognition motif-type RNA-binding domains. The *T. cruzi* genome contains approximately 70 unique RBP's. Approximately half of these had been previously cloned in the Tarleton Lab. Most of the remaining half have since been cloned and a protein array for analysis of RNA-binding activity utilizing non-radioactively labeled RNA is being developed. The goal is to first verify RBP activity for as many of these gene products as possible, then to identify RBP's that bind transcripts from parasite lifecycle stages present in mammalian hosts. This information should increase our understanding of gene regulation in *T. cruzi* and highlight approaches to more effective, less severe treatments and vaccines for *T. cruzi* infection.

What is the True Cost per Minute When Using Prepaid Telephone Calling Cards?

Erendira Casas and Natalia Nicholls
Dr. Julia Marlowe, Department of Housing and Consumer Economics, The College of Family and Consumer Sciences, University of Georgia

Consumers complain about prepaid telephone cards. A research project was developed to investigate the true cost of the cards and information available from customer service. Because there is no regulation requiring disclosure information with prepaid phone cards in Georgia, consumers cannot easily find the real cost per minute.

The UGA President's Venture Fund provided funding to purchase prepaid telephone cards. Bilingual UGA students made international calls to Spanish-speaking countries. Students called the customer service number to ask questions about fees and then used the cards to call friends or family in Spain, Mexico, Peru, Colombia, Argentina, and Guatemala. Many customer service representatives did not know the information or could not give an exact answer to questions about fees.

The actual cost of the card was the price paid divided by the number of minutes the students were actually able to use. This figure was compared to the expected cost, which was calculated by dividing the price of the card by the number of minutes that the student was told he/she had when the card was first used. On average, the actual cost per minute was 87% higher than the expected cost per minute. This study confirms consumer complaints about prepaid phone telephone cards.

One implication of the research is that consumers need to be aware of hidden charges. Another implication is that consumer protection efforts could be implemented or strengthened. Government protection could mandate disclosure information so that consumers would know what fees are charged before they purchase the cards.

Analysis of Pax6a Expression Using a BAC Transgene

Anjali Chaudhari, Jorn Lakowski and Dr. James D. Lauderdale, Department of Cellular Biology, University of Georgia

The Pax6 gene encodes a paired-box transcriptional factor necessary for development of the eye, brain, spinal chord, and endocrine pancreas in vertebrates. In contrast with other mammals and birds, zebrafish have two Pax6 genes, designated Pax6a and Pax6b, which are thought to have originated as the result of a genome duplication in the fish lineage. In current models of genome evolution, duplicated gene pairs may be retained if (1) one member of a pair acquires a new function or (2) the regulatory elements of the ancestral genes are divided between the duplicates such that expression of both is required to perform ancestral gene function. We hypothesize that Pax6a and Pax6b have been retained in zebrafish through the latter mechanism. As a first test of this idea, our lab has taken a transgenic approach in which a Pax6a BAC (Bacterial Artificial Chromosome) containing the green fluorescent protein as a reporter was introduced into

zebrafish embryos using microinjection techniques. Microinjection involves injection of DNA into a recently fertilized egg with a capillary needle and then allowing the embryos to develop. To identify the fish with the transgene, I screen for EGFP fluorescence, which is then compared to endogenous Pax6a expression pattern. Transgenes that reproduce Pax6a expression pattern will be used in future experiments testing the function of further regulatory elements.

Creating Expressed Sequence Tags of Human Embryonic Stem Cells

Disha Chhabra
Dr. Lee Pratt, Department of Plant Biology, University of Georgia

The purpose of this project is to use Expressed Sequence Tag (EST) sequencing to amplify and identify expressed genes in embryonic stem cells. The genes were isolated from the MedII induced differentiation of the inner cell mass to an early neural progenitor cell type. EST sequencing is a process that allows expressed genes in particular tissues or cell types to be identified through the utilization of complementary DNA (cDNA) libraries. These cDNA libraries are compiled through the reverse transcription of mRNA derived from an organism's cells. The transcribed cDNA is ligated into a plasmid vector of known sequence. Numerous plasmids, all containing different cDNA sequences, are inserted into separate *Escherichia coli* cells, which are then allowed to replicate. The plasmids are isolated from the bacterial cells and purified in a three day process after which each cDNA is sequenced from the 3' and 5' ends. Next, the sequences are analyzed for quality. The qualifying sequences are submitted into a database to be compared with other identified sequences. In this project, 29 novel genes were identified and a total of 3,714 genes were sequenced. Once the expressed genes are identified, they can be studied for their protein expression and possible theraputic opportunities. The novel cDNA clones containing full length open reading frames will be submitted to the Mammalian Gene Collection. The cell extracts are provided to the National Cancer Institute (NCI).

Inhibition of Corticotropin-releasing Factor Receptors during Repeated Restraint Reduces Hyperresponsiveness to a Subsequent Stressor

Christina Chotiwat, Tiffany D. Mitchell, and Dr. Ruth Harris, Department of Foods and Nutrition, Medical College of Georgia

Acute stress induces many neurological and physiological changes including a long term increase in sensitivity to subsequent stress. This hypersensitivity is characterized by exaggerated release of the stress hormone, corticosterone. The neurotransmitter corticotropin-releasing factor (CRF) inititiates responses to stress through CRF receptors (CRFR) and the corticosterone response is believed to be primarily controlled by CRFR1. Previous studies have shown that rats exposed to 3 hours of restraint for 3 consecutive days exhibit an exaggerated corticosterone response to a subsequent novel mild stress. Therefore, we hypothesized that antagonism of CRFR immediately before restraint would block the elevated corticosterone response to the mild stress. Here we determined the effect of selective CRFR1 or non-selective CRFR1 and CRFR2 antagonism during restraint on corticosterone concentrations in rats subsequently exposed to the novel mild stress of an intraperitoneal saline injection and housing in a new room. Rats received third ventricle infusions of 5□g αhCRF-(9-41), a non-selective CRFR antagonist, or subcutaneous injection of 5mg/kg NBI 27914, a selective CRFR1 antagonist, immediately before restraint on each day of restraint. In response to the mild stress administered 12 days later, restrained rats treated with αhCRF exhibited a lower corticosterone response than restrained rats treated with vehicle while rats treated with NBI 27914 were not different from their vehicle-treated controls. These data show that CRFR1 are not primarily responsible for initiating the long-term, stress-induced increased sensitivity to mild stress.

The Role of Angiogenic Factors in Vessel Formation

Amy Chudgar
Dr. Brenda Lilly, Vascular Biology Center, Medical College of Georgia

Blood vessel formation or angiogenesis is a multi-step process that requires the precise orchestration of cell proliferation, migration, and communication. An important initial event in angiogenesis is the joining of endothelial cells into cord-like structures that ultimately form tubes containing an inner lumen, and a surrounding basement membrane. The signaling mechanisms through which endothelial cells coalesce into intact blood vessels are complex, and not completely understood. Therefore, the goal of the study was to further define the mechanisms that promote vessel formation by evaluating angiogenic factors that have been implicated in the assembly of blood vessels. A three-dimensional collagen gel assay system in which endothelial cells form intact vessel was employed, and by the addition or depletion of select molecules, the importance of angiogenic factors for the formation of blood vessels was assessed. The results indicate that the phorbol myristate acetate (PMA), an activator of protein kinase C (PKC), augments vessel formation, and further that vascular endothelial growth factor (VEGF) is sufficient for vessel assembly. The data also demonstrates that angiopoeitin-1 (Ang-1) enhances vessel formation. These studies demonstrate the dependence of endothelial cells on multiple signaling pathways for vessel formation and suggest that individual angiogenic factors have unique roles in angiogenesis.

Exploration and Manipulation of Objects and Surfaces by Common Chimpanzees (*Pan troglodytes*) and Capuchin Monkeys (*Cebus apella*)

Collin Closek and Sarah Kilgore
Dr. Dorothy Fragaszy, Department of Psychology, University of Georgia

Human infants modify their manual actions in accord with the physical properties of objects and/or surfaces they explore, and they use objects to explore surfaces. These characteristics of action are thought to support the development of tool use. Do nonhuman animals also tailor their actions to the properties of surfaces and objects they explore, and do they use objects to explore surfaces?

This study investigated exploratory activity in eight capuchin monkeys (*Cebus apella*) and four chimpanzees (*Pan troglodytes*), all adults. Our work investigated two hypotheses: both chimpanzees and capuchins will explore surfaces in accord with the differential properties of the cubes and they will display distinct differences in exploring actions. Testing involved presenting one of four surfaces (wood, sponge, water, and netting) and one of two cubes (sponge, wood) for one minute. We scored from digital video the individuals' behavior with surfaces and cubes, with special attention to actions combining the cubes with the surfaces, for example banging, rolling and pushing the cube on the experimental surface or elsewhere. Like human children, (a) both species contacted the surfaces using the objects (for example, placing the cube on the experimental surfaces, and tapping or rolling it across the surfaces), and (b) both species differentiated actions combining the cubes with different surfaces. Chimpanzees performed more actions overall and a greater variety of actions with the cube on the surfaces. The data suggest that both capuchins and chimpanzees spontaneously explore their world in ways supporting the development of goal-directed action with objects (i.e., tool use). Differences between the genera in exploration match known differences in manual behavior, including tool use, in wild individuals. Further comparative work can establish if these characteristics of action are more elaborated in genera that routinely use tools compared those that do not.

Blockade of Cannabinoid Receptors in the Basolateral Nucleaus of the Amygdala Suppresses Stress-Induced Analgesia

Katherine Connell, Dan Olsen, Nathan Bolton and Dr. Andrea G. Hohmann, Neuroscience and Behavior Program, University of Georgia

Exposure to stress activates neurotransmitter systems in the brain that serve naturally to suppress sensitivity to pain. This phenomenon,

termed stress-induced analgesia, refers to an absence of pain sensation without loss of consciousness induced by exposure to a stressor. The brain's own marijuana-like chemicals, the endocannabinoids, act in the nervous system to suppress pain. SR141716A, an antagonist for cannabinoid receptors, interferes with the physiological actions of naturally existing endocannabinoids in the brain by blocking cannabinoid CB1 receptors that are located in the central nervous system. The present study was conducted to evaluate the site of action of endocannabinoids, for mediating stress-induced analgesia. We tested the hypothesis that microinjection of the CB1 antagonist SR141716A into the basolateral nucleus of the amygdala (BLA), a brain region implicated in stress, would suppress the stress-induced analgesia. Stress-induced analgesia was invoked in male Sprague-Dawley rats by exposing them to inescapable electric foot shock for 3 minutes. Immediately after exposure to the stressor, the latency for rats to withdraw their tails from a radiant heat source was measured. Increases in tail-flick latency following exposure to the stressor indicate the appearance of stress-induced analgesia. We predicted that blockade of cannabinoid neurotransmission in the BLA following local injection of SR141716A would reduce stress-induced analgesia relative to control rats. Rats microinjected with SR141716A in the BLA showed marked reductions in stress-induced analgesia relative to the controls. This observation provides further evidence that endocannabinoids act at CB1 receptors in the BLA to mediate analgesic effects of stress. These findings can serve as a basis for further understanding the neurochemical pathways of the cannabinoid transmitter system.

Effects of Shared Environment during Development on The Adult Behavior of *Drosophila paulistorum*

Paul Courtwright
Dr. Yong-Kyu Kim and Dr. Wyatt Anderson,
Department of Genetics, University of Georgia

Many psychological literatures have shown the effect of shared environment during early childhood on the adolescence's behavior utilizing twin and adoption studies. Our previous work has demonstrated that early association and familiarity reduce sexual attraction between siblings who have been raised together during early lifetime and thus they avoid mating with each other. Subsequently, we have studied the effect of shared environment with non-siblings on adult *Drosophila* behavior following the adoption studies in humans. Using an isofemale line of *D. paulistorum*, single pairs of sexually mature virgin flies were individually placed in vials containing food and were transferred into new vials daily. To reduce any effect of density during early development on the mating behavior of adults, 20 eggs were collected and placed in each vial. All siblings in the same vials from the same mothers were named Sibling Raised Together Communally (SRTC). One offspring from each of the different mothers was collected and raised together with other offspring, which were termed Nonsibling Raised Together Communally (NSRTC). These NSRTC flies were again regrouped into 6 treatments (NSRTC1, NSRTC2, NSRTC3, NSRTC4, NSRTC5, NSRTC6) depending on each of the six developmental stages at which they began having contact with nonsiblings. Then we observed the effect of this early association with nonsiblings on mating behavior at the adult stage. Pairs of 5-9 day old NSRTC flies were individually introduced into mating chambers. Observation continued for 10 min or until mating occurred. Courtship latency, courtship duration, and copulation duration were recorded and courtship index (CI) was measured. My current data show that there was no correlation between the lengths of contact with nonsiblings during development and courtship indices; the effect of early association with siblings before adoption was stronger than that of non-siblings.

Maintenance of Antigen-Specific CD8+ Memory T Lymphocytes in Experimental *Trypanosoma cruzi* Infection

Matthew T. Crim
Rick L. Tarleton, Department of Cellular Biology, University of Georgia
Diana L. Martin, Center for Tropical and Emerging Global Diseases, University of Georgia

Trypanosoma cruzi is the causative agent of Chagas disease, a condition affecting 16 to 18 million people and causing 50,000 deaths each year in Central and South America. A mouse model mimics human infection, as parasite persistence in muscle tissue is common in both mice and humans. Studies in gene-knockout mice have demonstrated the importance of CD8+ T lymphocytes in the concerted immune response to combat infection. CD8+ T cells respond to pathogen-derived peptides presented by the major histocompatibility complex (MHC) I. Previous studies reveal that one of these peptides, altered peptide ligand (APL) 20 (ANYKFTLV), is a target of CD8+ T cells during *T. cruzi* infection. Clonal expansion of antigen-specific CD8+ T cells in response to a foreign antigen is followed by the apoptosis of most of the population, but a small portion survives as memory cells. B-cell Lymphoma - 2 (Bcl-2) is an anti-apoptotic integral membrane protein localized in the outer mitochondrial membrane that prevents caspase activation. Up-regulation of Bcl-2 is linked to the survival and maintenance of antigen-specific CD8+ T cells. The importance of this mechanism in experimental *T. cruzi* infection is being examined by flow cytometric analysis of fluorescence-conjugated antibodies. It is expected that Bcl-2 will be up-regulated in APL20-specific CD8+ T cells. In order to examine the homeostatic proliferation kinetics of antigen-specific CD8+ T cells, the incorporation of bromodeoxyuridine (BrdU), a thymidine analogue, during the synthesis phase is also being examined by flow cytometric analysis.

The Role of Autophagy in Neurodegenerative Disease

Caelin Cubenas, Dong-Hwan Kim, Dr. Ruth Furukawa, Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia

Brain autopsy specimens from patients with neurodegenerative diseases contain hallmark pathological inclusions characteristic of each disease. A few examples of inclusions are Lewy bodies in Parkinson's disease, tau tangles and amyloid plaques in Alzheimer's disease, and Hirano bodies in numerous diseases. The physiological role and mechanism of toxicity of these inclusions is controversial and not fully understood. Previous studies as well as preliminary data from the slime mold *Dictyostelium discoideum* indicate that large inclusions can be cleared from cells by autophagy. Autophagy is a cellular pathway used to degrade large organelles that are damaged during aging or to recycle nutrients during starvation. This study will determine if autophagy plays a role in the degradation of model Hirano bodies in HR131 cells, which are *Dictyostelium* lacking an essential autophagy gene. Model Hirano bodies are cytoplasmic inclusions of paracrystalline actin arrays formed in vitro by expression of mutated forms of the 34 kDa actin bundling protein. Expression of the mutated and wild type 34 kDa protein fused to the enhanced green fluorescence protein will be controlled by folate. A fluorescence assay will be used to measure the rate of degradation of Hirano bodies. If autophagy is found to be essential to the degradation of these cytoplasmic inclusions, then pharmacological agents that stimulate autophagy may be developed in future studies as novel treatments for patients with neurodegenerative diseases.

The Effect of Different Bifunctional Linkers on Biological Activity of Functionalized Silicon Nanorods for Glucose Sensors

Sita Damaraju
Dr. William S. Kisaalita, Department of Biological and Agricultural Engineering, University of Georgia

There is a need for sensors to continuously monitor blood glucose for diabetic patients.

Such glucose sensors should be robust and stable in sensitive environment, i.e., inside the body. Nanotechnology is being used to develop implantable glucose sensors. Silicon nanorods were fabricated by the electron beam technique of glancing angle deposition (GLAD). These structures were then activated by linking enzyme to the nanorod surfaces. The effect of using different chemical linkers in the activation process was investigated. The enzyme, glucose oxidase (GOD), was used and assayed by absorbance at 450nm based on a series of reactions involving the oxidation of o-dianisidine. Four different chemical linkers were used: glutaraldehyde, 1% Polymaleic anhydride (PMA) solution in toluene, 5% Polymaleic anhydride (PMA) solution in acetone, and N-5-Azido-2-nitrobenzoyloxysuccinimide (ANB-NOS). The process with each linker was repeated six times. Based on these results, glutaraldehyde was 6-20 times better than the other linkers.

A Comparison Among Three Methods to Detect Newcastle Disease Virus in Formalin-fixed, Paraffin-embedded Tissues

Taylor Deal
Dr. Corrie Brown, Department of Veterinary Pathology, University of Georgia

Newcastle disease, caused by infection of Newcastle disease virus (NDV), is one of the most important avian diseases because of its economic impact on the poultry industry. The clinicopathologic lesions of this disease are varied and are no specific. Thus, immunohistochemistry (IHC) and in situ hybridization (ISH) have been used to detect viral infection in formalin-fixed, paraffin-embedded tissues. As an additional method, we developed the method of reverse transcription polymerase chain reaction (RT-PCR) of the matrix gene (232-bp) with formalin-fixed, paraffin-embedded tissues, and the sensitivity was compared to those of IHC for viral nucleoprotein and ISH for the matrix gene (850-bp). The tissues (spleen and lung) were collected from 4-week-old chickens experimentally infected with two NDV isolates, an avirulent virus (LaSota) and a virulent virus (from a 2002-2003 California outbreak). For RT-PCR, RNA was obtained from these tissues by digestion with proteinase K and subsequent extraction with phenol, chloroform, and isoamyl alcohol. The IHC and ISH were performed on 3-µm paraffin-embedded tissue sections. The RT-PCR with formalin-fixed, paraffin-embedded tissues was found to be an effective and sensitive method to detect NDV. All samples from infected chickens were positive by RT-PCR, including samples which were negative by both IHC and ISH. Therefore, RT-PCR is also a possible method to be utilized to do retrospective diagnosis of Newcastle disease in fixed tissues as well as IHC and ISH.

Establishing Mammalian Cell Lines that Modulate O-linked N-Acetylglucosamine, O-GlcNAc, levels to Characterize Its Role in Apoptosis and Insulin Action

Anjan Deka
Dr. Lance Wells, Complex Carbohydrate Research Center, University of Georgia

The post-translational modification of proteins with beta-O-linked N-acetylglucosamine, O-GlcNAc, occurs on many nucleocytoplasmic proteins, including transcription factors, hormone receptors, and viral proteins. The enzymes for the addition and removal of O-GlcNAc are O-GlcNAc transferase, OGT, and O-GlcNAcase. O-GlcNAcase is cleaved into its N-terminus and C-terminus by the enzyme Caspase-3, an executioner protease in apoptosis. Apoptosis, or automated cell death, has proven to be especially important in Type II diabetes and cancer. Recent research has shown that O-GlcNAcase remains active in its removal of O-GlcNAc following cleavage by Caspase-3. In addition, previous research has shown that the active site of O-GlcNAcase in its removal of O-GlcNAc lies in the N-terminus. With this information, the goal of the research project was to more carefully characterize the activity of O-GlcNAcase in mammalian cell lines. Bacterial transformation, nickel-column purification, and activity assays were used to verify the expression and activity in the N-terminus. Vector transformations were used to make the N-terminus available for transfer into mammalian cell lines. Transiently transfected cell lines are currently being tested for

sensitivity to apoptotic stimuli, the levels of O-GlcNAc, and insulin sensitivity. We predict that overexpression of O-GlcNAcase will lower O-GlcNAc levels and protect cells from apoptotic stimuli and the induction of insulin resistance. This work will aid in the fight against cancer and Type II Diabetes.

Microarray and qRT-PCR Analysis of Gene Expression in CD8+ T Cells from *T.cruzi* Infected Mice

Amanda L. Dempsey
Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia

Trypanosoma cruzi, the agent of Chagas disease is estimated to infect 16 to 18 million people resulting in an estimated 50,000 deaths yearly. The infection is generally chronic in nature with parasite persistence. Functional CD8+ T cells produce the cytokine interferon gamma (IFNg), which is crucial for parasite control. However CD8+ T cells isolated from muscle of *T. cruzi*-infected mice are hyporesponsive for IFNg production compared to T cells from the spleen. It is hypothesized that changes in gene expression are directly related to "muscle" T cell hyporesponsiveness. Our aims were to (I) assess expression of genes with known immunological importance in splenic and muscle derived CD8+ T cells from infected mice and (II) compare the kinetics of gene regulation in T cells from spleen and muscle following in vitro stimulation. Microarray analysis of total RNA from unstimulated splenic and muscle derived CD8+ T cells of naïve, acute and chronically infected mice was conducted using an array of 500 mouse genes. These data were then clustered to create an in vivo time course gene regulation profile. Likewise, microarray analysis was performed using RNAs from in vitro stimulated (0hr, 4hr, 16hr) splenic and muscle CD8+ T cells from chronically infected mice. Genes upregulated in muscle T cells compared to splenic T cells include Fas-ligand, granzyme-B and interferon-beta, which suggests possible roles for these genes in muscle T cell hyporesponsiveness. The regulation of selected genes identified by microarray analysis is currently being evaluated by quantifiable real time PCR.

The Artist in Cuba

Lauren Domenick
Dr. Dana Bultman, Department of Romance Languages, University of Georgia
Prof. Judy McWillie, Lamar Dodd School of Art, University of Georgia

Having traveled to Cuba through the UGA program in Visual Arts, I was struck by the inviting nature of the people and their amazing ability to absolve an American of the sins that he or she is inherently tied to by the acts of his or her government. I traveled to learn about a people and a culture that stunned me with warmth and optimism despite Cuba's physically decaying and ideologically stagnant state. It is the Cuban sense of resilience and determination and pride that has preserved and upheld the integrity of the nation and it is this integrity that I wish to communicate to people here in the United States. After having spent time in Cuba and researched its political and artistic history, I wish to maintain a correspondence and ongoing dialogue with artists in Cuba through sources that are available to them, to which the extent may be letter writing and telephone conversation, if feasible. I am going to use my research to create a new pathway that allows the exchange of ideas between citizens of the United States and Cuba, with sensitivity to the fissures in the political relationship of our two nations that stigmatize and jeopardize an intellectual and artistic relationship. I am going to foster this dialogue through conversation with Cuban artists inside and outside of their country that explores the daily concerns of Cuban people and that will ultimately result in a sculptural artifact of my creation that expresses the Cuban people to Americans in humanistic terms rather than in political terms.

Alternatively Spliced Transcripts of Matrix Metalloproteinase-2 in Ovarian Cancer Cells.

John DuVal, Susanne Warrenfeltz, Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

In a tightly regulated process, ovarian matrix metalloproteinase-2 (MMP2) is activated during ovulation by gonadotropins. Under normal conditions, proteolytic degradation of the

basement membrane during ovulation allows release of the mature oocyte to be freed from the basement membrane allowing its migration. However, over expression of MMP2 has a positive correlation with the development and progression of cancer. Since differences in the distribution of splice variants between pre-neoplastic and ovarian cancer cells may represent a molecular marker for ovarian cancer or an element of the mechanism for transformation from a pre-neoplastic cell to a cancerous cell. The goal of this project is to identify and characterize alternate transcripts of MMP2 in pre-neoplastic and transformed ovarian cancer cells. Alternatively spliced transcripts of MMP2 are being identified through Reverse Transcriptase Polymerase Chain Reaction, a process which allows for amplification of specific genetic sequences, from three ovarian cell lines: pre-neoplastic (IOSE-398) and two ovarian cancer cell lines (SKOV3 and OVCAR3). Specific transcripts will be amplified by designing primers which only bind to splice junctions allowing a search for all single exon deleted variants in the three cell lines allowing for confirmation of MMP2's presence in ovarian cancer and possible transcripts which may be present in certain cancers.

Laplace Force During Wetting of Vertically Aligned Nanorod Array

Dustin Dyer
Dr. Guigen Zhang, Department of Agricultural and Biological Engineering, University of Georgia

Vertically aligned nanorods have been incorporated into biosensors to increase the sensors' sensitivity since the increased surface area due to the nanorods provides additional active surface to secure the target molecules. Higher sensitivity is desirable because it increases precision and allows the detection of smaller concentrations. This technology can be applied to improve the effectiveness of existing biosensors such as those used in environmental, healthcare, and antiterrorism applications. Vertically aligned silicon nanorods created by vapor deposition have shown widespread deformation upon exposure to a water droplet. This presents a problem since many biosensors would likely be used in aqueous mediums. Such deformation is due to Laplace capillary forces caused by the nanorod-water interaction during the spreading of water through the nanorods. This study attempts to quantify the maximum amount of force water places on the nanorods by performing a series of Finite Element Analyses (FEA) using a beam model of an individual nanorod. Each analysis places a horizontal load at a different point along the vertical axis of the nanorod model. This load is increased in magnitude until the model reaches yielding. The maximum force and horizontal displacement at yielding was tabulated for each location. This displacement data was then compared with the observed residual deformations of the nanorods. With this information, we determine that the maximum amount of capillary force created by the water silicon-nanorod interaction is approximately 50 nN. This knowledge can be used to create mechanically stronger nanorods which should be designed to withstand at least this amount of force.

Undergraduate Psychology Majors: Perceptions and Initial Interests

Matthew Evans
Catherine L. Packer, Joy K. Harden, Deryl F. Bailey, Catherine Callender, and LaKeisha S. Gantt, Dr. Rosemary E. Phelps, Department of Counseling and Human Development Services, University of Georgia

On many college and university campuses, psychology is a high demand and popular undergraduate major. There is limited information available on how undergraduate psychology majors initially acquire information about psychology or what factors contribute to their career decision-making process. Findings can provide important information in helping psychology faculty better understand the needs and career concerns of undergraduate psychology majors. This study examined (a) how undergraduate psychology students develop an interest in psychology as a major, (b) how their perceptions of psychology change, (c) how they identify with the psychology profession, and (d) what are their career aspirations. The study sought to determine whether differences

would be found based on type of institution (i.e., liberal arts institution; doctoral-degree granting research institution).

Ninety-eight full-time undergraduate psychology majors at two state-supported, southeastern institutions participated in this study. Participants completed a demographic questionnaire, the Undergraduate Majors Questionnaire, and the Myers-Briggs Type Indicator – Form M.

Several significant findings based on type of institution were found. When undergraduate psychology majors first became interested in psychology, the extent to which participants' views and understanding of psychology changed, and plans to pursue a career in psychology differed based on type of institution. Students attending the liberal arts university became interested in psychology during their first two years of college, their views of psychology changed a great deal while in college, and more of them planned to pursue a career in psychology. On the other hand, participants at the research university first became interested in psychology in junior high school, their views changed only somewhat in college, and more of them were uncertain about pursuing a career in psychology at this time.

Expression of *Magnaporthe grisea* Extracellular Proteins in a Modified *Pichia pastoris* Expression System

Linda Fernekes
Dr. Sheng-Cheng Wu, Complex Carbohydrate Research Center, University of Georgia

Magnaporthe grisea is the causal fungal agent of rice blast disease responsible for the annual loss of 200 million tons of rice output worldwide. Under various growth conditions, *M. grisea* secretes a large number of extracellular proteins (ECPs), presumably required for growth, development, pathogenicity, maceration of host cell walls, and molecular signaling. A number of genes encoding ECPs have been previously identified using proteomics and bioinformatics technologies. In order to dissect their biochemical and biological functions, sufficient amount of pure ECPs will have to be obtained. This research established a modified procedure for expressing ECP-Myc-(His)6 fusion proteins in the heterologous yeast-like organism, *Pichia pastoris*. Gene fragments encoding six secretive xylan-degrading enzymes and two ECPs of unknown function were amplified by PCR and cloned into an expression vector, pPicH. Then, the constructs were transformed into *Pichia* cells, resulting in expression and secretion of at least three ECP fusion proteins in the culture media. Enzyme assays, gel electrophoresis and immuno-blotting analysis were used to confirm the authenticity of the expressed proteins. Finally, the expressed proteins are being purified from the culture filtrate by affinity chromatography using a nickel-containing resin column.

Production of Antibodies to Erythrocyte Invasion Proteins of *Plasmodium falciparum* and Their Use to Investigate Erythrocyte Invasion

Edmund Fomunung
Dr. David Peterson, Department of Medical Microbiology and Parasitology, University of Georgia

With the increasing number of deaths and growing resistance of the malaria-causing parasite to the available drugs, there has been a steady increase in research aimed at understanding this parasite. The goal of this research is to study certain proteins, in the Ebl 1 family, which are believed to be crucial for the invasion of red blood cells by this parasite. The expression of these erythrocyte-binding proteins will be studied in different parasite isolates. This will require the development of antibody reagents to detect these proteins. To that end, portions of specific proteins, JESEBL, EBA 175, BAEBL and EBL1, will be expressed in *E. coli*. The approach used is to clone the genes into the vector pGEX to provide for inducible expression and a means to affinity purify the expressed proteins. PGEX is a Glutathione S Transferase(GST) fusion protein system wherein genes are cloned into the vector to provide for high level protein expression in the *E. coli*. The GST fusion proteins can then be affinity purified on glutathione sepharose, which has a high affinity for GST. pGEX recombinants are

currently being screened on both a small scale- to verify protein production- and large scale-to obtain significant quantities of purified protein. In the future, these purified proteins will be used to produce antibodies for analysis of the expression of the erythrocyte-binding proteins. One such analysis includes using antibodies to determine the location of these proteins on merozoites. The location can help determine the precise roles of these proteins in erythrocyte invasion.

Gender Differences in 360-degree Feedback Related to Leader Effectiveness

Kate Fuller, Lauren Killion, and Liz Scharlau
Dr. Karl Kuhnert, Department of Psychology, University of Georgia

Leadership in the workplace is a key focus in industrial/organizational psychology. In this study, we examined differences in leadership styles across genders to identify differences between male and female business leaders. To compare effectiveness across gender, we used data collected from over 100 executives. The data collection method was 360-degree feedback with additions including self-report, customer ratings, and other ratings of the executive. We studied gender differences across individual leadership qualities, divided into eight leadership categories. Previous research found correlations between gender-stereotypical leadership styles and leadership effectiveness, but did not look at specific leadership qualities. We predicted women to surpass men on qualities related to participative leadership, including catalyzing teams, cultivating and retaining talent, and contextual grounding. Furthermore, we predicted men to excel on measures related to directive leadership, including managing performance, leading change, and creating a compelling vision. The goal of this research is to explain the gender differences in leader effectiveness ratings and to find ways to maximize leader effectiveness in the workplace for both genders. Additionally, findings from the research will help promote gender equality at work.

The Substrate Specificity of Rce1p

Tiffany Gartrell
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

The Rce1 protein is a membrane bound protein located in the endoplasmic reticulum. It plays a crucial role as a protease in the formation of mature Caax proteins such as yeast a-factor and mammalian Ras. These two proteins are important in cell signaling processes. The Caax motif consists of a cysteine, two aliphatic amino acids, and the last amino acid can be any amino acid. Proteins terminating in a Caax motif are modified at their carboxyl-termini in a sequential three-step process consisting of isoprenylation (farnesylation or geranylgeranylation), proteolysis, and carboxylmethylation. Rce1p along with the protease Ste24 (Afc1) specifically cleaves the aax portion of the a-factor Caax motif (CVIA). Further modification of Caax proteins leads to mature a-factor and Ras. Ras is an oncogene, and an important protein in cancer research. Mutations in the Ras gene, may cause the protein to loose its GTPase activity which leads to Ras being constantly in its active state. With a constantly active Ras, cell growth is uncontrolled which can lead to cancerous cells. The only inhibitors designed to block Ras maturation prevents the farnesylation of Ras. The negative side of these inhibitors, is that the Ras protein is not the only Caax protein inhibited from farnesylation. There might be other important Caax proteins that are being affected by these inhibitors. The inhibitors lack substrate specificity, and this is where the knowledge of Rce1p substrate specificity may be important. Ste24p and Rce1p are proposed to cleave distinct populations of Caax proteins. For example, Ras is exclusively cleaved by Rce1p. If all the substrates of Rce1p were known, then the potential side effect of Rce1p inhibitors could be evaluated. In this study two approaches were taken to determine the possible substrate specificity of Rce1p. The first approach used an anti-farnesylated cysteine antibody. Yeast a-factor from *Saccharomyces cerevisiae*, was used to analyze the farnesylated cysteine antibody. The antibody was suppose to

recognize methylated and unmethylated Caax proteins, and should not recognize unmodified Caax proteins. Consequently in a yeast strain that only has Rce1p, it should be able to recognize the various substrates that Rce1p was able to cleave. This part of the study was inconclusive, because the antibody was not specific to only Caax proteins. In the second approach the goal was to purify possible substrates of Rce1p. A group of Caax proteins were identified and recovered from a collection of GST fusion protein strains. All of the genes of yeast are known and a library of GST fusions was created that contained all of the yeast genes fused in frame to the C terminus of GST . The importance of using GST fusion proteins is that GST is a tag on the proteins that can be detected by anti-GST Western. The proteins were analyzed by SDS-Page and anti-GST Western to determine if the protein were produced and of the correct molecular size, before proceeding with purification This study was also inconclusive, because most of the GST-fusion proteins used in the study were either not detected or not of the correct molecular size.

Student Attitudes Concerning Abortion

Mary Gassama
Dr. James Bason, Survey Research Center,
University of Georgia

Young people have traditionally been considered apathetic concerning political participation. During the 2004 election year, there was much anticipation that most young people would vote due to the Vote or Die campaign sponsored by P. Diddy and other notable stars. However, although the number of young people who did vote increased, it was much less than the expected number. Despite low levels of political participation by the young, the young may still exhibit saliency towards other political issues. This research will examine attitudes of the young toward a more volatile issue, the abortion issue.

Data utilized in the study were collected from a random sample of 410 University of Georgia students who participated in a web based survey during November of 2004. Participants in the study voluntarily responded to a 40 items survey via an email invitation to participate in the study. Estimates from a sample of this size are subject to a sampling of error of +/- 5.0% at the 95 percent confidence interval. The response rate for the survey was 21.0%.

I hypothesized, based on a general level of apathy among the young, that University of Georgia students will not hold intense views on the abortion issue. However, I do expect both political affiliation and gender to be related to attitudes towards abortion. Contrary to my hypothesis, however, the results of the survey indicate that most students do have opinions about abortion. The data collected shows that there is a statistically significant relationship between political affiliation and attitudes towards abortion. However, no significant differences in attitude toward abortion were observed with regard to gender.

Economic Freedom and Its Impact on Standard of Living

Lindsey Giffin
Dr. David Mustard, Department of Economics,
University of Georgia

Economic freedom is a measure of the ability to conduct commerce in a free market environment under the protection of secure property rights and with minimal government interference. An abundance of research has shown that economic freedom increases economic growth. These studies have two primary limitations. First, they provide little information about how economic freedom affects a broader array of standard-of-living measures. Second, most studies examine only the static differences across countries with varying degrees of economic freedom. This study contributes to the literature by addressing each of these concerns. This paper examines the effects of changes in economic freedom, as measured by the Fraser Institute's Economic Freedom of the World Report, on a variety of standard of living variables, as measured by the World Bank's World Development Indicator. To identify these effects I used multivariate regression analysis that controls for other factors that could influence my outcome variables. The data are from a repeated cross section of nations between 1980 and 2001, a 21-year period when

many nations were undergoing fundamental changes in the extent to which they permitted economic freedom. Findings indicate that, in general, countries that increased economic freedom also experienced an increased standard of living. As globalization has increased the potential for development in many nations, economically free institutions are essential for taking advantage of this opportunity to improve the lives of citizens of developing countries.

Ethnomusicology and the Theory of Race: A Brazilian Case Study

Daniel Gough
Dr. Jean Kidula, School of Music, University of Georgia

The history of the concept of race within the theoretical framework of ethnomusicology is, at the very least, incredibly complex. However, until the last several decades, the role of race in ethnomusicology was not seriously examined. Taking cues from such areas as black cultural and literary criticism, ethnomusicologists now debate the validity of the use of Enlightenment reason, Afro-centrism, and a host of other viewpoints in the analysis of race in music. Nonetheless, much of the scholarship dealing with race and music has focused its attention on blacks in Africa, North America, and the Caribbean. Interestingly, the world-renowned Afro-Brazilian music scene in Salvador, Brazil (a nation that holds a very important place in the discussion of race in other social sciences), has been notably absent from these theoretical conversations. This paper will examine the intellectual history of the issue of race within the field of musicology as well as contemporary Afro-Brazilian music making in Salvador. By discussing how current theories of race can be applied to today's music making in Salvador, I hope to demonstrate the location of Afro-Brazilian musical experience in relation to this extant theoretical framework.

The Effect of the North American Beaver (*Castor canadensis*) on Riparian Vegetation along Sub-Antarctic Forested Streams in the Tierra del Fuego/Cape Horn Region of Chile

Clayton R. Griffith, Christopher B. Anderson, and Dr. Amy D. Rosemond, Institute of Ecology, University of Georgia

The North American beaver (*Castor canadensis*) was introduced to Navarino Island, Chile in the 1960s, where they have been changing the structure and succession of the riparian, or bank side, vegetation community. We assessed these changes due to their importance in managing beaver effects on the remote and pristine sub-Antarctic forests of southern Chile. To quantify beaver effects on non-native, species-poor riparian vegetation, two sites (a beaver meadow and a natural forest reach) at four different streams were compared, measuring canopy cover, basal area, understory woody and herbaceous vegetation richness, and forest regeneration. Measurements for herbaceous plants were taken using twenty 0.5 m2 plots per reach and recording coverage and assemblage. In addition, ten 50 by 1m transects were set perpendicular to the stream to quantify woody plant characteristics. Beaver significantly reduced canopy cover and basal area in the beaver meadow sites (Tukey-Kramer $p<0.05$ up to 30 m). Moreover, herbaceous vegetation richness was greater in beaver meadow sites than natural sites ($p<0.0001$) and was also associated with an increase in exotic species. Understory woody vegetation in beaver meadows showed an increasing trend in richness and percent coverage when compared to natural forests, but it was not statistically significant. Regeneration of the two dominant *Nothofagus* trees was significantly reduced in the beaver meadow sites ($p<0.0001$), but *N.antarctica* actually increased ($p<0.0001$). Overall, beavers modified the ecosystem from a closed forest to an open meadow facilitating the disturbing effect of enabling a road of exotic plant species into the interior of the island.

Adolescent Vulnerability to Nicotine Addiction: a Biological Basis

Christopher Hale
Dr. Thomas F. Murray, Department of Physiology and Pharmacology, University of Georgia

Adolescence is a period of high vulnerability to nicotine addiction. This study uses an animal model of cigarette smoke inhalation to study the differences between adult and juvenile nicotine exposure. Previous studies employing infusion models of nicotine exposure suggest that the neural effects of nicotine exposure in juvenile rats are distinct from those seen in mature rats. Specifically, nicotinic acetylcholine receptor (nAChR) upregulation appears to be greater in juveniles than adults. However, infusion studies are not a realistic model of the fluctuating blood nicotine levels resulting from periodic smoking. In this study, sections were made from control, exposed, and post-exposed adult and juvenile rat brains. The magnitude of nAChR upregulation was assessed using [^{125}I]epibatidine receptor autoradiography. Cerebral cortical nAChR upregulation was not significantly different between juvenile and adult brains. However, the magnitude of nAChR upregulation in the nucleus accumbens (*N. accumbens*) was greater in the juvenile than in the adult brains. The $\alpha4\beta2$ nAChR subtype is particularly susceptible to nicotine induced upregulation, and the greater upregulation of [^{125}I]epibatidine labeled receptors in juveniles seen in this study could be due an enhanced adaptive responsiveness of the $\alpha4\beta2$ nAChR in the juvenile N. accumbens. The upregulation of presynaptic nAChRs due to nicotine exposure could lead to increased dopamine release in the *N. accumbens*. Increased dopamine release in the *N. accumbens* is one process that has been implicated in addiction. The greater magnitude of nicotine-induced nAChR upregulation in the juvenile *N. accumbens* observed in this study could be a biological mechanism underlying juvenile susceptibility to nicotine addiction.

Gas Phase Synthesis and Time of Flight Mass Analysis of Novel Semiconductor Clusters Containing Sulfur and Group Thirteen Metals

Phillip Benson Ham III
Dr. Michael A. Duncan, Department of Chemistry, University of Georgia

Semiconductor materials are integral to the electronics industry. The dimensions in microelectronic circuits have been shrinking systematically by a factor of two every six years. Extrapolating just to the year 2012 suggests future transistor widths of 35 nm, the size of a few atoms. Therefore, as these circuits continue to become smaller and more efficient, new materials are needed. Semiconductor clusters of gas-phase sulfur and group thirteen elements were produced and analyzed using a linear time of flight mass spectrometer. This was achieved by mixing metal powders, metal salts, or other materials with sulfur and covaporizing and ionizing the mixture with a laser that emits green light at 532 nm. The laser desorbs the mixture and electric fields accelerate the clusters through the time of flight chamber. The mass spectra obtained reveal that certain gas phase clusters form and are stable when they satisfy condensed phase electron counting rules. In particular, specific semiconductor sulfur clusters exist isoelectronic to forms dictated by Wade's electron counting rules. Also, the most stable clusters formed contained an even number of valence electrons, meaning that no radical clusters were present in high concentration. This gas phase correspondence in stability to condensed phase studies suggests that well-developed structure and bonding ideas can be applicable for understanding the stability and structure of gas phase semiconductor clusters.

Antibody Depletion of Highly-abundant Proteins in *T. cruzi* for Fine-tuning of Proteomic Analysis

Matthew Haney
Dr. Rick Tarleton, Center for Tropical and Emerging Global Diseases, University of Georgia

Chagas' disease, caused by the protozoan parasite *Trypanosoma cruzi*, is the world's

leading cause of congestive heart failure and a common cause of death in South America where 18 million people are infected and 90 million risk infection. Current treatments for *T. cruzi* are inadequate, and better understanding of parasite morphology could potentiate future treatments. Shotgun proteome analysis using liquid chromatography and tandem mass spectrometry has identified nearly 3,000 *T. cruzi* proteins from the four major life-cycle stages (Atwood et al, submitted). Unfortunately, nearly 50% of all mass spectra collected map to only 8% of the identified proteins. Therefore a limited number of high-abundance proteins are masking detection of low-abundance proteins. The goal then was to generate protein-specific antibodies that could bind to and remove the 67 high-abundance proteins, thus exposing low-abundance proteins to mass-spectrometric identification. Previous lab efforts have successfully cloned 54 of the 67 proteins. Cloning of the 13 remaining genes was thus undertaken utilizing PCR amplification and the Invitrogen Gateway® technology. Antibodies subsequently produced to these top 67 proteins in mice will then be used to deplete these high-abundance proteins from crude *T. cruzi* cell extracts from various life-cycle stages before mass-spectrometric analysis. The proteins identified by high-throughput proteomic analysis will verify *T. cruzi* gene annotations, identify new potential vaccine candidates, and further basic understanding of *T. cruzi* biology, hopefully leading to new and more effective treatments.

Implications of Unique Mineral Assemblages Associated With Subterranean Coal Fires

Matthew Hastings
Dr. Paul Schroeder, Department of Geology, University of Georgia

Subterranean coal fires are a little known phenomenon to most of the public, despite the fact that they pose a significant global threat to the environment. It has been estimated that subterranean coal fires, just in China, contribute as much as 3% of total world carbon dioxide production annually. It becomes apparent that to develop an understanding of how these fires will affect the global climate, it is important to know if and how coal fires affected the climate in the past. An unusual coincidence of this characteristic mineralogy in the geologic record could be evidence for past coal fires.

Using X-ray diffraction and electron microscopy, we are able to identify a mineral assemblage that is unique from all other known geologic environments. Samples were collected from the anthracite coal region surrounding Centralia, Pennsylvania. This accidental fire has been burning since 1961, and remains the largest coal fire in the United States. Analysis of the samples using XRD has shown that there are two common mineral assemblages: these include vapor deposited phases, and alteration minerals formed from the intense heat and chemical exposure. These deposits do not appear to have any effect on the relative amount of CO_2 that is emitted into the atmosphere, and the record of past coal fires could help to explain trends in global climate shifts if these deposits are found to coincide. Further work is needed to better constrain the mineralogy of these deposits and whether they are similar to those found in other locations around the world.

Rank, Ritual, and Akbar the Great

Chris Holland
Dr. Farley Richmond, Department of Drama and Theatre, University of Georgia

Upon the third Mughal Emperor of the Indian subcontinent, Akbar the Great's ascension to the throne at just thirteen years old, no one could have foreseen the great acts which would occur under his reign from 1562 to 1605 C.E. Early on he was instilled with two important qualities: the inclination to all religion and his need for understanding of the truth. The combination of the two led to the Muslim ruler to move away from the tradition of an orthodox-Mullah system of law, where the Mullahs (Muslim theologians) interpreted the Muslim law (Shari'ah) based on their "religious opinions," as Akbar referred to it. Akbar's new method of rule culminated in the 1579 issue of the mahzar commonly labeled the "Infallibility Decree." This decree recognized him as sole decision maker over his vast empire.

The primary objective of my research is to understand how Akbar consolidated vast regions, with very diverse cultural and religious differences, to claim allegiance solely to him. This is done through examining his Imperial bureaucracy, the Mansabdari System. Although this system of mansabs (rank holders) was part of an administration tightly binding them to the central government, it would not have worked unless there was some "cohesive glue" tying them personally to Akbar. This "glue" was imperial ritual which pervaded all aspects of life for the bureaucracy. The aim is to show the necessity of ritual in the rule of Akbar's empire. Research is conducted through thorough examination of primary and secondary sources.

Creating an Inexpensive and Fast Method for Screening Potential Drug Compounds for Narrow Spectrum Targeting of the Heme Biosynthetic Pathway

Catherine Hudson
Dr. Harry Dailey, Department of Biochemistry and Molecular Biology, University of Georgia

The threat of infectious disease is rapidly growing out of control globally. Compounding this problem is the increase in drug resistant micro-organisms due to overuse and improper use of current broad spectrum antibiotic methods. Our research goal is to create a relatively quick and inexpensive method for screening a large number of drug compounds for their efficacy as narrow spectrum antibiotics. Specifically, we hope to determine and create antibiotics that will negatively affect the heme biosynthetic pathway in bacteria. Because heme is an important cofactor in many life processes, the targeting of this pathway will yield a very effective antibiotic. Our research focuses on four enzymes of the heme pathway that are dissimilar in bacteria and humans. We have created a library of mutant *Escherichia coli* that have one of the four genes of interest knocked out and replaced with a selective antibiotic resistance gene. In addition to this library, we have taken these mutants and transformed into them a low-copy vector containing the human analog of the replaced gene. The possible drug compounds will first be tested on wild-type bacteria to determine their efficacy in negatively affecting heme biosynthesis. After this initial screen, the possible compounds will be tested on the knockout mutants to determine narrowness of target of the single enzyme of interest. Compounds passing this screen will then be tested on the knockout mutants containing the human analogs in order to rule out possible toxicity to humans. This method that we have created will yield useable results with minimal cost and effort.

Comparing Voting Behavior of University of Georgia Students and Georgia Residents in 2004

Jamarri J. Ivy
Dr. James Bason, Survey Research Center, University of Georgia

A 2004 poll by Harvard's Institute of Politics concludes that college students favor Democrat John Kerry over Republican George W. Bush by a much larger margin than the public at large, with as much as 52 percent of college students favoring Kerry, as opposed to the 46 percent of the general population at the time (Schneiders/ Della Volpe/ Schulman). Harvard's poll reports that students identifying themselves as Democrats outnumbered the number of students identifying themselves as Republican or Independent. This research examines the voting behavior of 500 University of Georgia students during November 2004 to determine how students at the University compare to other Georgia residents. Using a web based survey instrument, a random sample of University of Georgia respondents were asked a variety of questions related to their political attitudes. The survey directly deals with party affiliation and voting behavior. The web survey results will be compared to responses of a random sample of 500 Georgia residents asked the same questions in a statewide RDD telephone survey conducted at the Survey Research Center in October before the election. Based on the fact that Georgia is considered a Republican stronghold, the research will examine whether Harvard's poll results apply to the state of Georgia, in order to further grasp the rather enigmatic young adult vote. Using a sample of undergraduate students at the University of Georgia the results will either reject or corroborate the findings that

UGA students are more likely democratic and favorable towards John Kerry than the Georgia public at-large, ultimately obtaining more of an idea into the political mindsets of 18-24 year old voters.

Research Experience for Undergraduates [REU]: Encouraging Underrepresented Students to Careers in Science via the GA Herbarium Cultivated/Economic Plant Voucher Collection

Ashley Jackson, Shauncre Mitchell, and Nikkitress Nelson
Dr. Wendy B. Zomlefer, Department. of Plant Biology, University of Georgia

This research project was designed to develop a comprehensive species archive of cultivated and economic plants from the University of Georgia campus, the State Botanical Garden of Georgia, and the Horticultural Test Gardens. National Science Foundation REU [Research Experience for Undergraduates] was created to encourage the participation of underrepresented students, particularly African American women, in the field of organismal/plant biology through the University of Georgia Herbarium. The authors as interns collected 500 plant specimens, recorded field data, identified plants, prepared label data, and pressed and mounted these specimens for archival storage for research use in the University of Georgia Herbarium. This was done to restore and expand the herbarium teaching collection, increasing the holdings by 20 percent. The mounted specimens will also enhance teaching and learning environments by providing tangible prototypes for this type of study. This pilot program will provide a model for a more permanent intern training program in the future.

A Selected Ion Flow Tube Study of the Reactions of a Sequence of Ions with Amines

Douglas M. Jackson, Nathan J. Stibrich, Dr. Nigel G. Adams, Lucia M. Babcock,
Department of Chemistry, University of Georgia

In seeking a viable pathway from interstellar species to more complex organics such as the amino acids glycine and alanine, it is possible that through a joining of amine and carboxyl functional groups, a product of interest may be obtained. As a prelude to such a study, the ion-molecule reactions of the simple ions N^+, N_2^+, Ar^+, CO_2^+, CO^+, and O_2^+ as well as the protonated species, $HCOOH_2^+$, $CH_3COOH_2^+$, and $HC(OH)OCH_3^+$, with reactant gases CH_3NH_2 and $CH_3CH_2NH_2$ have been investigated in a Selected Ion Flow Tube (SIFT) at 298 K. The neutral amines fragmented to some degree in all cases when reacted with ion species containing no acidic protons, fragmenting more with increasing recombination energy of the primary ion; whereas, the amines readily accept a proton from the protonated acids and methyl formate ions. The rate coefficients of these reactions have also been determined showing that they are nearly all gas kinetic with the ethylamine reaction rate coefficients tending to be slightly less than their methylamine counterparts.

The Management of Predation Among Young, Middle Class Drug Dealers

Scott Jacques
Dr. Mark Cooney, Department of Sociology, University of Georgia

This study addresses the issue of predation and its management in the social world of young, middle class dealers. Data are drawn from in-depth interviews with 11 former and current drug dealers from the suburban area of a major southeastern city of the United States. In contrast to the inner city drug dealers described by previous researchers, predation and violence play a comparatively minor role in these dealers' careers. Predation varies across dealers, however, and factors that increase an individual's likelihood of being preyed upon are discussed. Importantly, most acts of predation are not violently avenged but results in attempts to negotiate a solution or are simply tolerated. Thus, the paper shows that high rates of violence are not intrinsic to illegal drug markets.

Gene Expression in Human Embryonic Stem Cells

Natalie Jennings, Annie Tran, Ezinne Okwandu
Dr. Lee Pratt, Department of Plant Biology, University of Georgia

Embryonic stem cell research is a rapidly growing field that provides a promising future for regenerative medicine. Because embryonic stem cells are unspecialized cells in the human body that have the ability to differentiate into all other cell types, they have attracted scientific attention for use in treatment of cellular diseases through imposed differentiation. The purpose of this study is to identify genes expressed in human embryonic neuro-progenitor stem cells to gain an understanding of stem cell function and perhaps to discover new genes. Complementary DNA (cDNA) was made through reverse transcription of messenger RNA (mRNA) from human embryonic stem cells. This cDNA was ligated into a plasmid vector, which inter was electroporated into *Escherichia coli*, where it replicated with the bacterial chromosome. Plasmid vectors were isolated, thermal cycled, and their DNA inserts sequenced in both 3' and 5' directions. The 2,304 sequences produced were deposited in GenBank, adding to the collection of all DNA sequences available for comparison. With BLAST each sequence was compared, to all other DNA sequences to determine any similarities with known genes and to possibly identify novel genes. These data will help the scientific community learn more about the genes expressed in embryonic stem cells and might provide insight into what gives embryonic stem cells their abilities to differentiate into all other cell types. Our contributions to understanding the transcriptome of embryonic stem cells will assist in future use of stem cells in treating cellular degenerative diseases.

Bilingual Healthcare: Challenges posed and how they are met

Ashley Johnson
Dr. John Ross, Department of Romance Languages, University of Georgia

One of the most significant challenges facing healthcare providers today is the need to provide services in multiple languages to a growing community for whom meaningful access to healthcare remains sadly lacking. Supreme Court interpretation of Title VI of the Civil Rights Act of 1964 legally places the burden of overcoming language barriers on healthcare providers rather than on patients.

Healthcare providers have sought to fulfill this need in numerous ways that vary in cost and effectiveness. It is also important to note that there are technical and ethical considerations that must be addressed whenever people must communicate through an interpreter. All parties must keep in mind that interpretation is performed not only across languages, but across cultures as well, requiring that those communicating through an interpreter have some understanding of the unique demands of the situation.

While the need for bilingual healthcare is a national issue, it is one that strongly affects individuals at the community level. Thus, for this study, emphasis has been placed on resources that are available specifically to Athens residents. Interviews with healthcare providers and direct observations of healthcare settings have yielded an understanding of how the challenges of providing bilingual healthcare are being overcome on a local level, and will hopefully raise awareness of an important community issue.

***Vibrio fischeri ArcA*- Mutant Sheds New Light on Bioluminescence Regulation**

Ashley M. Johnson, Jeffrey L. Bose, and Dr. Eric V. Stabb, Department of Microbiology, University of Georgia

The Hawaiian bobtail squid, *Euprymna scolopes*, and its bioluminescent bacterial symbiont, *Vibrio fischeri*, provide a useful model for studying symbiotic relationships. Although bioluminescence is necessary for squid colonization by *V. fischeri*, it is a metabolically expensive process that actually causes a competitive defect *in vitro*. Describing the regulation of bioluminescence may lead to an understanding of its selective advantage for *V. fischeri*. Previous hypotheses that bioluminescence may aid *V. fischeri* in

maintaining redox balance by reducing excess reductant led us to investigate ArcAB, which forms a redox-dependent two-component regulatory system and may regulate the light-generating and oxygen-reducing lux genes. To begin testing this, we generated a *Vibrio fischeri arcA-* mutant (AMJ2), which we found was ~1000-fold brighter than wild-type. *ArcA* is a key metabolic regulator, and enhanced bioluminescence in its absence could result from either increased substrate availability or direct transcriptional regulation of the lux promoter. Two lines of evidence support the latter model. First, mutation of *arcA* did not enhance luminescence when the native *luxI* promoter-gfp reporter was replaced by the Ptac promoter. Second, a *luxI* promoter-*gfp* yielded 16-fold higher fluorescence in AMJ2 than in wild type. We also found that adding the reductant DTT, which activates *ArcA* in *Escherichia coli*, decreased luminescence in wild type but not AMJ2, indicating that *ArcA* responds to reducing conditions by repressing *lux*. Finally, AMJ2 produced the same amount of light in culture as both it and wild type produced in the light organ of *E. scolopes*, suggesting that *ArcA* transcriptionally represses luminescence of *V. fischeri* in culture, but that the *ArcA* regulon is derepressed during colonization of its mutualistic host. Contrary to our original hypothesis, bioluminescence does not act to consume excess reductant, evidenced by the fact that in the presence of excess reductant *ArcA* represses the *lux* genes.

The Journal for Undergraduate Research Opportunities: Building an Undergraduate E-journal for Research in the Arts and the Humanities

Jeremy Johnson
Dr. Pamela Kleiber, Center for Undergraduate Research Opportunities, University of Georgia

Undergraduate research plays a significant role in science but has been traditionally less well represented in the arts and humanities. To promote undergraduate research in the arts and humanities, the University of Georgia's Center for Undergraduate Research Opportunities established the Journal for Undergraduate Research Opportunities (JURO@GA). This e-journal was specifically designed to encourage undergraduate scholarship through online publishing opportunities in the arts and humanities. Since its inaugural issue the editorial staff of undergraduates has grown from three to nine and has experimented with many unique online formats seeking to challenge the boundaries of a traditional research journal while generating a valuable space for scholarship. The documented experience of the staff will assist others in establishing and managing e-journals in the arts and humanities and create dialogue on the use of the internet as an intellectual space for future undergraduate research in all fields.

Shahidki: The Black Widows of Chechnya

Jeremy Johnson
Dr. Amy Ross, Department of Geography, University of Georgia
Dr. Eve Troutt-Powell, Department of History, University of Georgia

The global phenomenon of suicide bombing has significantly marked modern memory. From Sri Lanka to Palestine to Columbia, suicide violence has profoundly shaped the nature of global conflicts. Suicide bombing has recently become a part of the current Chechen conflict. In Chechnya, the majority of suicide bombers are women. Despite intense reaction and condemnation of suicide bombers, female suicide bombers from Chechnya remain particularly unexplained in the eyes of Russians and the international community; few scholars are currently studying them. The individual motivations for suicide bombing in Chechnya are complexly entangled in the struggle of not only the Chechen people in their conflict with Russia, but also the struggle of women in Chechen and Russian societies. Chechen female suicide bombers come from one of the most war torn locations on the globe. Many are victims of rape and torture. Some have lost family members in the wars (thus leading to their commonly accepted title “black widows”) and others have been rejected by their families. This paper explores women’s history as part of the Chechen conflict particularly as suicide bombers while analyzing links between female identity formation in Chechnya and human rights abuses

in order to shed light upon the making of suicide bombers in Chechnya. Using the resources of EastView and the Columbia University libraries, this paper analyzes current English and Russian scholarship as well as Russian media sources including interviews with a failed suicide bomber (Zarema Muzhakhoyeva) and witnesses of recent suicide bombing hostage crises (Nord Ost' and Beslan).

Using PCR to Confirm the Serogroup and Serotype of *Salmonella* Samples

Elizabeth Kantor and Erika Lentini
Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia

Each year, millions of people and animals are infected by the dangerous pathogen *Salmonella*. The pathogen can be categorized into serogroup, which are then subdivided into serotypes. The identification is pertinent in treating the disease, as the virulence of the infection often depends on the specific bacterial species causing the infection. Serogroup is based on the presence of specific O-antigens, polysaccharides which form part of the outer bacterial membrane. Serotypes are determined by the structure of both cellular (O) and flagellar (H) antigens. The purpose of the project was to validate serogrouping and serotyping PCR primers using isolates obtained from cattle. A total of 168 samples were tested. By both PCR and agglutination, each sample was tested for the following common serogroups: B, C1, C2, D1, and E1. Of the 168 samples tested for these serogroups, 145 were conclusively serogrouped by both PCR and agglutination. Then specific PCR primers and restriction length polymorphism combinations were used to detect 5 of the most common serotypes: Typhimurium, Heidelberg, Hadar, Enteritidis and Newport. Thirty-four percent of the isolates were group B, with 35% of them being Typhimurium and 2% Heidelberg. Sixty-three percent were group C2, but not serotype Newport or Hadar. Another 3% of the samples tested were determined to be of the E1 serogroup. One hundred and forty-five of the 168 isolates tested, or 86%, were able to be serogrouped, as confirmed by both PCR and agglutination. Of the remaining 23 isolates that have not been serogrouped, 13 did not agglutinate with antiserum corresponding to all of the serogroups tested, nor did these 13 samples test positive for these serogroups via PCR. This means that PCR and agglutination only yielded inconsistent results in 10 isolates, or 6% of the total samples tested. It should also be noted that of these discrepancies, 50% tested positive for B via agglutination and negative for B via PCR, while the other 50% tested positive for the E1 serogroup via PCR and not by agglutination. The fact that these discrepancies are spread evenly indicates that both PCR and agglutination are equally effective in determining serogroup. Because only 5 common serotypes were tested, fewer isolates were able to be conclusively serotyped, accounting for the low percentages of isolates serotyped within each serogroup. New probes need to be designed to be able to detect more serotypes. However, PCR proves to be an effective procedure for serogrouping and serotyping *Salmonella* from cattle, but more probes need to be designed to allow the detection of more serotypes.

U.S. Foreign Policy towards Central Asia

Akrom Khaydarov
Dr. Gary Bertsch, Center for International Trade and Security, University of Georgia

The foreign policy of the U.S. towards the five new independent states in Central Asia – Kazakhstan, Uzbekistan, Tajikistan, Turkmenistan and Kyrgyzstan--emerged after the collapse of the Soviet Union in 1991. The U.S. has two main strategic interests in the Central Asian region. The first one is the geopolitical location of the region, which is a bridge between Europe, South Asia, the Far and Middle East. The second one is the geo-economical interests of the U.S. in the natural resources of the region.

Special attention is paid to the bilateral relations of the U.S. towards two leading countries of the region – Kazakhstan and Uzbekistan. U.S.-Kazakhstan relations reflect the cooperation of two states in security and economic spheres and the establishment of the "Energy Partnership." The U.S.-Uzbekistan relations shows the

development of the bilateral cooperation which rapidly changed after the 9.11 events and the U.S. military operation in Afghanistan. This activisation of relations led to the signing of the "Declaration on the Strategic Partnership and Cooperation" in March 2002, and expansion of the range of cooperation.

The research here utilizes primary sources from the Central Asian states and the United States. It involves interviews with officials and experts directly involved in the issue area. The analysis of U.S. foreign policy towards the Central Asian states determines that the U.S. foreign interests are divided in to three major fields of cooperation, embracing political and economical reforms and human rights issues in each country. American presence in the region is a factor of the stability and encouragement of the Central Asian states to achieve their goals.

"Comprehensive Responsibility" and Economic Growth

Gene Kim
Dr. Santanu Chatterjee, Department of Economics, University of Georgia

In recent years, corruption and governance issues have risen to the forefront of development economics, leading to several anti-corruption programs at national and international levels. As an interdisciplinary concern of legal, political, and ethical dimensions, corruption raises fundamental questions about the role of capital and the future of civil society, as well as the continuing role of traditional capital and trade networks in the lives of individuals. This paper will examine the relationships between environmental ethics, social responsibility, and corporate governance on investment and economic growth.

There are several prominent environmental, social responsibility, and corporate governance disputes between multinational corporations and local communities, and national governments in the world today. The fair appropriation of risks and profits is at the core of these disputes. Country-specific indices of environmental sustainability, political rights and civil liberties, and corporate governance will serve as proxies to an exhaustive survey of all possible court cases, regulatory agency investigations, and international sanctions. These indices will be tested for joint statistical significance, and potentially reveal relationships between environmental, social, and corporate policy as determinants of national economic growth and investment.

Attributional Style, Spirituality, and Religious Problem-Solving: Implications for Psychological Well-Being in African American College Students

Brittany King
Dr. Rosemary E. Phelps and Tonette Robinson
Department of Counseling and Human Development Services, The University of Georgia

Building upon the work of Callender (2003), the purpose of the current research project is to examine the influence of attributional style, religious problem-solving, and spirituality on psychological well-being in African American undergraduate and graduate students. Attributional style determines which forces individuals hold responsible for their successes and failures, while spirituality generally refers to a belief in a spiritual being or Higher Power. Religious problem-solving has been conceptualized in terms of three styles: self-directing, deferring, and collaborative. In this study, 75 African American undergraduate and graduate students who regularly attend church in Atlanta and Athens will complete a demographic questionnaire, along with the Extended Attributional Style Questionnaire, the Religious Problem-Solving Scales-Long Form, the Beck Depression Inventory-II, the Beck Hopelessness Scale, the Index of Race-Related Stress-Brief Version, and the Spiritual Well-Being Scale. After analyzing the data using regression equations, we hope to determine whether attributional style, religious problem-solving, and spirituality predict depression, hopelessness, and race-related stress in these students.

Quinic Acid Cluster Computational Model Analysis of RNA and Protein Intensities

Allison Koch
Dr. Jonathan Arnold, Department of Genetics, University of Georgia

The quinic acid cluster is a genetic network that is found in *Neurospora crassa*, which is a major model genetic system. This network quinic acid gene cluster and its products have been a major model for how genes are regulated. One way to speed up the process of our research would be to create a computer model that could predict the different levels of RNAs and proteins as the organisms are grown on quinic acid. The purpose of my project is to obtain experimental results that can be used to refine the regulation of the cluster model and verify the accuracy of its predictions. Applications of this kind of approach include metabolic engineering of useful biologicals, such as antibiotics.

The quinic acid cluster is a circuit used to help the organism utilize a carbon source, quinic acid. In this experiment, *Neurospora* is originally grown on medium containing sucrose. In the quinic acid cluster, sucrose acts as a preferred source of carbon. After the *Neurospora* developed, the organisms were transferred to grow on quinic acid-containing medium. Samples were collected at different time points and Northern Blot analyses were performed. They were probed with different genes in the cluster to determine their RNA intensities. Most of these measurements were previously taken by people in the lab. In my project, the RNA intensities of the *qa-1S* gene, a repressor for the whole cluster, were calculated. These measurements are being compared with the predictions of the computational model. In this way, the validity of the proposed model can be tested.

Another aspect of the computer model of the quinic acid cluster that could be integrated is protein analysis. For this part of the project, Western Blot analyses will be run on the different protein levels of the quinic acid gene products in the same shift experiment as before, beginning with the *qa-2* gene product. Hopefully, this will increase what is known of the protein intensities so that the model can be refined to predict them as well. In the end, an alternative hypothesis for explaining how a major genetic model is regulated will have been validated or developed.

Multiple Mates Enhance Offspring Viability for Female *Drosophila pseudoobscura*

Jessica Laverentz
Dr. Yong-Kyu Kim, Dr. Wyatt W. Anderson, & Dr. Patricia A. Gowaty, Department of Genetics, University of Georgia

Given the high costs of mating for female *Drosophila* and a morphology that allows sperm storage, the prevalence of multiple mating among females needs further investigation. Females who mate multiply rather than singly may offset survival costs with gains in reproductive output. *Drosophila* females who copulate repeatedly with the same male have a higher offspring production rate than females who copulate once, but benefits of multiple mates for females have not been found. We predicted that multiple mates for females would increase the proportion of emerging adult offspring to eggs laid, because greater variability in a female's offspring increases the probability that greater numbers will survive in variable environments. To test this hypothesis, we randomly assigned female *Drosophila pseudoobscura* to three treatments: 1) one copulation, 2) many copulations to one male, and 3) multiple mates. For all treatments, we counted the number of days each female lived, the number of eggs she laid each day until death, and the number of eclosed adult offspring she produced. Here, we show that across female lifetime, females who copulate with several males have significantly higher offspring viability than females who copulate with only one male, whether once or many times.

Hungary's PR Efforts in the Period of EU Accession: A Contemporary Case Study in International Public Diplomacy

Ivy Le
Dr. Ruth Ann Lariscy, Department of Public Relations and Advertising, University of Georgia

This study examines the role of public relations (PR) in one instance of globalization: Hungary's accession to the European Union (EU). Hungary joined the EU May 2004, little over a decade since its transition from communism to capitalism. The EU has never been an easy sell to the member nations — enlargement even less so. In Europe where many countries, including Hungary, have a tradition of national referendum on foreign policy decisions, popular support can legitimize or kill an international relationship. The Hungarian government's PR campaign to support its diplomatic efforts in joining the EU was domestic as well as Europe-wide in scope. The objectives were to educate about EU expansion and candidate countries (knowledge objective), to inoculate prejudices (attitude objective), and to motivate citizens to vote or, at the very least, to stop protesting (behavior objectives). Public diplomacy, PR directed at influencing a country's foreign policy, has become a notable tool for less powerful countries to participate in decisions that before were left to a few big players. This qualitative study analyzes press kits from the campaign, opinion polls commissioned by the EU, and interviews with some of the campaign's key players to investigate the power of conventional PR tools in bridging decades of political distance by shaping public opinion. This collection of information, a snapshot of the challenges of public diplomacy, facilitates future examination and interpretation.

Effects of Environmental Contaminant Perchlorate on Rat Thyroid Sodium-Iodide Symporter (NIS) mRNA Expression

Anna Lee, Irene Aninye, Matthew Taylor, Jeffrey W. Fisher, and Dr. Duncan C. Ferguson, Department of Physiology & Pharmacology, College of Veterinary Medicine, University of Georgia

The Na+/I+ symporter (NIS) is a glycoprotein that transports iodide into thyroid cells as an integral step for producing thyroid hormones, essential regulators of the basal metabolic rates of vertebrates. Ammonium perchlorate, a rocket propellant, has now become an environmental contaminant in water supplies in the southwest U.S. Perchlorate is a potent inhibitor of the functional activity of NIS, resulting in a relative iodine deficiency for hormone synthesis. We hypothesized that reduced serum thyroid hormone concentrations would result in increased thyrotropin (TSH) secretion by the pituitary gland, which is known to stimulate thyroidal NIS mRNA. In this study, 5 rats were exposed to 10 mg/kg/day of perchlorate in the drinking water for 21 days. Expression of thyroidal NIS was studied using mRNA extracted from the 5 control or 5 perchlorate-treated rats. The mRNA was reverse transcribed to produce cDNA, which served as a template for PCR with NIS-specific primers. Both semi-quantitative agarose gels and quantitative real time PCR were employed. Perchlorate treatment was shown to lead to a 3-fold increase in NIS mRNA expression, which approached statistical significance: NIS/18s mRNA ratio (mean ± SD(n)): control 3.2 ± 0.8(5), perchlorate 9.9 ± 3.0(5); $p=0.09$. In order to refine physiologically based pharmacokinetic models of perchlorate's thyroid toxic effects, continuation of this research will include *in vitro* studies to correlate mRNA expression to iodide uptake after the addition of various concentrations of bovine TSH in the Fisher rat thyroid cell line (FRTL-5).

A Study of the Physical and Biological Barriers to West Nile Virus Dissemination in Mosquitoes and Black Flies

Hayes Lee
Dr. Danny Mead, Wildlife Disease Study, University of Georgia

WNV was first discovered in North America in New York in the year 1999 and has since spread throughout North America. WNV is an arthropod-borne virus (arbovirus) that is maintained in nature through biological transmission between susceptible vertebrate hosts by blood-feeding arthropods. Although *Ornithophilic culex* species are considered to be the primary amplifying vectors, other insects are thought to be involved in transmission. Here, our objective was to investigate the WNV infection dynamics in mosquitoes and black flies, specifically in *Aedes aegypti*, A. *albopictus*, and *Simulium vittatum*. Insects were fed WNV spiked dog blood and groups of six insects were collected every three days for 21 days and fixed in 10% formalin. Samples have been paraffin embedded, cut to slides, and the route of virus dissemination throughout the 21 day period for each insect species are being analyzed by immunohistochemistry (IHC). A West Nile virus specific antibody is added to each slide and the virus' path through each insect body is tracked using special staining. Additionally, we are determining rate of virus replication throughout the time period using virus titration. In this study, we are determining the relative importance of specific tissues and organs for virus replication; and identifying the potential physical and biological barriers to WNV dissemination in each species.

Stochastic Simulations of Coevolution and Population Dynamics in Host-Pathogen Systems

Andrew Leidner, Matt Bonds, and Dr. Pejman Rohani, Institute of Ecology, University of Georgia

A central question in evolutionary ecology concerns the mutual selection pressure exerted by pathogens on social organisms. To address this issue, a mathematical model has recently been developed in the Rohani lab, which can be studied analytically to explore whether host-pathogen systems converge on a co-evolutionary equilibrium. The model diverges from other leading theories by demonstrating that increasing host sociality leads to decreased disease virulence and that disease prevalence can select for higher host sociality. My research tests the hardiness of these analytical predictions by building simulations with individual-object design, temporal dimensions and stochastically chosen events. The guiding question is: do hundreds of independently behaving organisms arrive at the deterministically-predicted co-evolutionary end point?

The results of the simulations suggest that the rate of mutation for both host and pathogen may prove a significant factor on a system's convergence to an equilibrium. To further test the model's rigor, this research compares the co-evolutionary outcome when host and pathogen mutation rates are relatively faster, slower or the same speed as the other.

The All-American Icon: Frank O'Hara and Coca-Cola Advertising in 1950's America

Megan Leroy
Dr. Susan Rosenbaum, Department of English, University of Georgia

The decade of 1950 in America was marked by new icons of Americanness and family values that were reflected not only in advertisements but in literary works. My research focuses on three poems by New York School poet Frank O'Hara—"Having a Coke With You," "A Step Away From Them," and "Song"—that engage Coca-Cola as a cultural icon. My research also focuses on the history of Coca-Cola's advertising as an evolving symbol of consumer culture in 1950's America. O'Hara was an avant-garde poet, one of the first to embrace pop culture icons such as Coke and to consider the connections between poetry and consumer culture, poetry and advertising. Both O'Hara and Coca-Cola claimed new audiences such as homosexuals (O'Hara) and women (Coca-Cola). Questions my project will consider include: How do O'Hara's view of Coke and actual Coca-Cola advertising ploys coincide? How did 1950's consumer culture shape the porous

boundary between advertising and art well before the dominance of pop art? By explaining O'Hara's poems in the context of the history of Coca-Cola advertising, I will show how he adapted this American icon to comment on an increasingly mobile, technological, and status-seeking society. However, hesitant to outright embrace consumerism and the complete American dream, O'Hara subversively altered the icon of Coke to create an image including more than the conventional, happy American family. O'Hara and his connections with Coca-Cola evolved not only as a product of Cold War America, but as a dynamic force acting within it.

Public Education and the Power Elite: Systematic Abandonment and Widespread Under-Funding

Brian Levy
Dr. Linda Grant, Department of Sociology, University of Georgia

Recent debates regarding Georgia's education system have tended to focus on the equality of school funding. Under the current procedures, each school district is expected, though not mandated, to pay a fair share to its school system, based on local taxes and property values. Because state funds are relatively controlled by the "local fair share" system and federal monies are minimal, local resources are likely the cause of any funding inadequacies that exist within Georgia's public schools. Utilizing school funding data from the Georgia Department of Education (DOE), this study will explore the nature of possible under-funding within Georgia—with geographic concentration of funding deficiency as its primary focus. As well, this study will search for a demographic correlation, comparing school enrollment data from the DOE to census data, to any under-funding that is found. Finally, if the current funding system proves to be geographically or demographically biased, possible alternatives, employing other states as case studies, will be explored.

Using Streptolysin O for Cell Permeabilization to Determine G-Protein Activation

Robin Nicole Ligler
Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

Streptolysin O (SLO), a toxin produced by *Streptococcus pyogenes*, creates pores in the plasma membranes of cells. These pores may be used to transport proteins and other molecules into the cell to observe cellular dynamics in a controlled environment. This experimentation attempted to establish a general protocol for permeabilization with SLO in eukaryotic cells that may be used to investigate the activation of G-proteins by G-protein coupled receptors (GPCRs). G-proteins are a class of proteins that serve as mediators between the ligand-bound form of GPCRs and an effector enzyme; there are many types of G-proteins, and a receptor, such as the human luteinizing hormone receptor, activates one or more types of these G-proteins. Many aspects of the SLO permeabilization conditions were evaluated, such as the cell concentration, the buffer, the concentration of toxin, and the storage of the toxin. With the optimization of this technique, it is possible to investigate the natural GPCR and G-protein interactions in the cell. One method of exploring these interactions is a trypsin sensitivity assay. Inactive GDP-bound G-proteins have a different conformation than active GTP-bound G-proteins, and trypsin recognizes this difference. This method of determining G-protein activation detects the activation at the receptor/G-protein interface, which is a more accurate place to determine activation in comparison to other methods. By using SLO-permeabilized cells, it is possible to retain an in vivo environment capable of supporting the investigation of GPCR and G-protein activation using the trypsin sensitivity assay.

Foreign Policy Attitudes of the Young: A Comparison of 18-24 Year Olds in Georgia and University of Georgia Students

Chen Lin
Dr. James Bason, Survey Research Center, University of Georgia

Two of the most important issues over the course of the 2004 election were youth participation in voting and foreign policy issues, with heavy focus on the War in Iraq. By linking these two important issues together, there can be an assessment of differences in attitudes of University of Georgia students as compared to youth age 18 -24 statewide in Georgia. The study will test the hypothesis that support for the war in Iraq will be higher among youth statewide than among University of Georgia students. Youth attending college are presumed to have more liberal attitudes than their counterparts statewide due to the influence of education on political ideology. Thus, University of Georgia students should exhibit less support for the war in Iraq than youth statewide. Data for the study come from two sources, a statewide RDD (Random Digit Dial) probability sample of 500 Georgians statewide, and a list-assisted random sample of 400 University of Georgia students who responded to web based survey. Sampling error for each sample is no greater than +/- 5.0% at the 95 percent confidence interval. Results of the study found significant differences on certain issues between University of Georgia students and youth statewide. However, contrary to expectations, University of Georgia students were not more liberal than youth statewide regarding attitudes towards the war in Iraq. In fact, attitudes between the University students and youth statewide were very close on the foreign policy items. However, political ideology, as measured by party affiliation, displayed a strong relationship with attitudes towards the war, regardless of educational status. Understanding current attitudes of youth may provide a better understanding of likely political ideology when these youth become the decision-makers of tomorrow.

Partita in Eb (PADK IV:20): A Modern Performance Edition

Janel K. Long
Dr. Jean Martin-Williams, School of Music, University of Georgia

Franz Krommer (1759-1831) is best known for chamber music. He wrote many pieces of Harmoniemusik (music for wind instruments), including numerous Partitas for winds. Many of these Partitas remain unpublished, surviving only in manuscript form.

The research process required a dual approach: the theoretical and historical aspects of the period, and the performance practice of the period.

Copies of three unpublished Partitas were obtained and the Partita in Eb (Padk IV:20) was selected to be prepared in a modern performance edition. Editorial decisions regarding discrepancy in notations within individual parts, between parts, and among modern and historical practices were made.

To better understand Krommer's compositions, the instruments for which he composed must be understood. Thus, the classical natural horn (a horn without valves) was selected for study due to this researcher's previous nine years of study of the modern valve horn. The researcher studied the general technique and performance practice of the instrument with Professor Richard Seraphinoff, Indiana University, one of the world's leading practitioners of natural horn.

The researcher presented a recital of natural horn music including the edition of the Partita on November 17, 2004.

History Defeated: The Art of Kara Walker

Lauren MacDonald
Prof. Isabelle Wallace, Department of Art History, University of Georgia

Within the first ten years of her career, contemporary American artist Kara Walker has already received considerable acclaim for her work, most notably as the youngest-ever recipient of a Macarthur "genius" grant in 1997.

Her cut paper installations revive the archaic, recreational craft of the silhouette, harnessing its graphic power and genteel connotations to deconstruct essential ideas about race and gender. Simultaneously she revives (or perhaps more appropriately, revisits) volatile black stereotypes, manipulating the icons and the pain, discomfort, and embarrassment they illicit in tandem. Her utilization of such abrasive imagery has sparked a heated racial dialogue in the art world; the controversy surrounding Walker's work is a strong indicator of both her impact in contemporary art and the power such "archaic" stereotypes still possess. Her work revels in the racially distasteful and taboo, articulating the very reasons such categories exist in America's collective visual memory; this "memory" is the decided source of Walker's artistic voice.

My paper will explore Walker's appropriation of historicized archetypes— especially those dealing exclusively with the South, derived from Gone With the Wind-style Antebellum romanticism and racial conventions of the 19th century—considering how history's fragility and subjectivity serves as the foundation of her work. In doing so, I will draw parallels between the constructed visual histories of her tableaux and those of the South's historical landmarks, particularly one of Walker's admitted inspirations: the Atlanta Cyclorama. Further I will explore how, in the introduction of such an egregiously invented narrative, Walker strives to emphasize what is problematic about the scope of American history as imagined by a dominant, white culture; the result is a history repressed, revised, or excised entirely. Indeed, in her work, medium and content are inextricably linked: rendered in "black and white," Walker's figures suggest a plain, unmediated truth, yet they are essentially reflections of the distortion white vision has historically imposed upon black identity.

Shakespeare's Words in Moving Images
Josh Marsh
Dr. Fran Teague, Department of English, University of Georgia

How best to imagine Shakespeare's words in moving images? Our culture values film and Shakespeare, though in very different ways. The general public tends to favor film – the more accessible – and deny the bard the subculture of praise attached to cinema. When these entities collide, the opportunity arises for overlapping genres and transcending classifications. The romantic comedy Shakespeare in Love wittily puts the dramatist into the world of show business. I want to put Shakespeare into the world of human culture. Specifically, Dr. Teague's Shakespeare and Film class provided the impetus for an ongoing experiment to combine the depth of a Shakespearean drama with cinema: our society's flagship for the culture of "cool." After viewing and critically assessing a variety of major motion pictures adapted from the works of Shakespeare, I endeavored to reproduce a modern version of The Merchant of Venice, a play whose content often results in controversy. Instead of focusing on the anti-Semitic attitude inherent in many of the play's characters, I concentrated on the relationships between the characters who ultimately survive the comedy with seemingly no sacrifice. This critical approach allowed the adaptation to better represent a variety of less-acknowledged events within the play. For the symposium, I will investigate this topic, and illustrate my points with examples from an original production.

The Effect of Mutations on the Substrate Specificity of RCE1
Jay McCracken
Dr. Walter K. Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia

Our purpose was to determine how different mutations in the amino acid sequence of posttranslationally modified proteins affected the substrate specificity of the RCE1 protease. Our hypothesis is that the two CAAX motifs CVIA and CTLM would be cleaved by Rce1p and that the CASQ motif would be cleaved by Ste24p. In the a-factor pathway, two different types of cells are needed to combine to form a diploid cell, a cells and α cells, which once inhibited can stop tumor growth caused by this pathway. In our experiment, twenty two mutants were created based on single point

mutations of amino acids of the protein sequence. These mutations were chosen because they were either highly conserved in many orthologs of rce1 proteases or highly variable and necessary for action. The experiment was transformed in a background strain of *Saccharomyces cerevisiae* which lacked both the mating factor and rce1 genes necessary for mating. The strain was transformed with RCE1 containing twenty-two different mutations producing twenty-two different strains of yeasts. These mutants were then transformed with the three different CAAX motifs (mating factor gene), CVIA, CASQ, and CTLM. This resulted in sixty-six different mutants where each of the twenty-two mutants now contained the three different mating factor motifs. Since CASQ is only cleaved by Ste24p, and our mutants lacked that gene, it was expected that none of the mutants with ste24 showed growth in the mating tests. The other two motifs, CVIA and CTLM which are cleaved by Rce1p, showed growth as predicted.

Conspecific Sperm Precedence in *Drosophila pseudoobscura*

Jon McGough
Dr. Yong-Kyu Kim and Dr. Wyatt Anderson,
Department of Genetics, University of Georgia

Drosophila females mate with more than one male in nature. Conspecific matings (matings with the same species) are usually successful in producing viable offspring. However, when matings between different species occur (heterospecific matings), offspring are often inviable or sterile. We expect natural selection to act against the formation of hybrids, which are reproductively wasteful. Utilizing 1) two strains of *Drosophila pseudoobscura*, Mainbody and Bogotá, which are in the process of diverging, and 2) sibling species, *D. pseudoobscura* and *D. persimilis*, which diverged 500,000 years ago, we tested the hypothesis that conspecific gamete precedence (CGP) reduces the cost of heterospecific mating and is favored in nature. In this experiment, we compared 1) the amount of sperm transferred per mating and 2) the number of progeny of each female after mating with both conspecific and heterospecific males. To measure sperm transfer, sperm was collected from recently mated females and stained with a DAPI solution on glass slides. The slides were then analyzed under a fluorescent microscope using NIH image software to measure the number of sperm transferred. To count the progeny, female virgin flies were first mated with a conspecific male for 48 hours and were then mated with a heterospecific male for an additional 48 hours, or vice versa. After mating, each female fly was transferred to different vials for 15 days, and adult offspring were later counted using mutant markers. Current data show that conspecific matings delivered more sperm, although statistically insignificant; and that Mainbody and Bogotá females produced more offspring with Mainbody males, regardless of the order of mating. These results may suggest 1) CGP did not yet occur between the diverging Mainbody and Bogotá strains and 2) gametes of Mainbody males are more effective in fertilization than their Bogotá counterparts. Observations between *D. pseudoobscura and D. persimilis* are currently being processed.

Phenotypic Changes in Dendritic Cell and T lymphocyte Subpopulations of Mice Infected with *Schistosoma mansoni* or Exposed to *S. mansoni* Eggs

Jonathan McWhorter
Dr. Daniel Colley, Department of Microbiology and the Center for Tropical and Emerging Global Diseases, University of Georgia

Schistosomiasis is a parasitic worm infection of 200 million people. Schistosomes live in blood vessels and release eggs which can go to the liver and induce the immune-mediated granulomas responsible for disease pathology.

In a mouse model, two forms of infection can develop: hypersplenomegaly syndrome (HSS) and moderate splenomegaly syndrome (MSS), mimicking the human schistosomiasis clinical spectrum. We have shown upregulation of the PD-L2 surface marker on some splenic dendritic cells correlates with a mouse being MSS. PD-L2 is a co-regulatory ligand for a regulatory marker PD-1 on T lymphocytes, and leads to down regulation of T lymphocytes. Our studies were done to determine if schistosome eggs

induce PD-L2 and PD-1 expression on dendritic cells and T cells, respectively.

Treatment of S. mansoni infected mice with a drug that kills schistosomes prior to egg production, and infecting with single sex schistosomes, can produce"egg-less" infections. At 10 weeks 4.9% +/ 0.4% of B220- dendritic cells in infected mice expressed PD-L2 as opposed to16.2% +/- 1.3% in treated mice.
S. mansoni egg injections into uninfected mice ('egg only" exposure) augmented the % of these cells that express PD-L2 (14.1 +/- 3.9 vs. 3.1 +/- 0.5; egg injected vs uninjected). Therefore, we propose PD-L2 expression by these cells is induced by schistosome eggs. We will also present data on PD-1 expression on CD4+ T lymphocytes, and correlations between these markers and morbidity.

Functional Analysis of Yeast Axl1, Ste23, and IDE Mutants
Amulya Nagarur
Dr. Walter K. Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia

The overarching aim of this research is to study two enzymes, Axl1p and Ste23p, of *Saccharomyces cerevisiae* (yeast), in order to gain more knowledge about a similar protein, insulin-degrading enzyme (IDE), which has shared homologies to both Axl1p and Ste23p. IDE is proposed to have a role in the prevention of Alzheimer's disease. Both Axl1p and Ste23p are proteases that are involved in the production of the yeast a-factor mating pheromone. The main focus of this research is to evaluate the effects of mutations on the function of Axl1p, Ste23p, and IDE via genetic tests. As a starting point for this study, a collection of Axl1p, Ste23p, and IDE mutants were characterized. Using Western Blot analyses, it was determined that the mutations do not alter protein expression. However, certain mutants were severely compromised in mating efficiency. It was determined that certain histidine and glutamate residues of an extended metalloprotease motif are essential for the activity of all three enzymes. Mutation of the first histidine residue in the motif shows a lack of mating activity in Axl1, Ste23, and IDE, as does site-specific mutagenesis at the first glutamate, second histidine, and third glutamate residues (HXCEHX69EX6EX57C…S). In conclusion, mating tests performed on axl1, ste23, and IDE mutants reveal that certain amino acid residues of the metalloprotease motif are essential for activity in the a-factor biogenesis pathway. Other residues are not critical; mutations at these residues do not compromise mating activity. As hypothesized, Axl1 and Ste23, homologues of IDE, are proteases, involved directly in the production of the a-factor signaling molecule. The next phase of this research involves making additional mutations via the recombinational transfer method, and evaluating their ability to promote a-factor production via genetic tests.

Detecting RSV Virus by Quartz Crystal Microbalance
Matthew Nicholson
Yiping Zhao, Department of Physics and Astronomy, University of Georgia

Respiratory syncytial virus (RSV) is highly contagious and causes an illness that resembles a moderate to severe cold. Immuno-compromised people, people with heart or lung problems, infants, and older adults have a risk of developing complications from RSV infection. Current PCR techniques can only detect up to a 10-6 dilution of RSV. A faster and more sensitive detection technique is needed. Here we developed a new detection technique using a quartz crystal microbalance that was made to specifically detect RSV virus. Using this technique we can achieve a detection limit of 10-10, which is 4 orders of magnitude higher than using PCR. Another benefit to the QCM technique over PCR is the fact that it can be used label free – the sample flowed over the crystal does not need to be modified or labeled in any way, thus making the QCM more physiologically relevant. Also, the QCM provides real-time data which is an advantage over the ELISA method which doesn't provide feedback until the entire process is completed.

Thiolated RSV antibody immobilized onto one of the gold electrodes of the piezoelectric quartz

crystal surface made it possible to specifically detect RSV. Different dilutions of RSV lysate were then pumped through a flow cell housing the quartz crystal. The frequency change was recorded and compared to the same dilutions of cell lysate which lacked the RSV proteins. We experienced a negative correlation in the change in frequency as the dilutions of RSV became more concentrated, and no correlation of frequency and concentration with the control cell lysate. Eventually the same technique could be used to detect various disease agents such as E. coli and salmonella.

A Novel Assay for Insulin Degrading Enzyme and it Yeast Orthologs

Tatyana Nienow
Dr. Walter K. Schmidt, Biochemistry and Molecular Biology, University of Georgia

Ste23p and Axl1p are recently-discovered metalloproteases found in the yeast *Saccharomyces cerevisiae*. They are involved in the maturation of the a-factor pheromone responsible for mating in yeast and are thought to cleave the a-factor precursor directly, although this has not yet been confirmed biochemically. Ste23p and Axl1p share significant sequential homology with insulin-degrading enzyme (IDE). Failure of IDE to cleave its primary substrate, insulin, has been implicated as a potential factor in Type 2 diabetes, while another substrate of IDE, β amyloid, forms the senile plaques found in Alzheimer's Disease if not cleaved and removed from the brain.

It is hoped that studying the function of Ste23p and Axl1p could lead to a better understanding of the functions of IDE, but currently there is little known about these orthologs, and there are few methods available with which to study their activity. Development of an assay would not only lead to a better understanding of the function of these particular proteases, but proteases of the M16 family as a whole. We attempted to design an *in vitro* assay for all three proteases, as there is no such assay yet available. The assay used a synthetic substrate derived from the yeast a-factor mating pheromone designed to fluoresce when cleaved by a protease. Unfortunately, the activity particulate fractions containing the proteases were too low for the assay to be of practical use, implying that they had little affinity for the substrate. Future attempts at developing an assay should involve altering either the method of purifying the proteases being tested, or using a different substrate in the experiment.

Fibroblast and Epithelial Cell Interactions in Tropical Pulmonary Eosinophilia

Kurinji Pandiyan
Dr. Julie Moore, Department of Animal and Dairy Science, University of Georgia

Tropical Pulmonary Eosinophlia (TPE) is a manifestation of the parasitic condition filariasis, which is characterized by the disfiguration and swelling of limbs. In the chronic state of TPE a condition of pulmonary fibrosis exists, wherein fibroblast cells, cells that produce connective tissue, proliferate extensively changing the lung morphology and decreasing lung capacity. This study was aimed at mimicking the condition of the lung during the pathological state of pulmonary fibrosis, by establishing a coculture between mouse fibroblast and lung epithelial cells, and determining the responses of the epithelial and fibroblast cell lines to the filarial parasitic sheath protein. The study also attempted to determine whether Matrix Metalloproteinases (zinc-ion-endopeptidases that cleave most components of the extra-cellular matrix and, hence, are linked to tumor metastasis and cancer) were produced by the cells in this condition and if so by which cells. On long exposure to the filarial parasitic sheath protein epithelial cells underwent cell death whereas fibroblast cells proliferated extensively, which correlates to the model of pulmonary fibrosis in the lung. Matrix Metalloproteinases 2 and 9 were detected at the RNA level by means of a Reverse Transcription – Polymerase Chain Reaction for mouse fibroblast cells. More cocultures are to be established between lung epithelial and fibroblast cells in order to see the effect of the two cell lines on each other for cell proliferation and production of Matrix Metalloproteinases.

Creation of a Novel Ribonuclease T1 Gene for Protein Folding Studies

Will Parker
Dr. Marly Eidsness, Department of Chemistry, University of Georgia

Protein folding is an important field of study due to its significance in disease profiles, such as Alzheimer's and Parkinson's diseases. Little is known about the actual process by which proteins fold *in vivo*, and experiments that attempt to solve the mysteries of protein folding are important in understanding the mechanisms of protein biosynthesis in the cell. In order to add to this body of knowledge, an experimental approach will be used to visualize proteins as they fold in a cell-free expression system using fluorescence spectroscopy. A two-fluorophore experiment utilizes a fluorophore incorporated into the nascent polypeptide chain being synthesized and a different fluorophore attached to trigger factor, a ribosome-bound protein positioned near the nascent chain tunnel exit. Experiments are designed to retain the nascent polypeptide chain on the ribosome after completion of its synthesis. To solve this problem, a modified ribonuclease T1 gene was created for use in cell-free expression systems that would, when translated, remain bound to the ribosome. The novel T1 gene was created using polymerase chain reaction strand overlap extension, PCR SOEing, with the gene ribonuclease T1 and neomycin phosotransferase II (NPT2). The importance of using ribonuclease T1 is its short length, well defined folded form, and sensitive assay, while the NPT2 gene is important in the predicted helical structure of its 50 amino acids. The NPT2 gene is attached at the C-terminal end of the T1 gene and is designed to end with two rare arginine codons that cause ribosomal pausing during synthesis, thus retaining the C-terminal end of the T1NPT2 polypeptide on the ribosome. The 50 amino acids of NPT2 allow the nascent polypeptide to remain bound to the ribosome, while still allowing the T1 portion of the expressed gene to extend out of the ribosomal tunnel far enough to allow to complete t folding. Proper folding is analyzed by ribonuclease T1 assays. This work describes cloning of the T1NPT2 construct and preliminary characterization of T1NPT2 in cell-free expression experiments.

Constitutively Active Lutropin Receptor Mutants Associated with Familial Male-Limited Precocious Puberty

Gehres Paschal, Krassimira Angelova
Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

Naturally occurring familial and somatic mutations in the lutropin receptor (LHR) gene can result in either gain-of-function, i.e. constitutive activation, or loss of function, and can lead to severe, irreversible conditions. Familial or sporadic precocious puberty is a particular type of isosexual puberty that usually appears between the ages of 3 and 4 years. A patient with this disorder has adult levels of serum testosterone and exhibit prepubertal Leydig cell hyperplasia. The most common locus of this disorder is in position 578 of transmembrane helix six of the receptor. Several mutations at this position have been identified that result in constitutive LHR activation, leading to a stimulation of the Gs pathway with increased activity of the enzyme, adenylyl cyclase, which is responsible for converting ATP into cAMP, a secondary messenger in the cell. Somatic mutations of the LHR such as Asp578H is (D578H) have also been identified in the DNA of Leydig cell tumors and metastatic thyroid carcinomas. Similarly, another naturally occurring somatic mutation at position 578 of the LHR, the replacement of Asp with Tyr, D578Y, has been found in the isolated specimens of young boys with severe Leydig cell hyperplasia. The purpose of this project is to characterize the binding and signaling parameters of two constitutively active forms of LHR using a transfected HEK 293 cell culture system. Binding experiments using radioactive [125 I] hCG were conducted in order to measure receptor-hormone affinity, and radioimmunoassays were used to measure concentrations of cAMP after hCG simulation. Results of these experiments show that the wild type receptor has a slightly higher binding affinity for hCG, suggesting that both the histidine and tyrosine mutations in position 578

of the receptor may cause structural modifications in the binding domain. Mutations within a transmembrane helix of a G protein-coupled receptor may cause local alterations in the conformation near the mutated residue, allosteric changes elsewhere in the protein, as well as changes in interhelical packing of the receptor. The results of the signaling experiments clearly suggest that both mutant forms of LHR found in patients result in elevated basal levels of cAMP, signifying the constitutive activation of adenylyl cyclase in the absence of ligand. The second part of this study involves a proteomic analysis of the cell-receptor systems. Variant down-stream protein expression of both constitutively active mutant forms of the LHR are evaluated using the Ettan DIGE, a 2-D Gel system which quantitatively detects changes in cellular protein expression and identifies proteins being overexpressed through mass-spectrometry. This information will aid in delineation of how the activating mutations regulate the amounts of certain types of proteins in the cell and how abnormal protein expression could be involved in the onset of pathophysiologoical events.

Analysis of Bmp Signaling During Thymus Organogenesis Using Neural Crest Specific Knockout Mice.

Seema R. Patel, Julie Gordon and Dr. Nancy R. Manley, Department of Genetics, University of Georgia

The purpose of this work is to test the hypothesis that Bmp4 expression and signaling is required for proper initial organogenesis of the thymus and parathyroid glands. Furthermore, in determining the signaling pathway of Bmp4 we may also determine if it is linked to any medical illnesses related to the thymus. During embryonic development, the thymus and parathyroid gland arise from the third pharyngeal pouch, with the parathyroid developing on the anterior portion and the thymus on the posterior end of the pouch. The bilateral primordia arise from interactions between the third pharyngeal pouch endoderm and surrounding neural crest cells. Bmp4 is a molecular signal found in the third pharyngeal pouch endoderm and surrounding neural crest cells. We have determined that Bmp4 is expressed solely in the thymus domain of the shared primordium, and this data suggests that it plays a role in early stage development of the thymus and parathyroid. Bmp4 could determine endoderm cell fate, be involved in the thymus and parathyroid domain formation or uphold the boundary between the two domains. To investigate these possible roles, we determined the expression pattern and function of Bmp4 during initial organogenesis in mouse embryos. To determine where Bmp4 is expressed, Bmp4lacZ embryos were collected and stained using x-gal. Through histology and three-dimensional reconstruction analysis, we determined that Bmp4 is expressed ventral-posterior in the third pharyngeal pouch and shared primordium at E10.5 – E12.5. Due to the Bmp ligand and receptor presence in neural crest mesenchyme and endoderm cells, the direction of the signal is unclear. To clarify the Bmp4 signaling pathway, we generated a neural crest specific knock out of Bmp4 or the Bmp4 receptor, using a Wnt1Cre deleter strain. Histology of E12.5 Bmp4 receptor-specific knock out embryos revealed that the size of the thymus appears smaller than the thymus seen in control embryos and the parathyroid gland appears larger than the parathyroid in the control. In addition, Bmp4 knock out embryos revealed the phenotype of the thymus and parathyroid to be normal. Initial analysis of the phenotypes from these mice suggests that Bmp4 signaling plays multiple roles during early organogenesis.

Marcus Tullius Cicero: The Foundations of a Legal Education during the Roman Republic

Kevin Patrick
Dr. James C. Anderson, Department of Classics, University of Georgia

Marcus Tullius Cicero, a prominent Roman lawyer and statesman, often alludes to the foundations of a legal education during the Roman Republic. “Marcus Tullius Cicero: The Foundations of a Legal Education during the Roman Republic” investigates Cicero’s references to a legal education, which surface in Cicero’s various orations, letters, and philosophical treatises. An analysis of the

orations "Pro P. Quinctio" and "Pro Sex. Roscio Amerino" provides details on Cicero's earliest conception of a lawyer's duty. Cicero believed that a lawyer was obligated to serve the Roman state and to uphold the rights and privileges of individual Roman citizens. When Cicero was at the pinnacle of his public career, "In Catilinam" and "Pro Murena" illuminate the importance of proper ethical foundations for a lawyer. The philosophical works of Cicero, such as "De Oratore," emphasize the importance of a liberal education, especially mastering the art of rhetoric. Thus, a chronological investigation into Cicero's references regarding a legal education demonstrates that the study of literature and philosophy was pivotal for an aspiring lawyer. The foundations of a legal education were deeply rooted in the cultivation of honorable characteristics. In the words of Cicero, the legacy of a proper legal education was that "the remembrance of our names should not pass away with life, but endure with all ages of the future."

How African Americans Think About the Links Between Disease and Race

Karen Petree
Dr. Celeste Condit, Department of Speech Communication, University of Georgia

The emerging field of pharmacogenics raises new questions about the relationships between genes, health, and race that need to be answered in order for drug development to properly benefit people of all genetic backgrounds. In particular, this research seeks to explore how African Americans think about the links between disease and race. The study contrasts participants' understandings of common diseases that are identified as particularly common in the African American community (diabetes and high blood pressure) with understandings of single gene disorders popularly identified as unique to the African American community (sickle cell disease). Twelve African American adults (7 males, 5 females) participated in semi-structured interviews, and their comments were coded into thematic categories by two independent coders. The results indicate that the most common cause to which high rates of diabetes and heart disease are attributed is distinctive African American diets (37.8%). In contrast, participants understand sickle cell disease as resulting from a genetic cause and therefore the largest group indicated that for a White person to have sickle cell they would have to have some African ancestry (36%). Such understandings or misunderstandings about disease can have a profound impact on a person's response to diseases and their treatments encountered within his/her community. Whether people are open to certain drugs or treatments is highly dependent on their perceptions of how diseases and drugs affect them in particular. This study has successfully identified a set of racially dependent medical perceptions, and also presents an analysis of the impacts of these perceptions in the field of pharmacogenics.

An Evaluation of Red Hat Inc.'s Business Practices, as it Relates to the Development and Distribution of Free and Open Source Software

Charlie Pitts, Jr.
Dr. Mark Huber, Management Information Systems, University of Georgia

In the global economy, supply and demand of computer software has an international reach and impact. Companies follow different paths for developing software for sell. Source code is the underlying ingredient of computer software. In most technology companies, source code is proprietary information and the source of the business value of the final product or service. Not all technology companies follow the proprietary source code model. Free software and open source software (F/OSS) are parts of movements in software development that allow for unfettered access to source code and the freedom to modify, copy, distribute and redistribute the source code.

F/OSS has advantages more suited for an interconnected world than traditional software development methods. F/OSS suffers from some of the same weakness and more than proprietary software. F/OSS products are maintained by an international community of people, non-profit entities and companies.

Red Hat Inc. (Red Hat) is one of the most successful companies whose business model includes the generation of value through the development and distribution of F/OSS. Incorporated in 1993, Red Hat has grown to report 3 million dollars in operating cash flows in the fourth quarter of FY2003.

The research methodology is a case study. I will triangulate news, financial reports, and other sources of information to see how Red Hat is achieving growth and technical excellence. I will use Porter Five Forces Model to examine the UNIX/Linux software and services market. Red Hat, as a case, is unique, but has the potential of disturbing the software industry.

The Discourse of Domestic Violence in the Latin American Community

Alison Powers
Dr. Vialla Hartfield-Mendez, Department of Spanish, Emory University

Latina victims of domestic violence and the organizations that assist them face a difficult set of challenges. Along with the language barrier and clash of American and traditional Latin American values, tension is created by the tenuous immigration status of many victims.

This project examines the discourse used by Latina victims to describe and deal with their experiences of violence. While principal emphasis will be given to the unique language of the victims, the study will also examine language used by advocacy agencies to discuss these sensitive experiences. Field work in the form of interviews and observations in Mexico City and in an Atlanta domestic violence support group provide data sources for the analysis. Information gathered in Mexico City provides a contextual reference and basis for analyzing the experiences of local Latina victims.

Since language is a specific product of a society as well as a universal product of human culture, a power structure is embedded and maintained through its use. Agencies must be aware that an important part of successful service is recognizing the significance of language and using it to restore a sense of autonomy and control to the victims. Organizations must avoid routine application of American usage, assumptions and values so as not to stifle or intimidate Latina victims. Informed use of language by agencies will facilitate the client's handling of her situation in a culturally relevant and appropriate fashion.

Information derived from the language analysis will be presented for discussion and incorporated into recommendations for agencies seeking to focus on providing services for the growing Latin American immigrant community.

Characterization of Chromosomal Integration by *Streptomyces* Bacteriophages: Use in Mammalian Genetic Engineering

Katherine Price
Dr. Janet Westpheling, Department of Genetics, University of Georgia

Recombinases (integrases) are enzymes that facilitate exchange between DNA molecules. Integrases derived by *Streptomyces* phages (viruses that infect these bacteria) have been shown to mediate efficient site-specific recombination in mammalian cells. Michele Calos and her colleagues at Stanford University have constructed cloning vectors containing *Streptomyces* bacteriophage integrases and used them to engineer mammalian chromosomes providing a safer nonviral approach to human gene therapy. Vectors containing the attachment sites of phages ΦC31 and R4 have been shown stably integrate into pseudo attachment sites found on mammalian chromosomes. We have recently isolated and characterized several new temperate phages from *Streptomyces* species and have begun an analysis of the mechanism of phage integration. Putative lysogens of phage MRT were isolated as turbid plaques and tested for the presence of phage by mitomycin C induction. Restriction analysis of released phage confirmed that the lysogens contained the phage used for infection. Libraries of phage MRT DNA are being constructed in non-replicating plasmid vectors to functionally identify the presence of the integrase gene and phage attachment site. Additionally, putative lysogens of phages DAH 1, DAH 2, DAH 4, DAH 5, and DAH 6 have been isolated and are being tested

for the presence of phage by the methods described above. Libraries of phage DNA will be made for those yielding positive results to functionally identify the presence of the integrase gene and phage attachment site. Our plans to manipulate these phage components for use in mammalian cell engineering will be discussed.

Cloning and Expression of a Trigger Factor Variant for Protein Folding Studies

Matt Rudy
Dr. Marly Eidsness, Department of Chemistry, University of Georgia

Trigger factor (TF) is a peptidyl-prolyl cis/trans isomerase (PPIase) and a protein folding chaperone. TF is a unique PPIase in that it binds to ribosomes at the exit site for newly synthesized proteins and may serve as a cotranslational folding chaperone. Protein biosynthesis on ribosomes is difficult to study due to the inherent asynchronicity of the process; ribosomes synthesize nascent polypeptide chains at variable rates. The goal of our research project is to ultimately visualize the protein folding process of a nascent polypeptide on a single ribosome. Our experimental design involves attaching a fluorescent molecule, called a fluorophore, to TF and a different fluorophore to the N-terminal amino acid of the newly synthesized protein and follow the interaction of the two fluorophores by fluorescence resonance energy transfer (FRET) measurements. This work describes the cloning of a TF variant encoding a site-directed cysteine residue at position 426 to make TF E426C in the vector pET28a. Expression of this TF variant generates a smaller peptide tag on the TF protein and will be useful for comparison to TF proteins expressed with larger peptide tags originating from a TOPO vector. Fluorophores attached to TF are designed to covalently bond to sulfur (from cysteine) via a maleimide based fluorophore to generate a thioether bond. The thioether bond is stable under reducing conditions of the cell-free expression experiments we use to study protein folding. TF has no naturally occurring cysteines, so TF mutants with specifically inserted cysteine residues allows attachment of fluorophores at desired points in the polypeptide chain. The goal of this paper is to describe the process of constructing a clone of TF E426C in the vector pET28a . Understanding how proteins fold is important because a protein's three-dimensional structure determines whether or not it can function properly. Protein misfolding is responsible for diseases such as Alzheimer's. If successful, the fluorophore attachment procedure applied to TF can be extended other proteins to help determine why protein misfolding occurs and how it can be treated or prevented.

***In Situ* Hybridization Detection of *Babesia microti* in Experimentally Infected Hamster Tissues**

Amy Sexauer, Fernando Torres-Vélez, Corrie Brown
Dr. Corrie Brown, Department of Veterinary Pathology, University of Georgia

Babesiosis is an emerging tickborne disease of humans, caused by the parasite *Babesia microti*. Clinical manifestation can range from asymptomatic and/or transient flu-like symptoms to acute and fatal, with this extreme exhibiting symptoms similar to malaria, including fever, chills, malaise, anemia, and fatigue, occurring most commonly in the elderly, immunocompromised, or splenectomized individuals. The reservoir is assumed to be field voles. Hamsters have proven to be a good experimental model of infection for this parasite. In this study, formalin-fixed, paraffin-embedded blocks from five hamsters experimentally infected with *Babesia microti* were examined by *in situ* hybridization to determine sites of replication of the parasite. A digoxigenin-labelled negative-sense riboprobe corresponding to the 16S ribosomal subunit gene was constructed and applied to the tissue sections. Using this technique, *Babesia microti* rRNA was detected in red blood cells throughout the body, as well as in Kupffer cells of the liver and fixed macrophages in other organs. These data indicate the presence of an extraerythrocytic phase of *Babesia microti*, which has been suggested but never before conclusively demonstrated. Demonstration of an extraerythrocytic phase in the life cycle of

Babesia microti has significant potential implications for further research into the interruption of transmission cycles of the parasite through the development of new drug therapies.

Utility and Revealed Preferences: An Analysis of Political Decisions through Voting Procedures in the Context of Economic Decisions through Market Mechanisms

Katherine Sheriff
Dr. Robert Grafstein, Department of Political Science, University of Georgia

The underlying notion of utility in decision making, that there exists differing intensities of any subject's preferences, provides more information about what is truly desired than a general ranking of the subject's preferences. However, due to difficulties in interpersonal utility comparisons, utility is used to explain rather than determine social and economic choices. Paul Samuelson's (1938, 1947) theory of revealed preferences explained that, because utility comparisons remain unknown, utility should be used to explain empirically demonstrated choices. The problem of implementing interpersonal utility comparisons in voting procedures presents a normative quandary for scholars of social choice. The purpose of this research is to determine the extent to which economic decisions offer insights into the use of utility comparisons for voting procedures.

Although seemingly disparate, political decisions through the voting method and economic decisions through market mechanisms reveal similar coordination patterns in a utility sense. Through a parallel analysis of such decisions, structural similarities were evaluated politically across societal preferences for voting, as well as economically across time for inflation and across nations for comparative advantage. Analysis results indicated that political and economic decisions may be compared successfully due to structural parallels. However, one fundamental exception to such similarities exists in the interpreted value of interpersonal utility comparisons, or lack thereof, relative to political and economic decisions.

Distribution of MMP-2, -9 and -19 Alternative Splice Variants in Pre-Neoplastic Ovarian Surface Epithelium and Ovarian Cancer Cell Lines

Adam Singer, Susanne Warrenfeltz, John Duvall
Dr. J. David Puett, and Chindo Hicks,
Department of Biochemistry and Molecular Biology, University of Georgia

Recent studies suggest that alternative splicing of normal genes may lead toward events associated with the progression of cancer such as transformation or metastasis, events in which the matrix metalloproteinases (MMP's) play a key role. The gonadotropic hormones, which stimulate ovulation through the up-regulation of MMP's, are implicated in the transformation of ovarian surface epithelium. This purpose of this project is to verify if alternative transcripts of the MMP family members exist in pre-neoplastic ovarian surface epithelium and ovarian cancer cells, to discern trends in the splicing events and to attempt to correlate these trends with transformation. RT-PCR was used in this project to search for alternative transcripts of MMP-2, MMP-9, and MMP-19. By selecting primers that overlap exon splice junctions, alternative transcripts were selectively amplified from three ovarian cell lines: one pre-neoplastic cell line, IOSE-398, and two neoplastic cell lines, OVCAR3 and SKOV3. Results indicated the presence of alternative transcripts in each cell line. The goal of this project is to fully characterize the distribution of single exon deletion splice variants of MMP-2, MMP-9 and MMP-19 in each cell line, and to test the hypothesis that these transcripts occur in nature by screening several ovarian tumors for the splice variants that occur in the cell lines. Differences in the distribution of splice variants across normal and transformed cells may represent a potential marker for ovarian cancer.

Does the Principle of Least Action Dispose of Dispositionalism?

Alexander J. Skiles
Dr. Yuri Balashov, Department of Philosophy, University of Georgia

My aim in this paper is to discuss whether the increasingly popular causal power or dispositionalist conception of natural lawhood and is undermined by the fact that physical systems obey certain natural laws difficult to expression in terms of causal transmission. In particular, I criticize those who infer the falsity of dispositionalism from what is sometimes called the principle of least action: a physical system's actual evolution is such that its time-dependent quantity of action over a given interval takes an extremum relative to other quantities of action it might have had. My argument is that dispositionalism neither conflicts with nor fails to explain why the principle of least action can be employed to derive accurate equations of motion. I conclude with a number of general strategies the dispositionalist can help herself to in order to resist similar objections couched in terms of conservation laws and global symmetry principles in physics.

Samuel Beckett and the Antinomies of Author and Audience

David M. Smith
Dr. Adam Parkes, Department of English, University of Georgia

My thesis will focus on the prose works of Samuel Beckett, with some excursion into his dramatic pieces and early critical essays. A major problem of Beckett's texts (which he deliberately exploits) is the relationship between the author and the literary audience. Many of Beckett's texts (especially The Unnamable) are constructed as a perpetual conflict between the author and reader which can never be resolved. I will examine approaches which have been proposed to understand this problem in Beckett; my own approach will focus upon what I take to be an anticipation of Beckettian problems in the aesthetic philosophy of Immanuel Kant. Kant attempts to resolve a number of "antinomies" (contradictions) which he claims have plagued philosophy and art. I argue that Beckett's conflict between his narrators and their audiences recapitulates Kantian antinomies; however, Beckett denies the possibility of resolving the conflict, which is the primary goal for Kant. I will not argue that Beckett was consciously aware of and influenced by Kantian aesthetics; rather, I will use Kant as an interpretative background to explain certain themes in Beckett. Through the comparison with Kant, I will demonstrate Beckett's connection to greater concerns of the Western tradition, in contrast with critics who interpret Beckett as an insular, solipsistic writer.

Projecting a Positive Educational Experience for Latinos in Georgia

Desiree Smith
Dr. Roberta Fernandez, Department of Romance Languages, University of Georgia

As Georgia continues to experience massive demographic growth in its Latino population, Latinos are accessing higher education at a lower rate than other groups. Institutions of higher education, in particular, have a unique opportunity to bring about widespread change. My study includes a "Literature Review" presenting the major themes found in the research about the educational experience of Latinos, as well as a section discussing two established programs that have increased Latino access to higher education. By conducting interviews of some Latino students attending the University of Georgia, I have identified factors that enhance the college experience of these students. I transcribed each interview and analyzed the data using qualitative research methods; then after categorizing and coding the data, I presented the major themes in the "Findings" section. Such findings include the critical role that support systems play in the acceptance, retention, and positive educational experiences of the Latino students who do attend college. In order to increase enrollment of Latinos in post-secondary institutions in Georgia, new initiatives, which I identify, must be taken at all levels of education, and current projects must continue to be funded.

Pancreatic Lesions in Chickens Experimentally Infected with Newcastle Disease Viruses of Different Virulence

Matthew Stewart, Nobuko Wakamatsu, Daniel J. King, Bruce S. Seal
Dr. Corrie C. Brown, Department of Veterinary Pathology, College of Veterinary Medicine, University of Georgia

Newcastle disease is a highly contagious poultry disease caused by varying strains of Newcastle disease virus (NDV). NDV has been classified according to five pathotypes that relate to the disease signs produced in infected fully susceptible chickens. The pathotypes of NDV, in increasing virulence, are asymptomatic enteric (avirulent) strains, lentogens, mesogens, and neurotropic and viscerotropic velogens. In this study, groups of White Leghorn chickens were inoculated intraconjunctivally with four isolates of NDV: California exotic Newcastle disease virus (CA END virus) - isolate from chickens during the 2002-2003 California outbreak (viscerotropic velogen), Beaudette C (neurotropic velogen), Anhinga (mesogen), and La Sota (lentogen). Birds were euthanized with collection of pancreatic tissues for histopathologic examination and immunohistochemistry for NDV nucleoprotein, along with two apoptosis assays. As negative control birds did, birds infected with La Sota and Anhinga had no viral infection in the pancreas with minimal apoptosis of pancreatic exocrine cells. Viral protein was detected in the pancreas from the birds infected with CA END virus and Beaudette C. By 3 days post inoculation, pancreatic exocrine cells and infiltrating lymphocytes and macrophages were infected with CA END virus. However, Beaudette C was detected only in pancreatic exocrine cells by day 6 postinoculation. Along with presence of viral protein, there were increased numbers of apoptotic cells in the pancreas from birds with CA END virus and Beaudette C. It was concluded that pancreatic apoptosis is associated with virulent NDV infection in chickens and may be a direct result of cellular infection. In addition, there may be a different mechanism of damage for the viscerotropic and neurotropic velogens. Clinical signs seen in chickens infected with virulent NDV, such as diarrhea and decreased egg production, may be associated with pancreatic damages.

Child Attentional Control in the Classroom Milieu

Christopher Stokes
Dr. Randy Kamphaus, Department of Educational Psychology, University of Georgia

Temperament theory suggests that one component of child mental health, attentional control, may either promote or interfere with academic achievement. Attentional control is the ability to orient, sustain, and shift attention (Posner & Rothbart, 2000). In a prior study, a key difference between student mental health groups (classified as low versus moderate mental health problems) was found: the moderate behavior problem group had more inattentional difficulties. These results were interpreted as supportive of temperamental theory implicating poor attentional control as adversely impacting daily classroom behavior which, in turn, adversely impacts academic achievement. The causes and contributors to attentional control problems, however, are not well studied and potentially myriad (e.g. intrauterine cocaine exposure; Mayes, 2003). This pilot study will assess the potential contribution of a heretofore unstudied contextual variable, the average level of child inattention in the classroom. It is hypothesized that average inattention in third grade classrooms (N = 25 for each of 5 classrooms for a total of approximately 125), as assessed by teacher's ratings of inattention for all children, will be correlated with target children's inattention (assessed by aggregated daily observations of inattention taken over a one month period) in these same classrooms (N = 25 across all five classrooms). A statistically significant relationship between average classroom inattention and target children's inattention will suggest that the contextual variable of inattention in the total milieu requires further research as a potential contributor to the development or exacerbation of an individual's attentional control in the classroom.

The Socialization of Anger among Maltreating and Nonmaltreating Mothers

Shana Strickland
Dr. Kimberly Shipman, Department of Psychology, University of Georgia

The purpose of this study is to investigate the emotional socialization practices of maltreating mothers and the effects on their children. The study specifically looks at how mothers socialize their children's anger and the regulation and coping skills those children use when they are angry. The sample consists of 40 maltreating mother-child pairs from the Department of Family and Child Services and a control group of nonmaltreating families that were recruited from community agencies. In this study, maltreating mothers are defined by specifically being physically abusive and nonmaltreating mothers had no instances of physical abuse or any other type of child maltreatment. The emotional socialization practices for the emotion of anger are compared by using the Meta Emotional Interview. Mothers will be compared on their awareness of their child's anger, the degree to which they accept this emotion and how they coach their child, and whether or not their child's expression of anger is regulated. It is hypothesized that maltreating mothers will be more aware of their child's anger, but less accepting and participate in less coaching of this emotion, causing their children to be more dysregulated than children from nonmaltreating families. The information obtained from this study will be useful for creating effective intervention programs for maltreating families by enhancing information on the socialization processes necessary for children's emotional development.

Drug and Nutrient Trafficking in the Human Pathogen *Cryptosporidium parvum*

Adam Stroupe
Dr. Boris Striepen, Department of Cellular Biology, University of Georgia

The gastrointestinal parasite *Cryptosporidium parvum* causes severe diarrhea, and in immunocompromised patients, cryptosporidiosis can become chronic and lead to death. Cryptosporidiosis is a pressing issue because there is no effective drug treatment for the disease. An unanswered question in the understanding of *C. parvum*'s drug resistance is how the parasite receives its nutrients: through the apical membrane or through the host cell. Knowing how the parasite receives its nutrients can provide a good target for drug trafficking; therefore, the flow of nutrient uptake was tested. In order for successful assays of drug and nutrient trafficking in *C. parvum*, the host cell, MDCK (canine kidney cells), grew in transwells until tight junctions allowed a complete monolayer to cover the porous membrane in the upper well of the transwell. Using different concentrations of MDCK cells and a voltmeter to check resistance between the upper and lower wells, the optimal time when the cells reach a complete monolayer was determined. The MDCK cells were successfully infected with 5 µl of *C. parvum* (1x105 cells). After the allotted time for infection, bromodeoxyuridine was added to the lower well of half the transwells to show uptake of nutrients through the host cell and the upper well of the other half to show uptake of nutrients through the apical membrane. After the selected time of exposure to bromodeoxyurdine, the cells were stained with a primary antibody that attaches to the incorporated bromodeoxyuridine and a secondary antibody that adds florescence to the incorporated area. This determined which *C. parvum* culture had a better uptake of the nutrients; unfortunately, the initial *C. parvum* concentration was inaccurate, making the microscopy results hard to determine. Nevertheless, the assay to set up transwell experiments with *C. parvum* was perfected, and future studies can determine the needed results.

Recruitment of Human Telomerase RNA to the Telomeres of Human Cancer Cells

Teerawit Supakorndej
Dr. Michael P. Terns, Biochemistry and Molecular Biology, University of Georgia

Telomeres cap the physical ends of eukaryotic chromosomes and protect them from end-to-end fusion and degradation. In most normal human somatic cells, telomeres become progressively shortened during DNA replication, leading to cellular senescence. The telomerase

ribonucleoprotein is responsible for telomere maintenance and elongation. The enzyme is inactive in most normal cells but is active in cancer cells, suggesting that it has important implications in tumorigenesis and cancer cell proliferation.

In humans, telomerase minimally consists of a catalytic reverse transcriptase subunit (hTERT) and an RNA subunit (hTR). In the telomerase-positive HeLa human cancer cell line, hTR accumulates in nuclear structures called Cajal bodies, the proposed site of telomerase biogenesis. However, little is known about the delivery of hTR from Cajal bodies to telomeres, where it serves as the template for telomeric repeat addition. We hypothesized that initial localization of hTERT to the telomere is required for hTR localization to the telomere. To test this, we generated stable telomerase-positive HeLa cell lines expressing fusion protein constructs consisting of telomere binding proteins (hTRF2 or hPot1) fused to hTERT. By relocating hTERT to the telomere through these fusion protein constructs, we observed that hTR in these stable cell lines accumulates in foci reminiscent in size and shape of telomeres. Ongoing experiments are being performed to determine if hTR redistributes to the telomeres in these cell lines, whether Cajal bodies also redistribute to the to the telomeres, and if hTR first exits Cajal bodies prior to associating with telomeres. Understanding the mechanisms involved in telomerase recruitment to telomeres is an important advancement of cancer biology.

Isolation of Mutants of *Arabidopsis thaliana* Having Insertions in Genes Thought to Encode Necessary Components of Plant Cell Wall Synthesis.

John Henry Theiss, Robert D. McCloskey Jr., Prashant Amin
Dr. Michael G. Hahn, Complex Carbohydrate Research Center, University of Georgia

The goal is to identify homozygous mutants in specific genes thought to be involved in the synthesis of cell wall polysaccharides. The focus is on mutants that have only one gene disrupted by the addition of a transforming-DNA (T-DNA) insert. The long-term goal of the project is to determine the function of the target genes and how they affect cell wall biosynthesis.

Arabidopsis thaliana was chosen for this experiment because its relatively small genome has been fully sequenced. Furthermore, it is easy to grow large numbers of *Arabidopsis*.

The gene targeted in this research (At1g53000) is believed to be a nucleotidyltransferase that synthesizes cytocen monophosphate 3-deoxy-D-manno-2-octulopyranosonic acid (CMP-KDO), an activated sugar nucleotide required for the synthesis of the pectic polysaccharide, Rhamnogalacturonan II (RG-II). RG-II is important in overall cell wall structure because there is evidence that RG-II cross-linking is required for the formation of pectin networks in plant cell walls.

The lab obtained two seed lots from the Salk Institute that are reported to have T-DNA inserts in At1g53000. Seed from each lot were grown and the plants tested, using polymerase chain reaction (PCR) and gel electrophoresis, for the presence of inserts. Salk_021554 was found to be without inserts. In contrast, our data show that some of the Salk_008109 plants have inserts in At1g53000. Interestingly, PCR data suggests the presence of two inserts in the gene, but the plants are all heterozygous for the mutation.
Seed from these heterozygous plants are being grown for the purpose of producing homozygous mutants, and confirming the existence of an extra insert. Once a homozygous mutant line has been isolated, further experiments to study the effect of this mutation on cell wall structure can proceed. This understanding will lead to benefits to the commercial, food, and metical community.

Trigger Factor (TF) Assisted Co-translational Folding Using Fluorophore Modified Nascent Peptides Synthesis and Characterization of Fluorophore-modified Trigger Factor for Protein Folding Studies

Tendoh Timoh
Dr. Marly Eidsness, Department of Chemistry, University of Georgia

Protein folding consists of complex mechanical processes that are conserved in all life forms, but poorly understood at the molecular level. Our ability to elucidate the structures and functions of proteins is a necessary step towards the eradication of most pathogens and genetic disorders in the development of therapies to combat protein-misfolding diseases. One particularly interesting protein in this ever-growing field of proteomics is the trigger factor (TF) of *Escherichia coli*. Our laboratory works with this bacterial prolyl isomerase, trigger factor (TF). Prolyl isomerases are involved in protein folding, as they catalyze the *cis-trans* isomerization of the peptide bond preceding proline in proteins. TF is an anomalous unique prolyl isomerase because it is the only one known to bind to ribosomes, the biological machines that synthesize proteins. We study its TF function role in the folding of newly synthesized proteins, called cotranslational folding. With very little being known about the stages of cotranslational folding, our group uses cell-free coupled transcription/translation to study cotranslational folding of nascent polypeptides. We are building a two-fluorophore cell free translation system by that incorporatesing probes into a nascent polypeptide and ribosome- bound TF. During cell-free translation, these probes will be detected by fluorescence resonance energy transfer spectroscopy (FRET), a technique that is sensitive to distance between fluorophores during cell-free translation. In this work, the synthesis and characterization of fluorophore-modified TF is described, in which the fluorescent dye, Alexa Fluor568, is covalently attached to a single cysteine in the TF variant, TFE426C (f-TF). New experiments will require that we continue to learn experimental methods of protein bioconjugation, and gain experience with peptidyl prolyl *cis/trans* isomerase (PPI) assays and fluorescence measurements of f-TF. Prolyl isomerase assays of f-TF are described as well as fluorescence measurements of f-TF and f-TF in a 1:1 complex with ribosomes.

Establishing a Tumor Marker Database through Chemiluminescent Immunoassay Analyses

Tyson Turner, Marcelo Rocha da Costa, Robert S. Galen, and Dr. David Puett, Department of Biochemistry and Molecular Biology and School of Pharmacy, University of Georgia

Early diagnosis of cancer, before clinical symptoms appear, is proven to save lives and is aided by the detection of tumor markers in the serum of patients suspected of having cancer. Tumor markers, biomolecules whose presence or absence in human blood correlates with a patient's disease status, can be detected in serum via chemiluminescent immunoassays. The work reported herein describes a database of tumor marker serum levels that can function as an integral tool for correlating tumor marker levels with the incidence of cancer. Serum samples were obtained from Athens Regional Medical Center, and the concentrations of three markers, human chorionic gonadotropin (hCG), carcinoembryonic antigen (CEA), and alpha fetoprotein (AFP), were measured using the Immulite 1000. The results were compiled into an Excel database. The levels of each tumor marker were quite varied, ranging from values of hCG as high as 133,597 mIU/ml to less than 1.0 mIU/ml, values of CEA from 7.1 ng/ml to 0.2 ng/ml, and concentrations of AFP from 123 IU/ml to 0.5 IU/ml. Limited access to patient information is available and will be used to correlate serum levels of each tumor marker with patient diagnosis and disease status. This research is ongoing as more serum samples are collected and tumor marker levels are measured and recorded.

Genetic Investigation of *Salmonella* Samples Found in Livestock

Katrin Usifo
Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia

Antimicrobial resistance is a public health problem of growing concern. Many pathogenic organisms have become multidrug resistant as a result of their exposure to various antibiotics. The emergence of multidrug-resistant *Salmonella* is linked to antibiotic use on animals raised for food. Research was conducted to investigate the distribution of *Salmonella* containing multidrug-resistant genes from Georgia farms. Samples were gathered from livestock from four Georgia farms. An average of 4 samples were taken from each animal or location. A total of 171 isolates were confirmed to be *Salmonella*. The Southern Blot technique was used as a primary method of analysis for presence of *ampC*, *flo*, and *tetA* genes corresponding to resistance to ampicillin, florfenicol, and tetracycline, and samples that were difficult to interpret as positive or negative were confirmed by PCR. Of the Salmonella samples tested, 42% contained ampC gene, 34% contained flo gene, and 23% contained tetA gene. Twenty-five percent of samples from Dairy Farm 1 were positive for *ampC*, *flo*, and *tetA*. Seventy-two percent of samples from Dairy Farm 2 were positive for *ampC*, and 55% for *flo* and *tetA*. Sixteen percent of samples from Dairy Farm 3 contained *ampC* gene and 33% contained flo and tetA genes. All samples tested from Dairy Farm 4 were negative for *flo* and *AmpC* genes and 22% tested positive for *tetA*. Further testing will be conducted to determine the resistance profile on remaining samples. Overall, *ampC* gene seems to be the most common among *Salmonella* isolated from cattle in Georgia at 42%. There is not a direct correlation between the use of antibiotics and the presence of resistance.

Characterization of Transgenic Mice Expressing a Genetically Altered Luteinizing Hormone Receptor

Javier Valle, Frank J. Michel
Dr. Prema Narayan, Department of Biochemistry and Molecular Biology, University of Georgia

Luteinizing hormone (LH), human chorionic gonadotropin (hCG), and follicle stimulating hormone (FSH) comprise the group of gonadotropins that is essential for sexual development in humans. LH is secreted from the anterior pituitary and hCG is secreted from the placenta. Both bind to a common G protein-coupled receptor (LHR) present in the Leydig cells of the testis or theca cells of the ovary and induce steroidogenesis. Constitutively activating luteinizing hormone receptor (LHR) mutations occur naturally in humans, resulting in a clinical disorder termed gonadotropin-independent precocious puberty. The aim of this study was to characterize the phenotype of a line of transgenic mice expressing a genetically engineered mimic of a constitutively active LHR made from an hCG-LHR fusion gene construct (yoked hormone receptor, YHR) and compare the findings with previously characterized lines of mice expressing the same YHR transgene. The experimental group of mice expressing this altered receptor (YHR+) was compared to control group littermates (wild-type, WT) before and after the age of puberty using hormonal and histological analyses. Male prepubescent transgenic mice displayed increased testosterone levels and seminal vesicle weights, along with reduced serum FSH levels compared to WT controls. Prepubescent, female transgenic mice exhibited an increase in ovarian estradiol levels and uterine weights and reduced serum LH and FSH levels compared to their pre-pubertal control group littermates. These results demonstrate that YHR is functional in vivo and are consistent with similar findings of a recent characterization of another line of YHR transgenic mice; therefore, these lines of YHR transgenic mice will be a useful model to study reproductive effects of premature LHR activation.

The Effect of Communism on Eastern European Literature: With a Focus on Ivo Andric, Wislawa Szymborska, and Ismail Kadare

Jora Vaso
Katarzyna Jerzak, Department of Comparative Literature, University of Georgia

In the works I have read this summer, one can see the reflection of the intensity of communist regimes in the respective countries. Ironically, all three writers, who end up as dissidents or exiles, were originally devoted Marxists. In Kolakowski's assessment, this ironic situation is justified by the impossibility of translating the theory of Marx into successful practice. Out of the three countries that I have researched, Albania emerges as the most totalitarian. This may be due to the lack of independence throughout Albanian history, before and after Communism. In effect Albania went straight form feudalism to Communism. This is very much reflected in Kadare's prose, the metaphors and allegories he uses in most of his work, e.g. The Ottoman Empire, in The Palace of Dreams, is a transparent metaphor for Hoxha's Albania. His continuous use of Communism as a background to all of his novels reveals the severity in which Communism affected Albania which is in turn reflected in his writing. More so than the other two writers, Kadare is unable to look past such a major part of Albanian history. His inability to look beyond Communism puts him in stark contrast to Andric and Szymborska. Andric's "chronicles" use historical past to show that the identity of a country remains constant throughout even the most dramatic political upheavals. Though Andric does not specifically mention Communism in his book The Bridge on the Drina, one can easily see that the bridge is similar to Bosnia in that it remains standing while different occurrences pass through. Among the writers I considered, Andric was clearly the least controlled one—his writing did not suffer any major changes after Communism became the official system in Yugoslavia. This is because Yugoslavia remained the most independent communist country in the Soviet bloc. This independence is reflected on Andric's work which remains unchanging even after Communism. This lack of change is due to the fact that Andric's "chronicles" and short stories focus more on the centuries of turmoil in the Balkans, rather than a specific system of government which never remains constant. It is for this reason that Andric's work will never become irrelevant. Communism in Poland, although not as tolerant as in Yugoslavia, never reached the extremes it did in Albania. Szymborska, who experienced the transition to Communism as a young woman, seems to be the one who was most disappointed by the reality of the new system. She experienced both extremes—that of communist idealism and then utter disillusionment—of the harsh system. As a result, she left the Communist party and devoted herself to more universal ideas. Paradoxically, her distancing herself from Communism and politics in general resulted in her poetry having a more universal expression and appeal. Of the three writers she is the most accessible to the Western reader because her writing depends the least on the particulars of Polish history and politics. To conclude, it appears that Communism has produced a nearly hermetic literature that requires a Western reader to know its historical and political background. Ismail Kadare has suffered the most as a writer. Though many of his books are critiques of Communism, the aggressive and totalitarian Communism which took place in Albania has more power on the writer than the other way around. Ivo Andric's work is not affected by Communism more than by the long history of conflict in the Balkans. Szymborska's poetry is neither focused on politics, history, or her specific country. Though she naturally refers to Poland, her work remains broad in appeal. The challenge of post-communist literature in Eastern Europe will be to leave behind Communism as the permanent point of reference without losing its identity. Polish literature may have made it there already while the Balkans are still in the position defined by Andric half a century ago: on the border between the Eastern and the Western worlds. Communism has done its part to hinder its progression.

Arts Integration in School Curriculum as a Motivator for Student Success

Erika Vinson
Dr. Richard Siegesmund, Art Education,
University of Georgia

This study examines the promotion of academic and social competencies among middle and high school students through an integrated arts curriculum. The study focuses on Davidson Arts Magnet School, a grade 6 through 12 high school in Augusta, Georgia. Davidson is nationally ranked for academic achievement and a GRAMMY Signature School. The school combines high expectations for students with a cooperative, nurturing environment. The Georgia Systemic Teacher Education Program sees Davidson's curriculum that combines fine arts and academics as a possible state model for education.

This is a mixed methods study. Analysis of quantitative data gathered through standardized testing and numeric assessments (including grade point average and attendance records) will be used to support analysis by factors such as mastery of school curriculum and academic dedication. The analysis will also consider how socio-cultural status (reflected by and free and reduced lunch status) impacts learning. Qualitative data gathered from semi-structured interviews, which follow anthropological methods, with Davidson faculty and staff will illuminate the quantitative data and give a more descriptive picture of Davidson's overall environment and methods for success.

Davidson students, all of whom actively participate in the fine arts, exhibit significantly higher academic achievement, discipline, and self-motivation than students at traditional schools. This suggests that the fine arts contribute to the personal and educational development of children of all backgrounds and abilities. It appears that the arts instill a positive attitude toward academic achievement. Therefore the preservation of the fine arts in school curricula should be a top priority.

Examining the Balance of Social and Economic Priorities for Development in Post-Liberalization India: the Case of Kerala

Katherine Vyborny
Dr. Kavita Pandit, Department of Geography,
University of Georgia

The state of Kerala in southern India, governed alternately by Communist and Congress parties since independence, has presented a controversial alternative "model" for development, prioritizing social equity and public programs over economic efficiency. This project takes a closer look at the case of Kerala to explore how its traditional emphasis on social priorities over economic efficiency has experienced the new challenges of India's liberalization and the resulting greater exposure to the world economy. Since the beginning of India's economic liberalization in the 1980s and 90s, how have economic factors at the international, national, state, and local level interacted to affect Kerala's economy and wider development? The economic effects of this exposure, along with the level of human development already achieved, may change the priorities of the public, of elites, and as a result of government policy, to reflect a higher prioritization of economic efficiency over the social equity that has been emphasized in the past. Economic and social statistical indicators, government budget documents, content analysis of a sample of historical Kerala newspapers, and interviews with twenty-five key actors in Kerala address the question: what is the current influence of factors on global, national, state and local levels on public priorities for development, and what is the current balance of the goals of social and economic development in Kerala's public opinion, politics, and ultimately public policy? A preliminary review of the data seems to confirm that the international influences of globalization, the involvement of international lending institutions, and migration, as well as the economic changes of India's liberalization on a national level, have impacted Kerala's development, and in response to these forces and to the attainment of developed-world standards in many social indicators (such as the low infant mortality rate) have created a shift in public opinion towards an emphasis on increased

economic efficiency over continued social development.

HOPE Scholarship Eligibility and Retention Rates as a Function of High School Characteristics

Daniel Waldroup
Dr. David Mustard, Department of Economics, University of Georgia

Georgia's popular HOPE Scholarship Program uses state lottery funds to pay the in-state college tuition of any Georgia high school student who graduated after 1993 with at least a 3.0 grade point average in core classes. Students who continue to maintain a "B" average in college can renew the scholarship until they reach 127 semester hours of college credit. Despite the simplicity and straightforwardness of the scholarship's requirements, there is significant variation in HOPE eligibility and retention rates amongst students from different Georgia public high schools. Using econometric regression methods on data collected from approximately 325 Georgia public high schools between the 1996-97 and 2001-02 school years, this project seeks to determine how high school factors affect HOPE Scholarship eligibility and retention rates. Potentially influential high school factors such as size, racial composition, poverty rate, and standardized test scores will be analyzed for their individual effects on rates of eligibility and retention. Finally, having determined which high school factors are most associated with HOPE Scholarship eligibility and retention, the project will propose potential policy and educational changes that may increase student HOPE Scholarship achievement.

Glycopeptide Isolation and Glycosylation Site Identification: A Standardized Procedure

Nicole Warren
Dr. Michael Pierce, Biochemistry and Molecular Biology, University of Georgia

The primary aim of the experiments described in this paper was to develop a standardized procedure to efficiently isolate and identify glycoproteins and their associated N-linked glycosylation sites. The significance of these experiments resides in the possibility of using this procedure to analyze complex glycoprotein mixtures such as human serum and experimentally observe their relevance as biomarkers for disease. This standardized protocol will provide a more efficient way to identify glycopeptides by preventing certain side reactions, such as protein carbamylation in the presence of urea, that interfere with the efficiency and quality of experimental data. In the initial stages of experimentation, three dilutions of bovine thyroglobulin (bThg) were used in order to observe the minimum amount of the protein that is required for detection of associated glycosylated proteins. Glycopeptides were isolated from bThg by a series of steps including proteolysis to fragment the denatured protein, lectin affinity chromatography to select for specific glycopeptides, and enzymatic deglycosylation to excise glycans from glycoproteins. Matrix Assisted Laser Desorption/Ionization (MALDI), Liquid Chromatography-Mass Spectrometry (LC-MS/MS, and data analysis using Masslynx software followed by use of the MASCOT database for protein sequencing were used to analyze and sequence experimental data. Of the three dilutions, consisting of 10mg, 1mg, and 0.1mg of bThg, N-glycosylation sites were observed with the glycoprotein's in the 10mg and the 1mg samples. The effectiveness of this procedure to identify individual glycopeptides from different proteins was then tested with mixtures of bThg and transferrin (Tf), proteins that are both contained in human serum. In conclusion, the protocol was successful for the efficient identification of both types of glycoproteins.

Creation of an *in vitro* Transcription System for Mycobacterium tuberculosis

Alyson Weber
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

Mycobacterium tuberculosis, the causative agent of tuberculosis (TB), is a highly successful human pathogen. Each year, an estimated ten million cases of active TB result in two to three million deaths worldwide. Studies indicate that SigC, one of twelve secondary sigma factors in

M. tuberculosis is required for pathogenesis in animal models of TB and therefore likely to be important for human disease. Expression of several genes is altered in a strain lacking SigC relative to a SigC+ strain. Establishing an *in vitro* transcription system will aid in identifying those genes directly transcribed by SigC as the gene products may be virulence factors that could serve as vaccine targets. An *in vitro* transcription system requires: core RNA polymerase (RNAPcore), a sigma factor that transiently associates with RNAPcore enabling the enzyme to bind at specific DNA sequences (promoters) and initiate trancription, a DNA template containing a promoter, and ribonucleotide triphosphate substrates. RNAPcore will be isolated from *M. smegmatis*, a related but nonpathogenic mycobacterium. RNAPcore consists of four subunits: 2□□and□′, encoded by the *rpoA*, *rpoB*, and *rpoC* genes, respectively. RNAPcore will be isolated by carboxy-terminal fusion of RpoC to 10 histidines (His-tag) for nickel affinity purification. The primary *M. tuberculosis* sigma factor, SigA, and SigC will be purified as amino-terminal His-tag fusion proteins in an *Escherichia coli* expression vector. SigA will serve as a positive control for *in vitro* transcription as many drug resistance genes have promoters that are recognized by the primary sigma factors in bacteria. Putative *M. tuberculosis* SigC and SigA promoters will be cloned onto a plasmid upstream of a transcription terminator to yield small *in vitro* transcripts that can be sized on denaturing acrylamide gels to determine their start sites. Progress toward development of this system will be presented.

Assessing Correlations Between Elite Media Coverage and Movement in Public Opinion Polls During Presidential Elections

Matthew Weiss
Dr. Audrey H. Haynes, Department of Political Science, University of Georgia

Media pundits speak regularly about which candidate is winning the media spin cycle. While this contest receives significant attention from the talking heads on cable news channels, does positive and negative news coverage really have an impact on public opinion polls and, subsequently, the results of an election? Previous research has suggested that media coverage can correlate to shifts in candidate support during a presidential election. Additionally, coverage of candidates regarding specific issues such as the economy has been proven to impact public preferences of candidates on those issues. Was this phenomena replicated during the 2004 presidential election and, if so, does it also exist for non-economic issues? The purpose of this research is to analyze the content of newspaper articles during the five months preceding the 2004 election in order to determine whether shifts in the tone of newspaper coverage correlate with a subsequent shift in the poll standings of either presidential candidate. Additionally, the research will attempt to determine whether such a correlation exists between newspaper coverage and poll standings for specific policy areas such as the war in Iraq and the strength of the economy. The findings of this research could play an important role in upcoming elections by determining how important it is for candidates to 'spin' news developments in order to influence media coverage. Further, such research may indicate whether specific political circumstances or a focus on specific policy areas can impact the strength of the correlation between media coverage and public opinion polling.

Antimicrobial Resistance in Salmonella of Bovine Isolates in Georgia

Lindsay Marie Williams
Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia

Salmonella enterica is a destructive infectious disease, and it causes tens of thousands of infections per year in humans. Antibiotic treatment of this bacterial infection is often ineffective due to antibiotic resistance. The use of antibiotics in food animals has been blamed for the emergence of *Salmonella enterica* strains resistant to those particular antibiotics or to other antibiotics used in the same human class. There have not been comprehensive studies of farms to date to determine if the prophylactic use of antibiotics is associated with the presence of antibiotic resistant *Salmonella*. The phenotypic

antibiotic resistance profile from 91 *Salmonella* isolates obtained from four different farms as part of a prospective comprehensive study were analyzed using minimum inhibitory concentrations (MIC). The antibiotics tested were, spectinomycin, ampicillin, amoxicillin-clavulanic acid, cephalothin, ceftiofur, trimethoprim, ticarcillin, difloxacin, tilmicosin, enrofloxacin, florfenicol, gentamicin, orbifloxacin, and tetracycline. *Salmonella enterica* samples were isolated from animals and their surrounding environments in four different farms in Georgia. In total, 91 isolates were tested (Farm 1: 7 environmental isolates; Farm 2: 45 isolates; Farm 3: 21 isolates; Farm 4: 18 isolates, 8 of those from the environment). Farm 1 showed 100% resistance to spectinomycin, tilmicosin, florfenicol, and tetracycline; 30% to ampicillin, amoxicillin-clavulanic acid, and cephalothin. Farm 2 showed 100% antibiotic resistance to ampicillin, amoxicillin-clavulanic acid, cephalothin, ceftiofur and florfenicol; 98% to tetracycline, 84% to spectinomycin 86% to gentamicin, 22% to ticarcillin, and 7% to trimethoprim. Farm 3, showed the following resistance, 67% to tetracycline, 57% to amoxicillin-clavulanic acid, 14% to ticarcillin, 43% to spectinomycin, 33% to ampicillin, and 24% to trimethoprim and florfenicol. Farm 4 showed almost no antibiotic resistance in the ten samples tested, with the exception of tetracycline (60%). Resistance to tetracycline seems to be consistently high in the *Salmonella* isolates from all the herds tested. However, resistance to certain antibiotics such as ceftiofur and florfenicol seems to be exhibited exclusively on individual farms. Resistance phenotypes seem to be associated with farm management practices.

Georgia's Environmental Literature: A Survey of Contemporary Works

Leslie S. Wolcott
Dr. Betty Jean Craige, Department of Comparative Literature, University of Georgia

This paper surveys recent literatures concerning the land and environment of Georgia from an ecocritical perspective. Though stories and accounts of Georgia's natural features have existed for hundreds of years, few if any scholars have examined the works as a cohesive group. My paper analyzes representative narrative, nonfiction, biographical, scientific, and journalistic literatures of recent years, and attempts to identify the environmental problems and solutions displayed throughout the works. In addition, this paper illustrates the importance of knowledge and education of and literature about the environment in attempts at conservation and preservation of Georgia's landscapes, renewable and nonrenewable resources. This project was inspired by my interest in environment and literature as well as the emerging field of ecocriticism. Dr. Betty Jean Craige of the Environmental Ethics and Comparative Literature departments provided resources and guidance, and the project was made possible by the CURO Summer Research Fellows program at UGA.

Regulation of Branched-chain Amino Acid Catabolism in *Streptomyces coelicolor*: Applications for Metabolic Engineering of Polyketide Antibiotic Biosynthesis.

Fei Yang, Ondrej Sprusansky, Karen Stirrett and Dr. Janet Westpheling, Department of Genetics, University of Georgia

Mutants of *Streptomyces* defective in the catabolism of the branched chain amino acids, valine, leucine and isoleucine, are also defective in antibiotic production, suggesting that some of the precursors for antibiotic synthesis come exclusively from this carbon utilization pathway. *Streptomyces*, a common soil bacteria that produce most of the natural product antibiotics used in human and animal health care, are unique among bacteria in that they have two pathways for branched chain amino acid degradation. These two gene clusters, *bkdA2B2C2* and *bkdA1B1C1*, each encode an apparently identical branched-chain amino acid dehydrogenase enzyme complex.

BkdR is a transcriptional regulator of the *bkdA2B2C2* cluster and the focus of the project is to understand the mechanism of this regulation. Analysis of the *bkdA2B2C2* shows that the cluster is transcriptionally active at the initiation of morphogenesis and antibiotic production. To investigate the mechanism of

BkdR regulation, a reporter gene fusion between the *bkdA2* promoter and the *xylE* reporter gene has been constructed. The *xylE* gene encodes a catechol dioxygenase that converts colorless catechol to a yellow oxidation product and will allow the rapid assessment of *bkdA2* mutations that affect regulation. Located within the regulatory region of this promoter is a nearly perfect 14bp inverted repeat sequence that might be a *BkdR* protein binding site. To test this hypothesis base changes will be introduced throughout the 14bp inverted repeat using site directed mutagenesis. To support the results of these experiments gel mobility shift experiments will be preformed on potential binding site mutants with purified *BkdR* protein. This work will contribute to the understanding and eventually the manipulation of an important metabolic pathway that leads to antibiotic production in these complex and interesting bacteria.

Analysis of the Interactions Between Chondroitins and Pectins

Stephanie Yarnell
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

Glycosaminoglycans (GAGs) are naturally occurring, heterogeneous, negatively charged, and N- acetylated, unbranched polysaccharides. Chondroitins are one of the four main classes of GAGs. The role of chondroitins in the extracellular matrix has been extensively studied. They contribute to the general structure and permeability properties of connective tissues and have been implicated in binding of pathogens to particular target cells, maintenance of cellular activities, and development of metastasis in cancer cells. In the peripheral nervous system, chondroitins are implicated in the rebuilding of damaged schwann cells and reconnecting severed inputs to schwann cells from astrocytes, but have also been implicated in markedly slowing the axonal regeneration in the distal segment of neurons.

Pectins are acidic, matrix polysaccharides that are primary structural elements of the matrix of the plant cell wall, and have been implicated in morphogenesis, pH regulation, ion balance, wall permeability, and plant defense. Thus, chondroitins and pectins serve similar functions within their respective organisms.

We have noted that enzymes that cleave chondroitins and those that degrade pectin share structural similarities, and enzyme structure is often driven by the three dimensional structure of the substrate. The similarity in function of GAGs and pectins, and the structural similarities of the enzymes that degrade them, led us to wonder if these were clues that could shed light on the mechanism of the role of pectins in human health. We therefore investigated the effects of chondroitins on selected pectin degrading enzymes, and of pectin on chondroitinases. Effects on both enzyme structure and activity were observed.

Civil Rights Figures Appearing in the Multicultural Archive of Georgia

Rafael R. Young
Dr. Timothy Powell, Department of English, University of Georgia

The Multicultural Archive of Georgia is a collaboration of Dr. Barbara McCaskill and Dr. Timothy Powell of The University of Georgia. The website archives pictures, stories, and digital media concerning the historic presence and roles of African and Native Americans in Georgia. Dr. McCaskill and Dr. Powell began this project intending to create a much needed website for teachers to use when teaching the history of minorities in Georgia. They intend to have the website added to Georgia's Quality Core Curriculum. The website is currently online and can be found at www.mcgeorgia.uga.edu.

I viewed several video tapes about the Civil Rights Movement taken from the Walter J. Brown Media Archives. Next, I chose nine pertinent clips, including figures such as The Rev. Dr. Martin Luther King, Jr., giving various speeches, James Meredith at the University of Mississippi, and Robert Kennedy discussing the Freedom Rides. I used other videos, books, and microfilm to provide information about what was happening and why each clip was important in brief paragraphs. These brief descriptions

will appear with each clip on the website so that both students and teachers can quickly identify which clip they need.

The clips and information found are important because they bring together three highly important organizations. These findings will not only appear on the Multicultural Archive of Georgia, but will also be placed in the Digital Archive of Georgia and the New Georgia Encyclopedia. This work heads future collaborations between the three groups.

Efficiency of Low-Cost Airline Carriers in a Deregulated Environment

Anne Zimmerman
Dr. David Kamerschen, Department of Economics, University of Georgia

The airline industry has suffered major blows since deregulation in the late 1970s and early 1980s. Deregulation resulted in the failure of many major airlines, such as Eastern, and the springing up of new low-cost carriers. Today, United Airlines, American Airlines and other North American carriers have filed for Chapter 11 bankruptcy in order to compete with low-cost airlines and survive in the competitive aviation environment. This study examines the economic secret behind the success of low-cost airlines and argues that they are best suited for the current flying industry. The focus is on Southwest Airlines, a Texas-based airline, which has managed to defy tradition and report an astounding fifty-five consecutive quarters of profitability. Southwest, the original low-cost carrier, has been emulated by numerous newer airlines such at JetBlue Airways. The paper examines data on industry ticket pricing, fuel costs, plane capacity, route choice, as well as other business success indicators. Operating profits and losses among network and low-cost carriers will be compared. Charts detailing airline cost and revenue per passenger mile will also provide valuable data analysis. Some factors influencing the accomplishments of Southwest include the invention of the two-tier pay system, choice of airports, efficiency, controlled growth, and a 'no frills' philosophy. As Chapter 11 bankruptcy filings persist and airlines restructure their business plans, the industry will continue to evolve and adapt to meet competition. Established major carriers of the past must understand the factors vital for profitability. They must continue emulating low-cost carriers such as Southwest if they plan to remain in business.

Symposium 2007

University of Georgia
Tate Student Center & Student Learning Center Fourth Floor Rotunda
April 9, 2007

CALL FOR ABSTRACTS

The Center for Undergraduate Research Opportunities at the University of Georgia provides a forum for all undergraduates to present original research and creative works sponsored by faculty members. Undergraduate students from all disciplines are encouraged to participate. Representatives of public and private higher education institutions in Georgia are encouraged to apply.

Presentations may be in the form of an oral presentation, poster session, exhibition, performance, or work of art. Students can also present a tutorial about a research methodology or new technology. Undergraduate researchers who are at various stages of the research process are encouraged to submit abstracts describing where they are in the research process and the issues they face. Those who wish to present their work should submit an application and an abstract of a maximum of 250 words (via the CURO web site) and a brief supporting letter from the sponsoring faculty member no later than January 12, 2007. Group research projects should be submitted with one application and one letter of faculty support. All abstracts will receive graduate student peer review with faculty guidance. All participants accepted into the Symposium will be notified by February 16, 2007, and their abstracts will be published in a book of abstracts. Sponsoring faculty will be invited to preside at their students' sessions.

Best Paper Awards
Papers on work being presented at the CURO Symposium submitted by March 19, 2007 will be considered for Best Paper awards in the categories of humanities, social sciences, civic responsibility focus, international focus, and sciences. Papers must be submitted electronically to curo@uga.edu. Maximum length is 20 pages, double spaced.

Purpose of the Symposium:
- To highlight excellence in research by undergraduate students
- To enrich the undergraduate experience by promoting communication and cooperation between faculty and students
- To provide a forum for undergraduates to communicate and disseminate their research findings and creative works
- To provide an opportunity for undergraduate researchers in the state of Georgia to engage with their peer researchers

Criteria for Selection:
- Originality and quality of research
- Quality of written abstract
- Ethical and responsible research
- Extent of the undergraduate student's involvement in development of the research design and execution of the project. Research presented at the Symposium should go beyond work completed for a class paper or project
- A letter of support from supervising faculty

This event will be free and open to the public. All interested faculty and students are encouraged to attend the CURO 2007 Symposium. For more information, contact curo@uga.edu, (706) 542-5871.

Monday, April 10th, 2006

Begin registration of oral and poster presenters; Students hang up posters — **9:00 a.m.**
Tate Student Center, Lower Lobby

Concurrent Oral Sessions — **10:10 a.m.**
Tate Student Center, Rooms 137, 138, 139, 140, 141

Performing Arts: Music — **11:15 a.m.**
Tate Student Center, Georgia Hall A

Concurrent Oral Sessions — **11:15 a.m.**
Tate Student Center, Rooms 137, 138, 139, 140, 141

Performing Arts: Creative Writing — **12:20 p.m.**
Tate Student Center, Georgia Hall A

Concurrent Oral Sessions — **12:20 p.m.**
Tate Student Center, Rooms 137, 138, 139, 140, 141

Performing Arts: Dance — **1:25 p.m.**
Tate Student Center, Georgia Hall A

Concurrent Oral Sessions — **1:25 p.m.**
Tate Student Center, Rooms 137, 138, 139, 140, 141

Performing Arts: Drama — **2:30 p.m.**
Tate Student Center, Georgia Hall A

Concurrent Oral Sessions — **2:30 p.m.**
Tate Student Center, Rooms 137, 138, 139, 140, 141

Welcome and Opening Session — **4:00 p.m.**
Tate Student Center, Georgia Hall A
Dr. David S. Williams
Director, Honors Program
Dr. David C. Lee
Vice President for Research

Introduction of Keynote Speaker
Ms. Melissa Cabinian
CURO Scholar and CURO Apprentice Program Alumna

Keynote Address: *"Polycentrism: Interdisciplinary Work in the Academy"*
Dr. Jace Weaver
Professor, Religion and Native American Studies
Director, Institute of Native American Studies

CURO National Science Foundation Promising Scholars and Outstanding STEM High School Teachers
Dr. David S. Williams
Director, Honors Program

Announcement of Excellence in Undergraduate Research Mentoring Awards
Dr. Arnett C. Mace
Sr. Vice President for Academic Affairs and Provost

Poster Session **5:00 p.m.**
Tate Student Center, Georgia Hall A & B

CURO Apprentice Dinner **6:45 p.m.**
Tate Student Center, Reception Hall

Art Gallery Talks **7:00 p.m.**
Student Learning Center, Fourth Floor Rotunda
Prof. Carmon Colangelo
Director, Lamar Dodd School of Art
Ms. Robin Dana
Gallery Director, Lamar Dodd School of Art

Dessert Reception & Announcement of CURO Scholars, CURO Summer Research Fellows, Best Poster, and Best Paper Awards **8:00 p.m.**
Dr. David S. Williams
Director, Honors Program
Student Learning Center, Fourth Floor Rotunda
Deborah Dietzler
Executive Director, UGA Alumni Association

Monday, April 10, 2006

Concurrent Oral Sessions
Tate Student Center Conference Rooms 137, 138, 139, 140, 141

Presentation of CURO Summer Research Fellowships, CURO Scholars, Best Poster, and Best Paper Awards	Dr. David S. Williams, Director, Honors Program Deborah Dietzler, Executive Director, UGA Alumni Association

The office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2001. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students. This year the Graduate School and the Honors Program have established a new award that recognizes graduate students devoted to the research mentorship of undergraduate students. Awards will be presented at the CURO Symposium Awards Ceremony on Monday, April 10, 2006 at 4:00 p.m. in the Tate Student Center, Georgia Hall.

2006 Awards

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Associate Professor of Textiles, Merchandising, and Interiors

Early Career Faculty Award
Dr. Rodney Mauricio, Professor of Genetics

Graduate Student Award
Christopher Anderson, PhD candidate in Ecology

Graduate Student Recognition
Dawn Holligan, PhD student in Plant Biology

2005 Awards

Faculty Awards
Dr. Gary Barrett, Odum Professor of Ecology
Dr. Sidney Kushner, Professor of Genetics

Department Award
Department of Cellular Biology.

2004 Award

Faculty Award
Dr. William S. Kisaalita, Associate Professor, Dept. of Biological & Agricultural Engineering

2003 Awards

Faculty Award
Dr. Jody Clay-Warner, Assistant Professor of Sociology

Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Tim Hoover, Undergraduate Coordinator

Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Professor
Dr. Marie-Michèle Cordonnier-Pratt, Senior Research Scientist

2002 Awards

Faculty Awards
Professor William D. Paul, Jr., Professor of Art
Dr. Katherine Kipp, Associate Professor of Psychology

Faculty Recognition
Dr. Susan Sanchez, Assistant Professor of Veterinary Medicine

Department Award
Department of Biochemistry and Molecular Biology
Dr. J. David Puett, Department Head

Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Professor of Physics and Astronomy
Dr. Heinz-Bernd Schuttler, Professor and Department Head of Physics and Astronomy
Dr. Jonathan Arnold, Professor of Genetics
Dr. Susmita Datta, Professor, Georgia State University
Dr. David Logan, Professor, Clark Atlanta University
Dr. William Steffans, Professor, Clark Atlanta University

2001 Awards

Faculty Award
Dr. Marcus Fechheimer, Professor of Cellular Biology

Faculty Recognition
Dr. David MacIntosh, Associate Professor of Environmental Health Sciences
Dr. Dean Rojek, Associate Professor of Sociology

Department Award
Genetics Department
Dr. John MacDonald, Department Head and Professor

Program Award
Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

Graduate Student Reviewers for CURO 2006 Symposium

Cady Berkel	Child and Family Development
Sarah Cooley	Marine Sciences
Sarah Craven	Microbiology
Patrick Curtis	Microbiology
John M. Davis	Ecology
Emily DeCrescenzo Henriksen	Microbiology
Geneva DeMars	Biochemistry and Molecular Biology
Anita DeRouen	English
George Felis	Philosophy
Joy Harden	Counseling Psychology
Jeff Lake	Plant Biology

Greta Polites	Management Information Systems
Chip Small	Ecology
Sara Steger	English
Jeff Stoike	Ecology
James Tucker Swindell II	Biochemistry
Meghan VanDeventer	Educational Psychology
Sarah Vess	Educational Psychology

Reviewers for Best Paper Awards

Faculty

Dr. Ronald Carroll	Ecology
Dr. Jody Clay-Warner	Sociology
Dr. Roxanne Eberle	English
Dr. William P. Flatt	Foods and Nutrition (Emeritus)
Dr. Richard K. Hill	Chemistry (Emeritus)
Dr. Sylvia M. Hutchinson	Center for Teaching and Learning (Emerita)
Dr. Sidney Kushner	Genetics
Dr. William Lanzilotta	Biochemistry and Molecular Biology
Dr. Kevin McCully	Kinesiology
Dr. Carolyn Medine	Religion, Institute for Women's Studies, Institute for African American Studies
Dr. Leara Rhodes	Journalism
Dr. Paul Sutter	History
Dr. Kalpen D. Trivedi	English
Dr. Lance Wells	Biochemistry and Molecular Biology

Graduate Students

Cady Berkel	Child and Family Development
Jeff Lake	Plant Biology
Greta Polites	Management Information Systems
James Tucker Swindell II	Biochemistry

Reviewers for CURO Summer Research Fellowships

Dr. Wyatt Anderson	Professor, Genetics
Dr. William Barstow	Department Head and Professor, Biological Sciences
Dr. Karen Bauer	Director, Office of Institutional Research Adjunct Associate Professor, Institute of Higher Education
Dr. Roxanne Eberle	Associate Professor and Undergraduate Coordinator, English
Dr. Leara Rhodes	Associate Professor, Journalism
Dr. Scott Shaw	Professor, Physics and Astronomy
Dr. Regina Smith	Associate Vice President for Research
Dr. Katharina Wilson	Professor, Comparative Literature

CURO Advisory Board

Dr. E. M. Beck	Professor, Sociology
Dr. Gary Bertsch	Director and University Professor, Center for International Trade and Security
Dr. Margaret K. Cramer	Physician, University Health Center Women's Clinic
Dr. Art Dunning	Vice President for Public Service and Outreach
Dr. Stuart Feldman	Director and Professor, Interdisciplinary Toxicology Program
Dr. Freda Scott Giles	Associate Professor, Theatre and the Institute for African American Studies
Dr. Maureen Grasso	Dean, Graduate School
Dr. David Lee	Vice President for Research and Associate Provost
Prof. Jere Morehead	Vice Provost for Academic Affairs
Dr. J. David Puett	Department Head and Regents Professor, Biochemistry and Molecular Biology
Dr. Fausto Sarmiento	Assistant Professor, Geography
Dr. Steven Stice	Senior Research Scientist and Associate Professor, Animal and Dairy Science
Dr. Katharina Wilson	Professor, Comparative Literature
Melissa Cabinian	Undergraduate Student
Melvin Hines, Jr.	Undergraduate Student
Douglas Jackson	Undergraduate Student

Ex Officio

Dr. David S. Williams	Director of the Honors Program, Foundation Fellows, and CURO
Dr. Pamela B. Kleiber	Associate Director of the Honors Program and CURO

CURO Gateway Seminar Faculty

Professor Mark Callahan	Ideas for Creative Expression (ICE)
Dr. Ron Carroll	Ecology
Dr. Kathleen DeMarrais	Social Science Education
Dr. Joseph Dominick, Jr.	Journalism
Dr. William Eiland	Art History
Dr. Marcus Fechheimer	Cellular Biology
Dr. Katarzyna Jerzak	Comparative Literature

Faculty Mentor	Dr. Michael Bender, Department of Genetics

An Immunohistochemical Study to Investigate the Potential Role of Intercellular Adhesion Molecule-1 (ICAM-1) and Fractalkine in Placental Malaria

Laura Beth Agnew
Dr. Julie Moore, Department of Infectious Diseases, University of Georgia

Placental malaria can cause premature deliveries, low birth weight babies, and maternal anemia, and it is an important public health concern in areas where malaria transmission is endemic. During human placental malaria, Plasmodium falciparum-infected red blood cells (iRBC) are harbored in the intervillous spaces of the placenta, and this sequestration leads to a higher concentration of malaria parasites than is found in the periphery of the body. Recent studies have investigated the interaction between iRBCs and the syncytiotrophoblast (ST) membrane, and it is believed that the consequences of their interaction may better explain the phenomenon of placental malaria. The purpose of this study is to compare the immunohistochemical staining of infected and normal placental tissue sections to determine if infection has an effect on the concentration or localization of two immunological molecules, intercellular adhesion molecule-1 (ICAM-1) and fractalkine. This experiment uses the Avidin Biotinylated enzyme Complex (ABC) staining method to visualize the location and intensity of both molecules following incubation with primary antibody, biotinylated secondary antibody, ABC, and enzyme substrate. Previous studies have suggested that both ICAM-1 and fractalkine might play important roles in the immunology of placental malaria by aiding in the sequestration of iRBCs in the intervillous spaces of the placenta, and both molecules are expressed by the ST. If more intense staining of these molecules is seen in placental tissues infected with malaria and if the staining is localized to areas such as the ST and intervillous spaces of the placenta, then this study would suggest that ICAM-1 and fractalkine are key immunological compounds in placental malaria and that one or both might be yet another reason for the higher concentration of iRBCs seen in placental tissues.

Capital Punishment: A Closer Look

Laura M. Aikens
Dr. Dean Rojek, Department of Sociology, University of Georgia

Capital punishment is an issue of great contention. The deterrence doctrine predicts that as the harshness of the punishment increases, the likelihood a person will commit a crime decreases. It also requires that the punishment swiftly follow the act to be effective. It would follow from this theory that capital punishment is the most effective way of deterring crime. However, even proponents of the deterrence doctrine do not believe that capital punishment can be applied to murderers. The perpetrators are usually under the influence of alcohol or drugs and therefore not in a rationally thinking state of mind. For deterrence to work, people must be rational. Other than the fact that capital punishment has no effect on crime rates, there are many other problems with the death penalty. There is an incredible amount of money and time that must be put forth in a death penalty case. The recent advent of DNA analysis has helped to prove several individuals' innocence, individuals who were sitting on death row. Some wonder if capital punishment constitutes "cruel and unusual" punishment because of the frequency of botched executions. Many countries disapprove of our use of the death penalty, and recent pressure from them has influenced some of our policies regarding it. A final issue many antagonists of capital punishment put forth is that it has become a form of vengeance, something which is not the responsibility of our justice system.

Development of the AFFECT Module: A Family-Focused Emotion Communication Training (AFFECT) Module

Grace A. Anglin – CURO SUMMER FELLOW, CURO APPRENTICE & Rebecca D. Trupe – CURO SUMMER FELLOW
Dr. Kimberly Shipman, University of Colorado Medical School

Our research focused on developing an intervention program called A Family Focused Emotion Communication Training Module

(AFFECT) aimed at teaching caregivers how to effectively communicate with their children about emotional experiences. Emotional management skills, normally learned from the primary caregiver, are important for the psychosocial adjustment of the child. Emotional management skills include the child's ability to recognize their emotions and the emotions of others, to understand the causes and consequences of emotion, and to modify and regulate their emotions. Children developing within "at risk" contexts, such as physical maltreatment, generally have less developed emotional management skills and display increased emotional and behavioral problems. Our research helped develop an intervention program aimed at teaching caregivers to effectively manage their own emotions and communicate with their children about emotions. In developing the intervention, we adapted techniques from dialectical behavior therapy for teaching emotion regulation skills, as well as designed supplemental handouts, worksheets, and homework activities for parents to reinforce the components of the program. In addition, we created a behavioral coding system that will be used to test the effectiveness of the intervention program at teaching emotion-focused communication skills (e.g., active listening skills, emotion coaching skills, emotion support skills). The AFFECT Module is still in development and has not yet been clinically tested using the coding system. However, we intend to use the coding system in future pilot studies to evaluate the AFFECT Module so it can be applied as an intervention for maltreating parents.

The Influence of Gender on the Relationship between Transplant Consequences and Health Outcome

Grace A. Anglin – CURO APPRENTICE
Dr. Ronald Blount, Department of Psychology, University of Georgia

Pediatric transplantation, formerly considered a last option for terminally ill children, has become the treatment of choice for a number of serious medical conditions. Life-saving organ transplantation is not a "cure," but rather, a transition from a chronic, life-threatening disease to a second chronic condition that requires living with and caring for a transplanted organ. To prevent organ rejection, a patient must take immunosuppressant medication daily for life. Patients follow, or adhere to, their prescribed medication regimen to varying degrees, with adolescent transplant patients often less medically adherent than other age groups. As a result, they are at increased risk for organ rejection. Unwanted side effects of necessary transplant medications which include excessive hair growth, weight gain, and limited athletic ability often create psychological barriers to proper adherence. What is unknown is how transplant consequences differentially affect adolescent male and female recipients. Interviews were completed with pediatric solid organ transplant recipients (ages 11-18) and their parents to determine how gender influences the relationship between transplant consequences and health outcome (e.g., quality of life, medication adherence). Interview questions assessed physical side effects, functional impairments, and quality of life. Medical adherence was based on patient and parent report, prescription drug refill records, and immunosuppressant drug levels. The results of this study will be used in the development of intervention programs to target the unique challenges of male and female adolescent transplant recipients.

New Light on an 18th-Century Terracotta Sculpture: The Study for Sleeping Shepherd in the High Museum

Elaine A. Augustine
Dr. Alisa Luxenberg, Department of Art History, University of Georgia

Works of art that are neither signed nor dated produce research opportunities for art historians to assign authorship as well as determine the year(s) in which they were completed. Study for Sleeping Shepherd is a small terracotta sculpture in the High Museum of Art in Atlanta. Art historians have attributed the work to Louis-Claude Vassé as the study for Sleeping Shepherd (marble, 1751), his reception piece into the French royal art academy and dated it circa

1740-1745. However, that dating can be challenged through visual comparisons, exhibition records, and biography. In addition, the material of this work—fired clay—affects any interpretation of its function and stylistic qualities. While terracotta was traditionally used to create preparatory works of art and not given a careful finish, it was also becoming, by the 1730s, desired by French art collectors who appreciated its surface qualities. My contribution to the study of this sculpture is to compare it with the finished marble reception piece Sleeping Shepherd as well as with ancient statues and contemporary sculptures by other French artists. These comparisons aid in determining a more precise date in which the High's terracotta may have been executed. I will also explore the motivation for and meaning of depicting a sleeping nude shepherd in relation to the classical revival in 18th-century French art. Research into contemporary criticism of Vassé's art and the provenance of this terracotta may help us to understand how some of his contemporaries perceived his art.

Photography
Allison Banks
Prof. Michael Marshall & Prof. Stephen Scheer, Department of Photography, University of Georgia

I have always believed in the importance of awareness of places, both large and small, and of our interpretations of them, our memories and imagined histories of them. When I began making photographs, it was very much an exercise in thinking about how I grew up, and where I came from. The photographs were my interpretation, my applied meaning, and my dream of a world. Since then, I have continued to broaden the terms of my history, becoming aware of the greater context in which I am situated.

My interest in the idea of The Neighborhood has grown, and I have begun exploring the ways in which we dress our yards, prune our shrubs, walk our dogs, park our cars, and feed our birds. I concentrate my vision on what is small, not entire yards, and thus each photographed object becomes a symbol of itself, encouraging us to consider new ideas about its meaning. In this way, I hope to more broadly define what it means to own a piece of land, to care for it, and decorate it. My photographs are quiet, personal, and about a certain way of seeing and arranging photographic space. I hope for them to be not only about how things look, but also about how we look at things and how it is possible that by slowing down and reflecting on what may initially seem small or inconsequential, we may come to recognize something more in our lives.

Efficiency Evaluation of Cotton Production Practices using Stochastic Frontier Analysis
Allyson L. Barnes
Dr. Timothy Park, Department of Agricultural and Applied Economics, University of Georgia

The overall objective of the study is to evaluate different technologies and cultural practices used in the production of upland cotton in South Georgia using stochastic frontier analysis. Stochastic frontier analysis recognizes that for a given level of inputs, producers can attain a maximum output, which is identified as the production frontier. Other producers may experience random shocks such as adverse weather, pest infestations, constraints on soil quality, along with limitations on managerial skill, resulting in output that lies below the frontier. Efficiency scores summarize how far below the frontier producers are operating. A stochastic frontier analysis is estimated in a statistical model to identify the key factors that influence the technical efficiency and cost

efficiency of cotton producers. Survey information from South Georgia cotton producers was gathered including combinations of tillage techniques and adoption of cotton transgenic technology along with the input, cost, and yield data on a field level. We include data on the tillage method used by the farmer (conventional tillage and strip tillage) along with five types of cotton, including conventional and transgenic varieties which have a built-in resistance to specific pests such as the cotton bollworm and the tobacco budworm. The efficiency model demonstrated that production methods using transgenic cotton varieties resulted in greater net returns and efficiency rankings than conventional cotton. Net returns and efficiency rankings were highest with conservation tillage. The research results will stress the advantages of the stochastic frontier approach for evaluating efficiency effects in crop production and outline additional applications of the technique for extension advisors assisting Georgia crop producers.

A Novel Pathway for Polysaccharide Precursor Synthesis

Liron Bar-Peled
Dr. Maor Bar-Peled, Department of Plant Biology, University of Georgia

Polysaccharides are the most abundant class of molecules in nature. They have numerous functions such as structural support (cellulose in plant cell walls), storage (starch), cell-to-cell communication (glycoproteins and glycolipids), protein trafficking and protein folding. Polysaccharides are synthesized from activated sugar-moieties known as nucleotide sugars. We are trying to address the different pathways by which these precursors are synthesized. One route by which nucleotide sugars are made involves a family of enzymes known as nucleotide sugar pyrophosphoyrlases (PPase) which convert a nucleotide (NTP) and sugar-1-phosphate to a nucleoside diphosphate (NDP)-Sugar and inorganic pyrophosphate. PPases are very specific enzymes and convert only one type of sugar-1-phosphate and nucleotide to respective nucleotide sugar. We have identified a gene in *Arabidopsis thaliana* that encodes a protein that shares 29% amino acid sequence identity to the well-characterized uridine diphosphate (UDP)-Glucose PPase. The recombinant gene was over-expressed in *Escherichia coli*, and the protein was purified via affinity chromatography. A series of assays were conducted varying the type of nucleotide and sugar-1-phosphates used, and it was discovered that this enzyme converts five different sugar-1-phosphate's and uridine triphosphate (UTP) to respective nucleotide sugars. This enzyme has been termed UDP-Sugar PPase due to its broad sugar-1-phosphate specificity. Initial biochemical characterization shows differences in kinetics between UDP-Sugar PPase and other substrate-specific PPases. Since there are other enzymatic pathways by which nucleotide sugars are made in vivo, it remains unclear what biological role UDP-Sugar PPase has in vivo and which is the major pathway toward nucleotide sugar production.

Striking the War Machine: The Anti-War Folklore of American Civilians and GI's during the Vietnam War

Betsy A. Beasley
Dr. Elissa Henken, Department of English, University of Georgia

Typical popular conceptions of the Vietnam War tend to construct two polarized camps of American reactions to the war. According to this view, "doves"—or those opposed to the war—consisted of college students, activists, hippies; "hawks"— those supporting the war—were the U.S. government, anyone involved in the U.S. military, and anyone over thirty. This dichotomy is problematic, as I discovered upon evaluating the folklore of the Vietnam War. I came to the project to look to the historical record to evaluate the chants, legends, personal experience narratives, jokes, folk songs, and folk images of both American civilians and enlisted Americans in Vietnam. A group's folklore concerning a specific topic like the war reflects as well as determines how the group feels about it; folklore both expresses a group's attitude toward the subject and influences how members of that group approach the subject, being affected as they are by folk culture. As such, historical

folklore, difficult as it is to collect, is imperative to a thorough examination of history. Through my research, I found that the dialogues of civilian protestors and of American GIs were more similar than different; in fact, most folk culture of American enlisted men was remarkably anti-war. While civilian protestors were more visible in their opposition, many American GIs fought against the war subtly, through their everyday speech rather than through marches and sit-ins. Although GI protest folklore did include some overtly anti-war speech, such as slogans on buttons distributed by Vietnam Veterans Against the War, most anti-war folklore took the form of jokes, songs, and rumors that only hinted at an anti-war message. The folklore of these GIs did not pronounce disapproval of the war, as did the folklore of civilian protestors. Rather, this form of GI folklore—as exemplified by one rumor that the toy company Mattel had manufactured the American military's M-16s—communicated a distrust of the war machine, and of the war itself, without resorting to slogans used by civilian protestors (such as "Hey, hey, LBJ, how many kids did you kill today?") that were much more explicit forms of protest. This study is significant in that it bridges the imagined irreconcilable opposition between GI and civilian protestor during the period. While each side implemented very different methods to demonstrate their contempt of the war, surprisingly a number of themes developed between the two sides, proving that, despite perceptions in the popular imagination, civilian protestors and American GIs were not such polar opposites after all.

The Effects of Media on Economic Policy and Business Decisions in Brazil and Argentina

Ashley N. Beebe – CURO SUMMER FELLOW
Dr. James Holmes, Center for International Trade and Security, University of Georgia

Despite strong, liberal medias in Brazil and Argentina, very little research analyzes the media in Latin American countries. My research analyzes how the media, business, and economic sectors interact in Brazil and Argentina. The research process included a thorough investigation of both through an interview with Dr. Anthony Pereira, Brazilian expert at Tulane University, the use of literature in the University library, and the use of various electronic news sources. The research reveals that Brazil's outlook in the business, media, and economic sectors is far more positive than Argentina's. This is true because Argentina, whose social and political infrastructure has been historically strong, is at the mercy of a weak economic situation. Everything from education to healthcare, the strength of the media to trust in the government, has been adversely affected by the recent economic collapse. While showing signs of growth, Argentina's nationalism, dwindling middle class, and the weakening social infrastructure all severely inhibit growth in the country. In contrast, Brazil is making great strides in erasing the effects of clientalism and personal favors that pervade the media, political, and business sectors. In addition, Brazil possesses a stabilizing economic and political situation, a market with huge potential for growth, and much of the infrastructure to support and maintain growth in the future.

Differentiation of Human Embryonic Stem Cells into Endothelial Progenitors

Ingrid Bloom – CURO SUMMER FELLOW
Dr. Steven Stice, Department of Animal and Dairy Science, University of Georgia

Endothelial cells line blood vessels and form the interface between circulating blood in the lumen and the rest of the vessel wall. Bone morphogenic protein-4 (BMP-4) is known to play a role in vascular development in other species, but its function in humans is unclear. An in vitro model of blood vessel development was designed to explore the role of BMP-4 in the formation of endothelial cells derived from human embryonic stem cells (hESC). The hypothesis was BMP-4 treatment of hESC preferentially directs differentiation toward endothelial cells.

Using a Pasteur pipette formed into a hook, hESC colonies were manually passaged onto collagen-laminin gel-coated plates. The colonies were grown with or without BMP-4 for

3 days, and BMP-4 supplementation was stopped. After 3-4 days in culture there was a dramatic reduction in the size of the BMP-4 treated colonies. In the untreated cultures, a "cell sheet" morphology grew along the gel surface in addition to "gel-invading" cells. In the BMP-4 treated cultures, the "invading" cells were seen, but the "cell sheet" was lacking. This led to the hypothesis BMP-4 inhibits hESC differentiation resulting in the "cell sheet" morphology. In addition, an extensive cell network resembling vascular capillaries was observed in the BMP-4 culture.

Fluorescence Activated Cell Sorting was used to detect an almost four-fold increase of cells expressing platelet-endothelial cell adhesion molecule-1, an endothelial protein marker, in the BMP-4 treated cultures. These data suggest that BMP-4 plays a role in the differentiation of hESC toward endothelial cells.

Construction of Three Rce1p Mutant Plasmids to Aid in the Characterization of Rce1p Enzymatic Activity

Sarah Breevoort
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Rce1p is a relatively uncharacterized protease that is required for the post-translational processing of proteins containing a CaaX motif. The CaaX motif is composed of cysteine (C), two small aliphatic amino acids (a), and almost any amino acid (X) in the terminal position. CaaX proteins require post-translational modifications to exhibit biological activity. Rce1p cleaves the –aax potion of the CaaX motif of mammalian Ras proteins and the yeast **a**-factor pheromone in the CaaX modification pathway. Ras proteins play a significant role in signal transduction; however, the hyperactive form of Ras is associated with 30% of human cancer tumors, including more than 90% of pancreatic cancers and 50% of lung cancers. Inhibiting the post-translational modifications of Ras is proposed to disable, or at least moderate, its cancer-causing activity by rendering it biologically inactive. One possible means for Ras inhibition would be to block the activity of Rce1p. In this study, the ultimate goal is to characterize the enzymatic activity of Rce1p and Rce1p mutants through their interactions with inhibitors. Towards this end, three plasmids were constructed containing Rce1p mutants and expressed in yeast. The extracts were isolated, and the plasmids were analyzed for proper Rce1p expression in vivo by yeast patch mating. A second verification was obtained by western blot analysis. These plasmids will be used in conjunction with a larger pool of Rce1p plasmids encoding additional mutants for in vitro inhibitor profile studies. These studies may ultimately yield novel Rce1p inhibitors that may be useful as anti-cancer drugs.

Antagonistic Effects of Naturally Occurring Altered Peptide Ligands on *Trypanosoma cruzi*-specific CD8 T Cell Response

Melissa Cabinian – CURO SCHOLAR
Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia

Persistent infection with the protozoan parasite *Trypanosoma cruzi* results in Chagas disease, the leading cause of heart failure in South America. Although infected hosts develop a vigorous anti-*T. cruzi* immune response, *T. cruzi* is able to resist complete immune clearance by evasion mechanisms not yet understood. CD8 T lymphocytes are responsible for immunity to intracellular pathogens and necessary for the control of *T. cruzi* infection. Peptide targets of the CD8 T cell response in *T. cruzi*-infected humans and mice are primarily encoded within the *trans*-sialidase (*ts)* gene superfamily. *T. cruzi* expresses numerous related *ts* proteins which may result in the presentation of altered peptide ligands (APLs) to responding T-cells. APLs can antagonize T cells specific for the homologous antigenic epitope through a low affinity interaction with the T cell receptor (TCR). In this study, the effects of APLs on the ability of naïve and effector TsKb20-specific T-cells to respond to TsKb20 (ANYKFTLV), a *ts*-derived cytotoxic T lymphocyte (CTL) epitope, are evaluated. Several APLs were shown to inhibit TsKb20-specific effector T cells from producing

interferon-γ in response to TsKb20. Future work will focus on evaluating the impact of APLs presented on cells targeted for cytotoxic killing by TsKb20-specific CD8 T-cells. Antagonism of the activation of naïve CD8 T-cells will also be assessed by vaccinating mice with dendritic cells presenting APLs and TsKb20, then measuring the subsequent T cell expansion using class I major histocompatibility tetramers specific for TsKb20. The identification of antagonistic APLs will allow us to investigate the role of TCR antagonism in the ability of *T. cruzi* to evade immune responses.

The Mythological Present

Ian Lewis Campbell – CURO SUMMER FELLOW
Dr. Glenn Wallis, Department of Religion, University of Georgia

Myth is believed to be a phenomenon of human culture that has been relegated to ancient man, a phenomena that our modern world has surpassed by scientific knowledge. Yet, myth exists in our modern society in a similar form. Myth is a tool of placement, identity, and understanding with which modern man uses to contemplate the world.

This paper presents a theory of how myth works in the present by answering several questions: What is Myth? How does myth arise and function? Who is the mythmaker? Kenneth Burke defines myth as "a narrative that effects identification within the community that takes it seriously, endorsing shared interests and confirming the given notion of order." It arises out the collective, social action of living in a politicized culture, and not only grants a semblance of order but is a foundation of authority. The myths we find in our contemporary political world are not static creations but are used by mythmakers (anyone in a position of authority that relies on myth for that authority) to create new myths that reinforce power.

Using past theories of myth formulated by Roland Barthes, Kenneth Burke and Ernst Cassirer, I will present a comprehensive theory that explains the function of myth in the present, western world, and the influence it has in our political lives.

Characterization of IS*492* insertion at the *eps* locus of *Pseudoalteromonas atlantica*

Peter R. Caruana
Dr. Anna Karls, Department of Microbiology, University of Georgia

Pseudoalteromonas atlantica is a pioneer biofilm-forming, Gram-negative bacterium that is found in water columns and on solid surfaces of the Atlantic and Pacific oceans. Expression of extracellular polysaccharides (EPS) is important in biofilm formation by bacteria. Interestingly, *P. atlantica* exhibits on-off phase variation of peripheral extracellular polysaccharide (^{P}EPS) production resulting in two colony morphologies, mucoid (M, $^{P}EPS^{+}$) and crenated (C, $^{P}EPS^{-}$). This phase variation is associated with the transposition of a mobile DNA element, IS*492*. The correlation between phase variation and insertion of IS*492* into *eps* genes that are required for ^{P}EPS production was investigated.

Independent crenated variants of mucoid *P. atlantica* were isolated and characterized by a polymerase chain reaction (PCR) assay in which the primers amplified a predicted target site in an *eps* gene on the chromosomal DNA. DNA sequencing of PCR products revealed the exact site of insertion for each isolate. My results suggest that a correlation exists between the insertion of IS*492* at the *eps* locus and the M→C phase variation. In addition, sequence data suggests that the insertion of IS*492* is site-specific, a feature not commonly associated with bacterial insertion sequences. To further characterize the target site preference of IS*492*, current experiments are designed to follow the insertion of a "genetically marked" IS*492* element following its introduction into *P. atlantica* via conjugation on a mobilizable suicide plasmid.

LHR Expression in Transfected Ovarian Cells

Priya Chandan

Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

Ovarian cancer is the fifth most common cancer in women. Epidemiologic evidence implicates the gonadotropic hormones in the etiology of ovarian cancer, due to the correlation between high serum levels of the gonadotropic hormones and an increased risk of ovarian cancer. The gonadotropic hormone signaling pathway ultimately leads to the expression of matrix metalloproteinases (MMPs). MMPs degrade the proteins of the extracellular matrix, specifically collagen, which is a necessary function in both normal ovulation and tumor migration and invasion. This biochemical evidence substantiates the epidemiologic risk correlation. These studies test the hypothesis that stimulation of the luteinizing hormone receptor (LHR) in ovarian cells will lead to increased expression of MMPs and therefore contribute to ovarian tumorigenesis. LHR was introduced into a human ovarian cancer cell line (SKOV3), which does not express the receptor under normal culture conditions. The goal of the project is to determine the time point of peak LHR expression, stimulate the receptor with hCG (human choriogonadotropin) at this time point, and then analyze MMP expression due to LHR stimulation. Samples were taken at different time points and analyzed to determine LHR expression at the RNA level. Expression was found as early as 6 hours, with peak expression occurring at 25 hours. Further analysis of this peak in expression is needed. In addition, further research is needed to define the dose response of MMP protein expression following LHR activation.

Glycomics and Glycoproteomics on Complex Glycoprotein Mixtures: Optimization of Separation Methods for Glycopeptide and Oligosaccharide Analysis

Anureet J. Cheema
Dr. Michael Pierce, Department of Biochemistry and Molecular Biology, University of Georgia

Cell surface glycoprotein glycans are critical for cell-cell and cell-matrix interactions as well as regulation of cell growth and enzyme activity. Therefore, some of them are of particular importance as cancer biomarkers, which have altered glycosylation sites. The research reported here involved developing a standard procedure for the analysis of N-linked glycans as well as the sites of N-linked glycosylation in complex mixtures of glycoproteins, such as blood serum. As a reservoir of diverse proteins, serum can be of great importance in research and diagnosis of different disease stages. To reduce the interference of highly abundant proteins during analysis, albumin and immunoglobulin removal procedures were developed and optimized with blue sepharose and Protein A columns. Glycopeptides were isolated through a series of steps in which the serum glycoprotein mixture, devoid of albumin and immunoglobulins, was denatured, reduced, carboxyamidomethylated and trypsinized to fragment the peptides. From the peptide mixture, specific glycopeptides were isolated by size exclusion chromatography and lectin chromatography. Peptide N-glycoamidase F (PNGase F) was then used for the detachment of oligosaccharides, which were then subjected to permethylation and analyzed by Matrix Assisted Laser Desorption/Ionization-Time of Flight (MALDI-TOF) mass spectrometry. The deglycosylated oligosaccharides were also analyzed by Liquid Chromatography-Mass Spectrometry (LCMS/MS). The optimized procedure proved to be an efficient means of separating and identifying oligosaccharides in the complex glycoprotein mixture. In the future, such a procedure could be used to analyze serum and other complex glycoprotein mixtures in order to identify biomarkers for development and diseases, including cancer.

American Stranger

Shehzeen Choudhury
Dr. Judith Ortiz Cofer, Department of English, University of Georgia

My current project is a collection of short stories that explore cultural boundaries, political, and moral issues from national and international perspectives. I write about boundaries because they seem concrete at first glance but are in reality quite permeable. In the short story "American Stranger," I have tried to merge the

American world with the Bangladeshi world through the custom of the arranged marriage and the conflicts that ensue. All my stories are based on or inspired by true stories. Following the traditions of Bangladesh for fourteen years and seeing a cousin get married to a man who only saw her for a few seconds in candlelight made me want to explore the emotions that come with this experience shared by many in various corners of the world. Although the setting is unique, I believe the feelings of love, loss, sacrifice, and compromise that the story conveys are not restricted to one region in the world but are truly universal. Through this story I have tried to portray a world of traditions by describing the reactions from two different points of view. Here the distinct stories of two individuals from two different paths of life meet and are soon to become one.

Effects of Glycosaminoglycans and Pectins in Early Stages of Angiogenesis

Amy V. Chudgar
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

Angiogenesis, or the sprouting of new blood vessels from pre-existing vessels, is a complex procedure that involves dozens of regulators and components and requires the precise orchestration of recruitment, migration, and interaction of endothelial cells, extracellular matrix (ECM) components, and growth factors. Although vessel formation is necessary for normal development, excessive or insufficient angiogenesis is harmful and leads to numerous pathologies, including tumor growth, inflammation, and ischemia. Glycosaminoglycans (GAGs) are a major component of the ECM and serve an important role in vessel formation by regulating smooth muscle cell proliferation, functioning as receptors for proangiogenic growth factors, and serving a critical role in cell adhesion, locomotion, and the insolubility of the ECM. Pectins are the major acidic polysaccharide component of plant cell matrices and serve similar functions in plants to those served by GAGs in animals. Pectins may offer a potent method of regulating angiogenesis. We have previously demonstrated that pectins are able to affect GAG degrading enzyme activity, and GAGs are able to affect pectin degrading enzymes (PDEs). To apply this information to angiogenic processes, we examined whether pectins could compete with GAGs, possibly inhibiting angiogenic events and offering therapeutic applications. An in vitro system mimicking early tube formation in angiogenesis was developed to study the process using human umbilical vein endothelial cells (HUVECs). The tube-forming assay was performed using different concentrations of GAGs and pectins, and experiments were analyzed through light and fluorescent microscopy. The results of these experiments will be presented.

Modeling the Effects of the North American Beaver (*Castor canadensis*) on Sub-Antarctic Stream Food Webs in the Cape Horn Archipelago, Chile

William M. Collier – CURO SUMMER FELLOW
Dr. Amy Rosemond, Institute of Ecology, University of Georgia

The North American beaver (*Castor canadensis*) was introduced into southern South America in 1946 and throughout the last half-century has established significant populations and expanded its range into Chile. Beavers alter both habitat and resources available to organisms in terrestrial and aquatic ecosystems, potentially affecting community composition and diversity, food web dynamics, and overall ecosystem processes. In this context, the goal of our research was to specifically address the influence of the beaver on species-level and trophic-level food web dynamics of streams. Effects of beaver were assessed using data from four catchments and three habitat types: natural stream reaches uninfluenced by beaver, beaver ponds created by damming, and reaches immediately downstream of beaver dams. Species-level richness and Shannon-Weiner diversity of aquatic macroinvertebrates were significantly reduced in beaver ponds compared to natural and downstream sites; however, these changes were accompanied by increased biomass and density of macroinvertebrates in

beaver pond sites. Using empirical data, we constructed descriptive models with STELLA™ modeling software to explicitly determine the effects of beaver on the aquatic communities impacted by their activities. A unique model was created for each habitat and then analyzed between habitat types to assess the impacts of beaver on the relative importance of both individual taxa and functional groups (groupings of taxa based on their feeding mode). Our results illustrate the large impact that beaver can have on sub-Antarctic stream food webs by significantly changing macroinvertebrate community composition, trophic structure, and energy flow from food resources to stream consumers.

Role of Calcium Independent Phopholipase A_2 ($iPLA_2$) in Phospholipid Metabolism in Chemotherapeutic–Induced Cancer Cell Death

Kimberly Coveney – CURO SUMMER FELLOW
Dr. Brian Cummings, Department of Pharmaceutical and Biomedical Sciences, University of Georgia

Phospholipase A_2s are historically classified into three categories, cytosolic Ca^{2+}- dependent PLA_2 ($cPLA_2$), secretory Ca^{2+}-dependent PLA_2 ($sPLA_2$) and Ca^{2+}-independent PLA_2 ($iPLA_2$). Like all phospholipases, $iPLA_2$s are activated by extracellular signals to cleave phospholipids, thereby releasing lipid fragments into the intracellular environment which then act as signaling molecules within the cell. Upon cleavage with $iPLA_2$, phospholipids release arachadonic acid and glycerol into the cell. Arachadonic acid then serves as an intracellular signaling molecule for the inflammation response.

Under normal conditions, phospholipases aid in the maintenance and upkeep of cellular bilayers, thereby playing an integral role in the viability of the cell. However, any artificial manipulation of the resident phospholipases could disrupt this type of cellular maintenance system fueled by the activity of phospholipases such as $iPLA_2$. This research focuses on the effect that bromoenol lactone (BEL), a calcium independent phospholipase A_2 ($iPLA_2$) inhibitor, has on cellular viability and the phospholipid profile of the cell. This pharmacological agent was administered alone and in conjunction with the chemotherapeutics vincristine and cisplatin to test the hypothesis that $iPLA_2$ inhibition mediates cell death in these cells by altering the release of death inducing lipid signals.

Prostate carcinomas (PC-3) and lung carcinomas (A549) were both examined to explore the effect that cell origin has on the reaction to the aforementioned treatments. Preliminary data show that the combinatorial therapy, which employs the simultaneous administration of BEL with a prescribed chemotherapeutic, is able to effectively decrease the amount of certain phospholipids within the cellular membrane while not altering others. The summation of death caused by the aforementioned chemotherapeutics and that caused by the inhibition of an integral enzyme involved in cellular membrane integrity ($iPLA_2$) is greater than that caused by chemotherapeutic use alone. Certain phospholipids, most notably 14:0-16:0 Phosphatidyl Choline, have shown such consistent decreases in numbers during combinatorial treatments that their role in membrane integrity and viability is being furthered examined.

Understanding Cellular Immortality: Telomere Functioning in Yeast

Nathan L. Crain
Dr. Michael McEachern, Department of Genetics, University of Georgia

Cellular immortality, a characteristic of carcinogenesis, is achieved through the maintenance of telomeres, the DNA-protein complexes found at the termini of eukaryotic chromosomes. Telomere maintenance occurs by two distinct mechanisms: repair by telomerase, a reverse transcriptase, or repair by recombination (RTE – *r*ecombinational *t*elomere *e*longation). Although the majority of human cancer cells utilize a telomerase-dependent maintenance pathway, about 5% of human cancers undergo a recombination method of telomere lengthening,

termed ALT (*a*lternative *l*engthening of *t*elomeres). RTE pathways are best understood in yeasts. Previously, the McEachern lab identified a mutation in the yeast *Kluyveromyces lactis*, stn1-M1, which maintains very long telomeres by recombination and closely resembles human ALT cells. Studies have shown the genes RAD50 and RAD59 are necessary for RTE in *Saccharomyces cerevisiae*. The objective of this study is to characterize the role of RAD50, RAD51 and RAD59 genes in determining telomere length by recombination in stn-M1 mutants. Crosses of the genes regulating telomere length were generated by tetrad analysis. The mutants were then plated on growth media and screened for colony morphology and telomere length. Our results have shown that the RAD59 gene is not required in *K. lactis* RTE. This might be explained by the fact that *S. cerevisiae* has telomeres heterogeneous in sequence, while *K. lactis*, like humans, has homogeneous telomeres. Further analysis of stn-M1 mutants will be presented.

Strategy and Intent Versus Function: A Comparative Study of Moro Islamic Liberation Front and the Shining Path, Two Terrorist Groups

Leigh E. Creighton – CURO APPRENTICE
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

Terrorist groups are usually defined by the violent methods they use to achieve their stated goals as well as common goals, which generally entail the control of land, the desire to replace one government or regime with another, or a combination of the two. Throughout its history as well as the present, the Philippines has been a country known for its continuous onset of one terrorist group after the other. The Moro National Liberation Front (MNLF) of the Philippines aimed for the establishment of an independent Islamic State in the southern Philippines. The Shining Path (Sendero Luminoso), a Peruvian terrorist group founded in the late 1960s aimed to replace the Peruvian government with a peasant revolutionary regime and dispel all foreign influences. The focus of my paper is a comparison between the Shining Path's and MNLF's goals or intentions versus the actual results of their actions. I hypothesize that there will be a general congruence between many factors of the two groups, such as their targets, weapons, members and leaders. I am interested in the cause and effect relationship between the terrorist groups and their corresponding country's populace. I predict that the methods or tactics the terrorists use depends on the approval or disapproval from the populace.

AUX Launch: Art, Representation and Commerce on the Web

John Crowe – CURO SUMMER FELLOW
Professor Mark Callahan, Institute for Creative Exploration, University of Georgia

AUX Launch utilizes the web as a platform where the lines of separation between art, design, and commerce are blurred. Competition between traditional music industry distribution strategies and alternative models such as file-sharing and inexpensive downloads is contributing to the emergence of new web-based models of artistic representation and content distribution. This project combines creative and technological research in the creation of a web site that accompanies the publication of AUX, a collection of experimental sound from Athens, Georgia. The development of the AUX web site is one component of collaborative project supported by Ideas for Creative Exploration (ICE), an interdisciplinary initiative for advanced research in the arts at UGA. The initial stage of the project brought together recording artists who share a connection with Athens' thriving independent music scene and graduate students in the Lamar Dodd School of Art's acclaimed Printmaking and Book Arts program. The result was a limited-edition audio CD in unique packaging printed and assembled by hand. AUX Launch supports the distribution of the CD and will remain online as documentation of the project when the edition is no longer available. The site, AUXcd.com, provides information about the artists on the compilation and sense of context for the project within the global community. The development of the site is the result of individual effort using

Macromedia Flash software and original ActionScript programming. The project evolved through numerous prototypes and code refinements to launch-ready status. The innovative design reflects the unconventional nature of the compilation through the use of layered graphics, sound, animation, and minimal text. A dynamic interface activates subtle contrasts in color, negative space, and popup animations, creating moments of intuitive navigation and discovery.

The Effect of Polymer Scaffolds with Nanopillar Structures Fabricated Using Solvent Leaching/Gas Forming Method on Long Term Osteoblast Response

Sita M. Damaraju
Dr. William Kisaalita, Department of Biological and Agricultural Engineering, University of Georgia
(Sita Damaraju, Ke Cheng, Guigen Zhang, and William S. Kisaalita)

The main objective of bone tissue engineering is to design robust skeletal implants which mimic the mineral component and the microstructure of natural bone. As a result, the functions of osteoblasts (bone forming cells) are better controlled in the new bone formation. In this study, nanotechnology is being used to develop Poly (L-Lactic acid) (PLA) scaffold structures consisting of nanopillars which are made out of nano-hydroxyapatite (NHA). These structures are hypothesized to improve the control of osteoblast behavior and response. NHA/PLA scaffolds were fabricated by the solvent leaching/gas forming method with ammonium bicarbonate as the porogen additive. An advantage of these 3-D nano-structures is that they are fabricated without using any special equipment, and porosity of the scaffold can be easily controlled or modified by this method. The fabricated scaffold is highly porous, and the pores are interconnected. The average pore size is about 200 micrometers, which provides a greater surface area for cells growth. The TE-85 bone tumorigenic cells, obtained from a tumor infected bone, were cultured in the scaffolds. Because TE-85 cells can proliferate in vitro, they are an excellent model to investigate bone formation in vitro. Results indicate that TE-85 cells are biocompatible with the fabricated scaffolds to facilitate cell adhesion. Later, the osteoblasts will be seeded on fabricated scaffolds to investigate the adhesion, proliferation and long-term functionality and matrix production. The results observed will be compared to standard PLA scaffolds without nanopillars.

Theory and National Identity: Yugoslavia in the Late 1940s and 1950s

Michael W. Davis
Dr. Keith Langston, Department of Germanic and Slavic Languages, University of Georgia

During the late 1940s and 1950s, Tito's communist regime in Yugoslavia was forced to face the recurring conundrum facing Belgrade: how to assimilate the various ethnic and religious factions into a greater Yugoslav identity. Ethno-religious tensions had provided opposition to Yugoslav identity since the nation's inception in 1918, and prior governments had compensated by establishing Orthodox Serbian preeminence at the expense of the national minorities. Tito's regime established the most viable sense of a greater Yugoslav identity following its split with the Cominform in 1948, an event that forced the regime to contemplate how to draw upon the support of all its citizens in the face of Soviet and Western pressure. As historians such as George Hoffman, Charles McVicker, Fred Neal, and Paul Shoup note, Tito's regime devoted considerable effort toward generating a body of theory to underlie the new Yugoslav identity. Primarily this was accomplished through theoretical positions regarding domestic policies and foreign diplomacy. This paper will focus upon the theoretical positions (though not actual implementation) regarding the withering away of the state and party, rejection of collectivization of agriculture and recognition of the peasantry, socialist democracy, and nonalignment during the Cold War. The importance of these positions in reducing tensions between the ethno-religious factions will be discussed in context of the larger

struggle to establish a coherent Yugoslav identity.

Prediction of Maximum and Minimum Air Temperature of a 24-Hour Period with Artificial Neural Networks

Richard W. Dewey
Dr. Ronald McClendon, Department of Biological and Agricultural Engineering, University of Georgia

Foreknowledge of maximum and minimum temperatures is useful for the development of weather simulations and for the protection of crops from freezes. The goal of this study was to develop artificial neural network (ANN) models to predict maximum and minimum temperatures of a 24-hour period six hours before the beginning of that period. An ANN is a network of processing units connected in a manner similar to neurons. ANNs can automatically adjust themselves to predict trends in a data set. Using data from the Georgia Automated Environmental Network to train the ANNs and the mean absolute error (MAE) of ANN predictions as a performance measure, many ANN design factors were tested for their effects on performance. Air temperature, humidity, wind speed, solar radiation, and seasonality produced the lowest MAE when all were used together in an ANN. The optimum duration of recorded data for these inputs was in the range of 2 to 8 hours. "Ward Network" architectures tended to have lower MAEs for minimum temperature prediction than standard backpropagation networks, but both types of architecture had similar MAEs for maximum temperature prediction. Two ANNs with one output node each had lower MAE than one ANN with two output nodes. The best models developed had MAEs of 2.124 °C on maximum temperature prediction and 1.675 °C on minimum temperature prediction. Future research could experiment with other design decisions to improve the ANNs' performance on winter and spring days with high humidity and wind speed, which were the most error-inducing days.

The Enigmatic Origins of the Bell Beaker Phenomenon

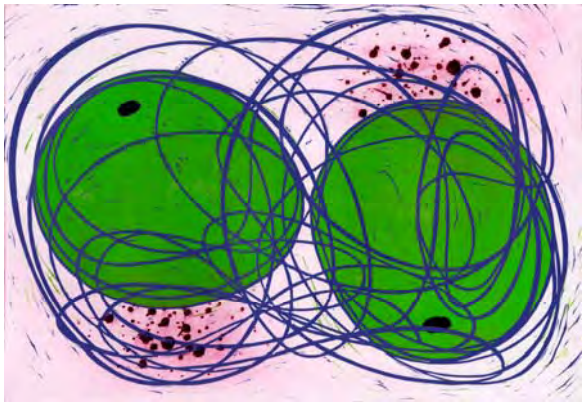
Jana Dopson
Dr. Ervan Garrison, Department of Anthropology and Department of Geology, University of Georgia

Bell Beaker pottery is an important, enigmatic, and well-documented phenomenon which appears suddenly and briefly in the archaeological record through most of Europe. These bell-shaped goblets are extremely uniform considering their geographic distribution and are surprisingly widespread considering their short persistence. Previous research has suggested a variety of diverse origins for the Bell Beakers including as status symbols associated with knowledge of copper metallurgy, and recent carbon dating indicates possible Iberian genesis. Thorough review of current literature in French and English provided the basis for investigation and was supplemented by interviews of leading Swiss Beaker archaeologists and on-site investigation of Swiss museum holdings. Two major points of contention in Beaker research include where the Beakers originated geographically and whether the Beakers indicate the spread of a people or simply the expansion of ideas. Stylistic analysis of goblet decoration led to many competing theories about Beaker origins, but modern radiocarbon data show that the Beakers are oldest in Iberia and get progressively younger to the north and east. Careful study of Beaker accompaniments has shown that regional ceramics are important to understanding the cultural and social settings of the Beaker period, and three distinct Beaker sub-cultures have been identified. The contemporary existence of these groups and the lack of evidence revealing large-scale migration imply that the archaeological Beaker culture is more representative of ideological, technological, and stylistic spread than en masse population movement. Beaker data are most consistent with a hypothesis supporting Iberian origins, metallurgy, and social status as important facets of Beaker success in Europe.

Containerized Shipping: A Gap in National Security

William M. Draxler & Joshua R. Heard,
Roosevelt @ UGA
Dr. Michael Speckhard, Department of International Affairs, University of Georgia

Although it is the lifeblood of the global economy, the containerized shipping system is also a major vulnerability in American national security. This key instrument of globalization has many economic advantages, but it also provides an avenue for criminal syndicates to engage in human trafficking and drug trafficking. Worse, a terrorist organization could very well use a shipping container as a delivery system for a weapon of mass destruction or to smuggle terrorists into the country. These containers could be used to transport illicit material to a destination where it would be used to construct a weapon of mass destruction. To address this threat, the Bureau of Customs and Border Protection has erected numerous programs to secure the supply chain, but these are riddled with problems. We propose a series of measures to correct the problems in two of these programs, the Container Security Initiative and the Customs-Trade Partnership Against Terrorism. These measures include increasing staff, distributing better detection equipment, and establishing the authority of customs officials to improve implementation of these programs. We also propose an independent measure for establishing a new standard in the security of ship manifests and also the development of a culture of security, both small steps in insuring security in every stage of the global supply chain.



Printmaking

Cameron Dye
Prof. Joe Sanders, Department of Printmaking, University of Georgia

My work is an exploration in aesthetics as I combine kitsch imagery along with a formalist sensibility. I am influenced by a wide variety of sources from the works of surrealists like André Masson and Stanley William Hayter to images from popular culture, such as cartoons, cereal boxes, and psychedelic posters. My prints usually begin as abstract, automatic drawings and slowly develop into images with intentionally cute and grotesque, representational imagery. I am interested in creating images with tension between opposing elements, such as cute and grotesque, or tasteful and tasteless, as a way of creating excitement.

Phenotypical and Genotypical Antibiotic Resistance Analyses of Fecal Bacteria Isolates in Dairy Cattle

Jodi L. Dyer
Dr. Susan Sanchez, Athens Diagnostic Lab, College of Veterinary Medicine, University of Georgia

The emergence of antibiotic resistance in both commensal and pathogenic bacteria throughout the world is being heightened by the overuse of antimicrobial therapies both in humans and in agricultural applications. Common therapeutic treatments in food animals are thought to play a major role in the selection of resistant bacterial strains within animals, and conjugation within the gastrointestinal tract has been suggested as a means of transfer for genes that confer this resistance between both individual bacteria and bacterial species. Phenotypic resistance characterization and gene specific screening were conducted for Gram negative, lactose fermenting, normal flora isolates, including Escherichia coli, for the antibiotic resistance genes flo, tetA, strA, strB, and ampC, which encode resistance for chloramphenicol and florfenicol, tetracycline, streptomycin, and ampicillin, respectively. Two genes typically found in a single locus in some conjugational plasmids isolated from Salmonella, tetA and strA, were concurrently present in 36% of the

tested Enterobacteriaceae isolates, while 68% of these additionally carried flo, also a common component of this location. Approximately 11% of the isolates contained all five of the genes. This study was carried out on bovine fecal samples from which multi-drug resistant (MDR) Salmonella had been isolated. The farms in this study were chosen because they were known to carry MDR Salmonella, and the therapeutic use of antibiotics was known and made available. The results of the Gram negative resistance screenings were compared to the profiles of these MDR Salmonella isolates. The presence of similar to greater proportions of these resistance genes in different bacterial species within the commensal bacteria of animals, as indicated by comparison to the Salmonella profiles, suggests the presence of a resistance reservoir within their common environment. The importance of this experiment is the potential implications that a growing antibiotic resistance gene pool within food livestock could have upon their conference to human populations and the rising difficulties of medicinal treatment.

Rock, Paper, Scissors
Lauren Dykes
Dr. David Saltz, Department of Theatre and Film Studies, University of Georgia

Three haunting stories of young women struggling with their bodies and the world surrounding them. The line between victim and violator is constantly blurred, with each girl left alone to discover if she is to blame for her pain.

The Effects of Cocaine on the Isolated Rabbit Heart and the Increased Cardiovascular Risk It Presents in the Presence of the Non-selective Beta Blocker Propranolol
Edmond N. Fomunung – CURO APPRENTICE
Dr. Benedict Lucchesi, Department of Pharmacology and Toxicology, University of Michigan Medical School

Cocaine, a crystalline alkaloid obtained from the leaves of the coca plant is highly addictive and potentially fatal. This has made its possession and distribution illegal in most parts of the world. The current study was performed to evaluate the biochemical processes underlying the toxic effects of cocaine on the heart. Cocaine has been reported to inhibit the reuptake of the certain neurotransmitters: norepinephrine, serotonin, and dopamine, and is known to block sodium channels. In this study, we sought to examine this mechanism of action and to evaluate the cardiovascular risk associated with the use of the beta-blocker propranolol. New Zealand white rabbit hearts were isolated and perfused at 30ml/min. The hearts were subjected to a period of hypoxia-reoxygenation, after which one was treated with cocaine, and another with both cocaine and propranolol. The electrocardiogram, coronary perfusion pressure, and left ventricular diastolic pressure were monitored closely on a trace using a multichannel recorder. Cocaine caused an immediate and drastic drop in both LVDP and CPP with eventual return to normal in the isolated heart. When the cocaine-exposed heart was treated with propranolol, the LVDP never recovered from the initial drop, and the heart eventually lost function. Our data suggest that cocaine exerts its toxicity on the isolated heart by significantly depressing heart function, as confirmed by the drop in LVDP and CPP. The data also suggest that when beta-blockers are introduced to a cocaine-exposed heart, the effects are particularly toxic and potentially fatal.

Being (Interpretations of Interpretations)
Charlotte Foster
Prof. Rebecca Enghauser, Department of Dance, University of Georgia
(Emily Crate, Charlotte Foster, Joseph Hutto, Leah Chapman, and Mary Mattmann)

Being (Interpretations of Interpretations) was developed through abstract gesture studies in the modern dance idiom. My goal was to develop new movement phrases which would produce an emotionally affective work. The abstract gesture studies were based on emotional responses to war, specifically the emotions of denial, courage, and detachment. Movement vocabulary was abstracted from photographs of people that exhibited strong emotion. I examined select photographs and identified details to influence

the shape, texture, and emotional response of my movement. These movements were threaded together using various speeds and dynamics that were determined in part by the dancers. Throughout the process, it became unnecessary that the audience draw a connection between my movement and war and more important that the audience have their own interpretation of the work.

Though each dancer brought a unique experience to the stage and had various strengths and weaknesses, they worked together as a congealed group, attempting to change their movement tendencies and adapt to each other. They also contributed largely to the creation of the piece in rehearsal. The dancers formed a supportive environment were I felt free to create, allowing me to experiment and grow as a choreographer. Without these specific dancers, this project would not have been so successful.

The Effect of *Aedes aegypti* Larval Nutrition on Metamorphosis

Laura Frame
Dr. Aparna Telang & Dr. Mark Brown, Department of Entomology, University of Georgia

Females of the mosquito species *Aedes aegypti* transmit yellow and dengue fever viruses through blood feeding on human hosts. An effective way to control viral outbreaks is to control mosquito populations in high risk areas. This is best done when mosquitoes are in their larval stage. Food for larvae can be limited by factors such as intra- and interspecific competition and the ephemeral nature of their aquatic habitat. Feeding by the last larval stage provides energy and nutrients required for growth, metamorphosis and reproduction. I hypothesized that if food for 4^{th} (final) stage larvae were limited, their ability to metamorphose and their resulting adult size would be affected. Specifically, I allowed 4^{th} stage larvae to feed for particular lengths of time and then housed them in fresh water only. When these larvae were allowed to feed for only 12 hours, few became adults, whereas most were developmentally arrested. Remarkably, arrested larvae survived for two weeks; and the implications for this survival await further study. Allowing larvae to feed for 24 hours resulted in 70% becoming adults. Female *A. aegypti* needed to feed longer as larvae to pupate compared to males. Females that fed longer as larvae attained a larger adult size. Female size has been found to strongly correlate to reproductive capacity, but how this affects her ability to transmit diseases awaits further study. This experiment indicated that food availability strongly affects the metamorphic capacity of *A. aegypti* larvae and thus limits mosquito populations.

Puppet Regimes

Mary Gassama – CURO APPRENTICE
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

My research examines the political life of Laos and Cambodia in relation to Vietnam beginning from 1980. Although recognized as independent states, Laos and Cambodia were puppet regimes controlled by Vietnam. During the early 1980s, Vietnam had thousands of troops positioned in both Laos and Cambodia. Additionally, contact between the government of Vietnam and the governments of Cambodia and Laos exceeded the number of contacts usually made between sovereign states. Did Vietnam really control Laos and Cambodia? What steps did Vietnam take to gain a hold on both Laos and Cambodia? What characteristics did Laos and Cambodia have to make them susceptible to domination? What reasons did Vietnam have for wanting Laos and Cambodia under its control? My research considers these questions to understand the Laotian and Cambodian governments. I reviewed and examined sources such as the Xinhua General Overseas News Service and the British Broadcasting Corporation, paying special attention to the relationship between Vietnam, Cambodia, and Laos. Newspaper articles reporting the daily activities of the governments of Vietnam, Laos, and Cambodia provide evidence that Laos and Cambodia were puppet regimes. Although there have been academic books that detail the history of Indochina (Thailand, Vietnam, Laos, and Cambodia), books that focus on the relationship between

Vietnam, Laos, and Cambodia are uncommon. This research advances our knowledge of puppet regimes and the governments that control them: it displays the behaviors of dominating countries and their subordinates.

Ceramics
Alexis Gregg
Prof. Ted Saupe, Department of Ceramics, University of Georgia

My recent work in clay has taught me the power of intuition. I no longer dwell on the significance of what I'm doing. Instead, I allow my hand to respond to the surface as if I could close my eyes. The forms I have been creating give me an excitement and drive that I have not experienced before. It is as if clay has taught me to play, and when art making is fun, the results are also good. After the initial form is made, I step back and find the hidden faces and shapes that appear. I have come to realize the energy that is put into making a piece defines the energy it possesses on its own. Ultimately, I want my work to stand strongly as individuals with personality and mystery.

The Creation of 16S rDNA Clone Libraries for the Identification of Bacteria in the Gut Microbial Flora of *Drosophila melanogaster*
Kristen E. Habel
Dr. Larry Shimkets, Department of Microbiology, University of Georgia

Drosophila melanogaster has the longest history of any model organism and has been used by thousands of researchers around the world for over a century. In recent years these tiny organisms have played an important role in immunological and evolutionary ecology, specifically in the examination of immune effector systems and the role that pathogens play in the microevolutionary processes of these systems. Despite this abundance of research on host-pathogen interactions in Drosophila and the evolutionary consequences of these interactions, little is known about the normal microbial flora of Drosophila and the effect these bacteria have on host immunity. In this study, 16S rDNA gene sequences were used to identify bacterial species that make up the gut microbial flora of *Drosophila melanogaster*. Fly populations were collected from ten different longitudes along the East Coast, and two flies from each population were homogenized. Bacterial DNA was extracted from the homogenized flies and amplified using polymerase chain reaction. Gel electrophoresis was then used to isolate the target 16S rDNA sequences which were inserted into vectors and transformed into electrocompetent cells. The 16S rDNA gene in each plasmid was sequenced and examined with a local alignment algorithm to identify the different species of bacteria in each population. This data may indicate a clinal trend in the species of bacteria living in different fly populations and possibly allow for future studies of the microbial flora of Drosophila, including the identification of sexually transmitted bacteria.

Antibody Depletion of Highly Abundant Proteins in *Trypanosoma cruzi* for Fine-tuning of Proteomic Analysis
Matthew Haney – CURO SUMMER FELLOW
Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia

Trypanosoma cruzi is a protozoan parasite that causes Chagas disease, the world's leading cause of congestive heart failure and a common cause of death in South America. Current treatments for Chagas are inadequate, though better understanding of parasite morphology could potentiate future treatments. Specifically, improved knowledge of *T. cruzi*-specific proteins may reveal novel candidate vaccines and potentially lead to improved treatment of the

disease. With this in mind, shotgun proteome analysis using liquid chromatography and tandem mass spectrometry identified roughly 3,000 *T. cruzi* proteins from the four major life-cycle stages (Atwood et al, 2005). Unfortunately, nearly 50% of all mass spectra collected mapped to only 8% of identified proteins, meaning a limited number of high-abundance proteins mask the detection of low-abundance proteins. To expose these low-abundance proteins to mass-spectrometric identification, protein-specific antibodies could be generated to bind to and remove the 67 high-abundance proteins from *T. cruzi.* To facilitate the subsequent cloning process, this protein group was first narrowed to 48 proteins based on homology. Previous lab efforts successfully cloned genes for 35 of the 48 proteins, so cloning of the 13 remaining genes was undertaken utilizing PCR amplification and the Invitrogen Gateway® technology. From a vector for protein expression, 32 of the total proteins were generated via autoinduction and purified under denaturing conditions. The antibodies subsequently produced to these 32 proteins in rabbits and mice will next be used to deplete high-abundance proteins from crude *T. cruzi* cell extracts before final mass-spectrometric analysis. The proteins identified by this new high-throughput proteomic analysis will verify *T. cruzi* genome annotations, identify new potential vaccine candidates, and further basic understanding of *T. cruzi* biology, hopefully leading to new and more effective treatments.

O-glycans and Congenital Muscular Dystrophy

Sana F. Hashmi – CURO APPRENTICE
Dr. Lance Wells, Department of Biochemistry and Molecular Biology, University of Georgia

Alpha-Dystroglycan (aDG) is a key glycoprotein necessary for proper neural and muscle function. In several forms of congenital muscular dystrophy, mutations exist not in the protein itself but in the glycosyltransferases necessary for the O-mannose addition and extension of the glycan structure necessary for proper aDG function. In order to map and characterize the glycans of aDG, the following objectives are being addressed. First, aDG is being purified from various sources. The initial protein sample, from rabbit skeletal muscle, has been purified based on its ability to interact with the lectin WGA (wheat germ agglutinin) and the extracellular protein laminin-1. Purity of the preparation was confirmed by SDS-PAGE followed by silver staining and tryptic digestion followed by LC-MS/MS analysis. aDG from brain has also been demonstrated to bind to the lectin WGA, confirming that it contains terminal sialic acid and/or N-acetylglucosamine glycans. Second, the glycans are being released by a combination of chemical and enzymatic steps for further characterization by chromatography and mass spectrometry. Third, the sites of glycosylation, with an emphasis on the disease-causing O-man sites, are being mapped using mass spectrometry techniques for O-glycosylation including neutral-loss MSn and beta-elimination/Michael addition approaches. This investigation sets the stage for future work in comparing aDG from various tissues, including mouse models of congenital muscular dystrophy. Defining the glycans and sites of modification is the first step toward assigning functional roles for the glycans and is an essential step toward the development of glycopeptide-based therapeutic approaches for treatment of several forms of congenital muscular dystrophy. This work is partially supported by grants from UGARF and MDA (LW).

Synthesis of Dipeptidyl Acyloxymethyl Ketones (AOMK) Inhibitors of Yeast Enzymes Rce1p and Ste24p

Ned W. Hembree – CURO SUMMER FELLOW
Dr. Timothy Dore, Department of Chemistry, University of Georgia

Thirty percent of all human cancers contain a mutated, mature form of Ras, a protein containing a C-terminal tetrapeptide sequence referred to as a CaaX motif. Proteins containing this motif undergo a three step post-translational modification pathway: isoprenylation of the cysteine residue, cleavage of the aaX group and carboxyl methylation of the newly exposed C-

terminal end. By inhibiting steps in this pathway it might be possible to create novel treatments for cancers caused by Ras mutations. The focus of the research conducted for this paper is to synthesize various dipeptidyl (acyloxy) methyl ketone (AOMK) inhibitors and test their inhibition properties on Ras converting enzyme (Rce1p) and Steril 24 (Ste24), two enzymes responsible for the proteolytic cleavage of the aaX motif in CaaX proteins. Selective inhibition of Rce1p interests us because of its essential role in the maturation of Ras. The potential inhibitors consist of a varied benzoate group attached to any of three different benzyloxy-protected dipeptides, Z-FK, Z-FA, and Z-FR. Using a fluorescence quenching assay, the percent activity relative to the uninhibited enzyme can be determined. These activities, coupled with the inhibitory activity of other compounds are needed so that an inhibitor profile of Rce1p and Ste24p can be established. The goal is to investigate if selective inhibition of each enzyme is possible.

Homer's Voice Recalled: Christopher Logue's *Iliad* Accounts

Alicia Higginbotham – CURO SUMMER FELLOW
Dr. Thomas Cerbu, Department of Comparative Literature, University of Georgia

British actor, pornography writer, and poet Christopher Logue has been translating pieces of the *Iliad* since 1959 and has never learned a word of Greek. His translations, each containing only one or two segments of the 24-segment whole, make reference to Shakespeare, World War II, and Revlon lipstick ads. He has left behind the formal constraints of what scholar D. S. Carne-Ross calls "translationese" to find the voice of Homer once again.

Obviously, such an undertaking confronts many problems. Like any translation, Logue's *Iliad* must honor the original while also creating a new poem in English that responds to contemporary modes of thought. Logue also must contend with the long tradition of *Iliad* translations that precede his. Using translation theory, critical studies of both Logue and Homer, and interviews with Logue and current translation scholars, I explore the success of Logue's translations within both the postmodern poetry and classics studies communities.

Christopher Logue feels responsible to these scholarly fields only secondarily, however. The passion that pushes him to continue revising and adding to his *Iliad* segments is the conversation he has through the poem about the legacy of war. By connecting Logue's translations to his body of original poetry and by exploring supplementary texts which he found especially enlightening throughout his work, I will show how the *Iliad*, possibly the greatest war poem in history, is the perfect vehicle for Logue to make a statement on, among other episodes of violence, the Vietnam War, the war in Iraq, and the current trend of international terrorism.

Isolation and Characterization of a Novel Heterotrophic Anaerobic Thermophile from the Uzon Caldera (Kamchatka, Russia)

Maggie M. Hodges
Dr. Paul Schroeder, Department of Geology, University of Georgia

Microbiologists have been seeking to characterize the microbial ecology of systems such as deep sea vents, geothermal hot springs, salt lakes, and acid-mine drainage sites, hoping to form a more complete picture of the environment in which organisms on ancestral earth would have thrived. The anaerobic chemolithoheterotrophs and chemolithoautotrophs living in these ecological niches are reminiscent of the earliest life forms present on earth, anaerobic archaea and bacteria. The Kamchatka Microbial Observatory is an international/interdisciplinary program supported by the National Science Foundation which has as a goal the elucidation of the interactions that connect the geology, microbial ecology, and geochemistry in the terrestrial hot springs of the Uzon Caldera. Located on the far-eastern Russian peninsula of Kamchatka, the Uzon Caldera is a host for microbial diversity that is found across a wide range of physical and geochemical gradients, including magmatic and meteoric (atmospheric) water sources. Twenty-

five isolates were obtained from samples retrieved during the 2003 field season, in addition to four isolates acquired from samples brought back in 2004. The glycolitic and peptidolytic anaerobic thermophile that was isolated from these field samples indicates a novel species, exhibiting 98% 16s rDNA sequence similarity to Caldanaerobacter subterraneous subsp. tencongensis. This isolate has a temperature growth range from 44-76°C, with an optimal temperature for growth at 62-63°C. The optimal pH25°C for growth of the isolate fell between 6.3-6.7, while incubated at 72°C. Future research will seek to further describe the geology and geochemistry of the hot spring in which this new species was discovered

Para Risas?: The Relationship between Sports and Gender in an Ecuadorian Fishing Village

Michael J. Hotard
Dr. Michael Harris, Department of Anthropology, University of Georgia

Golosina, Ecuador is a small fishing village in which there are clear gender divisions between males and females. These divisions are brightly reflected in the sporting activities that are common throughout the village. However, sport is also a site in which ordinary gender roles are relaxed and challenged. It offers individual women ways to temporarily transcend their gendered social restrictions; but as an institution, it serves to strengthen, reinforce, and magnify entrenched gender divisions in Golosinana life. This paper explores articulations between sports and gender in Golosina. The cultural significance given to sports in this small village allows its effects to ramify beyond the court or field and into other domains of village life. By examining the behavior of the town's athletes and the construction of their sporting events, I will show how some gender roles in the village are reproduced. I will analyze the disparities in formal opportunities for males and females and the differences in how male and female athletes view themselves and each other. Through these comparisons, I discuss how gender roles are reflected in the institution of sport and how this institution itself serves to reinforce such roles. This study is specific to Golosinan life, but the patterns and social forces it reveals can be applied to other cultures as well.

Matrigel Invasion Assay for Ovarian Cancer Cell Lines

Staci R. Hutsell
Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

Ovarian cancer is the fifth most common cancer in women, and approximately 16,000 women die annually from this disease. Metastatic invasion, one hallmark of cancerous growth, can be viewed as a series of stages: escape from the primary tumor and intravasation into the vascular systems, survival in the circulation and avoidance of host defense mechanisms, arrest at a new site and extravasation into the tissue, and finally growth at the new site. Several in vitro assays mimic this in vivo metastatic process. The objective of this project was to develop and implement an assay for cell invasiveness which could be used to determine the metastatic effects of hormonal stimulation of the luteinizing hormone receptor. Using a Boyden chamber insert design, cells invading through Matrigel, a synthetic tissue barrier, were stained and counted. Percent invasion was determined by dividing the average number of invading cells by the average number of migrating cells for each cell line. The invasion index was determined by dividing the percent invasion for the test cell line by the percent invasion of the control cell line. The invasive properties of the BG-1 ovarian cancer cell line (70% invasion) were similar to the positive control cell line HT-1080 (60-70% invasion), whereas the CaOV3 ovarian adenocarcinoma cell line was considerably less invasive (15% invasion). The invasion indexes for BG-1 and CaOV3 were calculated to be approximately 1.2 and 0.2, respectively. In addition, the luteinizing hormone receptor (LHR) and a constitutively active LHR mutant were introduced into BG-1 cells to compare the invasive properties of wild type and mutant receptor. Comparing invasion through matrigel after stimulation of the introduced receptor, the results show no significant contribution of LHR

stimulation to the invasive properties of the cells. Therefore, metastasis will occur with or without LHR stimulation, and further research will determine pathways to increased cellular invasion.

Attention!Deficit-Hyperactivity:Disorder?
Joseph Hutto
Prof. Rebecca Enghauser, Department of Dance, University of Georgia
(Joseph Hutto, Mary Mattman, Laura Henry, Montez Nash, and Leah Chapman)

With this project I set out initially to create a piece that was very personal and about some very serious issues but also to create a piece that was light hearted and entertaining at the same time. I intended to create from my own personal experience of my childhood and adolescence and thus created characters out of my actual family members. I then decided to put this personal history up against my own personal relationship history and created characters out of all of my ex-girlfriends or ex-crushes. This covers my life story from early childhood to today and highlights certain events throughout. I then decided to satire each of these moments and to make the piece humorous. I titled the piece "Attention!Deficit-Hyperactivity:Disorder?" in reference to the fact that I do actually struggle with this disorder and have for a long time. This allowed me to utilize the image of changing channels on the television screen, which is a frequent example of what ADHD feels like. This helped me to incorporate the TV sitcom elements and tied in the music as well. I was originally greatly inspired by the music, which is all from television shows, movies, and video games from my childhood to today. I chose music that was appropriate to each scene or scenario and also that was without lyrics, so that they would not interfere with my artistic expression in each case. I attempted to weave all of these elements together to create a colorful fantastic farce of actual events and to better tell my story.

Assessing Opinions of Georgia Residents on Poverty and Labor Markets in 2005
Jamarri J. Ivy – CURO APPRENTICE
Dr. James Bason, Survey Research Center, University of Georgia

Poverty inflicts some 210,000 families in the State of Georgia. Identified as a social problem, poverty has far-reaching and detrimental effects on Georgia's economy, as well as overall society. A 2004 poll by the Carl Vinson Institute of Government concluded that Georgians are highly concerned with the problem and show pessimism about a future solution to poverty. My research examines the opinions of 500 Georgia residents during October 2005 on issues relating to poverty. Census Bureau reports released in August of 2005 show that poverty rates are still on the rise, and household incomes failed to increase for the 5th straight year. The Georgia Poll directly deals with opinions on causes of poverty, definitions of poverty, labor markets across various demographics, and how the worsening state of the economy has had an effect on Georgians. The statewide RDD telephone survey was conducted at the Survey Research Center. Based on the fact that poverty is one of the major problems afflicting the state, the research will examine whether the results of the Carl Vinson Institute of Government Poll still apply to the opinions of Georgians in 2005, in light of higher poverty levels since the 2004 poll. The results help to further knowledge of the public's perception of poverty, the relationship between the current poverty level and the opinions of Georgians, and the overall resolve of Georgia residents to solve the problem. When a social problem is as sweeping as is the case with poverty, a collective effort becomes ideal.

Hepatic Expression of Deiodinase-1 in the Rat
Natalie M. Jennings – CURO APPRENTICE
Dr. Duncan Ferguson, Department of Physiology and Pharmacology, University of Georgia

This study examined the effects of thyroid-inhibiting drug PTU on the hypothalamic-pituitary-thyroid regulation of pregnant rats and their offspring. The thyroid gland regulates basal metabolism and is critical in growth and development. The purpose of this research is to understand the developmental differences of rat

thyroid status through the comparison of data from each level of PTU exposure among various age groups. Pregnant rats were exposed to PTU in drinking water from gestation until weaning. There were three levels of PTU exposure: 0, 3, and 10 ppm, and three age groups under study: pup (offspring), dam (mother), and adult (pup 2 months after weaning, last exposure to PTU). Deiodinase 1 (D1) enzyme, which converts thyroid hormones T4 to T3 through the removal of iodide, was examined in liver homogenates. To determine D1 mRNA expression, mRNA was extracted and D1-specific mRNA was quantified with real-time PCR. Liver assays measured D1 activity based on the amounts of 125I produced when D1 removed iodide from radioactive rT3. Relative D1 levels are expected to decrease with increasing PTU doses, with the thyroid status of the dams affecting that of their offspring. The relative amount and expression of liver D1 can then later be analyzed along with other data to broaden the understanding of developmental interruptions. The information using this standard anti-thyroid drug will establish a foundation for other studies evaluating other thyroid disruptors such as perchlorate, a chemical that is an environmental hazard in human drinking water in many areas of the U.S.

Design of an Inducible System for Expression of the Human Luteinizing Hormone Receptor

Barrett Jones
Dr. Susanne Warrenfeltz, Department of Biochemistry and Molecular Biology, University of Georgia

The human luteinizing hormone receptor (hLHR) is a G-protein coupled receptor that is vital for human reproduction, but its expression may influence the formation or progression of ovarian cancer. hLHR expression has been shown to decline from low-grade to high-grade ovarian cancer and is much lower in malignant ovarian epithelial tumors than in benign ovarian epithelial tumors. An inducible expression system which provides regulated expression of hLHR in ovarian cancer cells may allow for the elucidation of a correlation between hLHR expression and ovarian cancer. The goal of this project was to produce a plasmid that, when introduced to ovarian cancer cells, places the expression of hLHR under the tetracycline responsive element. Primers were designed and synthesized for PCR amplification of hLHR that provide the correct restriction sites needed for insertion into the pTRE2hyg2-6xHN expression vector. Attempts made to ligate the insert and vector and transfect competent E. coli cells with the ligation mixture were unsuccessful. In the future, once the ligation is successful and the hLHR-pTRE2hyg2-6xHN plasmid is complete, the plasmid can be introduced into ovarian cancer cells that lack hLHR since residual expression could compromise control over the total hLHR expression levels in the transformants. The transformants can then be monitored at different hLHR expression levels for matrigel invasion characteristics and be compared to wild type ovarian cells from the same line to reveal any changes in cancer aggressiveness.

Creative Writing

Betsy Jones
Dr. Phil Williams, Franklin College of Arts & Sciences, University of Georgia

This piece is a non-fiction narrative that explores the theme of home (what it is and how it is constructed) and how a sense of place and a relationship with the natural world directly affect the creation of home.

Edward Abbey begins *Desert Solitaire* with a simple observation: “Every man, every woman, carries in heart and mind the image of the ideal place, the right place, the one, true home, known or unknown, actual or visionary.” Locating that true home can be a life struggle.

Writing about “home” is tricky. Home is the topic of many a bumper sticker and crocheted pillow. It’s where the heart is, there’s no place like it, and it’s where they have to take you in. Home depends on many factors: rooms, memories, people, tastes and smells. But, it also involves an understanding of the natural world outside of the kitchens and Christmas decorations. This understanding and

relationship, what Emerson calls "an original relation to the universe," is key in connecting with the past and the future, key to crafting a home.

The Role of Sympathetic Nerves in Leptin-induced Loss of Body Fat

Lisa Jordan – CURO SUMMER FELLOW
Dr. Ruth Harris, Department of Food & Nutrition, University of Georgia

Leptin is an adipocyte-derived hormone involved in energy metabolism and body weight regulation. Leptin reduces body fat when administered to experimental animals, but it is unclear why obese individuals remain fat while possessing high circulating levels of leptin. Understanding leptin's functions and mechanisms could provide insight about possible leptin malfunction in these individuals. One possible mechanism by which leptin could reduce body fat is by activating the sympathetic nervous system (SNS) to increase lipid mobilization from adipocytes. Here the effect of continuous infusion of leptin on peripheral sympathetic nerve activity, as measured by norepinephrine turnover (NETO), was investigated in both white adipose tissue (WAT), the major fat storage site, and brown adipose tissue (BAT), the major site for thermogenesis in rodents. It was hypothesized that leptin would increase NETO in these tissues. Fifty-five male Sprague-Dawley rats were divided into three treatment groups: leptin-infused, control, and pair-fed. Pair-fed rats were used to control for the inhibitory effect of leptin on food intake and were restricted to food intake of leptin-infused rats. Rats were infused for four days with 40µg per day of leptin or phosphate buffered saline from intraperitoneal miniosmotic pumps. Leptin affected sympathetic activity in a depot-specific manner. NETO in inguinal WAT was significantly increased in leptin-infused and pair-fed rats compared with controls. NETO in intrascapular BAT was significantly increased in leptin-infused rats compared with controls and was even further increased in pair-fed rats. Leptin did not increase NETO in retroperitoneal, epididymal, or mesenteric pads. There was no relationship between increased NETO and reduction in size of fat pads, suggesting that the SNS does not account for the specific reduction of body fat in leptin treated animals.

Tangerine Blush: Engineering Soybean to Produce β-carotene in Seed Cotyledons

Blake L. Joyce
Dr. Wayne Parrott, Department of Crop and Soil Sciences, University of Georgia

Consumers associate quality of food with color and flavor. Without certain carotenoids egg yolks, butter, and even shrimp would be white instead of their expected color. Soybean meal is a chief source of animal feed in the US but is devoid of carotenoids. If soybean feed already contained carotenoids, farming industries would have a more economical choice for animal feed. The goal of the project was to genetically engineer soybean to produce carotene, the precursor for other agriculturally important carotenoids. Soybean embryos were transformed using microprojectile bombardment with a plasmid containing the phytoene synthase (crtB) from Erwinia uredovora gene for phytoene, placed behind a cotyledon specific promoter and with hygromycin resistance as the selectable marker. Endogenous soybean enzymes then change the phytoene into β-Carotene. Three engineered lines were obtained. One line of the three turned orange, denoting the successful expression of carotene in the seed tissues. Engineering with additional genes for carotenoid synthesis should allow for production of other carotenoids, such as canthaxanthin.

Development of a Diagnostic Test for *Mycobacterium avium*

Simon Kahsay
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia
(Simon Kahsay, Russell Karls, and Craig Greene)

Mycobacterium avium is a bacterium that resists common antibacterials due to the presence of very long fatty acids (mycolates) in its cell wall that constitute an extremely hydrophobic barrier. *M. avium* is virtually ubiquitous in soil and water and can cause tuberculosis-type diseases

in immune-compromised humans, birds, and genetically-predisposed pet animals, such as miniature schnauzer and Bassett hound dogs and Abyssinian cats. Effective treatment of infected pets requires the prompt institution of anti-mycobacterial therapy; however, no clinical test is available to veterinarians for the rapid diagnosis of *M. avium*. The work presented in this report describes progress toward the production of a polymerase chain reaction (PCR) assay for the rapid detection of this bacterium in clinical samples. Oligonucleotide primers designed to recognize a discriminatory region of the *M. avium* 16S rRNA operon produced the expected PCR product with purified *M. avium* DNA. Annealing temperature, extension time, and number of cycles were optimized to enhance the efficiency of the PCR reaction and the product yield. The PCR assay was used with crude DNA templates obtained from *M. avium* bacilli following various cell lysis approaches (boiling, mechanical disruption, and use of detergents). Mechanical lysis was found to be essential for detection of the PCR product. Current research is investigating modifications to cell lysis procedures to detect these bacteria in the presence of host cells and tissues. The results of these experiments are anticipated to aid production of an assay that will enable clinicians to rapidly screen for the presence of this bacterium.

"Fracturing Fairy Tales": Lu Xun's Old Tales Retold Reveal Power in Ancient Chinese Mythology

Laura B. Kearns
Dr. Kam-ming Wong, Department of Comparative Literature, University of Georgia

A society's mythology often represents its belief system and cultural practices. The study of mythology as it changes over time thus allows one to perceive and understand stages in history. Lu Xun's Old Tales Retold, written from 1922 to 1935 following China's 1919 May Fourth Movement, exaggerates mythology's historical value to comment on a pivotal piece of Chinese history. The text's eight short stories find their basis in classical Chinese myths that had once been the core of China's culture. These ancient myths had helped shape the ancient feudal and Confucian society that subsisted until its collapse in 1911 with the birth of the Republic of China. As an outsider seeking an insider's knowledge of Chinese culture, I read not only English translations on the May Fourth Movement and Lu Xun's life, but I also translated and compared the Chinese texts of Lu Xun's Old Tales Retold and the vernacular and ancient Chinese myths that were the basis of Lu Xun's book. When the ancient government and society were drastically shifting, Lu Xun transformed ancient, essential myths into modern stories to convey his opinion on the permanency and significance of the changing circumstances. Native Chinese scholars have done studies on Lu Xun's Old Tales Retold, but a foreigner's comparative study of Lu Xun's text and ancient Chinese myths allows a fresh perspective. By explaining how Old Tales Retold reveals both the significance of a certain historical period and the perception of an individual's (Lu Xun's) beliefs, this analysis will permit me to demonstrate the true insight mythology has of mankind.

The Effects of Social Experience on Aggressive Behavior in Drosophila

Jayne M. Kelly
Dr. Yong-Kyu Kim, Department of Genetics, University of Georgia

Aggressive behavior is observed in all animals, including humans. Prior data showed that aggression is influenced by genes as well as environment. To determine what affects aggression in fruit flies, and ultimately humans, both *Drosophila melanogaster* and *D. pseudoobscura* were observed. The amount of aggression exhibited by flies with varying amounts of social interaction and by flies of different ages was compared. It is predicted that socially-isolated flies will exhibit more aggression than socialized flies, while older flies should display more aggression than their younger counterparts. In order to test these predictions, a plastic arena and a video camera were used to observe pairs of similar flies in three combinations. These included: isolated (I) vs. isolated (I), socialized (S) vs. socialized (S),

and isolated (I) vs. socialized (S). Isolated flies represented those raised with no social interaction since before birth, while the socialized flies were those raised in groups since birth. During observations seven behaviors were tallied: chasing, wing vibration, wing threat, fencing, boxing, holding, and lunging. Social isolation seems to play a part in the amount of aggression exhibited by the flies. This is supported by the fact that, in regard to a few of the aggressive behaviors, the isolated flies demonstrated significantly more aggression than the socialized flies for both *D. melanogaster* and *D. pseudoobscura*. We did not see the effect of age on Drosophila aggressive behavior, but further research with substantially different age groups may provide further insight into this topic. By determining what influences aggression in Drosophila, including a lack of social experience and age, we obtain a better understanding of the factors that may affect aggression in humans.

Healing Arts: The Use of Drama Therapy in Treating People Suffering from Trauma

Carey J. Kirk – CURO SUMMER FELLOW
Dr. David Saltz, Department of Theatre & Film Studies, University of Georgia

This study investigates the use of a relatively new field in the treatment of trauma survivors: drama therapy. Bosnian teachers suffering from trauma were interviewed on their experiences participating in a five-year drama therapy program provided by the ArtReach Foundation. Questions included describing themselves before the program began, how they felt while taking part in the drama therapy sessions, and how they believe the program affected them personally and as a teacher. The effectiveness of drama therapy as a treatment for trauma is assessed through the improvement of these teachers as measured by their self-reported changes. Possible reasons for the teachers' improvements were inferred by comparing the teachers' self-reported experiences to themes that emerged in my participant observations of drama therapy sessions in Atlanta, Bosnia, and New York, and in literature on drama therapy and trauma. These reasons include: the use of metaphors and props to provide distance, a heavier reliance on movement and visual stimuli that is shown to better access the implicit memories formed during a traumatic event, the incorporation of 'surplus reality', and techniques such as role-reversal and scene directing that provide the trauma survivor with insight and a safe and guided environment in which to enact their repetition compulsions. Based on these results, further research could more quantitatively measure symptom improvement by using the Trauma Symptom Checklist or Harvard Trauma Questionnaire and compare the effectiveness of drama therapy to talk-based therapies in the treatment of trauma.

Systems Biology of the Quinic Acid Cluster in *Neurospora crassa*

Allison L. Koch
Dr. Jonathan Arnold, Department of Genetics, University of Georgia

Neurospora crassa is a widely used model system for biological research. This bread mold contains the quinic acid gene cluster, which encodes the organism's pathway for utilizing quinic acid as a carbon source. When *N. crassa* is grown on sucrose medium, the quinic acid gene cluster is inactive. When the organism is shifted to a medium that has quinic acid instead of sucrose, the quinic acid cluster genes are activated. To see the gradual changes in expression of these genes, samples were taken at multiple time points after the shift to quinic acid. The RNA samples from these time points were analyzed with micro array chips, which gave the precise measurements of the RNA levels of each of the 11,000 genes in the genome. These RNA measurements at the multiple time points were compared to predictions of a genetic network model. A genetic network has three collections of reactions with genes and their products as species: (i) Central Dogma describing how genes make proteins; (ii) a biochemical pathway describing what the proteins do; (iii) how certain proteins regulate gene expression. This model makes predictions of the changes in the quantities of RNA under the same experimental conditions. If the data agree with the predicted values of the model, then the genetic network is

validated. We would have a validation, for example, of what proteins do and how genes are regulated. Thus, measured RNA levels of all genes allow us to validate the molecular mechanism by which *N. crassa* utilizes a carbon source.

Identification of a New IS Element from *Streptomyces coelicolor*.

Alina Kuo
Dr. Janet Westpheling, Department of Genetics, University of Georgia
(Alina Kuo, Karen Stirrett, and Janet Westpheling)

Insertion sequences (IS) are genetic elements (in most cases, self mobilizing DNA fragments) that move from place to place in the genome. In the process, they may alter gene expression, inactivate genes, or cause gene rearrangements. These elements may also be used as tools to direct changes in gene expression or insert foreign genes of interest into chromosomes and thus allow for stable genetic manipulation.

Streptomyces are common soil bacteria that produce the vast majority of natural antibiotic products and pharmacologically active metabolites used in human and animal health care. Many of the most important strains are genetically uncharacterized and do not respond to classic genetic manipulation. Here we report the identification of a previously unknown IS element from *Streptomyces coelicolor* that is capable of genetic transfer to a variety of relatively uncharacterized antibiotic producing strains. An 836 bp DNA fragment containing an IS element isolated from the *Streptomyces* phage MRT displayed the capacity for phage mediated recombination between various *Streptomyces* spp. Subsequent conjugation experiments revealed differences in the frequency of insertion for three species of *Streptomyces*. Using phage DNA as a probe, the presence of an IS element in these strains was confirmed by Southern hybridization which showed that insertion was apparently random. A series of experiments and techniques are being used to identify the element's target sequence by locating the junction fragment between the IS element and the site of insertion in the chromosome. The broad host range of this element, the fact that it inserts randomly, and its relatively small size make it a potentially excellent tool for the genetic manipulation of important antibiotic producing strains for which there are relatively few genetic tools.

Striking A Balance: How Young Children Hammer

Sonika Kushwaha & Sarah Reagin
Dr. Dorothy Fragaszy, Department of Psychology, University of Georgia
Dr. Kathy Simpson, Department of Kinesiology, University of Georgia

Striking an object using a tool (a hammer), has been an essential manual skill in human history. Based on a dynamical systems perspective, a person 'self-organizes' movements relative to factors shaping the movement, e.g., gravity or motor development. The study's purpose was to determine if older versus younger children would move more joints to produce increased hammering velocity and striking accuracy and exhibit more posturally stable positions during hammering. We videotaped 26 children (12, 18 and 24 mo.) while they hammered a peg. The child's body positioning and arm striking technique were coded. The youngest children typically sat in symmetrical leg positions, with their legs in full contact with the ground. Older children sat with an increased variety of leg positions. Younger children used shoulder extension or rotation to move the entire arm as a unit; older children primarily utilized elbow flexion/extension with some wrist motion. The leg positions adopted by the younger children increased postural stability to resist gravitational torques. The developmental shift from moving the arm primarily about the shoulder to the elbow and wrist joints during striking follows Schöner's and Dounskaia's predictions that a multi-joint movement skill progresses from single to multi-joint motions and from proximal to more distal joints. Biomechanically, the elbow flexion and extension strategy is more likely to require less muscular torque to produce the movement. These findings are, to date, the first to portray the progression of motor patterns

from less to more biomechanically effective striking when using a tool.

Student Willingness to Pay to Avoid Unpleasant Odors on Campus

Victoria S. LeBeaux
Dr. Jeff Mullen, Department of Agricultural and Applied Economics, University of Georgia

The city of Athens is proud to be home to the University of Georgia, with its renowned academic and athletic programs. Unfortunately, the city is also home to a number of problems linked to the University's successful growth. Among these problems are those faced by the wastewater treatment facilities which serve Athens. These treatment plants, built in the 1960s, were not designed to handle the volume of wastewater which is now generated in Athens. One of the results of these outdated and under-equipped facilities, is a foul odor which permeates the east side of the campus. Replacing the plants will cost approximately $170 million. This study will examine the students' attitudes about the odor and determine their willingness to pay for eliminating the problem. Students living in University Housing will be randomly selected to participate. The study will be administered as a contingent valuation survey through interviews and the mail. A key goal of the survey is to eliminate possible bias. This will be accomplished by asking both closed and open ended questions and by varying the payment vehicles and the numeric starting point of the valuation question. Full results from the survey have not been attained at this date. Preliminary data, however, suggest that underclassmen, students who do not work to support themselves, and students who live closest to the treatment plant will be willing to pay the most money to eliminate the smell. Resultant data provide significant information concerning the value students place on public goods.

Pulmonary Responses to Ozone in Obese Mice

Anna Lee
Dr. Stephanie Shore, Department of Public Health, Harvard School of Public Health

Recent epidemiological data suggest that obesity can be a causative factor for asthma. The mechanistic basis of this relationship is yet to be fully discovered. Data from this lab indicate that obese mice as a result of a genetic deficiency in either leptin (*ob/ob* mice) or the long form of the leptin receptor (*db/db* mice) have increased responses to ozone, an asthma trigger, compared to lean wild-type mice. To determine the reason for these differences, we measured pulmonary expression of TNFα and IL-1β since both have been proposed to play a role in the induction of neutrophil chemotactic factors following ozone exposure. We also measured the short form of the leptin receptor, Ob-Rα, in *db/db* versus wild-type mice to determine whether leptin can signal through Ob-Rα in *db/db* mice. The experimental procedure began with exposing *ob/ob*, *db/db* and wild-type mice to 2ppm ozone or room air for 3 hours and harvesting the lungs 4 or 24 hours after the cessation of ozone or room air. RNA was extracted from homogenized lung tissue and reverse transcribed for real time RT-PCR. Our results showed that there is a direct incremental increase in TNFα and IL-1β pulmonary mRNA expression only for the *db/db* mice after ozone exposure. The real time PCR for the Ob-Rα gene indicates that it is very strongly expressed in both wild type and *db/db* mice. Our data indicate that *db/db* mice differ from *ob/ob* likely as a result of leptin signaling through the short leptin receptor isoform, which may account for observed differences in responses to ozone in these mice.

The Evolution of Virulence in a Two Disease System

Andrew Leidner – CURO SUMMER FELLOW
Dr. Pejman Rohani, Department of Ecology, University of Georgia

An important issue in population biology is the dynamic interaction between pathogens. Interest has focused mainly on the indirect interaction of pathogen strains, mediated by cross immunity. However, a mechanism has recently been proposed for 'ecological interference' between pathogens through the removal of individuals from the susceptible pool after an acute infection. In 2003, Rohani et al. explored this

possibility through modeling historical measles and whooping cough records. They showed that ecological interference is particularly strong when infections are fatal and permanently remove susceptibles. Based on these interactions between two competing diseases, Rohani et al. demonstrated disease interference has substantial dynamical consequences, making multi-annual outbreaks of different infections characteristically out of phase. This ecological interaction between diseases may have even more profound implications for the evolution of competing pathogens. To examine the evolutionary aspects of multi-pathogen communities, we have formulated a stochastic agent-based model. We show that the evolutionary consequences of interference for pathogen virulence are substantial and counter-intuitive.

Family Involvement in Education: Is there a Magic Bullet?

Brian L. Levy, Roosevelt @ UGA
Dr. Larry Nackerud, School of Social Work, University of Georgia

Resonating with voters and seemingly necessary, education reform has become a growing concern in the American political climate. This anxiety seems justified, as an alarming 10% of all individuals between the ages of sixteen and twenty-four have not completed high school and are not currently enrolled (Child Trends DataBank 2004). Empirically, parental involvement has been touted as an answer to America's educational woes. Still, as is evidenced by the Family Involvement Initiative of 1994, policies to improve involvement are undeniably general and lack specific emphasis on socio-ethnic variations between parents. This is an interesting approach, considering the discrepant rates of dropout for different ethnicities: Hispanic individuals at 24%, Black American individuals at 12%, and White American individuals under 7% (Child Trends DataBank 2004). This policy analysis, through an exhaustive academic literature review, argues that the overall effect of parental involvement on academic achievement is moderated by ethnicity. More specifically, different parenting styles and forms of involvement are noted to be more or less efficacious for varying races. Upon a comprehensive synthesis of the literature, I conclude with an examination of the flaws in current American policy and recommendation for necessary changes. A holistic approach that recognizes the importance of ethnic diversity and its relation to parenting styles and involvement, as well as the value of long-lasting outreach programs, is found to be most effective.

Identifying GPI-Anchored Proteins in Breast Cancer Cells

Chen Lin – CURO APPRENTICE
Dr. Michael Pierce, Department of Biochemistry and Molecular Biology, University of Georgia

According to the American Cancer Society, more than 200,000 people are diagnosed with invasive breast cancer in the United States alone. If preemptive symptoms can be identified, this number will be significantly reduced. The linkage between glycosylphosphatidylinositol (GPI), anchored proteins found on the plasma membranes of eukaryotic cells, and cancer cells is a new frontier of science. Few GPI-anchored proteins have been identified, although their synthesis is associated with the Golgi and the rest of the secretory system. Most GPIs are recognized in their free form, or when covalently linked to proteins or sugars. They serve many roles that include acting as enzymes and as receptors in cell adhesion. Another characteristic of GPIs that has been previously shown is that they bind to Clostridium septicum (a bacteria) alpha toxins, which will help us identify these proteins. We used these alpha toxins to explore GPI-anchored proteins in relation to cancerous breast cells. Mass spectrometry was used to identify the GPI-anchored proteins present. The purposes of these experiments were to collect and identify GPI-anchored proteins from membrane fractions and determine if breast carcinoma cells display significantly more GPI-anchored proteins than non-diseased breast tissue. If there appears to be a correlation between GPI-anchored proteins and their prevalence in breast cancer cells, then they can become possible indicators for the cancer,

which will aid in developing early detection diagnostic techniques in the future.

A Conserved Neural Signaling Pathway Regulates Hunger-induced Stress Tolerance in Drosophila

Patrick R. Lingo
Dr. Ping Shen, Department of Cellular Biology, University of Georgia

All animals have an innate tendency to avoid stress. Moreover, their stress tolerance can be modified based on physiological needs. This study is designed to test the hypothesis that the regulatory mechanism(s) underlying stress response might be evolutionarily conserved in diverse animals, including humans. Using the fruit fly, *Drosophila melanogastor*, as a model, we previously showed that Drosophila neuropeptide F (NPF, a homolog of human neuropeptide Y, NPY) and its receptor NPFR1 promote acquisition of less accessible/palatable foods in starved larvae. Here we describe a simple assay to assess foraging activities of larvae under stressful conditions (noxious, low temperatures). In the assay, larvae (deprived or non-deprived) are introduced to pre-chilled foods, ranging in temperatures from 11°C-20°C. Their feeding activities are indicated, semi-quantitatively, by the presence of dyed food in the gut. At 11°C, wild-type fed larvae showed little feeding response, while a majority of larvae fasted for two hours displayed feeding activity. We further show that the NPF system is responsible for hunger-driven, cold-resistant foraging: overexpression of NPFR1 in fed larvae proved sufficient to significantly increase feeding activity. Conversely, down-regulation of NPFR1 expression in deprived larvae suppressed feeding response. These findings suggest that activity of the conserved NPY-like system is an essential component of the dynamic regulation of stress tolerance in response to an animal's physiological needs. A conserved Drosophila insulin-like signaling system has been shown to directly regulate the NPY-like system. We are currently investigating the role of fly insulin-like signaling in stress response.

Risk Communication among Non-Clinical Healthcare Employees: The Key to Preserving Infrastructure in a Medical Emergency

Lindsay Looft & Kevin Chang, Roosevelt @ UGA
Dr. Corrie Brown, Department of Pathology, University of Georgia

During a threatening medical outbreak, non-clinical hospital employees play an essential role in maintaining a functional healthcare environment. An intact infrastructure allows healthcare professionals to provide immediate quality care. However, without proper knowledge of an infection's risks, many employees fail to arrive at their workplace out of fear for their personal safety. The events at the Morgan Processing and Distribution Center, where traces of anthrax caused absenteeism rates to reach thirty percent, evidence the consequences of such a scenario. To prevent situations of this nature, it is imperative the Department of Health and Human Services, in conjunction with the Centers for Disease Control and Prevention, develop a curriculum for risk communication. In this circumstance, risk communication means providing employees with an empowering knowledge of disease that creates a sense of personal safety and security which, based on literature reviews and interviews with hospital employees, will serve as an effective means of reducing absenteeism rates. Then, hospital leaders should be responsible for communicating risk and protection methods to staff members. This proposal recommends the first curricula on risk communication focus on anthrax, a biological agent, and avian flu, an emerging infectious disease. These curricula should communicate general risks of both infectious diseases and bioterrorism. Further, they should aim to dispel common public misperceptions of the two genres of threat. Additionally, there must be official records of all employees who have received available vaccinations, in the unlikely spread to hospital workers. Risk communication among non-clinical workers is crucial in cultivating a sense of security, thus ensuring

fully capable healthcare systems in the face of a medical emergency.

Permethylation of 2-Aminopyridine Labeled Oligosaccharides: Facilitating the Analysis of Complex Glycan Mixtures

Lindsay Looft
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia
(Lindsay Looft, Gerardo Alvarez-Manilla, and Michael Pierce)

Oligosaccharide moieties from glycoproteins are responsible for many physiological functions including cell-cell and cell-matrix interactions. The structural analysis of these oligosaccharides facilitates the understanding of their role in oncogenesis and development. Through labeling with fluorescent tags, such as 2-aminopyridine (2-AP), oligosaccharides can be easily detected and quantified when separated by high performance liquid chromatography (HPLC). Despite this sensitivity, it is difficult to assign oligosaccharide identity using this methodology without suitable standards. Another means of analyzing oligosaccharides is through permethylation, which homogenizes charge density and creates a non-polar compound that can be easily analyzed by matrix assisted laser desorption ionization-time of flight (MALDI-TOF) mass spectrometry. Though this particular method enables glycan identification with excellent resolution, it can be difficult to analyze glycans in complex mixtures due to the presence of many peaks. Additionally, permethylation is not suitable for glycan quantification and modifies the chemical nature of oligosaccharides, thus rendering them useless for other physiological studies. For these reasons, it is desirable to fractionate and quantify oligosaccharides prior to permethylation; however, the current standard procedure for permethylation results in incomplete derivatization when applied to 2-AP labeled oligosaccharides. In this study, oligosaccharides prepared from glycoproteins, such as human orosomucoid, bovine thyroglobulin, and fibrinogen, were purified after proteolysis and Peptide N-glycoamidase F (PNGase F) release and a portion of them was labeled with 2-AP. A method of permethylation is being developed for an accurate and reliable structural analysis of these oligosaccharides using MALDI-TOF. Ultimately, the successful permethylation of 2-AP labeled glycans will facilitate the analysis of complex biological samples such as tissues, serum, or cell lines.

Migration of the Avant-garde in Early Modernist Visual Art: The Question of Sequence in Innovative Form and Ideology

Laura C. Mackert
Dr. David Roberts, Department of History, University of Georgia

My research explores the intellectual and artistic migration from Europe to the United States—from Paris to New York City—that occurred during the first few decades of the twentieth century. I examine the adoption and adaptation of Europe's Early Modernism by the American cultural elite. In particular, I discuss New York's Greenwich Village—Alfred Stieglitz and the 291 Gallery, the Arensberg Circle, the Armory Show, the cohabitation of European and American members of the avant-garde—and the place it held in further Modernist innovation, both in America and abroad. I treat my study of the intellectual migration of Early Modernism as a case in which I examine how such phenomenal innovation proliferates among individuals and whole cultures. Specifically, I am interested in the relationship between avant-garde technique and avant-garde idea. Analyzing the relationship between form and ideology, scholars often conclude that technique necessarily succeeds idea in the arts. In "Early Modernism: Literature, Music, and Painting in Europe, 1900-1916," for example, Christopher Butler favors the notion that new techniques develop to accommodate and express new ideology. Not convinced that this chronology accurately describes the relationship between Modernist form and ideology, I critically examine the historiography of this pivotal moment in Early Modernism—the movement of the avant-garde from Europe to America—in order to test analyses like that of Butler. Even if ideological innovation conventionally precedes technical innovation, the phenomenon of Modernism may have

manipulated this sequence. Perhaps innovation in form played a more influential role in the development of Modernism than many scholars acknowledge. Citing the unique occasion of the artistic and intellectual migration in the early twentieth century, I argue that Modernist form and idea developed simultaneously, and that often avant-garde technique even inspired innovative ideology.

Effect of Introduced Predator, the American Mink (*Mustela vison*) on Ground Nesting Songbirds in the Cape Horn Archipeligo, Chile

Brett M. Maley
Dr. Amy Rosemond, Institute of Ecology, University of Georgia

Invasive species are one of the greatest threats to global biodiversity. The American mink, *Mustela vison*, was introduced to Tierra del Fuego Island (southern Chile) to begin a fur trade in the 1940s. The fur industry was not successful, and now the predatory mink has invaded a large part of the Fuegian/Cape Horn Archipelago. The mink has only been present on Navarino Island, where our study was conducted, for approximately three years. We expected mink to have a significant negative impact on ground-nesting songbird nests via egg predation because mink are known to be predators of such nests, and they lack an evolutionary history with birds in this area. To test this hypothesis, we used artificial nests and eggs and the Mayfield method to quantify nest predation in four different habitats: anthropogenically impacted shrublands, beaver meadows, secondary forest, and primary forest. Predators were identified by the teeth marks in the plasticine eggs. The mink was found to be the most frequent nest predator, with birds being the other major source of attack on artificial eggs. Mink depredation events were more frequent in disturbed habitats, i.e. shrublands and beaver meadows than in less disturbed habitats. While artificial nests may overestimate the importance of small avian predators, this study showed that mink can be a major threat to ground nesting songbirds in the Cape Horn area. Further, the greater effect of mink in more disturbed habitats suggests that conservation and management efforts may need to be prioritized in those areas.

Female Choice in Sexual Selection in *Drosophila pseudoobscura*

Jon McGough – CURO SUMMER FELLOW
Dr. Wyatt Anderson, Department of Genetics, University of Georgia

In some Drosophila species, single females are surrounded by multiple males in nature. Classically, females are choosy and perhaps select high fitness males. Therefore, genes of high fitness should be passed to future generations. Using isofemale lines from *D. pseudoobscura*, we tested the hypothesis that Drosophila females mate randomly among males, expecting to find that females chose males of higher fitness more often than males of lower fitness. For each observation period, fourteen sexually mature males were individually marked with fine dots of paint and released into a glass cage where they were allowed to mate with single females that were later introduced to the cage. Cuticular hydrocarbon levels and mating speeds were subsequently measured for the males that did not mate or mated multiple times. Current data show that approximately 20% of males were not accepted by females, about 30% mated 1-2 times, and about 10% mated more than 10 times during the 5-day period. Similar trends were observed for *D. melanogaster* and *D. hydei*. Also, differences were found in the levels of male-dominant cuticular hydrocarbons between males that mated multiple times and ones that did not mate. Multiply-mated males produced significantly more male pheromones and mated more quickly with females. Due to the variation in mating frequency among males, these results suggest that *D. pseudoobscura* females mate non-randomly. The results also suggest cuticular hydrocarbon levels and mating speeds can serve as indicators of individual vigor and physical status in males.

The Employment of Fiscal Policy as the Primary Means of Controlling Inflation and Promoting Short-Term Stabilization, with

Focus on the 1980s and 1990s in the United States

Balaji L. Narain
Dr. Harrison Hartman, Department of Economics, University of Georgia

The purpose of this research was to analyze the various effects of fiscal and monetary policies on inflation and real GDP from 1980 through 2000. At present, most officials in Congress, the Executive Branch, and the Federal Reserve propound that the central bank is better suited to promoting stabilization in the short-term, defined here as less than one year. Using data compiled from the St. Louis Federal Reserve's archive of economic information and the IRS website, average tax rates, average Federal Funds rates, levels of changes in federal funds rates and tax rates, inflation rates, and GDP were calculated for the years 1980 through 2000. Data were compared against one another to identify trends as to which policy method produced greater effect in the short term. It was predicted that fiscal policies, usually involving a longer inside time lag than monetary policy, reflected a much shorter outside time lag, implying that fiscal policies are more effective in the short run. As expected, the data illustrated that increases in the money supply or decreases in interest rates did not see an associated increase in GDP until an average of one year later. By contrast, fiscal policies produced an associated increase or decrease in GDP within an average of two to three months after being signed into law. Congress should thus make greater use of its ability to foster economic growth. The concluding recommendation would then be for increased coordination between Congress and the Federal Reserve to promote stable short-term GDP growth.

Evolution of US Trade Policy: A Reconsideration of US Anti-Dumping Laws

Balaji L. Narain & Kate Bryant, Roosevelt @ UGA
Dr. James Holmes, Center for International Trade and Security, University of Georgia

The purpose of this research was to analyze the malignant effects of anti-dumping margins on American trade with China. Congress has continued to maintain its stance toward China as a non-market economy. This leaves China open to punitive damages when goods produced in China sell at a price in the United States varying either from the price of the good sold in China or at a price lower than marginal cost of production. In recent years, Congress has displayed a proclivity to enact stringent anti-dumping margins on Chinese imports. More detrimental than general tariffs, anti-dumping margins compel foreign producers to collude with domestic manufacturers, damaging consumers and downstream manufacturers by forcing them to negotiate with collusive producers. When the price of imported unfinished production factors rises, export sector manufacturers must lower expenses to remain in business, usually accomplished by reducing employment levels. Thus, antidumping margins protect a small segment of the population at the expense of a larger segment. After reviewing Congressional Budget Office and Commerce Department data, we compared estimated losses, including legal fees and rent seeking, to estimated benefits computed by the Commerce Department, thus ascertaining that anti-dumping margins impose a net loss on society. Fortunately, there are numerous policy options to increase American competitiveness without anti-dumping margins. Government subsidization of tertiary education will allow more American students to pursue higher studies and contribute more effectively to global commerce. Additionally, reducing the Federal budget deficit will reduce the trade deficit by helping US goods sell less expensively overseas.

Adapting Yeast for the Study of Pitrilysin and other M16A Enzymes

Tatyanna Nienow – CURO SUMMER FELLOW
Dr. Walter Schmidt, Department of Biochemistry and Molecular Biology, University of Georgia

Pitrilysin is a zinc-dependent metalloprotease found in *Escherichia coli*. Although it was first discovered more than a decade ago, there is still little known about its function in *E. coli*; not

even the natural substrate of pitrilysin is known. Pitrilysin shares significant homology with several other proteases, including Ste23p and Axl1p, involved in the production of the a-factor mating pheromone in the yeast *Saccharomyces cerevisiae*, and human insulin-degrading enzyme (IDE), which has been implicated as a potential factor both in Type 2 diabetes, and in the formation of beta amyloid plaques found in Alzheimer's Disease. All four proteases, when inserted into yeast, can cleave a-factor in vivo. All four proteases share several highly conserved sequence motifs, but only one, the HXXEH motif common to this family of metalloproteases, is known to be important for protease function. Site-directed mutations were introduced into the HXXEH motif and several other conserved motifs of pitrilyisn through PCR-mediated recombinational cloning. After verifying the presence of the desired mutation through DNA sequencing, the activity of the mutated proteases were determined through an in vivo yeast mating assay. Several of the mutations showed a complete loss of measurable activity, suggesting that those residues are necessary for function. This is the first time there has been any demonstration of sequences outside the metalloprotease motif being necessary for protease function. The success of this assay also demonstrates the effectiveness of the yeast mating pheromone pathway for functional studies of these enzymes.

Effects of a Boring Lichen on Shell Strength of the Marsh Periwinkle Snail *Littoraria irrorata*

Carmel L. Norman
Dr. David Porter, Department of Plant Biology, University of Georgia

The marsh periwinkle snail *Littoraria irrorata* is an herbivorous gastropod commonly found in tidal salt marshes of the eastern United States. It has been observed that the shells of many *L. irrorata* individuals are colonized by the lichen *Pyrenocollema halodytes* which bores into and erodes the snail shells. This study is an investigation of how the degree of colonization of the lichen affects the snail shell strength. The hypothesis is that increased colonization by the lichen leads to decreased shell strength, and decreased shell strength could make the snails more susceptible to predation by blue crabs and diamondback terrapins. The experimental snails will be collected from salt marshes near the University of Georgia Marine Institute on Sapelo Island, Georgia. Snails of different sizes and differing degrees of lichen colonization will be tested. Forces needed to cause cracking of the shell will be applied and measured using an Instron 2401 materials testing machine. The biomass of lichen on each shell will be measured by weight from the cracked and then decalcified shell. Changes in the snail density could have ecosystem-wide implications. Silliman and Bertness (2002, PNAS 99:10500) have described salt marsh trophic dynamics as a cascade of predation by blue crabs on snails which graze on the salt marsh cordgrass, *Spartina alterniflora*.

Development of Real-time PCR to Measure mRNA Expression of Stress Peptides in Specific Brain Nuclei of Rats

Ezinne A. Okwandu – CURO SCHOLAR, CURO APPRENTICE
Dr. Ruth Harris, Department of Food and Nutrition, University of Georgia

Stress induces release of the neuropeptides corticotrophin releasing factor (CRF) and urocortin (UCN), which, generate a variety of stress responses including activation of the hypothalamic-adrenal pituitary (HPA) axis and release of the stress hormone corticosterone. Previous findings reveal that feeding high fat (HF) diets increased weight loss and corticosterone release in stressed rats. The next step is determining whether the increased response to stress is associated with increased release of CRF and UCN in areas of the brain that influence food intake and the HPA axis. Real-time PCR is faster and more quantitative than in-situ hybridization. Therefore, methodology has been developed to measure mRNA expression of CRF and UCN in specific brain nuclei. A rat brain atlas was used to identify the coordinates of the paraventricular nucleus (PVN) of the hypothalamus, which expresses CRF mRNA, and of the Edhinger

Westphal nucleus, which expresses UCN mRNA. A cryostat was used to make 500 um slices at appropriate coordinates in the brain, and then small tissue punches were made from these nuclei. Total RNA was extracted from the tissue and used to measure mRNA expression by Real-time PCR, using 18S rRNA expression as an internal standard. Total RNA extraction from very small amounts of tissue was optimized, and we determined that 35-50 ug of tissue collected from bilateral 0.75 um diameter PVN punches was adequate for measurement of CRF mRNA. This technique will be used to measure the effects of HF diet and of stress on neuropeptide expression in specific brain nuclei.

Carolina

Ezinne A. Okwandu – CURO SCHOLAR, CURO APPRENTICE
Dr. Pamela B. Kleiber, Center for Undergraduate Research Opportunities, University of Georgia

This dance is choreographed to a song called "Carolina," in which the singer praises a beautiful girl named Carolina. The dance reflects my belief that each girl is an embodiment of the beautiful Carolina. The style of the dance and the dancers' dress is contemporary/traditional West African.

Forwarding the Agenda of the Right: The Intercollegiate Studies Institute's (ISI) Influence on Campus Student Newspapers

Kathryn E. Otrosina
Dr. Kathleen deMarrais, Department of Elementary and Social Studies, University of Georgia

The Intercollegiate Studies Institute (ISI), founded in 1953 by Frank Chodorov, aims to further the ideals of the conservative movement. Under the presidency of E. Victor Milione in the 1970s, the ISI began paying special attention to eliminating the liberal bias in higher education. The ISI's Collegiate Network now sponsors 95 college newspapers around the country to mentor young members as part of a larger conservative agenda (deMarrais 2005, Saloma 1984). The purpose of this study is to examine how ISI's College Network influences young adults through their involvement in campus-based student newspapers. This paper uses a case study approach to examine the CN's national Campus Magazine Online in comparison to three other ISI/CN-sponsored newspapers at Dartmouth, UCLA, and the University of Georgia. Research questions include: 1. How does the CN's Campus Magazine Online influence the content of the three university publications? 2. What structure does ISI use to attract and inform student members? An analysis of the Campus Magazine Online in comparison to the three other ISI-sponsored newspapers demonstrates there are large sums of money given to these alternative student newspapers. Second, the ISI uses specific, well-developed strategies to inculcate students into the rightist ideology through the use of networking, lectures, internships, conferences, and fellowships. Third, the ISI introduces young members to influential, high-powered conservatives, many of whom came through the ISI system themselves, to give the students something to aspire to. Through these student publications, future leaders in the conservative cause learn how to forward the agenda of the right.

Construction & Expression of Fusion Protein yHCG1 & LHR ECD & ECLs for Expression in Insect Cells

Travis M. Palmer
Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

The luteinizing hormone receptor (LHR) is a vital component to the overall scheme of reproduction and differentiation in many male and female vertebrates. The LHR belongs to an even larger category called Glycoprotein Coupled Receptors, which is composed of an extracellular domain (ECD), seven transmembrane section, three extracellular loops (ECLs), and three intracellular loops. Previous research suggests that the ECD of the LHR is sufficient for high-affinity binding of the hormone and that the ECLs of the receptor are not required for this high-affinity interaction. However, experiments also suggest that the

ECLs may contribute to signal-transduction events and may directly contact the hormone. Therefore, the construction and subsequent use of a single-chain ECD-ECL fusion protein (which contains both the alpha and beta subunits of hCG, the LHR ECD, and its three ECLs) in binding studies may measure any contact between the ECLs and hCG. This fusion-protein construct was designed to include the appropriate ECL DNA segments. These segments were amplified by the use of the Polymerase Chain Reaction (PCR) and will be subsequently ligated together to form the complete fusion-protein construct. After infection of this construct in an insect-cell system, binding studies will provide insight into the structural mechanism by which hCG binds LHR and activates a signal cascade. Understanding this important mechanism may contribute to the understanding of constrictively-activated and other malfunctioning Lars that lead to either infertility or precocious puberty.

The Genomic Instability of Human Embryonic Stem Cells

Kurinji Pandiyan – CURO SCHOLAR, CURO SUMMER FELLOW
Dr. Steve Stice, Department of Animal and Dairy Science, University of Georgia

Human Embryonic Stem Cells (hESCs) are undifferentiated, pluripotent cells obtained from the blastocyst stage of the human embryo. Before these cells can be used for different medical applications, it is crucial to address the fundamental question of how hESCs maintain their self-renewal properties without increasing genomic instability. It is known that the proliferation of most cell populations results in alteration of telomere (ends of chromosomes that are involved in the replication and stability of DNA molecules) dynamics. This is significant because alteration in telomere dynamics can induce chromosomal abnormalities that could eventually trigger cancer mechanisms. It is crucial to understand which method of culturing hESCs is least likely to induce telomere shortening. This project was designed to compare the different methods of culturing hESCs and to investigate the correlation between telomere length and the integrity of hESCs and how both are affected by different passaging conditions. Our hypothesis was that bulk-passaging techniques resulted in more telomere shortening of hESCs than manual passaging. Genomic DNA was extracted from hESCs cultured by enzymatic and manual passaging techniques and digested using the restriction enzymes Hinf1 and Rsa1. Southern blotting was done to the digested DNA using a radioactively labeled oligo A10 probe specific to telomeres. The telomeric repeats did not appear in many of the samples, primarily due to insufficient DNA loaded. However, one of the bulk-passaged samples did exhibit bands corresponding to a high molecular weight (>20kb). This result is interesting in that normal hESCs have been found to exhibit telomeric DNA of molecular weight (8-10kb), and we expected shortening of telomere length due to bulk passaging. We assume that this data could be due to inefficient restriction digestion. The procedure will be repeated with new samples generated using different passaging techniques.

Activation of Innate Immune Response by Wild-type and Attenuated Rabies Virus

Marlena L. Pichon – CURO APPRENTICE
Dr. Zhen Fu, Department of Pathology, University of Georgia

Rabies virus (RV) infects the Central Nervous System (CNS) beginning at the spinal cord and continuing up to the brain. Despite extensive research in the past 100 years, the pathogenic mechanism by which RV causes neurological diseases is not completely known. At the time of death, only mild inflammation and neuronal damages were seen in patients. Recently, our laboratory has shown that wild-type RV evades the innate immune responses, thus contributing to its pathogenicity. Functional genomics investigation has indicated that attenuated RV activates host innate immune responses, particularly the interferon (IFN) and chemokine pathways. On the other hand, wild-type RV does not activate these pathways. We have used real time-polymerase chain reaction (PCR) to confirm the microarray data. Mice infected with attenuated B2C or wild-type silver-haired bat

RV (SHBRV) were sacrificed and brains were removed for RNA extraction. Real time-PCR was performed on the expression of chemokines such as Rantes, IP-10, MIP-1, and MCP. Our data show that attenuated B2C consistently up-regulated the expression of these chemokine genes. SHBRV, on the other hand, showed little up-regulation of chemokine expression. These results further demonstrate that the wild-type RV evades the body's innate immune response whereas attenuated RV activates them.

Morphogenesis of the Rat Cerebellum
Patrick G. Pilie
Dr. Alexandra Joyner, Skirball Institute, New York University School of Medicine

The cellular composition of the cerebellum is conserved throughout all vertebrates, and the five major cell types are present in all regions of the cerebellum. The cerebellum is made up of three distinct layers including: the molecular layer, the Purkinje cell layer, and the granular layer. Four fissures initially divide the cerebellum into five cardinal lobes that further divide and become ten distinct lobules. Using histological and immunohistochemical markers we studied the regional changes that occur during foliation in the developing rat cerebellum. Cresyl Violet stains the nuclei of all cells and was used as a counter stain on the 7-10mm cerebellar sections while the Purkinje cells, granule cells, and glial cells were stained using the antibodies Calbindin, Kip1/P27, and GFAP respectively. Sections of cerebellum from various ages of rats were used in this study including embryonic day 20, postnatal day 0, postnatal day 4, and postnatal day 6. Interestingly, regional differences in the phenotypes of Purkinje cells, granule cells, and glial cells can be seen as early as embryonic day 20 while the cerebellar cortex still maintains its smooth, unfolded appearance. When comparing lobe 3 to lobe 5 at various stages in development, striking differences can be seen in Purkinje cell and granule cell organization and maturation as well as in the protein expression patterns of calbindin, Kip1/P27, and GFAP. This study provides an evolutionary perspective on what is being conserved during cerebellar foliation when comparing the rat and mouse cerebellum on the cellular and molecular level; and this study shows that each of the five cardinal lobes of the cerebellum takes on a unique identity and unique time of maturation based on characteristic protein expression patterns and cellular morphology.

NADH/Flavoprotein Imaging of the Zebrafish Lateral Line System
Erika Porter – CURO SUMMER FELLOW
Dr. Charles Keith, Department of Cellular Biology, University of Georgia

The purpose of this research is to develop a noninvasive method that uses the measurement of metabolic load in order to build a three-dimensional reconstruction of the electrical activity of the neurons in zebrafish and neuron-like cells. The method uses a two-photon fluorescence microscope and sensory stimulation to measure the ratio of certain mitochondrial coenzymes across cell membranes. This ratio reveals the metabolic load being placed on the cell during sensory stimulation. The coenzymes NADH and flavoproteins show distinct behavioral patterns of fluorescence during the aerobic respiration that occurs during sensory stimulation. The auto fluorescence of the coenzymes allows the microscope to detect the membrane potential which develops as NADH and flavoproteins enter and leave the cell. With the correlation of a time course, these fluctuations give the ability to quantify a relationship between changes in the metabolic load and in the fluorescence indicators as a measurement of neuronal activation. In these analyses, the input and output of the neurons can be separately identified and can be used to establish a quantitative model of cellular interactions in the sensory neurons.

The Interaction of Geography and Identity in Ruth Klüger's *Still Alive*
Radhika Prabhakar
Dr. Martin Kagel, Department of Germanic and Slavic Languages, University of Georgia

Holocaust memoirs encompass a significant portion of WWII literature and are essential to

our understanding of the details and emotional impact of this genocide upon the persecuted, as well as upon German and Western society as a whole. In studying Ruth Klüger's Holocaust memoir *Still Alive,* I am interested in discovering the influence of geography on the formation of Klüger's sense of identity. *Still Alive* was received with great acclaim when it was originally published in German in 1992, winning, among other accolades, the prestigious Prix Memoire de la Shoah. Audiences were fascinated by its stark, understated portrayal of the Holocaust. Klüger's work is unique in the canon, not only because she is one of few female, widely-known Holocaust authors and was a child during her imprisonment, but also because she writes in what could be considered a revisionist, "post-Holocaust" milieu. Her work therefore provides an unusual perspective on the influence of geography on identity for survivors. I am specifically interested in addressing how Klüger's work relates to the greater body of memoir literature and how within her work the issues of her identity in relation to geography and space, are examined. My initial impressions suggest that Klüger uses places, rather than time periods, as the building blocks of her recollection. Klüger also allows the physical geographic aspects of a place to influence her general intuitions and recollections of that locale. Thus, this study will also allow me to observe whether the interaction of geography and identity is a common thread in Holocaust memoir or if such a relationship is unique to Klüger, due to the circumstances of her childhood, her camp experience, and the social and political context of her writing.

Reforming the Kingdom: Educational, Economic, and Political Change in Saudi Arabia

Tyler B. Pratt, Elizabeth Kirby & Aqsa Mahmud, Roosevelt @ UGA
Dr. Sherry Lowrance, Department of International Affairs, University of Georgia

The U.S.-Saudi relationship has traditionally been dominated by narrow energy interests; in return for Riyadh's continual stabilization of world oil prices, Washington provided advanced weaponry and overlooked the country's turbulent internal affairs. The presence of 15 Saudi citizens amongst the September 11th hijackers and the threat posed by the growing militant Islamist movement demand a harsh reevaluation of the U.S.-Saudi relationship. Alarming trends within Saudi Arabia, including the monarchy's growing political instability, the economy's unstable dependence on oil, a glaring lack of political representation, and an education system that radicalizes Saudi youth, threaten to further destabilize the country and undermine U.S. efforts to combat the worldwide terrorist movement. The situation calls for nothing less than a widespread reform of Saudi society. However, change will not come easily to the Kingdom; power is concentrated in the hands of entrenched interests that profit from the explosive status quo. The prospect of empty promises and token reforms will be appealing but ultimately insufficient. In our paper, we examine the dangers confronting Saudi Arabia and propose a comprehensive overhaul of U.S. policy toward Riyadh. We assert that Washington should use its considerable diplomatic and economic resources to encourage reform in three areas. The Saudi education system must be significantly retooled to prevent the continued radicalization of Saudi youth. Economically, Saudi financial transactions should be subjected to stringent and transparent regulations. Lastly, cautious political reform in the Kingdom should continue, driven by economic and social progress that prepares Saudi society for meaningful decentralization of power.

Differences in Environmental Reporting: China & the United States

Kelly Proctor – CURO SUMMER FELLOW
Dr. Lee B. Becker, Director of Cox Center for International Mass Communication Training and Research, University of Georgia

Although China is rife with environmental problems, government-censored newspapers have not always presented the whole, dirty picture. Now the burgeoning economy is making the country more progressive. Newspapers are more willing to report on the environment—and

sometimes on the government corruption and other problems that may hamper environmental cleanup efforts.

This project charts the environmental coverage of two Chinese newspapers, the progressive *JieFang Daily* and the more conservative *NanFang Daily*, compared with the *New York Times*. During a 15-week period, I analyzed the international news, national news, local news, science, education, opinion, and business sections of these three newspapers. Next, I observed the number of news items, the size of the items, frequency, attitude, and subject.

I found that Chinese newspapers relied overwhelmingly on government sources and reported from government meetings. While the *Times* spoke with government as well, its reporters also spoke with citizens affected by pollution. Its articles were longer and more frequent. Also, Chinese newspapers almost exclusively quoted and praised Chinese officials' progressive plans for environmental cleanup, without reporting conflicting opinions. However, there was slightly more balanced reporting within Guangdong's *JieFang Daily*, which is in a more commercialized zone than Shanghai's *NanFang Daily*, and thus must rely on better journalism (as defined by American standards) to hook readers.

Although these two Chinese newspapers still seemed reluctant to criticize the government in the style of the *New York Times*, this project suggests that with financial incentive from the country's burgeoning consumer class they may be more willing to do so in the future.

Detection of *Babesia microti* in Human Tissue through In Situ Hybridization

Sarah B. Puryear
Dr. Corrie Brown, Department of Pathology, University of Georgia

In the northeastern United States, the emerging tick-borne disease *Babesia microti* is the causative agent of human babesiosis. Ticks of the Ixodes species serve as vectors. The white-footed mouse and meadow vole have been identified as reservoirs. Although traditionally considered a strict intra-erythrocytic parasite, much debate has arisen in recent years concerning a possible extra-erythrocytic phase during the life cycle in the host. In this study, formalin-fixed, paraffin-embedded tissues (liver, lung, and spleen) from five experimentally infected hamsters, one uninfected hamster, and spleen from a confirmed non-fatal human case of babesiosis were examined using a recently developed in situ hybridization assay. Using a digoxigenin-labelled anti-sense riboprobe to hybridize to the 16S-like small subunit of the parasitic rRNA in the tissue samples, the sites of parasite infection were located. *Babesia microti* rRNA was detected in erythrocytes within blood vessels throughout the infected hamster tissues and human spleen. In addition, cytoplasmic staining was noted within fixed macrophages in the hamster livers and spleens and in the human spleen. These results indicate the possibility of a previously unrecognized extra-erythrocytic stage of Babesia microti in the mammalian host.

Scientific Illustration

Courtney Reece
Prof. Gene Wright, Department of Scientific Illustration, University of Georgia

Most often, scientific illustrators use their artwork as visual communication to teach scientific concepts. Although a unique path, I use scientific illustration to blend my passion for art with my interest in science and medicine. It not only allows me to express myself, but also to combine the precision and academics of a scientist with the passion and creativity of an artist. I have always had a strong desire to share knowledge and my art with others, and through this major I am able to accomplish both.

After graduating from Georgia with an interdisciplinary degree in scientific illustration, I plan to attend graduate school to obtain my medical illustration degree. Having an interest in a variety of medical fields, I am excited to have the opportunity to explore each of them in depth. I will be able to study with experts in a range of medical fields, while also exploring new techniques in my artwork. Even more thrilling is the possibility of my illustrations being used to teach scientific concepts to students ranging from elementary school to medical school.

Effect of Trait Anxiety on Explicit Memory for Positive and Negative Words Presented Under Divided and Restricted Attention

Eva B. Reed
Dr. Richard Marsh, Department of Psychology, University of Georgia

The current study investigates memory biases in anxious participants to clarify how anxious participants' memory differs from that of non-anxious participants. A memory bias in high trait anxiety participants for negative words has been demonstrated, suggesting that highly anxious individuals may remember a greater number of negative words versus neutral or positive words (Aureille, 1999; Eysenck & Byrne, 1994). The current study examines the effects of divided attention during encoding on memory in non-anxious and anxious participants through a number identification task completed while studying the target stimuli. This study also utilizes a restricted attention task in the form of a lexical decision task and full attention task in order to establish a negative bias in anxious participants. All memory tests will be completed on the computer. Past research has demonstrated that divided attention during encoding hinders recognition, a measure of explicit memory. The current study will use the State Trait Anxiety Inventory (Spielberger, 1983) to measure the participants' trait anxiety levels and a remember/know/new paradigm to test their memory. The remember/know/new paradigm, a valuable memory test, examines the strength to which an item was encoded, with "remember" representing a stronger encoding experience than "know." Because a negative memory bias for negative/threatening words has been found for anxious participants, the amount of "remember" responses for negative/threatening words should be higher in anxious participants. The division and restriction of attention during encoding should prevent the negative memory bias from occurring and therefore eliminate the higher proportion of "remember" responses in anxious participants.

ATB & the Angel of History: A Case Study of the Dialectic in Trance Music

Tom R. Ribitzky
Dr. Beatrice Hanssen, Department of Germanic and Slavic Languages, University of Georgia

As a subgenre of techno, trance is among the most innovative and integrative forms of music. As an area of study, it is not yet quite so rich. Often dismissed or misinterpreted by researchers or journalists who are far removed from the world of trance, the music and its culture rarely leave the clubs and record stores. Up to this point, no one has been able to successfully fuse a passion for the music with an interest in its theoretical and conceptual basis. In order to identify the musico-historical legacy of trance and where it fits in our society, my research focuses on a particular DJ/Producer (ATB, the only trance artist to have reached the #1 spot on the UK's pop charts) and uses constructs such as aura, the trance, and the "Angel of History" theorized by the German dialectical sociologist Walter Benjamin to analyze ATB's lyrics and how they interact with the music. From the lens of the Frankfurt School, launched by Benjamin and Adorno, the case study will shed light on the

general features of trance music. The goal of this multidisciplinary approach to trance is to examine what exactly trance is, where it came from, and where it is going in terms of academic inquiry.

The Effect of Land Use Strategies on the Functional Diversity of Neotropical Nematode Communities

Russ Richardson – CURO SUMMER FELLOW
Dr. Ronald Carroll, Institute of Ecology, University of Georgia

Managed ecosystems often differ greatly in structure and function from unmanaged ecosystems. Shade-grown coffee resembles tropical forest more than coffee monocultures due to higher plant diversity, consequently supporting greater biodiversity at other trophic levels. The increase in biodiversity is thought to lead to a reduction in pest effects. Coffee is also economically important, being the world's second most traded commodity. The ability to adjust the proportion of plant-feeding nematodes in an organic cropping system without chemical inputs is critical. These nematodes cause a reduction in root structure, leading to yield reduction and crop failure. This study seeks to test the hypothesis that shade-grown organic coffee may be grown with a lower proportion of plant-parasitic nematodes than monoculture coffee. Cropping system samples were taken from a four-year-old garden plot experiment on the Maquipucuna Foundation's Orongo Research Farm in Palmitopamba, Ecuador. Nematodes were identified into five functional groups: bacterial feeders, fungal feeders, predators, omnivores and plant feeders. Plant-feeding nematodes were proportionally more abundant in the coffee monoculture treatment (T5) than in the coffee/plantain polyculture (T1) (T5 avg: 28.5%; T1 avg: 3.3%; α=0.05). Statistical significance was not discovered among predator nematode populations, indicating that they were not directly responsible for lowering plant-parasitic nematode numbers. Soil temperatures in the edge coffee monocultures were significantly higher (2°C) than in the other polyculture cropping systems (α=0.05). Soil temperature seems to play some role in mitigating parasitic nematode infestation, perhaps in combination with other factors such as biodiversity. The results from this short-term study are promising and warrant further investigation.

Analysis of *Mycobacterium shottsii* Pathogenesis Using Zebrafish as a Model System

Rebecca L. Satterfield
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia
(Rebecca Satterfield, Frederick Quinn, Donald Evans, and Russell Karls)

Mycobacterium shottsii, a newly-identified bacterial species, was the most prevalent mycobacteria detected in diseased striped bass (*Morone saxatilis*) from the Chesapeake Bay during an epizootic outbreak in the year 2000. By 16S rRNA sequence analysis, *M. shottsii* was found to be closely-related to *M. marinum*, the cause of skin and soft tissue lesions in fish and human fish-handlers. *M. shottsii* would not likely cause a similar disease in humans due to its inability to grow at human body temperatures. However, this pathogen, like *M. marinum*, has proved devastating to fish-associated industries. In order to identify virulence mechanisms employed by bacterium, zebrafish (*Danio rerio*) were employed as a surrogate host for infection. Our laboratory and others have demonstrated that *M. marinum* bacilli replicate within the phagosomes of fish macrophages in vivo. The studies presented here were designed to determine if *M. shottsii* can also survive and replicate within fish macrophages. An *M. shottsii* strain was engineered to express green fluorescent protein to facilitate detection by fluorescent microscopy. To study the interactions of the bacilli with zebrafish macrophages in tissue, the fish coelomic cavity was first injected with mineral oil to recruit immune cells. Seventy-two hours later, infection was established by injection of 106 to 107 *M. shottsii* into the peritoneum. Twenty-four hours later, host cells from the coelomic cavity were extracted and purified by a 45.5% percoll gradient. Macrophage phagosomes were labeled with a specific

fluorescent dye and fixed with formalin. Preliminary fluorescent microscopic examination of host cells indicated that GFP-labeled bacilli co-localized with labeled phagosomes of some host cells. Since the GFP was not degraded, it suggests that these bacilli survived within host macrophages. Therefore, approaches that target the killing of intracellular pathogens should be applied when designing vaccines or therapies against *M. shottsii*.

Sequence Polymorphisms in the Mismatch-repair (TcMSH2) and Glutathione-S-transferase (Tc52) Genes of *Trypanosoma cruzi* Isolates from United States

Mason Y. Savage
Dr. Michael Yabsley, Wildlife Disease Study, University of Georgia

Trypanosoma cruzi is a vector-borne parasite that infects a wide range of mammals and causes clinical disease in domestic animals and Chagas disease humans. Studies in South America have identified single-nucleotide polymorphisms (SNP) in two gene targets (TcMSH2 and Tc52) which support the existence of two major phylogenetic lineages (Types I and II). These lineages have been shown to differ in their ability to cause clinical disease. Based on previous studies, we hypothesize that these two lineages will be in North American wildlife. In this study, we analyzed the sequences of these two genes from seven isolates of *T. cruzi* from the United States including four raccoons, one opossum, one dog, and one vector (*Triatoma gerstackeri*) and compared them to South American isolates. DNA from each isolate was extracted, and the amplification of two genes was conducted by PCR analysis. The two genes targets, Tc52 and MSH2, were then sequenced and compared to South American isolates to identify any SNP. The MSH2 gene of the raccoon and dog differed from South American strains by three SNP and were of Type II, while the opossum and Triatoma isolates differed by two SNP and were of Type I. For the Tc52 gene, no SNP were identified in the raccoon and dog isolates, while five SNP were detected in opossum and Triatoma isolates. Although several SNP were identified, none resulted in amino acid substitutions in the proteins. These data show that the two major phylogenetic lineages of *T. cruzi* are present in North America, but that there are genetic differences between South American and North American strains. Further studies will characterize the virulence of these genetic variants of *T. cruzi* for laboratory animals.

Determining What Causes Certain Carbohydrates to be Expressed in Certain Cells

Rouhin Sen – CURO APPRENTICE
Dr. Michael Tiemeyer, Department of Biochemistry and Molecular Biology, University of Georgia

Cell-surface carbohydrates play an extremely important role in various cell functions such as cell recognition and adhesion, protein stability, receptor ligation, and transmembrane signaling. Such functions require regulated carbohydrate expression. The mechanisms that determine what causes carbohydrates to be differentially expressed in specific tissues are mostly unknown. To determine the genetic pathways that control glycan expression, we are investigating a carbohydrate known as the HRP-epitope, which is expressed predominantly in the neural tissue of arthropods, including Drosophila. Synthesis of the HRP-epitope requires the activity of at least one synthetic enzyme known as fucosyltransferase. There are four identified fucosyltransferases in Drosophila, FucTA, FucTB, FucTC, and FucTD. By introducing each of the fucosyltransferases into mutant flies that fail to make HRP-epitope we are testing their ability to synthesize the glycan in vivo. FucTA has shown the ability to synthesize HRP-epitope in vitro and in vivo. FucTD transgenics do not rescue HRP-epitope expression in embryos, but the enzyme is expressed in the nervous systems. The effect of FucTD expression in neural and non-neural tissue will clarify its potential role in glycan synthesis and normal development.

Changes in the Synaptology of Corticostriatal and Thalamostriatal Innervation in the

MPTP-treated Monkey Model of Parkinson's Disease

Deep J. Shah
Dr. Yoland Smith, Division of Neuroscience,
Yerkes National Primate Research Center,
Emory University

The key pathological feature of Parkinson's disease is the loss of dopaminergic neurons in a brain structure named the substantia nigra pars compacta (SNc). The loss of these neurons causes numerous morphological and physiological changes in the basal ganglia, a group of tightly interconnected brain nuclei, to culminate in the symptoms of Parkinson's disease (PD). Following dopamine depletion, altered glutamatergic transmission from the cerebral cortex (cortex) and the thalamus induces dysfunction of the striatum. However, the exact mechanisms by which projections from the thalamus contribute to these changes remain poorly understood. To address this issue further, we studied potential changes in the synaptic organization of thalamic and cortical inputs to the striatum in a nonhuman primate model of Parkinson's disease. Recently, the loss of glutamatergic axo-spinous innervation of striatal neurons has been reported in both the rat model of PD (Ingham et al., 1988) and in human PD (Stephens et al., 2005). Because of the traditional view that axon terminals from the cortex form asymmetric axo-spinous synapses, while afferents from the thalamus primarily form axo-dendritic synapses in the striatum (Smith et al., 2004), corticostriatal afferents were thought to be mainly affected in PD. However, data from this project demonstrated that about one-half of all axon terminals from the thalamus also form axo-spinous synapses in the monkey striatum. These findings, therefore, suggested that thalamostriatal afferents forming axo-spinous synapses may also be affected in PD. To explore further the effect of nigrostriatal dopamine depletion on thalamostriatal synaptology, an electron microscopic analysis of the synaptic organization of corticostriatal and thalamostriatal axon terminals in the dopamine-depleted striatum of MPTP-treated monkeys, the gold standard animal model of PD, was used. Results indicated that the density of corticostriatal, but not thalamostriatal, innervation increases in the MPTP state, providing the first neuroanatomical substrate that accounts for the increased glutamatergic transmission in the striatum of animal models of PD. These findings appear paradoxical in light of spine loss reported previously in rodents and human PD. Studies are currently underway to determine the extent of spine loss in MPTP-treated monkeys. Evidence for increased corticostriatal activity in PD paves the path for developing novel therapeutic approaches that modulate specific glutamatergic pathways in PD.

Integrating Computational and Experimental Analysis to Study Transposable Elements (TEs) in *Medicago truncatula*

Deep J. Shah & Paul Ruddle
Dr. Susan Wessler, Department of Plant Biology, University of Georgia
(Deep J. Shah, Paul Ruddle, and Dawn Holligan)

Transposable elements (TEs) are genetic elements that can move (transpose) from one genetic locus to another and, in doing so, frequently increase their copy number. To date, TEs have been found in all characterized eukaryotic genomes where they frequently are the most abundant component. The availability of large quantities of genomic sequences from several eukaryotic species has, in recent years, facilitated the study of TEs. Although several studies in the last decade have provided insight into the impact of TEs on genome structure and organization, many aspects of TE biology are still not well understood. In this study, we analyzed a significant fraction (~100Mb) of the available *Medicago truncatula* (Medicago) genome sequence. Medicago is a member of the Leguminosae family, which includes several agriculturally important crops such as soybean and garden pea. Within the legume family it is considered to be a model organism because of its small genome size (~500Mb), relatively fast generation time (~3 months, seed to seed), and capacity for genetic manipulation including transformation. For the analysis of the Medicago database, we devised bioinformatics strategies,

such as BLAST and RepeatMasker, to identify and characterize a wide variety of TE types and used the output of this computational analysis to develop experimental tools, specifically Transposon Display (a modification of traditional Amplified Fragment Length Polymorphism). Based on preliminary results, we find that Medicago contains all of the classes of TEs found in previous analyses of plant genomes, including transposase encoding elements, retrotransposons, Helitrons and miniature inverted-repeat transposable elements (MITEs). The information generated from this study will facilitate annotation of the Medicago genome as well as the genomes of other legumes and will furnish valuable tools, such as molecular markers, for the genetic analysis of Medicago.

An Exemplary Being: The Prostitute in the Early Plays of Bertolt Brecht

Arthur H. Shockley
Dr. Martin Kagel, Department of Germanic and Slavic Languages, University of Georgia

Prostitution is an unavoidable image in the early works of the German playwright Bertolt Brecht (1898-1956). The female population of his early plays is comprised of women who, even if they are not explicitly prostitutes, are bought and sold in their romantic relationships. My research attempts to determine what purpose the ever-present prostitute serves in Brecht's early works. I analyze two of Brecht's lead female characters for this purpose, Marie of *In the Jungle of Cities* (1922) and Jenny of *The Rise and Fall of the City of Mahagonny* (1930). My analysis of these characters shows that the image of the prostitute fits into Brecht's larger commentary on the commodification of human relations, which he viewed as a given fact of capitalist society. The world of Brecht's early plays is one in which individuals, isolated in their struggle for material survival, inevitably treat each other as objects for their own selfish purposes. It is how his characters negotiate the disconnection between their ideals and the dehumanizing rationality of capitalist society that determines their situation. When Brecht's female characters hold onto an ideal of romantic love and refuse to recognize the practical nature of their relationships, as Marie does, they become powerless. It is only the prostitutes, who acknowledge their sexuality as a commodity and are willing to use it as such, that hold any control over their situation, as in the case of Jenny. By fully embracing the capitalist ethos, Brecht's prostitutes absurdly become exemplary, attaining a level of self-determination rare in his early plays.

Cloning, Expression, and Verification of *Pyrococcus furiosus* Protein, PF1476

Anjali Shroff
Dr. Robert Scott, Department of Chemistry, University of Georgia

Transcriptional regulation is one mechanism whereby the expression of various genes in an organism can be coordinated in response to various environmental factors and the needs of an organism. In the archaeal domain of life, the mechanisms of transcriptional regulation are not fully understood. Studies in this area could have important research and industrial applications such as providing proteins and enzymes functional at higher temperatures. This investigation seeks to characterize a potential transcription factor that could regulate the expression of genes in the archaeon *Pyrococcus furiosus* in response to cold shock. The protein of interest is encoded by the gene PF1476, a member of the PadR-like family which includes the PadR protein, a bacterial transcriptional regulator. PF1476 protein (PF1476p) was previously identified from cell extract by a pull-down assay using the promoter of PF1479, a gene determined to be regulated during cold shock by microarray analysis. A plasmid containing recombinant PF1476 with an N-terminal histidine tag was transformed into *Escherichia coli*. Then, protein expression was verified using sodium dodecyl sulfate polyacrylamide gel electrophoresis and mass spectrometry. Finally, a culture was grown for large-scale protein expression, and cell extract was prepared for a Fast Protein Liquid Chromatography procedure in order to purify the expressed protein. Since PF1476p had a histidine tag, a nickel affinity column was used to purify it from the *E. coli* cell extract. Future

studies will include an electromobility shift assay, which will determine if the protein binds to the promoter DNA, and characterization of the potential transcription regulator.

Johnny Cash, Mythology, and the Possibilities of Experimental Historiography
Matthew R. Smith
Dr. Steven Soper, Department of History, University of Georgia

Microhistory uses a variant of the Scientific Method to explore how a historical problem can be solved through an attention to detail. Like scientists, microhistorians do not automatically assume that one diagnosis is better than another. A set of incoherent narratives or cultural meanings often arises after researching an event. Such narratives materialize from the careful interpretation of primary sources, wherein the microhistorian assumes a detective-like role, sifting through artifacts to better understand cause-and-effect. Each narrative or strain of cultural meaning is researched in time, until the microhistorian determines what social or cultural impetus drove a certain mode of historical understanding. Microhistorians discount the type of intellectual shortcuts and broad-stroke generalizations sometimes used by biographers or historians. Microhistorians are not indicting conventional historians or biographers, though; rather, their primary purpose is to show how conventional histories often speculate on how people fit into the larger structure of society. Johnny Cash's life serves as a good example of how history and biography often create an imbalance between a man's real life and the way history evaluates his legacy. In researching the reactions to the Folsom concert of January 1968, I have concluded that the Folsom live performance was both spontaneous and unique. By focusing on one event in Johnny Cash's life, I will show how certain historical truths are more evident when the scale of observation is smaller. The Folsom event allows microhistorians to analyze a well-chronicled event, without the mythmaking and hindsight revision often present in contemporary historical narratives.

Drawing & Painting
Samuel Stabler
Prof. Joseph Norman, Department of Drawing and Painting, University of Georgia

My work is an assimilation of the many things that I experience day to day, from the mundane to the extraordinary. The subject, imagery, color palette, and techniques come from things I have observed. I have had the fortune to spend time in Italy, central Europe, and Cuba. It is primarily from these travel experiences that I have found the content that drives my work. I am inspired by the deep greens of the Cuban rainforest and the pastels of Caribbean architecture. I documented the vibrant earth tones of Italy and the countless shades of gray from the cities of Eastern Europe. I sketch the lines in the architecture and the textures of the land as I move from place to place. In every location, I seek out the local artists. My subject matter is sparked by the many people I meet. Most importantly, I notice subtle cultural differences and how that might define me and my own beliefs.

Grandma Wobbly's Olde Fashioned Fudge Shoppe

Angela Still
Dr. Judith Ortiz Cofer, Department of English, University of Georgia

I have always had a fascination with magic, with other worlds, liminal spaces. I used to dream of slipping off sideways into a parallel universe, tumbling out of my bed and landing in Nod, of doing an Alice down the rabbit-hole. Most people will tell you that their favorite childhood memories revolve around a special birthday, or a favorite pet, or a well-tramped vacation spot. My favorite childhood memories tend to lean more toward exploring that strange, secret garden just off Misselthwaite Manor, or walking headlong into an old wardrobe hidden in a dusty attic space, or crying over the death of a wise old spider.

Almost all of the books I dearly love are, in their own way, magical. Whether about a lonely, pining millionaire on an exclusive island or a hobbit that must save the world, all of the stories that I carry with me take me away from my own world, be it for good or ill. Books are my parallel universe, my rabbit-hole. Somewhere along the way, I decided that I wanted to be the one who told the stories, the one who brought other people along on wonderful adventures into the unknown. I wanted to be the magician. So I turned to the greatest liminal space of all—my imagination—and I started to write.

I am reading a fairy tale called "Grandma Wobbly's Olde Fashioned Fudge Shoppe" about an interesting young lady named Serpetina. She is one in a long line of fudge makers, serving up chocolaty goodness in a tourist town. Each day, she creates a special batch, just for the visitors, though I'm not sure they'll be coming back for more.

Three Republican Archetypes Square Off in North Georgia

Sara E. Swart
Dr. Charles Bullock, Department of Political Science, University of Georgia

The centuries-long political isolation of north Georgia is gradually coming to an end. Historically, North Georgians have elected Southern Democrat candidates. As the Georgia Democratic Party moves away from its roots, North Georgians increasingly support the more conservative Georgia GOP, and some of the state's most politically active individuals and organizations are based out of the area. The "Flaggers" are one such case; the group became nationally known in 2001 and usually supports Republican candidates. Nonetheless, Republicans' fate in North Georgia remains undecided, since the influential wealth of suburban Atlanta counties backs priorities radically different from those of North Georgians. An explanation of how North Georgians view certain Republican candidates reveals what's required for political success in the region from both individual candidates and the GOP. The subject of this study is the Republican primary race for the 50th state Senate seat, in which a staunch conservative activist, comparatively liberal lawyer, and gentleman educator battled out two races. This paper explores the reasons for activist Nancy Schaefer's victory in both elections, using sources that best capture North Georgia's political climate, including interviews with candidates, their managers, and influential local figures; state records, especially those regarding finance and election results; and local news outlets' reports on the issues. In conclusion, this study finds that Nancy Schaefer was able to mobilize Republicans' base, Christian conservatives, by casting her opponents as too liberal for North Georgia on the hot issues of the campaign. Future key issues in North Georgia politics are also discussed.

The Case for Increased Federal Funding of Embryonic Stem Cell Research

Christine E. Tarleton – CURO APPRENTICE, Roosevelt @ UGA
Dr. Steven Stice, Department of Animal and Dairy Science, University of Georgia

The debate over providing federal funding for embryonic stem (ES) cell research is shaped by two conflicting ideals: alleviating the suffering of those afflicted with a number of diseases versus safeguarding the value of nascent human

life. ES cells are undifferentiated cells that have the potential to give rise to all specialized cells in the body (i.e. neural cells) and are capable of self-renewal for a prolonged period of time (years). The controversy surrounding these cells arises because they are derived from a group of cells called the inner cell mass in four to five day old human embryos, usually excess or discarded embryos from IVF (in-vitro fertilization) procedures. This paper addresses the moral questions surrounding the controversy as well as the likely benefits of increased federal funding for ES cell research. Specifically, the proposal focuses on the shortcomings of President George W. Bush's 2001 decision regarding federal funding for ES cell research and advocates for the lifting of the ban against using federal funds for research involving ES cells derived from embryos after the August 9, 2001 cut-off date. Passage of The Stem Cell Research Enhancement Act (H.R. 810) would lift this ban, allowing scientists the opportunity to developed new and improved cells that could be used in research and the clinics. At this time, the bill has been passed by the House and is slated to come to a vote in the Senate early this year. Lesser known benefits of government investment in ES cell research such as the creation of new jobs and overall improvement to the US economy are given special emphasis.

Molecular Epidemiology of *Salmonella enterica Typhimurium* on Poultry and Dairy Farms in Georgia

Elizabeth C. Theriault & Jordan Bray
Dr. John Maurer, Department of Poultry Science, University of Georgia

Salmonella colonizes cold- and warm-blooded animals and, with exceptions, exists as an innocuous transient component of the animal's normal flora. In humans, Salmonella causes a self-limiting gastroenteritis in most healthy adults, and life-threatening septicemia in the young and elderly. Many foodborne illnesses associated with this organism have been linked to consumption of meat or eggs tainted with Salmonella. In order to reduce human cases of salmonellosis, it is necessary to better understand the ecology of Salmonella on the farm. *Salmonella enterica serovar Typhimurium* has been determined as a primary cause of salmonellosis and has been isolated from multiple dairy and poultry farms. We determined the genetic relatedness of this *S. enterica serovar* by Pulse-Field Gel Electrophoresis. The PFGE gel patterns were compared to each other within and between the two groups. A greater degree of genetic diversity was observed in bovine isolates compared to the avian *S. serovar Typhimurium* strains. The difference in diversity between these isolates may be attributed to the management and production practices employed in raising the two different animal species. In the case of poultry production, a company owns or controls all aspects of poultry production, contracting with local farmers and providing them the birds, feed, and technical service necessary for raising meat birds. This practice potentially limits birds' exposure to Salmonella and may explain the paucity of strains. In contrast, dairy cow production tends to be individually owned and operated, where animals acquire Salmonella from their immediate environment, and therefore may explain the greater genetic diversity in bovine isolates from multiple dairy farms. Therefore, for dairy farms, an on-farm biosecurity program and possible intervention strategy, e.g., vaccination may prove best at reducing Salmonella. Poultry farms may need to direct methods of prevention and treatment toward preventing vertical transmission of Salmonella from parental genetic stock of birds to the progeny, meat birds slated for consumption.

The Albany Movement: Black and White Perspectives in Albany, Georgia, 1961-62

Courtney M. Thomas – CURO APPRENTICE
Dr. Barbara McCaskill, Department of English, University of Georgia

In December 1961, the sleepy southwest Georgia town of Albany dramatically changed when the black community, discontented with a separate-but-not-equal transportation system and recreational, educational, and social facilities, attempted to desegregate the town. Members of the Southern Christian Leadership Conference (SCLC) and the Student Nonviolent

Coordinating Committee (SNCC), two organizations that worked for equal rights for people of color, traveled to Albany to assist the local blacks. These efforts became known as the Albany Movement. The demonstrations against segregation in Albany lasted for nearly nine months and attracted the involvement of prominent Civil Rights leaders such as the Rev. Dr. Martin Luther King, Jr., Ella Baker, and Ralph Abernathy. Yet the stand-off ended in August 1962 with no concessions for the town's black citizens. My presentation will focus on my role this year in creating a pedagogical website about the Albany Movement, as a student member of The University of Georgia's Civil Rights Digital Library Initiative. After discussing the Initiative's history and its goals to support research and instruction on the Civil Rights Movement, I will share my research on the differing perspectives of Albany's black and white citizens toward the Movement. I will illustrate my talk with quotations from newspaper articles in 1961-62 issues of *The Albany Herald* and *The Albany Times*, as well as news footage of demonstrations by protestors during the Albany Movement and interviews with prominent figures in the Movement. My research on the Albany Movement proves significant because it focuses on the forgotten civil rights movements in southern Georgia which are often overshadowed by the civil rights activities that occurred in the Atlanta area.

NIRS Detection of Brain Activity During Low Intensity Exercise

Jenna L. Thomason
Dr. Kevin McCully, Department of Kinesiology, University of Georgia

Brain activity has previously been mapped using expensive techniques such as fMRI and PET. Recent studies have suggested that near infrared spectroscopy (NIRS), a noninvasive and relatively inexpensive technology, can also be used to detect brain activity. The aim of this study was to determine if NIRS is useful for detecting brain activity during either exercise or a cognitive task. The experimental subjects were assigned to one of two conditions: (1) low-moderate intensity cycling on a stationary bike while undergoing cycles of on/off cognitive activity (using a cog task), or (2) a sub-maximal one arm hand grip exercise. In each condition, two eight channel probes were secured on the subject's head; the device emits low power light which is scattered by the brain tissue. Differential absorption of light by HbO2 and Hb was used to identify brain activity. Increases in oxygen saturation were interpreted as increases in blood flow and thus increases in regional brain activity. Preliminary results suggest that the NIRS device can detect cognition. If confirmed, the results of this experiment could result in a simpler, more cost-effective and noninvasive way of detecting brain activity in comparison to currently accepted methods.

Development of a Trypsin Assay in a Permeabilized Cell System to Characterize the Luteinizing Hormone Receptor Induced Activation of G-Proteins

Dan W. Thon
Dr. David Puett, Department of Biochemistry and Molecular Biology, University of Georgia

Certain mutations in the human luteinizing hormone receptor (hLHR), a G-protein coupled receptor (GPCR), are believed to cause a constitutive activation of the Gα-subunit of the stimulatory G-protein signaling pathway (Gαs). The stimulatory G-protein signaling pathway is activated by hLHR due to binding of the ligand, luteinizing hormone (LH), which is secreted by the pituitary gland and is essential to normal sexual function. The constitutive activation of the Gs pathway in the absence of ligand creates various reproductive pathologies such as precocious puberty in boys. The nucleotide bound state of the Gα-subunit changes during activation from the inactive, GDP-bound state to the active, GTP-bound state. This study utilized an assay exploiting trypsin's ability to selectively digest the inactive conformation over the active conformation of the Gα subunit to characterize the mechanism(s) of Gαs activation by native and mutant hLHRs through monitoring the nucleotide bound state of Gαs. A membrane permeabilization step was added to the assay in order to allow reagents to interact with intracellular proteins of the HEK-293 cells,

which were transiently transfected with hLHR, to prevent the uncoupling of hLHR from Gs. A toxin produced by Streptococcus pyogenes, Streptolysin O (SLO), creates large pores (~35nm) in the plasma membrane in a controlled and reproducible manner. The use of a SLO permeabilized cell system during the adaptation of the trypsin assay may allow for a better characterization of how mutations in the hLHR cause a constitutive activation of the Gs signaling pathway, and consequently, reproductive pathologies in humans.

Analyzing the Effects of Pectin Degrading Enzymes and Their Inhibitors on the Neurological Development of Drosophila

Annie Tran – CURO APPRENTICE
Dr. Michael Tiemeyer, Department of Biochemistry and Molecular Biology, University of Georgia
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

The glycosaminoglycan moieties of proteoglycans modulate the growth, differentiation, and function of cells in animals. Glycosaminoglycans (GAGs) provide structural support and influence cell signaling events in many tissues. In addition, neural development and the maintenance of normal neural architecture are both sensitive to GAG-dependent signaling pathways. In comparing the enzymes used to degrade GAGs, structural similarities were found with the enzymes used to degrade pectins. Pectins are acidic polysaccharides that constitute a major component of plant cell walls. Anecdotal evidence suggests that pectins have medicinal benefits for human health, although the relevant mechanisms are unknown. Recently it was shown that the three-dimensional structure of some endopolygalacturonases (EPGs, a class of pectin degrading enzymes) are similar to those of chondroitinases (a type of GAG degrading enzyme). Therefore, we hypothesized that pectin degrading enzymes may interact with GAGs in animal tissues, perhaps interfering with normal GAG-dependent cell signaling activities. To test for potential GAG-EPG interactions in vivo, an endopolygalacturonase and a polygalacturonase-inhibiting protein were subcloned into a Drosophila transformation vector that places transcription of the enzyme or enzyme inhibitor under control of an inducible promoter (UAS element). By mating transformed progeny to Drosophila strains that express induction factors (Gal4) in specific tissues, the effect of altered GAG activity on tissue development will be assessed. Because of the sensitivity of normal neural architecture to GAG-dependent signaling pathways, our initial disruption studies have focused on axon pathfinding defects in the embryonic nervous system.

Testing the River Continuum Concept in Sub-Antarctic Streams

Amy E. Trice
Dr. Amy Rosemond, Institute of Ecology, University of Georgia

The river continuum concept's (RCC) basic premise is that energy inputs and other abiotic properties vary along a stream gradient with predictable consequences for biota and ecosystem processes. However, the application of the RCC in particular situations has been refuted, given the inherent differences of ecosystems compared to the Eastern Temperate Deciduous Biome, where the idea was developed. Knowledge of streams in the temperate forests of southern South America is extremely limited, which has limited its incorporation into general explanations, such as the RCC that try to summarize important ecological processes. Therefore, we undertook to describe a longitudinal pattern of benthic invertebrates in the Cape Horn Biosphere Reserve, Chile (55°S) to see if a Sub-Antarctic River Continuum exists. Streams in this biome extend from sea-level to above tree line in short, steep catchments, which are therefore expected to be less predictable along a continuum, and rather more influenced by physical disturbance. To test this hypothesis aquatic macroinvertebrates were collected along an altitudinal gradient from sea-level to headwaters to describe species richness, abundance, composition, functional feeding groups, and biomass. The Robalo River did not follow the overall RCC predictions. Species richness and

biomass did not vary along the gradient. Functional feeding groups were also uniform through, with the exception that shredders did not occur above tree line (above 470 m). Our findings showed that sub-Antarctic stream benthos contained a large number of generalist species found throughout the stream reach.

Effects of Nitrate Contamination on Leaf Breakdown in a Stream at the State Botanical Garden of Georgia

Christy M. Turner
Dr. Sue Eggert, Department of Entomology, University of Georgia

Groundwater contamination from the University of Georgia swine farm has resulted in nitrate concentrations consistently exceeding 15 mg/L in a small stream at the State Botanical Garden of Georgia. The effects of the high nitrate levels on ecological functioning in streams at the Botanical Garden are unknown. Breakdown rates of leaf species typically categorized as having fast (*Liquidambar styraciflua*), medium (*Acer rubrum*), and slow (*Quercus rubra*) rates of breakdown were measured in a nitrate-contaminated stream and nearby reference stream (nitrate <1 mg/L) during the winter of 2005 to test the hypothesis that leaves placed in the nitrate-contaminated stream would have faster breakdown rates than leaves placed in the reference stream due to the nitrate's nutritional enrichment of leaf matter to the microbial and macroinvertebrate organisms that break it down. Preliminary data showed a mixed response in leaf breakdown rates between the two streams. *Liquidambar styraciflua* leaves broke down faster in the nitrate-contaminated stream compared to the reference stream, while *Quercus rubra* leaves broke down faster in the reference stream. *Acer rubrum* breakdown rates were similar between streams. My data show that elevated nitrate levels affect and may negatively impact the breakdown rates of some leaf species, as well as the overall health of the stream.

Trans-sialidase Specific $CD8^+$ T Cell Responses in *T. cruzi* Infection of Balb/C Mice

John (Jake) E. Turrentine, Jr.
Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia

Trypanosoma cruzi, the causative agent of Chagas' disease, afflicts approximately 18 million people throughout Latin America. In both human and mouse models, peptides of the trans-sialidase (ts) gene family of *T. cruzi* have been identified as important targets of $CD8^+$ cytotoxic T cells in *T. cruz*i infection. Infected C57BL/6 mice develop strong and focused $CD8^+$ T cell responses to a few ts-derived MHC-I epitopes. However, in infected humans, the $CD8^+$ T cell response to ts peptides is lower and appears to be less restricted. To determine if the strong and focused response in C57BL/6 mice is also evident in other mouse strains, especially those strains exhibiting greater susceptibility to *T. cruzi* infection, this project examined immune responses in the Balb/C mouse strain.

Enzyme-linked immunoSPOT assays and in-vivo cytolytic T lymphocyte assays have been used to probe for immunogenic *T. cruzi* ts-derived peptides in Balb/C mice from a screening of ten predicted MHC-I binding peptides. One peptide, TSKD-14.1, elicited a focused immune response in the Balb/C mice. In recent intracellular cytokine staining experiments, the strength of the $CD8^+$ T cell response to TSKD-14.1 has been shown to vary according to infecting parasite strain. To determine whether there are other immunogenic ts peptides in Balb/C mice, future ELISPOT and in-vivo CTL assays will survey an additional pool of ts peptides selected on the basis of MHC-I binding affinity predictions and *T. cruzi* genomic data. By exploring the ts peptide response in Balb/C mice and other mouse strains, we hope to determine whether resistance to *T. cruzi* infection correlates with the magnitude of the ts-specific $CD8^+$ T cell response.

Identification of Transcription Factors that Bind to WhiB3 Promoter in Mycobacterium Tuberculosis

Katrin Usifo

Dr. Joel Ernst, Department of Microbiology,
New York University Medical School

Mycobacterium tuberculosis is a global health threat that takes a life every fifteen seconds. Mycobacterium tuberculosis whiB3 is a postulated transcriptional regulator whose expression is markedly increased in bacteria isolated from the lungs of mice compared to bacteria grown in broth culture. WhiB3 expression peaks early after infection of mice, then decreases. In vitro experiments show that the whiB3 transcript is induced in aerated conditions compared to hypoxic cultures. The purpose of this project is to use Electrophoretic Mobility Shift Assay (EMSA) to determine whether transcription factors bind to whiB3 promoter under transcriptionally induced and repressed conditions. Reverse Transcriptase PCR was performed to determine the transcriptional start site of whiB3 and thus identify the promoter region. RT-PCR results confirmed the putative transcriptional start site of whiB3 at ~ –102 base pairs. EMSA was performed with four different regions of the promoter and proteins isolated from bacteria grown in broth in aerated and hypoxic conditions. EMSA results showed gel shifts under both aerated and hypoxic conditions. Binding patterns differed based on transcriptionally inducing and repressing conditions. However, binding patterns were the same with different regions of whiB3 promoter sequence. Although duplexes could out-compete each other, unrelated non-TB DNA and DNA from a coding region of another gene (acr) could not out-compete labeled duplexes. These results suggest that DNA-binding proteins under aerated and hypoxic conditions bind to whiB3 promoter. The specificity of DNA-protein interactions for whiB3 promoter remains to be determined.

Emotion, Identity, and Cardiovascular Response

Alexander Watts
Dr. Dawn Robinson, Department of Sociology,
University of Georgia

Contemporary sociological theories of identity make conflicting predictions about the relationship between identity disruption (i.e. the discrepancy between an outside observer's assessment of one's identity versus one's own views) and the valence of emotion. Identity control theory predicts that all identity disruption leads to negative emotion. Affect control theory, in contrast, predicts that negative identity disruption leads to negative emotion, while positive identity disruption leads to positive emotion. A critical test of these competing predictions would require measures that separately measure positive emotion, negative emotion, and identity disruption. This research will review the literature on the self-report and physiological measures of emotion and present the results of an experiment designed to independently manipulate positive and negative identity disruption. A sample of University of Georgia undergraduate students will participate in an IRB-approved experiment in which they receive positive and negative feedback in response to a social performance. Participants' views of their own social competence will first be assessed using the short form of the Texas Social Behavior Inventory. Research participants will then give a brief prepared speech, ostensibly to two unseen raters. Participants will be randomly assigned to subsequently receive feedback that is either (1) highly negative or (2) highly positive, or (3) to receive no feedback. Skin temperature, skin conductance, skin resistance, and peripheral blood flow will be measured through a skin temperature probe, Galvanic Skin Response electrodes, and an infrared plethysmograph and will be used to index both the type and magnitude of emotional response to the feedback. The devices for measuring physiological responses are relatively unobtrusive, so acclimation to the equipment is not necessarily critical. The subjects will, however, be given a moment to adjust during a brief seeing test before their performance. Self-views of competence will be crossed with the nature of the feedback to distinguish between those whose positive identities have been disrupted, whose positive identities have been confirmed, whose negative identities have been

disrupted, and whose negative identities have been confirmed. The self-report and physiological measures of emotion and identity disruption will then be used to distinguish between the predictions of identity control theory and affect control theory.

An Emerging International World Order: The Case for Mandatory Foreign Language Proficiency within the United States Public School System

Daniel J. Weitz, Roosevelt @ UGA
Dr. Linda Harklau, Department of Language and Literacy Education, University of Georgia

Both historically and within present times, the United States has maintained the English language as its unofficial yet universal channel of communication. While emphasis upon a central conduit of dialogue befits the interests of any nation, modern society has progressively become interdependent in many aspects of human existence, and, as such, the language barrier oftentimes poses a significant obstacle to cross-cultural cooperation. In refusing to allow modification and thus modernization upon the status quo of communicative expression within the United States, hindrances relative to economic interests, societal tolerance and understanding, and overall political cordiality among international counterparts have correspondingly emerged with the United States' failure to evolve with the progression of an internationally oriented state of mankind. This paper illustrates how the United States, existing among the world's foremost international actors, would greatly benefit economically, socially, and politically from the implementation of a mandatory foreign language curriculum throughout the national public school system, as this adaptation would support the United States' potential leadership stature within the emerging international world order.

Improving Ultrasound Arterial Assessment by Standardizing Probe Selection and Optimization Settings

Cary F. West & Danielle Morozewicz
Dr. Kevin McCully, Department of Kinesiology, University of Georgia

Ultrasound technology is widely used to make assessments of arterial function. However, the accuracy of these assessments has been called into question. A proportion of this variability may be controlled through standardizing measurement protocols. Therefore, the aim of this study was to assess variability due to probe selection and optimization settings. Ten healthy 20-26 year old male and female subjects were tested. Brachial artery size (diameter) was measured thirty times a second using a B-mode Ultrasound unit equipped with a high-resolution video capture device. To assess variability due to probe selection and optimization, we manipulated three parameters: 1. probe frequency; 2. measurement location; and 3. image display size. To assess variability due to probe selection, we compared three probes. To assess intersession variability, we continuously made recordings for twelve minutes, with the probe being removed and re-positioned between each four-minute duration. Coefficients of variation for probe frequency, measurement location, image display size, and probe selection were 2.2%, 2.2%, 1.1%, and 3.9%, respectively. Intersession variability was 4.0% while using constant probe and optimization settings. In conclusion, the optimization setting most likely to decrease reliability is probe selection. However, as long as probe selection and optimization settings are kept constant, our intersession variability shows that reliable measurements can be made.

Analysis of Interactions between EPGs/PGIPs/Pectins Using Surface Plasmon Resonance

James M. Wheeler
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

Endopolygalacturonases (EPGs) are important fungal pathogenicity factors and are among the first enzymes secreted when fungi are grown on isolated plant cell walls as a sole carbon source. As a defense against fungal attack, plants produce proteinaceous EPG inhibitors known as

polygalacturonase-inhibiting proteins (PGIPs). PGIPs are soluble, leucine rich repeat (LRR) glycoproteins, found in the extracellular matrix of most plants. PGIPs may form high-affinity complexes with EPGs in a reversible, stoichiometric manner. The mode of action of a particular fungal EPG and its inhibition by PGIPs may be critical factors in determining whether the fungus is a viable pathogen. To fully understand the interactions of these two classes of molecules and their role in host-pathogen interactions, the mode of action of EPG hydrolysis and of PGIP inhibition must be understood at the molecular level. Pectin is the natural substrate for EPGs, and our research and that of others indicates that the pectin binds both the EPG and the LRR inhibitor PGIP. This implies that pectin plays an active role in the formation of an EPG/PGIP/pectin complex and is not simply a passive substrate. This has major implications in understanding the role of this ternary EPG/PGIP/pectin in pathogenesis, as well as understanding the role of glycosaminoglycan/LRR/receptor complexes in animals. These interactions are studied through surface plasmon resonance (SPR) using EPGs from various fungal sources and site directed mutant PGIPs. SPR is also used to look at the interaction of PGIPs with pectins, as well as the effect of pectins on EPG-PGIP complexes.

A Tangled Topic: The Connect Sum of Mathematical Knots

Rachel E. Whitaker
Dr. Jason Cantarella, Department of Mathematics, University of Georgia

Mathematical knots are closed, three-dimensional curves that cannot be distorted to produce the unknot, a simple loop. They are categorized by their minimal crossing number, or the fewest number of crossings possible after distorting the knot to its simplest form. Knots which can be expressed as a joining, or connected sum, of other knots are called composite; otherwise, the knot is prime. Knot theory has many applications to the biological sciences, including the modeling of DNA and protein folding. One of the most prominent questions in knot theory is deceptively simple: determining whether two knots are equivalent. The VIGRE [Vertical Integration of Research and Education] Geometric Knot Theory group has been working to create a library of all knots with relatively low crossing number. While libraries exist to classify prime knots, one including composite knots would be beneficial. However, there is no distinct way to join any two knots; the knots' reversible, mirror, and amphichiral symmetry affect which composite knot is formed. Therefore, computer programs are necessary to test aspects of the symmetry of knots in order to compare them and determine equivalency. Our program, written in the C programming language, reverses the orientation of a knot or any number of specified components in a link (a collection of knots). Subsequently, our programs to convert the format of knots between VECT and Fe formats allow us to utilize Brakke's Evolver program to generate proportional representations of the connected sum knots for the library that are visually appealing.

Reconstructing Maginot: Missile by Missile

Adam P. Williams, Roosevelt @ UGA
Dr. James Holmes, Center for International Trade and Security, University of Georgia

Just over three-quarters of a century ago, the French senate approved the construction of the largest defensive structure the Western world has ever known. Although its shortcomings tend to be overstated, the series of concrete fortifications envisioned by War Minister André Maginot not only failed to prevent a German invasion but also served to cripple France's foreign policy altogether, ensuring France would be ill-prepared for the looming Nazi blitzkrieg. Today, critics accuse the United States of constructing its own, modern Maginot Line, only with rocket fuel and guidance chips replacing concrete and barbed wire. National missile defense—a program that has existed in varying forms since the 1960s—has, many political changes notwithstanding, remained a fixture of America's long-term strategic thinking. Consuming the largest single portion of the Defense Department's acquisition budget (some $8.8 billion for fiscal year 2006), national

missile defense has become a top priority in the United States' approach to countering the growing threat of nuclear, chemical, and biological weapons. Despite the tenuous consensus in Congress regarding missile defense, many still question the strategic worth, not to mention the feasibility and cost-effectiveness, of this so-called "star wars" system. The paper will analyze the strategic value of missile defense systems against some feasible alternatives aimed to mitigate the risks posed by weapons of mass destruction. Then, by approaching missile defense through the eyes of history, it will determine whether America's 21st century bulwark is doomed to share a fate similar to that of its infamous French predecessor.

Development of Transgenic Zebrafish to Understand the Role of Hyal-2 in Tumor Formation

Dustin Williams – CURO SUMMER FELLOW
Dr. Scott Dougan, Department of Cellular Biology, University of Georgia

Jaagsiekte sheep retrovirus (JSRV) is an infectious virus that encodes an oncoprotein that induces ovine pulmonary adenocarcinoma by transforming lung epithelial cells. This cancer shows similarities with bronchioloalveolar carcinoma in humans, a cancer not strongly associated with smoking. The oncoprotein is the virus envelope protein (ENV). The receptor for this protein is Hyal-2, a membrane protein of undetermined function. Hyal-2 is deleted frequently in human lung tumors, opening the possibility that it functions as a tumor suppressor. Currently there are few genetic model systems in which to study the role of Hyal-2 in oncogenesis. To study this problem, ENV will be overexpressed in zebrafish using the GeneSwitch system from Invitrogen. The system consists of two plasmid vectors, pSwitch and pGene. The pGene vector contains the gene to be expressed. PSwitch encodes a transcription factor, the GeneSwitch protein, which binds to pGene, resulting in the expression of the gene of interest. However, the GeneSwitch protein can only activate transcription in the presence of the drug mifepristone. Thus, gene expression can be induced ubiquitously at any stage of development upon addition of mifepristone. Traditional methods of introducing genes into fish yield low transfection rates of 1-5%. Instead, a transposon system will be used to insert ENV. Transposons containing the pSwitch and pGene-ENV constructs will be coinjected into early embryos with transposase mRNA, which will mediate integration randomly into the genome. This method yields significantly higher transfection rates of up to 50%. After the constructs are injected, the fish will be screened for tumors. If tumors are found, a variety of opportunities will be opened to study tumorigenesis and will allow use of zebrafish as a genetic system to dissect the role of Hyal-2 in tumor formation.

Beta-amyloid Immunoglobins as a Potential Early Marker for Alzheimer's Disease

Jennifer S. Wilson
Dr. L. Stephen Miller, Department of Psychology, University of Georgia

Recent developments in Alzheimer's Disease (AD) research show that certain immunoglobulins (IgG) circulating in the bloodstream may mark the presence of the amyloid plaques that characterize the progression of this disease. Gathering at receptor sites for advanced glycation end products (RAGE), amyloid peptides accumulate over time within cortical areas of brain tissue. Plaques formed in this process are associated with impairment of cognitive functioning such as memory and decision-making. In response to the increased presence of amyloid ABeta proteins and RAGE cells, data suggest an increase in levels of anti-RAGE and anti-ABeta IgG. Because this natural immune response can be observed in a simple blood sample, many of the previous limitations in diagnosing AD can be reduced. Current methods of diagnosis, such as neuropsychological testing or MRI scanning, are expensive, time-consuming, and can often only detect the disease in its later stages. This study examines the relationship between the levels of anti-Ab and anti-RAGE IgG biochemical markers, and changes in cognitive functioning over time. Levels of the IgG markers in blood

plasma samples were compared with test scores from the Repeatable Battery for the Assessment of Neuropsychological Status (RBANS). The purpose of the study was to determine which domains of cognition tested by the RBANS best correlated with concentration of the biological blood markers. Establishing correlations between the RBANS, and anti-ABeta and anti-RAGE IgG will help to explain differences in specific IgG levels within groups of individuals diagnosed with AD. This will further define the role of IgG blood sampling as a potential predictive method for identifying the disease and may help to establish a stratified approach to classifying individuals with AD, thus allowing treatment to be better tailored to the needs of each patient.

Genetic Manipulation of *Actinosynnema pretiosum*.

Charles Wooten – CURO SCHOLAR
Dr. Janet Westpheling, Department of Genetics, University of Georgia
(Charles Wooten, Brandan Hillerich and Janet Westpheling)

Actinosynnema pretiosum is a soil bacterium that produces the maytansinoid, ansamitocin, an important anticancer chemotherapeutic agent. Maytansinoids are effective antitumor agents derived from plants and microorganisms. Very little is known about the biosynthetic pathways that lead to their synthesis. *Actinosynnema pretiosum* is a member of the family of bacteria called actinomycetes. These Gram positive filamentous soil bacteria make most of the natural product antibiotics used in human and animal health care including a number of anticancer therapeutics. *Actinosynnema pretiosum* ssp. auranticum is an uncharacterized member of this family of bacteria and is particularly unresponsive to conventional genetic analysis. In fact, many of the tools developed for genetic manipulation of the model organism in the group, *Streptomyces coelicolor*, do not work in this strain. In an effort to develop genetic tools to manipulate the strain and to engineer the pathway for ansamitocin biosynthesis, we will test a number of plasmids and insertion sequences from *S. coelicolor*. Here we will report the development of protocols for the introduction of these tools into *Actinosynnema pretiosum* with the long term goal of using these tools for mutagenesis (by integration into genes), gene replacement, and the engineering of the ansamitocin biosynthesis pathway for novel antibiotic production.

Identifying IS*492* Chromosomal Insertions in *Escherichia coli*

Lanelle D. Wright
Dr. Anna Karls, Department of Microbiology, University of Georgia

Pseudoalteromonas atlantica, a Gram-negative marine bacterium, produces extracellular polysaccharide (EPS), to which other marine organisms attach in the formation of biofilms on solid surfaces. EPS production is turned off and on and by MooV-mediated insertion and excision of the mobile element IS*492* at the *eps* gene. In *P. atlantica* IS*492* appears to insert specifically into one site within the *eps* gene. This study asks what is the specificity for IS*492* insertion in a naïve host, *Escherichia coli*. Studying IS*492* insertion in *E. coli* will provide insight into the mechanisms of DNA recombination by a novel family of DNA recombinases (Piv/MooV family) and will contribute to understanding medically important events associated with DNA recombination, including cancer.

An IS*492* insertion assay in *Escherichia coli* was developed using an IS*492* construct that contains a tetracycline resistance gene (IS*492*Δ*mooV*::*tet*) and an *eps* target plasmid. IS*492*Δ*mooV*::*tet* insertion events into the target plasmid were selected for by isolating *E. coli* strains resistant to tetracycline (Tet^R). Tet^R *E. coli* isolates that did not contain IS*492*Δ*mooV*::*tet* insertions into the *eps* target plasmid were screened for IS*492*Δ*mooV*::*tet* insertions into the chromosome using Polymerase Chain Reaction (PCR) designed to amplify the chromosomal DNA that border IS*492* insertions. The PCR protocols were optimized for specificity by changing primers, altering annealing temperatures, and adding dimethyl sulfoxide, but

sequencing of the PCR products from these PCR assays indicated that IS*492*Δ*mooV*::*tet* did not insert into the *E. coli* chromosome. It is possible that there is not an appropriate target site for IS*492* insertion on the *E. coli* chromosome. This will be addressed in future experiments by introducing the *eps* target sequence from *P. atlantica* into the *E. coli* chromosome and then assaying for insertion of IS*492*.

Graphic Design
Jennifer Xin
Prof. Lanny Webb, Department of Graphic Design, University of Georgia

Graphic design involves the use of typography, color, imagery, and concept to organize and deliver content, to elicit a feeling or response appropriate to the client's needs. In my work, I try to achieve a balance between a playfulness that will draw in the viewer and a sense of order to establish a hierarchy of information. The end product should be regarded as effortless and simple. To me, the overall message should never be obscured or overtaken by the artist's own whimsies or stylizations; otherwise it ceases to operate as a vehicle for communication and instead begins to call attention to itself as an end unto itself. Ultimately, my work is about using elements of design in its essence and letting that speak directly without attempting to embellish and clutter with excess.

Urban Sprout is a hypothetical seed company that caters to city-dwellers. It specializes in gardening kits that provide everything one initially needs to start planting. The company's aim is to promote awareness of nature in urban environments. Its main clientele include young professionals, teenagers, and children. I created a business stationary system, seed packaging, and cartons for a gardening kit that is playful and hip.

Effects of Market System Entry on Rural Indigenous Women in Ecuador
Sarah M. Yagoda
Dr. Jose Alvarez, Department of Romance Languages, University of Georgia

Indigenous communities in Ecuador's Andean region were not exposed to significant economic development until the 1980s. Because of the short time that business initiatives have been carried out in the area, limited research has been conducted on how indigenous women's gender and familial roles are affected by "empowerment" projects intended to increase their ability to earn independent incomes. Therefore, this research focuses on some effects of these development programs. This will in turn help to determine the validity of common assumptions about these types of projects, namely that they help women obtain more equality. This research will also explore how equality is defined by the women who are affected by these initiatives, as well as by the people who organize the projects. My research is being conducted in three phases. First, I am reviewing what has already been published in the U.S. and Ecuador on this topic. Second, women who are involved in one economic development project in the region have been interviewed, and I am transcribing the recorded conversations. Third, I will travel to the region from March 5, 2006 to March 17, 2006 to interact with the women involved in the project. Plans are also being finalized to interview representatives from Ecuadorian foundations which work with women's issues and economic development. The data collected so far suggest that economic development programs alter women's traditional roles in ways many women describe as positive, but they can also cause conflicts when male heads-of-household resist their female counterparts' participation in empowerment projects.

Regulation of Branched-Chain Amino Acid Catabolism in *Streptomyces coelicolor*: Applications for Metabolic Engineering of Polyketide Antibiotic Biosynthesis

Fei Yang – CURO SUMMER FELLOW
Dr. Janet Westpheling, Department of Genetics, University of Georgia
(Fei Yang, Karen Stirrett, and Janet Westpheling)

Streptomyces are soil bacteria that produce over 70% of antibiotics used in human and animal health care. Mutants of Streptomyces defective in the catabolism of the branched chain amino acids, valine, leucine, and isoleucine, are also defective in antibiotic production, suggesting that some of the precursors for antibiotic synthesis come exclusively from this carbon utilization pathway. The *Streptomyces coelicolor bkdA2B2C2* gene cluster encodes a putative branched chain amino acid dehydrogenase Complex, and *bkdR*, a leucine response regulator, represses these genes at the level of transcription. The promoter contains a nearly perfect 14bp inverted repeat that may be the binding site of the *bkdR* protein. To examine the regulation of the *bkdA2B2C2* cluster and to investigate the role of *bkdR* in its regulation, a transcriptional fusion between the *bkdA2B2C2* cluster promoter and the *xylE* reporter gene was constructed. Strains expressing *xylE* convert colorless catechol to a yellow oxidation product. The *bkdA2B2C2-xylE* construct was introduced into wild-type *S. coelicolor* M145 as well as the *bkdR* mutant; M145 containing a promoter less copy of the *xylE* gene was used as a negative control. The *bkdR* mutant containing the *bkdA2B2C2-xylE* fusion will be yellow as expression of the cluster in the mutant is constitutive. *bkdA2B2C2-xylE* expression in wild type will be assayed in minimal liquid media cultures with glucose, maltose, mannitol, leucine, isoleucine, or valine as sole carbon source for induction times and levels. In addition, degenerative PCR will be used to generate base changes in the promoter region of this cluster, and *xylE* assays will be used to examine their effect. As a result of this analysis, I hope to gain an understanding of the role *bkdR* plays in the regulation of the *bkdA2B2C2* cluster and identify the environmental signals that induce transcription. This work will contribute to the understanding of the morphogenic pathways that contribute to antibiotic production and their eventual manipulation for novel antibiotic synthesis.

Unraveling the Molecular Basis of the Role of Pectins in Human Health

Stephanie Yarnell – CURO SUMMER FELLOW
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

Glycosaminoglycans (GAGs) are unbranched carbohydrate polymers. They are a component of the extracellular matrix and contribute to the general structure and permeability properties of connective tissues. GAGs have been implicated in binding of pathogens to particular target cells, maintenance of cellular activities, and development of metastasis in cancer cells. Pectins are the primary structural elements of the matrix of the plant cell wall and have been implicated in morphogenesis, pH regulation, ion balance, wall permeability, and plant defense. We noted that microbial enzymes that cleave GAGs and those that degrade pectin share structural similarities, and enzyme structure is often driven by the three dimensional structure of the substrate. The similarity in function of GAGs and pectins, and the structural similarities of the enzymes that degrade them, led us to wonder if these were clues that could shed light on the mechanism of the role of pectins in human health. As a first step, we have used reducing sugar and UV-based assays as well as fluorescence to investigate the effects of GAGs on selected pectin degrading enzymes (PDEs) and of pectin on GAG degrading enzymes. Our data demonstrate that pectins are able to affect GAG degrading enzyme activity, and GAGs are able to affect PDEs. Thus, it is a reasonable assumption that the receptors for GAGs involved in such activities as neural development and tumor development are potential targets for pectins and that the role of the GAGs themselves in development may be altered by PDEs.

The Relationship between Children's Emotional Responses to Puppet Vignettes and their Social Competence

Jessica Zabell, Sara Douglass & Crystal Barber, Georgia College & State University
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Young children's social and emotional competence is closely related to their peer relations. Children who lack understanding of appropriate emotional expressions in social contexts are more likely to engage in conflict and aggressive behaviors. It is thus imperative to seek early indicators of children's social deficiencies. Such indicators would allow early interventions to coach appropriate emotional competence to promote healthy social adjustment and successful interpersonal relations. In the present study, puppet vignettes were used to assess children's ability in recognizing appropriate emotions. The aim of this study is to discern whether children's emotional responses to conflict situations may be related to their social competence rated by their teachers. A total of 121 three-year-olds (boys = 59) from the local Head Start program were recruited to participate in a larger study conducted by Chiang and Zabell, et al (2005, 2006). The puppet vignettes, outlining imaginary scenarios to elicit various emotional responses, were randomly presented to the participant. The conflict vignette involved a child grabbing a favorite toy from the participant. Fifty–three participants whose responses were anger or sadness were used for data analyses. Their responses were correlated with the Teachers' Social Competence Behavior Evaluation (SCBE) rating. Two-Way (2 X 3) ANOVA (Emotion x SCBE) were further used to compare the differences. The results showed that children reporting anger were rated more aggressive and oppositional versus those reporting sadness; children reporting sadness were rated more calm and cooperative versus those reporting anger. More results and implications will be discussed at the conference.

Symposium 2008

University of Georgia
Tate Student Center & Student Learning Center
April 7, 2008

CALL FOR ABSTRACTS

The Center for Undergraduate Research Opportunities at the University of Georgia provides a forum for all undergraduates to present original research and creative works sponsored by faculty members. Undergraduate students from all disciplines are encouraged to participate. Representatives of public and private higher education institutions in Georgia are encouraged to apply.

Presentations may be in the form of an oral presentation, poster session, exhibition, performance, or work of art. Students can also present a tutorial about a research methodology or new technology. Undergraduate researchers who are at various stages of the research process are encouraged to submit abstracts describing where they are in the research process and the issues they face. Those who wish to present their work should submit an application and an abstract of a maximum of 250 words (via the CURO web site) and a brief supporting letter from the sponsoring faculty member no later than January 18, 2008. Group research projects should be submitted with one application and one letter of faculty support. All abstracts will receive graduate student peer review with faculty guidance. All participants accepted into the Symposium will be notified by February 15, 2008, and their abstracts will be published in a book of abstracts. Sponsoring faculty will be invited to preside at their students' sessions.

Best Paper Awards
Papers on work being presented at the CURO Symposium submitted by March 17, 2008 will be considered for Best Paper awards in the categories of humanities, social sciences, civic responsibility focus, international focus, and sciences. Papers must be submitted electronically to curo@uga.edu. Maximum length is 20 pages, double spaced.

Purpose of the Symposium:
- To highlight excellence in research by undergraduate students
- To enrich the undergraduate experience by promoting communication and cooperation between faculty and students
- To provide a forum for undergraduates to communicate and disseminate their research findings and creative works
- To provide an opportunity for undergraduate researchers in the state of Georgia to engage with their peer researchers

Criteria for Selection:
- Originality and quality of research
- Quality of written abstract
- Ethical and responsible research
- Extent of the undergraduate student's involvement in development of the research design and execution of the project. Research presented at the Symposium should go beyond work completed for a class paper or project
- A letter of support from supervising faculty

This event will be free and open to the public. All interested faculty and students are encouraged to attend the CURO 2008 Symposium. For more information, contact curo@uga.edu, (706) 542-5871.

Monday, April 9, 2007

Begin registration of oral and poster presenters; Students hang up posters — **8:30 a.m.**
Tate Student Center, Lower Lobby

Concurrent Oral Sessions — **9:05 a.m.**
Tate Student Center, Rooms 137, 138, 139, 140, 141, 142

	Lindsey Thomas	A Study of Site Formation Processes for the Northwestern Hawaiian Islands
	Faculty Mentor	Dr. Ervan Garrison, Department of Anthropology
	Andrew M. Durso	Environmental and Ontogenetic Changes in Detection Probability of Pond-breeding Salamanders in the Georgia Piedmont
	Faculty Mentor	Dr. John Maerz, Department of Forestry Research

12:20 – 1:10 p.m. Fourth Concurrent Session

Room 137	**Noona Oh**	Gender Meaning Parity and the Gay Movement: A Cross-cultural Study of Developing Movements
	Faculty Mentor	Dr. Dawn Robinson, Department of Sociology
	Michael W. Davis	Sexuality in Israel: Birth of the Gay Rights Movement and Its Struggles for Acceptance in Israeli Society
	Faculty Mentor	Dr. Randy Sturman, Department of Religion
	Maggie Mills	An Empirical Study of Government and Dissident Interactions in Cambodia and Indonesia, 1980-2005
	Faculty Mentor	Dr. Stephen Shellman, Department of International Affairs
Room 138	**Crystal Rapier**	Effects of Mg/HA on Growth and Differentiation of Osteoblast Cells (Bone Cells) in a Hydroxy Apatite Scaffold
	Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
	Anant Mandawat, Bradley Allen	Expression and Renaturation of Recombinant HL-1, a Lectin-like Protein that May Function as a Type II Diabetes Therapeutic
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology

	Ezinne A. Okwandu	Characterizing PGMRC1, an Enzyme Suspected in the Regulation of the Cytochrome P450 CYP51A1
	Faculty Mentor	Dr. William Lanzilotta, Department of Biochemistry & Molecular Biology
Room 139	**Ashley A. Wilkinson**	Investigation of State-controlled Media Outlets and Their Reports on Internal Conflict: A Xinjiang Province Case Study
	Faculty Mentor	Dr. Stephen Shellman, Department of International Affairs
	Danielle L. Pearl	Media Development, Journalism and Democratization in Croatia
	Faculty Mentor	Dr. Keith Langston, Department of Germanic & Slavic Languages
	Katherine B. Church	National Geographic Magazine: What Gets Covered around the World?
	Faculty Mentor	Dr. Leara Rhodes, Department of Journalism
Room 140	**Hsuan Ju Susan Fang**	The Marriage of Expression and Design
	Faculty Mentor	Prof. Christopher Hocking, Departments of Studio Foundations, Drawing & Painting
	Brian L. Harper	Creation of a Computer Game from Concept to Completion
	Faculty Mentor	Dr. Mike Hussey, Department of Theatre & Film Studies
Room 141	**Tulsi Patel**	Developing a Biocontrol Agent for Chinese Privet, *Ligustrum sinense*
	Faculty Mentor	Dr. Scott Gold, Department of Plant Pathology
	Brian T. Laughlin	Functional Analysis of the *Magnaporthe grisea* Secretome
	Faculty Mentor	Dr. Alan Darvill, Departments of Biochemistry & Molecular Biology, Plant Pathology
	Laura A. Thornsberry	The Analysis of Synthetic Neoglycolipids by FTICR Tandem Mass Spectrometry
	Faculty Mentor	Dr. Jon Amster, Department of Chemistry
Room 142	**Jimari L. Jones, Jeremy Atkins**	Early Childhood Education and Family Literacy in Athens
	Faculty Mentor	Dr. Elizabeth DeBray-Pelot, Department of Lifelong Education, Administration & Policy
	Crystal Barber, Kimberly Kite, Toni McCranie, LaToya Jones, Shananikia Marshall	The Influence of Parental Attitudes on Children's Gender Toy Preference
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

	Lionel (Leo) H. White	Mothers' Parenting Styles and Their Toddlers' Compliance
	Faculty Mentor	Dr. Hui-Chin Hsu, Department of Child & Family Development

1:25 – 2:15 p.m. Fifth Concurrent Session

Room 137	**William C. McWhorter, Naseem Esteghamat**	The Path Less Taken: A Progressive Approach to Stem Cell Extraction and Grading
	Faculty Mentor	Dr. J. David Puett, Department of Biochemistry & Molecular Biology
	Elizabeth A. Godbey	Differentiation of Human Embryonic Stem Cells to a Vascular Phenotype
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
	Kiya Birku	O-GlcNAc Modifications in Obese Mouse Models
	Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology Dr. Ruth Harris, Department of Foods & Nutrition
Room 138	**Nari Shin, Celina Correa, Yuliya Kuzovkova**	The Interaction between Culture, Poverty, and Educational Achievement: How Policy Can Better Impact the Graduation Rates of Georgia's Latino and African American Youth
	Faculty Mentor	Dr. Larry Nackerud, School of Social Work
	Robert B. Lindell	A Field Guide to English/Spanish Medical Translation
	Faculty Mentor	Dr. David S. Williams, Honors Program
Room 139	**Anh V. Trieu, Ashley Bowen**	Trade for Humanity: A Proposal for Viet Nam
	Faculty Mentor	Dr. Maurits Van der Veen, Department of International Affairs
	Aaron M. Sayama	North Korea: Options for Dealing with a Nuclear Armed State
	Faculty Mentor	Dr. Stephen Shellman, Department of International Affairs
	Aqsa Mahmud	Under the Rug Swept: Rural Punjab Women in the Ecotone of Urbanization
	Faculty Mentor	Dr. Fausto Sarmiento, Department of Geography
Room 141	**Zach Fox**	A Cellulosic Ethanol Plan for Athens
	Faculty Mentor	Dr. Thomas Adams, Department of Biological & Agricultural Engineering
	Bryan P. Davis	Awareness of Student Expenditure Patterns
	Faculty Mentor	Dr. Lance Palmer, College of Family & Consumer Sciences

	William Patrick Dever	The Economic Implications of a Marijuana Decriminalization Policy in the United States
	Faculty Mentor	Dr. William Lastrapes, Department of Economics
Room 142	**Sara Douglass, Kelli Webb, Matthew Anderson, Ankita Patel, Jeramy Denton**	The Stability of Children's Gender Toy Preference through a Two-year Longitudinal Study
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University
	Traci N. Tucker	An Affect Control Model of Attribution
	Faculty Mentor	Dr. Dawn Robinson, Department of Sociology
	Christopher MacLean	The Effect of Cognitively Challenging Talk on Oral Language Development in Low-income Preschool Children
	Faculty Mentor	Dr. Paula Schwanenflugel, Department of Educational Psychology

2:00 – 3:20 p.m. Creative Writing & Dance

Tate Student Center, Georgia Hall A

Creative Writing & Dance Presenters

Alisan J. Atvur	*Small Emergencies: Poems*
Faculty Mentor	Dr. Ed Pavlic, Department of English
Brittney Inman	*Living in Fire, Ice, and Cardboard*; *Hotter'N Hell*; *Green with a Cowboy Print*; and *Thanksgiving with the Pope, Popeye, and the Mafia*
Faculty Mentor	Prof. Judith Ortiz Cofer, Department of English
Kacie Versaci	*Chicken Water*, *What Are We?*, and *We Are Nothing But the Scraps*
Faculty Mentor	Prof. Judith Ortiz Cofer, Department of English
Hariqbal Basi	*Bollywood Fusion*
Faculty Mentor	Prof. Bala Sarasvati, Department of Dance Dr. Pamela Kleiber, Honors Program
Cara O'Grady	*Brief – Solo Study Utilizing Crafting Devices in Dance* Choreography
Faculty Mentor	Prof. Bala Sarasvati, Department of Dance
Mia Holtzman	*The Integration of Aesthetic Principles and Human Movement*
Faculty Mentor	Prof. Bala Sarasvati, Department of Dance

Mary Mattmann	*Gone but not – Making Dance through Improvisation*
Faculty Mentor	Prof. Rebecca Enghauser, Department of Dance

2:30 – 3:45 p.m. Sixth Concurrent Session

Room 137	**Mia Catherine Morgan**	Zeolites of Eastern Uganda and Their Scientific, Social, and Economic Potential
	Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
	Samantha E. Keyes-Blumer	The Role of Extremism in the Arab-Israeli Conflict
	Faculty Mentor	Dr. Christopher Allen, Department of International Affairs
	Yael Miller	US Involvement in the Reconstruction of Lebanon
	Faculty Mentor	Dr. Sherry Lowrance, Department of International Affairs
	Andrew I. Gladden, Patrick Bentley	Escalation or Acquiescence? An Analysis of Sequential Dissident Responses to Repression in Indonesia
	Faculty Mentor	Dr. Stephen Shellman, Department of International Affairs
Room 138	**Katharine A. Owers**	The Effects of Heat Shock on the Lethality of Subsequent Infection in *Drosophila melanogaster*
	Faculty Mentor	Dr. Daniel Promislow, Department of Genetics
	Nithya M. Natrajan	Effects of Glycerol on Processing of Kit Ligand Mutants in Mammalian Cells
	Faculty Mentor	Dr. Mary Bedell, Department of Genetics
	Jessica M. Bryant	Katanin Plays a Role in Microtubule Dynamics and Ciliary Assembly in *Tetrahymena thermophila*
	Faculty Mentor	Dr. Jacek Gaertig, Department of Cellular Biology
	Leilah D. Zahedi	The Effects of Colostral Leukocytes on TNFα Levels in Neonatal Calves
	Faculty Mentor	Dr. David Hurley, Department of Large Animal Medicine
Room 139	**Rebecca Anne Creasy**	Formulation of a Stable Acidified Dairy Beverage Containing Ellagic Acid
	Faculty Mentor	Dr. Louise Wicker, Department of Food Science & Technology
	Amy J. Burrell	Construction of and Use of GAUT1 and GAUT7 Reporter Gene Constructs to Study GAUT1 and GAUT7 Transcriptional Activity in Plants
	Faculty Mentor	Dr. Debra Mohnen, Department of Biochemistry & Molecular Biology

	Lamar H. Moree	Gene Knockout Analysis of Two Putative Xylanase-regulating Transcription Factors in the Rice Blast Fungus
	Faculty Mentor	Dr. Alan Darvill, Departments of Biochemistry & Molecular Biology, Plant Pathology Dr. Sheng-Cheng Wu, Complex Carbohydrate Research Center
	Mandy Redden	Towards a More Effective Delivery System for Anti-cancer Drugs
	Faculty Mentor	Dr. Robert Arnold, Department of Pharmaceutical & Biomedical Sciences
Room 140	**Sana Hashmi**	Site-mapping and Glycan Characterization of Functional Alpha-Dystroglycan
	Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology
	Yayne Fekadu	The Interaction of Natural Killer Receptor + T-cells with *Campylobacter jejuni*
	Faculty Mentor	Dr. Joan O'Keeffe, Department of Biochemistry, National University of Ireland, Galway
	Ezinne A. Okwandu	Tax Binding to Various CBP Domains
	Faculty Mentor	Dr. Jennifer Nyborg, Department of Biochemistry & Molecular Biology, Colorado State University
	Richard C. Piercy	Expression, Optimization and Crystallization of Cystathionine β-Synthase and Cystathionine γ-Lyase
	Faculty Mentor	Dr. Cory Momany, Department of Biomedical & Pharmaceutical Sciences
Room 141	**Seychelle M. Vos**	Initial Sequencing and Tissue Distribution of Toll-like 3 Receptor mRNA in White-tailed Deer
	Faculty Mentor	Dr. Elizabeth Howerth, Department of Veterinary Pathology
	Aaron C. Petrey	Polygalacturonase-inhibiting Proteins and Their Relationship to Polygalacturonases
	Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center
	Liron Bar-Peled	Analysis of Why RNase P Is Essential for Cell Viability in *Escherichia coli*
	Faculty Mentor	Dr. Sidney Kushner, Department of Genetics
	Zion Firew	Characterization of Putative Genes that Encode the Enzymes Arabinose Kinase and Galactose Oxidase: Enzymes Involved in the Biosynthesis of Sugar Nucleotides
	Faculty Mentor	Dr. Maor Bar-Peled, Department of Plant Biology

Room 142	**Sonia Talathi**	Calcium-independent Phospholipase A_2 Are Novel Targets for Inhibition of Prostate Cancer Cell Growth
	Faculty Mentor	Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences
	Paul A. Henkel	RGS Proteins Regulate LPA Signaling in Ovarian Cancer Cells
	Faculty Mentor	Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Sciences
	Rachelle W. Wallace	Identification of L-PHA Reactive Glycoproteins from Invasive Breast Carcinoma Tissue: Potential Biomarkers for Early Detection
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology
	Madeline C. Elliott	Calmodulin Activation of Estrogen Receptor α: Cloning and Expression of a Fusion Protein for Defining the Calmodulin Binding Determinants
	Faculty Mentor	Dr. Jeffrey L. Urbauer, Department of Biochemistry & Molecular Biology
Room 143	**Andrew C. McKown**	Determining Cost of Medical Sharps Disposal at a Local Health Center in Uganda
	Faculty Mentor	Dr. Robert T. Chen, Centers for Disease Control & Prevention
	Christina L. Faust	Influence of Bivalves on the Persistence of Avian Influenza Virus in Water
	Faculty Mentor	Dr. David Stallknecht, Department of Infectious Diseases
	Melinda B. Murray	Evaluation of Direct Plating Methods to Enumerate *Alicyclobacillus* in Beverages
	Faculty Mentor	Dr. Larry R. Beuchat, Department of Food Science & Technology
Room 145	**Brian Levy**	The English-only Movement: A Critical Analysis through Comparative Study of French Language Regulation
	Faculty Mentor	Dr. Larry Nackerud, School of Social Work
	Elizabeth K. Hebbard	A Universal Language? Translation and Cultural Imperialism in the Writings of Karl Vossler and Alphonse Daudet
	Faculty Mentor	Dr. Martin Kagel, Department of Germanic & Slavic Languages

Melissa E. Whatley	The Effect of Age on Subject Doubling in French
Faculty Mentor	Dr. Diana Ranson, Department of Romance Languages
Katie Griffith	Subject Expression in Nicaraguan Spanish: An Analysis of Linguistic and Pragmatic Factors
Faculty Mentor	Dr. Diana Ranson, Department of Romance Languages

4:00 p.m. Welcome and Opening Session

Tate Student Center, Georgia Hall A

Introductions and Welcome	Dr. David S. Williams, Director, Honors Program Dr. David C. Lee, Vice President for Research Dr. Arnett C. Mace, Jr., Provost
Introduction of Prof. Fink	Douglas Jackson, CURO Summer Research Fellow and CURO Scholar
Keynote Address ***The Researcher and the Wide, Wild World of the Internet***	Prof. Conrad Fink Josiah Meigs Distinguished Teaching Professor Morris Chair of Newspaper Strategy & Management
CURO Promising Scholars	Dr. David S. Williams, Director, Honors Program
Excellence in Undergraduate Research Mentoring Awards	Dr. Arnett C. Mace, Jr., Provost Dr. Pamela Kleiber, Associate Director, Honors Program

5:00 p.m. Poster Presentations

Tate Student Center, Georgia Hall A & B

Laura M. Aikens	Self-concept Perception following Subliminal Exposure to Brand Personalities
Faculty Mentor	Dr. W. Keith Campbell, Department of Psychology
Shivan P. Bhatt	Membrane Topology Studies of Rce1p
Faculty Mentor	Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology
Kiya Birku	O-GlcNAc Modifications in Obese Mouse Models
Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology Dr. Ruth Harris, Department of Foods & Nutrition
Sarah R. Breevoort	Towards the Discovery of Ras-converting Enzyme Inhibitors: A Novel Oncogenic (Anti-cancer?) Target
Faculty Mentor	Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology

Ashley C. Burch	Developing Synchronization Protocols in Ewes
Faculty Mentor	Dr. William Graves, Department of Animal & Dairy Science
Charles P. Callihan	Sexual Selection and the Relevance of Female Choice in *Drosophila*
Faculty Mentor	Dr. Wyatt Anderson, Department of Genetics Dr. Yong-Kyu Kim, Department of Genetics
Colony C. Canady	The Role of Hispanic Media in Athens-Clarke County
Faculty Mentor	Dr. Leara Rhodes, Department of Journalism
Kevin K. Chang	Immobilization of Xyloglucan-specific Endo-β-1,4-Glucanase: Activity and Nectarin IV Inhibition
Faculty Mentor	Dr. William York, Department: Biochemistry & Molecular Biology
Chuan Cheng	Analyzing the Interactions of Acidic Matrix Polysaccharides with Cell Surface and Matrix Proteins Using Surface Plasmon Resonance
Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center
Jean Chi	Strength in Numbers: Parasite Transmission and Virulence in Monarch Butterflies
Faculty Mentor	Dr. Sonia Altizer, Institute of Ecology
Lauren Coffey	The Repression of Dissent: Multi-Group Dissident Responses to State Repression in Burma, 1980-2005
Faculty Mentor	Dr. Stephen Shellman, Department of International Affairs
Caelin A. Cubeñas	Studies of Hirano Bodies and Oxidative Stress in Neuroglioma Cells
Faculty Mentor	Dr. Marcus Fechheimer and Dr. Ruth Furukawa, Department of Cellular Biology
Kimberly B. Cunningham	Association between Infant Feeding and Body Composition
Faculty Mentor	Dr. Alex Anderson, Department of Food & Nutrition
Dilhara T. De Silva	Mechanisms of Bromide- and Bromate-induced Kidney and Liver Cell Death
Faculty Mentor	Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences
Vanessa M. del Valle	Analysis of the Self-serving Bias Using EEG
Faculty Mentor	Dr. W. Keith Campbell, Department of Psychology
Andrew M. Durso	Environmental and Ontogenetic Changes in Detection Probability of Pond-breeding Salamanders in the Georgia Piedmont
Faculty Mentor	Dr. John Maerz, Department of Forestry Research

Madeline C. Elliott	Calmodulin Activation of Estrogen Receptor α: Cloning and Expression of a Fusion Protein for Defining the Calmodulin Binding Determinants
Faculty Mentor	Dr. Jeffrey L. Urbauer, Department of Biochemistry & Molecular Biology
Christina L. Faust	Influence of Bivalves on the Persistence of Avian Influenza Virus in Water
Faculty Mentor	Dr. David Stallknecht, Department of Infectious Diseases
Yayne Fekadu	The Interaction of Natural Killer Receptor + T-cells with *Campylobacter jejuni*
Faculty Mentor	Dr. Joan O'Keeffe, Department of Biochemistry, National University of Ireland, Galway
Grant M. Fiddyment	Mathematical Computing: Exploring the Relationship between the Critical Group and Structure of Graphs
Faculty Mentor	Dr. Dino Lorenzini, Department of Mathematics
Mary B. Gassama	Investigation of the Genetic Population Structure of the Canine Hookworm, *Ancylostoma caninum*
Faculty Mentor	Dr. Ray Kaplan, Department of Infectious Diseases
Gabrielle D. Gay	Effects of 8-2 Fluorotelomer Alcohol on Gene Expression and Pregnancy Outcome in Mice
Faculty Mentor	Dr. Mary Alice Smith, Department of Environmental Health Science
Courtney Grant	An Investigation of Botulinum Neurotoxin Interactions on RhoA Activity Using *In Vitro* Assays
Faculty Mentor	Dr. Julie Coffield, Department of Physiology & Pharmacology
Sana Hashmi	Site-mapping and Glycan Characterization of Functional Alpha-Dystroglycan
Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology
Paul A. Henkel	RGS Proteins Regulate LPA Signaling in Ovarian Cancer Cells
Faculty Mentor	Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Sciences
Annie Huang	Epistatic Interactions among Long-lived *Drosophila melanogaster* Mutants
Faculty Mentor	Dr. Daniel Promislow, Department of Genetics
Margaret A. Hubbard	Magnitude of the Inverse Relationship between Nighttime Transpiration and Hydraulic Redistribution in *Quercus laevis*
Faculty Mentor	Dr. Lisa A. Donovan, Department of Plant Biology

Justin L. Hula	Taking *Clostridium thermocellum* ORFans from the ORFanage and Crystallizing Them in Search of Possible Novel Folds
Faculty Mentor	Dr. Claiborne Glover, Department of Biochemistry & Molecular Biology
Jae W. Jeon, Daniel Alvarez, Jarrad Barber	Genetic and Environmental Effects on Aggressive Behavior in *Drosophila*
Faculty Mentor	Dr. Wyatt Anderson, Department of Genetics Dr. Yong-Kyu Kim, Department of Genetics
Heather E. Johnson	Screening of Fosmid Library of Environmental Genomic DNA from Sapelo Island
Faculty Mentor	Dr. James Hollibaugh, Department of Marine Sciences
Joseph P. Johnson	DNA Recognition by a Novel Recombinase
Faculty Mentor	Dr. Anna Karls, Department of Microbiology
Sara B. Johnson	A Biotechnological Approach to Restoration of American Chestnut (*Castanea dentata*): Mass Propagation via Somatic Embryogenesis
Faculty Mentor	Dr. Scott Merkle, Department of Forestry Research
Kunal N. Kanani	Sampling Ambient Air to Test for Polycyclic Aromatic Hydrocarbons
Faculty Mentor	Dr. Geoff Smith, Department of Chemistry
John R. Killey	Diagnostic Assay for *Mycoplasma bovis* Using Immunohistochemistry
Faculty Mentor	Dr. Corrie Brown, Department of Veterinary Pathology
Aaron K. McPherson	The Influence of Muscle Length on Muscle Oxygen Saturation
Faculty Mentor	Dr. Kevin McCully, Department of Kinesiology
Natalie D. Kolleda	Tracking Continent-wide Parasite Spread in Monarch Butterflies: Launching a New Citizen Science Project, MonarchHealth
Faculty Mentor	Dr. Sonia Altizer, Institute of Ecology
Christopher H. Kragor	Synthesis and Photochemistry of 8-Cyano-7-hydroxyquinoline (CHQ): A Photolabile Protecting Group with a High Photochemical Quantum Efficiency for Biological Use
Faculty Mentor	Dr. Timothy Dore, Department of Chemistry
Aqsa Mahmud	Under the Rug Swept: Rural Punjab Women in the Ecotone of Urbanization
Faculty Mentor	Dr. Fausto Sarmiento, Department of Geography
Dakia McCray	Models of Diversity
Faculty Mentor	Dr. Victoria Plaut, Department of Psychology

John Nagao	Annotation of Cuticular Protein Genes in *Anopheles gambiae*
Faculty Mentor	Dr. Judith Willis, Department of Cellular Biology
Nithya M. Natrajan	HESX1 Mutations in Idiopathic Hypogonadotropic Hypogonadism
Faculty Mentor	Dr. Lawrence Layman, Department of Obstetrics & Gynecology, Medical College of Georgia
Victor M. Orellana	Kinetics of Inhibition of Polygalacturonases and Polygalacturonase-inhibiting Proteins
Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center
Shreyal C. Patel	Infectious Plant Pathogen: *Botrytis cinerea*
Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center
Tulsi Patel	Developing a Biocontrol Agent for Chinese Privet, *Ligustrum sinense*
Faculty Mentor	Dr. Scott Gold, Department of Plant Pathology
Daniel Perry	Metropolis Monte Carlo Simulations of Thin Ferromagnetic/Antiferromagnetic Bilayers
Faculty Mentor	Dr. David Landau, Department of Physics & Astronomy
Aaron C. Petrey	Polygalacturonase-inhibiting Proteins and Their Relationship to Polygalacturonases
Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center
Natalie M. Picchetti	Effects of Alcohol Use on Cognitive Ability
Faculty Mentor	Dr. Jennifer McDowell, Department of Psychology
Crystal Rapier	Effects of Mg/HA on Growth and Differentiation of Osteoblast Cells (Bone Cells) in a Hydroxy Apatite Scaffold
Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
Rachel M. Rarick	Migration Reduces Parasite Prevalence in Monarch Butterflies
Faculty Mentor	Dr. Sonia Altizer, Institute of Ecology
Clare H. Scott	Identifying the Source of an Introduction of Yellowfin Shiner
Faculty Mentor	Dr. John Wares, Department of Genetics
Neel N. Shah	Construction of Plasmids for Deletion of the Polyphosphate Kinase Gene in *Mycobacterium tuberculosis*
Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases
Christopher S. Sharp	Development of Leptin Resistance through High-fructose Diet
Faculty Mentor	Dr. Ruth Harris, Department of Food & Nutrition

Karin K. Sheehan	Short-term Storage of MDBK Cells
Faculty Mentor	Dr. Jeremiah Saliki, Athens Diagnostic Laboratory
Myra J. Stone	The CO-H2 Variation in Translucent Clouds at Small Scales
Faculty Mentor	Dr. Loris Magnani, Department of Physics & Astronomy
Ryan J. Summers	Characterization of the *vgat* Expression Pattern in the Developing Mouse Brain
Faculty Mentor	Dr. Brian Condie, Department of Genetics
Sonia Talathi	Calcium-independent Phospholipase A_2 Are Novel Targets for Inhibition of Prostate Cancer Cell Growth
Faculty Mentor	Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences
Christine E. Tarleton	Gene Expression Profiles of Neuronal Cells Derived from Human Embryonic Stem Cells
Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
Prince Tieku	Glycosyl Composition Analysis of *Rhizobium leguminosarum* 3841 Bacteroids
Faculty Mentor	Dr. Russell Carlson, Department of Biochemistry & Molecular Biology
Jake E. Turrentine	Parasite Strain-dependent Cariation in CD8+ T Cell Responses Is a General Characteristic of Experimental *Trypanosoma cruzi* Infection
Faculty Mentor	Dr. Rick L. Tarleton, Department of Cellular Biology
Anna Tyler	The Effect of Women as Candidates in Congressional Campaigns
Faculty Mentor	Dr. Ruthann Lariscy, Department of Advertising & Public Relations
Seychelle M. Vos	Initial Sequencing and Tissue Distribution of Toll-like 3 Receptor mRNA in White-tailed Deer
Faculty Mentor	Dr. Elizabeth Howerth, Department of Veterinary Pathology
Rachelle W. Wallace	Identification of L-PHA Reactive Glycoproteins from Invasive Breast Carcinoma Tissue: Potential Biomarkers for Early Detection
Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology
Brooke L. Wheeler	Investigation of the Horizontal Transfer of Virulence Factors of *Staphylococcus aureus* between Humans and Companion Animals
Faculty Mentor	Dr. Susan Sanchez, Athens Diagnostic Laboratory
Jasmaine D. Williams	The Broken Bridge: Discovering Why Alpha-Dystroglycan Loses Its Function
Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology

Kathryn E. Williamson	Titanium Carbide Nanocrystals: A Storage Medium for the Coming Hydrogen Economy?
Faculty Mentor	Dr. Steven P. Lewis, Department of Physics & Astronomy
Shannon F. Yu	Molecular Regulation of Parathyroid Organogenesis in the Mouse
Faculty Mentor	Dr. Nancy R. Manley, Department of Genetics
Jessica Zaleon	Lectin Histochemistry of Cell-surface Glycoproteins of the Non-pathogenic Ciliate *Tetrahymena thermophila* and the Pathogenic Ciliate *Ichthyophthirius multifiliis*
Faculty Mentor	Dr. Thomas Krunkosky, Department of Veterinary Anatomy & Radiology

6:15 p.m. Art Gallery Talks

Student Learning Center, Fourth Floor Rotunda

Introductions	Prof. Georgia Strange, Director, Lamar Dodd School of Art Ms. Nora Wendl, Gallery Director, Lamar Dodd School of Art

Visual Arts Presenters

Roman Alvarado Benitez	*Calendar: Year of the Boar 2007*
Faculty Mentor	Prof. Susan Roberts, Department of Graphic Design
Nikki Couppee	*Flavor of Jude*
Faculty Mentor	Prof. Rob Jackson and Prof. Mary Hallam Pearse, Department of Jewelry & Metalwork
Rachel Egger	*Plasse*
Faculty Mentor	Prof. Susan Roberts, Department of Graphic Design
Hsuan Ju Susan Fang	*The Marriage of Expression and Design*
Faculty Mentor	Prof. Christopher Hocking, Departments of Studio Foundations and Drawing & Painting
Comusina Celan Hardman	*The Face of Costa Rica*
Faculty Mentor	Prof. Joseph Norman, Department of Drawing & Painting
Carol M. Herbert	*NERUDA*
Faculty Mentor	Prof. Susan Roberts, Department of Graphic Design
Cassie L. Hester	*Hand to Mind Coordination*
Faculty Mentor	Prof. Susan Roberts and Prof. Alex Murawski, Department of Graphic Design

Matt Howell Faculty Mentor	*It's lonely out here* Prof. Alex Murawski and Prof. Susan Roberts, Department of Graphic Design
Kerry Jones Faculty Mentor	*Intersections* Prof. Andrea Trombetta, Department of Fabric Design
Chandler Leathers Faculty Mentor	*Soldier Series Fall 2006* Prof. Michael Marshall and Prof. Stephen Scheer, Department of Photography
Patricia Lynn Rhudy Faculty Mentor	*Conversations with God* Prof. Ted Saupe and Prof. Sun Koo Yuh, Department of Ceramics
Lindsey Thomas Faculty Mentor	*The Caddo Bateau* Prof. R. G. Brown, Departments of Sculpture and Studio Foundations
Laura Wood Faculty Mentor	*Poppy Reliquaries* and *Tissue Ring* Prof. Rob Jackson and Prof. Mary Hallam Pearse, Department of Jewelry & Metalwork

Art exhibit arranged by Ms. Nora Wendl, Gallery Director, Lamar Dodd School of Art

8:00 p.m. Dessert Reception & Awards Ceremony

Student Learning Center, Fourth Floor Rotunda

Presentation of CURO Summer Research Fellows, CURO Scholars, UGA Libraries Undergraduate Research Awards, and Best Paper Awards	Dr. David S. Williams, Director, Honors Program Ms. Florence E. King, Assistant University Librarian for Human Resources and Director, Student Learning Center Ms. Deborah Dietzler, Executive Director, UGA Alumni Association

The office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2001. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students. In 2006, the Graduate School and the Honors Program established a new award that recognizes graduate students devoted to the research mentorship of undergraduate students. Awards will be presented at the CURO Symposium Awards Ceremony on Monday, April 9, 2007 at 4:00 p.m. in the Tate Student Center, Georgia Hall A.

2007 Awards

Master Level Faculty Award
Dr. Timothy Hoover, Associate Professor of Microbiology
Early Career Faculty Award
Dr. Steven Stice, Professor of Animal & Dairy Science

2006 Awards

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Associate Professor of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Professor of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD student in Plant Biology

2005 Awards

Faculty Awards
Dr. Gary Barrett, Odum Professor of Ecology
Dr. Sidney Kushner, Professor of Genetics
Department Award
Department of Cellular Biology

2004 Award

Faculty Award
Dr. William S. Kisaalita, Associate Professor of Biological & Agricultural Engineering

2003 Awards

Faculty Award
Dr. Jody Clay-Warner, Assistant Professor of Sociology
Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator
Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Professor
Dr. Marie-Michèle Cordonnier-Pratt, Senior Research Scientist

2002 Awards

Faculty Awards
Professor William D. Paul, Jr., Professor of Art
Dr. Katherine Kipp, Associate Professor of Psychology
Faculty Recognition
Dr. Susan Sanchez, Assistant Professor of Veterinary Medicine
Department Award
Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head
Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Professor of Physics and Astronomy
Dr. Heinz-Bernd Schuttler, Professor and Department Head of Physics and Astronomy
Dr. Jonathan Arnold, Professor of Genetics
Dr. Susmita Datta, Professor, Georgia State University
Dr. David Logan, Professor, Clark Atlanta University
Dr. William Steffans, Professor, Clark Atlanta University

2001 Awards

Faculty Award
Dr. Marcus Fechheimer, Professor of Cellular Biology
Faculty Recognition
Dr. David MacIntosh, Associate Professor of Environmental Health Sciences
Dr. Dean Rojek, Associate Professor of Sociology
Department Award
Genetics Department
Dr. John MacDonald, Department Head and Professor
Program Award
Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

Thanks and Acknowledgements

Graduate Student Reviewers for CURO 2007 Symposium

Chris Bennett	Computer Science
Sarah Craven	Microbiology
John M. Davis	Ecology
Geneva DeMars	Biochemistry & Molecular Biology
Matt First	Marine Sciences
Ivy Holliman	History
Mary Johnson	Forestry & Natural Resources Management
Lisa Kanizay	Plant Biology
Maria Ruth Martinez Rodriguez	Anthropology
Anna McKee	Forestry & Natural Resources Management
Rebecca Nordin	Educational Psychology
Greta Polites	Management Information Systems
Semmy Purewal	Computer Science
Sarah Reiff	Cellular Biology
Jane Shevtsov	Ecology
Chip Small	Ecology
Sara Steger	English
James Tucker Swindell II	Biochemistry

Reviewers for Best Paper Awards

Caroline Barratt	Reference Librarian, UGA Libraries
Dr. Brian Cummings	Assistant Professor, Pharmaceutical & Biomedical Sciences
Dr. Christy Desmet	Associate Professor, English
Dr. Jay Hakes	Director, Jimmy Carter Library & Museum
Diana Hartle	Reference Librarian, UGA Libraries
Dr. Margaret Holt	Professor Emerita, Adult Education
Dr. Sylvia Hutchinson	Professor Emerita, Language & Literacy Education and Institute of Higher Education
Greta Polites	Graduate Student, Management Information Systems
Deb Raftus	Reference Librarian, UGA Libraries
Dr. Dawn Robinson	Associate Professor, Sociology
Jill Severn	Reference Librarian, UGA Libraries
Dr. Fran Teague	Meigs Professor, English
Elizabeth White	Reference Librarian, UGA Libraries

Reviewers for Excellence in Undergraduate Research Mentoring Awards

Dr. Sheila W. Allen	Dean and Professor, College of Veterinary Medicine
Dr. Marcus Fechheimer	Professor, Cellular Biology, Franklin College of Arts & Sciences
Dr. Kecia M. Thomas	Interim Director, Institute for African America Studies; Professor, Psychology, Franklin College of Arts & Sciences

Reviewers for CURO Summer Research Fellowships

Dr. E. M. (Woody) Beck	Professor, Sociology
Dr. Diane Bates Morrow	Associate Professor, History and African-American Studies
Dr. Fran Teague	Meigs Professor, English
Dr. Daniel Promislow	Professor, Genetics
Dr. Jean Martin-Williams	Professor, Brass
Dr. Rodney Mauricio	Associate Professor, Genetics
Dr. Loris Magnani	Professor, Physics & Astronomy
Dr. Regina A. Smith	Associate Vice President for Research

CURO Advisory Board

Dr. Wyatt Anderson	Alumni Foundation Distinguished Professor, Genetics
Dr. E. M. Beck	Professor, Sociology
Dr. Gary Bertsch	Director and University Professor, Center for International Trade & Security
Dr. Margaret K. Cramer	Physician, University Health Center Women's Clinic
Dr. Art Dunning	Vice President for Public Service and Outreach
Dr. Maureen Grasso	Dean, Graduate School
Dr. David C. Lee	Vice President for Research and Associate Provost
Dr. Barbara McCaskill	General Sandy Beaver Teaching Professor, English
Prof. Jere Morehead	Vice President for Instruction
Dr. David Saltz	Department Head and Associate Professor, Theatre & Film Studies

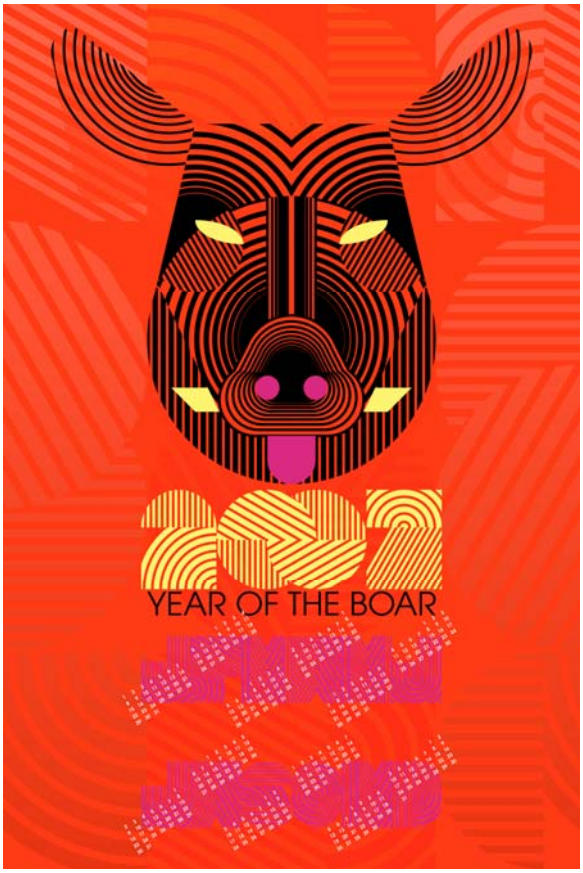
Self-concept Perception Following Subliminal Exposure to Brand Personalities

Laura M. Aikens – CURO SCHOLAR
Dr. W. Keith Campbell, Department of Psychology, University of Georgia

Marketing research has concluded that brand name products can be rated on five personality dimensions: sincerity, ruggedness, competence, excitement, and sophistication. An extension of this work has shown that following an interaction with products possessing certain brand personalities, individuals rated themselves higher on related dimensions. Furthermore, psychological research has shown that the self-concept can be influenced by unconscious sources. The goal of the present research was to examine the effect of implicit exposure to brand personalities on self-concept. We hypothesized that subliminal exposure to brands from one dimension will increase the cognitive accessibility of related personality characteristics. This research may aid in understanding the influence of commercialized media on personality. In Study 1, participants were primed with the names of either sincere brands (e.g. Hallmark) or rugged brands (e.g. NorthFace). To assess if this priming affected self-concept, participants were presented with adjectives and asked to decide if the word described them or not. In Study 2, participants were tested on various dispositional attributes including self-monitoring and materialism. The rest of the procedure was the same as Study 1 except brand logo primes replaced brand word primes. Results of Study 1 indicated that participants primed with sincere brand names more often described themselves as "sincere." Results for Study 2 indicated that dispositional materialism affected self-description after priming. Overall, these results suggested that self-concept can be influenced by brand names, but further research in necessary to fully understand the relationship.

Calendar: Year of the Boar 2007

Roman Alvarado Benitez
Prof. Susan Roberts, Department of Graphic Design, University of Georgia



Graphic Design differs from Fine Art primarily in the immediacy of its communication. Although subtlety is a great asset and is often employed in my own designs, my goal is usually to communicate efficiently. This calendar was designed for self-promotional purposes and employs the simple idea that 2007 is a year of the boar in Chinese astrology. The more important aspects of this poster are the influences of modernist and pre-Hispanic American design. My goal was to create a composition that showcased the essential geometry of an image and entertained the viewer without excessive decoration. The primary image was first abstracted free-hand from a photograph. The resulting image was scanned and imported into Adobe Illustrator where it was further simplified. The striations were added last and

are meant to follow the planes of the original image.

Epson Ultrachrome Ink on coated paper

Small Emergencies: Poems
Alisan J. Atvur – CURO SCHOLAR
Dr. Ed Pavlic, Department of English, University of Georgia

The original poems found in my creative thesis entitled *"The Bored Orderly: Poems"* are the result of two years of research in the field of modern American and Polish poetry. My research advisors are Dr. T.R. Hummer, nationally renowned poet and essayist, and Dr. Katarzyna Jerzak, associate professor of comparative literature at the University of Georgia. My thesis is a result of my fascination with the limpid, intelligent verse of Polish poets Wisława Szymborska and Zbigniew Herbet as well as American poets Carl Dennis and Tony Hoagland. The concern of my poetry is foremost the lucidity of well-crafted verse. Though my poems do not share a common theme or subject, many of the poems tackle the psychosis of the modern flâneur. The elegiac voice of many of the poems is a result of having lost several women in my life in the past six years. Works that most directly influenced the poems found in my thesis include Carl Dennis' *Practical Gods*, Wisława Szymborska's *Collected Poems*, Donald Hall's *Without*, Tony Hoagland's *What Narcissism Means to Me*, David Kirby's *Saving the Young Men of Vienna*, Rodney Jones' *Salvation Blues*, T.R. Hummer's *The Angelic Orders* and William Matthew's *Search Party*. As my interdisciplinary degree involves poetry, writing and education, the presentation of my thesis will consist of the reading of several of my poems punctuated with a discussion on my editing positions with the *Georgia Review* and the *Chattahoochee Review* and my research in introducing poetry to younger audiences.

The Influence of Parental Attitudes on Children's Gender Toy Preference
Crystal Barber, Kimberly Kite, Toni McCranie, LaToya Jones & Shananikia Marshall
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Parental influence on toy preferences is evident for children as young as two years of age. The communication between the parents and their children during play is crucial to the development of the children's gender identities. Existing literature addresses how parents interact with their children according to each child's gender. However, parental gender attitudes and their influence on the development of children's preferences for gender-specific toys were not explored in previous studies. The benefit of examining parental attitudes is to aid our understanding of children's development of stereotypical or neutral gender behaviors. The current study surveyed parental attitudes towards gender, their observations of children's toys selections, and the toys they would purchase for their children. Children's toy preferences were assessed through interviews and real toy selection at school. Surveys were sent to parents of 62 children, between the ages of three and four. The preliminary data based on 35 returned surveys showed that parental gender attitudes were consistent with children's selection of gender specific toys. Mothers reported stronger gender stereotypical attitudes toward boys' choices of toys than fathers. Additional data analyses and results will be discussed at the conference. Further analysis is underway to determine the trend in larger data sets.

Analysis of Why RNase P Is Essential for Cell Viability in *Escherichia coli*
Liron Bar-Peled – CURO SCHOLAR
Dr. Sidney Kushner, Department of Genetics, University of Georgia

In *Escherichia coli* there are eight genes that encode tRNALeu, including leuU, which has been suggested to be essential for cell viability. LeuU encodes tRNALeu2, the tRNA that recognizes the leucine codons CUU and CUC.

In the *E. coli* chromosome, leuU is part of an operon, composed of itself and a protein-encoding gene, secG. Although the function of encoded leuU tRNA is well characterized, how it is processed into a mature tRNA is not well understood. However, two essential endoribonucleases, RNase E and RNase P, have been shown to be required for maturation of tRNAs. After verifying that the leuU gene was essential for cell viability, we hypothesized that if RNase P were required for generation of the mature of tRNALeu2, we might be able to suppress the lethality associated with the loss of RNase P by providing tRNALeu2 exogenously. Accordingly I constructed a plasmid in which the leuU gene was transcribed from an inducible promoter and would not require RNase P for its maturation. This plasmid was found to complement a leuU deletion strain but not a temperature sensitive RNase P mutant. The results suggest that the enzyme's essential function is not confined to the production of a single tRNA species.

Bollywood Fusion
Hariqbal Basi
Prof. Bala Sarasvati, Department of Dance, University of Georgia
Dr. Pamela Kleiber, Honors Program, University of Georgia

Bollywood Fusion is a compilation of a variety of music and choreography, both traditional and modern, with Indian influence. The piece begins with traditional pieces of music, to which I perform a knife dance wearing more traditional attire. This music has more subtle beats, played with traditional and basic sounds accented by drums. Towards the middle of the performance, the music changes to a remix of modern, westernized music complementing the traditional Indian singing. This demonstrates not only the westernization of modern Indian music but also the impact of the East on western pop-culture, since this section of music was actually taken from a Hollywood soundtrack (Moulin Rouge). The latter part of the dance is indicative of what would be found in a modern Bollywood film. This demonstrates the westernization of Bollywood and how Indian songs and choreography in modern films now incorporate modern, "electric" sounds and dance moves. The title of the piece reflects India's film industry (Bollywood) and the "fusion" of western and eastern culture. The flow of the piece from traditional to modern demonstrates the progressive introduction of "fusion" elements in the music and dancing and the gradual blending of cultures, becoming increasingly apparent through the performance.

Membrane Topology Studies of Rce1p
Shivan P. Bhatt – CURO APPRENTICE
Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

A CaaX protein possesses the CaaX tetrapeptide structural motif: a C-terminal sequence comprised of the amino acid cysteine (C), two aliphatic amino acids (aa), followed by any amino acid (X). CaaX proteins fulfill important cellular processes such as signaling (Ras, Rac, RhoB), protein folding (Hsp chaperones), and fungal mating (*Saccharomyces cerevisiae* a-factor). This study focuses on Ras converting enzyme (Rce1p), an ER-localized membrane protease involved in the activation of the Ras signaling molecule. Ras is an important CaaX protein because hyperactive mutants of Ras are common in cancerous cells. Consequently, investigation of Rce1p membrane topology may assist in designing novel anti-cancer therapeutics. This study assessed fusions of a SUC2/His4C dual activity topology reporter attached to the C-terminus of 15 variously sized truncations of Rce1p. These Rce1p fusions were assessed for their glycosylation status after treatment with Endoglycosidase H and growth status on media containing histidinol. Reliable topology predictions for 10 fusions were included in the final assessment of Rce1p membrane topology. These topology predictions 1) provide empirical evidence for the existence of at least 7 Rce1p transmembrane spans and 2) highlight ambiguous regions of the protease as a focus for future topology studies.

A Genetic Exploration of Causal Factors Underlying Differential Recruitment Patterns in Chilean Barnacles

John C. Binford – CURO SCHOLAR
Dr. John Wares, Department of Genetics, University of Georgia

Recent studies have revealed a shift in the recruitment pattern of barnacles and mussels occurring at 32°-33° South latitude along the Chilean coastline. Populations north of this demarcation are characterized by decreased density and low recruitment rates compared to populations south of this proposed break. The objective of this project is to understand the dynamics of planktotrophic species, and, in turn, obtain a more holistic visualization of the marine communities along the South American coastline. The cause of these recruitment patterns is hypothesized to stem from the presence of selection factors or effects of physical oceanography. In order to distinguish between these two causes, we sequenced a 710 base pair fragment of the Mitochondrial Cytochrome Oxidase 1 gene in two species of barnacles, *Notochthamalus scabrosus* and *Jehlius cirratus*, in order to understand the nature of the gene flow present in these populations. Samples were obtained from six sites, including locations both north and south of the proposed ecological break. Statistical and phylogenetic analysis evidenced notably different patterns of genetic structure in each species. In *N. scabrosus*, genetic difference between northern and southern populations links recruitment rate and genotype, whereas *J. cirratus* is characterized by panmixia. The two species' different genetic structures reveal physical oceanography as an improbable primary cause of these recruitment patterns. Instead, it appears site-specific selection is partially driving the pattern in *N. scabrosus*. It is our hope that conservation efforts will be aided with this information, and nuclear genes are currently being analyzed to accompany this data.

O-GlcNAc Modifications in Obese Mouse Models

Kiya Birku
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia
Dr. Ruth Harris, Department of Food & Nutrition, University of Georgia

Non-insulin dependent diabetes (type II diabetes) has recently become the leading cause of new cases of blindness in the United States as a result of retinal cell decay due to glucose toxicity. Contrary to the influential role that type II diabetes plays in today's society, the genesis of this epidemic has yet to be determined. However, it has been suggested that type II diabetes is an adaptation to nutrient excess and low energy expenditure. O-linked β-N-acetylglucosamine (O-GlcNAc) is a post-translational modification of intracellular proteins and is a proposed glucose sensor that mediates signal transduction cascades based on the metabolic state of the cell. Studies have shown that elevated levels of the O-GlcNAc modification on intracellular proteins induces insulin resistance, the distinguishing characteristic of type II diabetes, measured by glucose uptake in response to acute insulin stimulation. Testing for the abundance of O-GlcNAc modified proteins and the cycling enzymes in different organs of *db/db* K/O mice that are obese, leptin-and insulin-resistant will help us understand the relationship between O-GlcNAc and the diabetic state of the whole animal. Global O-GlcNAc levels, as well as the abundance of the cycling enzymes, will be evaluated in K/O and wt mice organs using western blot analysis.

Towards the Discovery of Ras-converting Enzyme Inhibitors: A Novel Oncogenic (Anti-cancer?) Target

Sarah R. Breevoort – CURO SUMMER RESEARCH FELLOW
Dr. Walter K. Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

The ultimate implication of this long-term project is the isolation of possible inhibitory compounds, which could potentially be developed as anti-cancer drugs. The proteases Rce1p and Ste24p promote a proteolytic step associated with the maturation of proteins containing a CaaX motif, where C is a cysteine, a is typically a small aliphatic amino acid, and X is one of several amino acids. Rce1p in particular is considered a chemotherapeutic target because of its crucial role in the maturation of Ras oncoproteins. Hyperactive forms of Ras are commonly associated with cancer, and thus inhibiting Ras maturation is proposed to disable, or at least moderate, its oncogenic activity. Because of the critical role Rce1p has in Ras processing, compounds that inhibit Rce1p would be lead candidates for a therapeutic drug. In this study, the inhibitory profiles of the Rce1p and Ste24p CaaX proteases using peptidyl(acyloxy)methyl ketones(AOMKs) and inhibitors identified by high throughput screening (HTS) are compared. It is concluded that AOMKs, although displaying better inhibitory properties than certain previously reported Rce1p inhibitors, are unlikely candidates for therapeutic drugs due in part to an inability to enhance potency. Nevertheless, several instances of selectivity for one CaaX protease over the other exist, which makes these compounds effective tools for investigating CaaX protease enzymology. The inhibitory profiles of compounds identified by HTS and their analogs are also evaluated and several appear to be potent Rce1p inhibitors. These compound analogs are farnesyl mimics, and are hypothesized to inhibit Rce1p activity by blocking the farnesyl binding pocket of the enzyme necessary for proteolysis of the substrate. These studies suggest that although AOMKs are unlikely drug candidates, certain farnesyl mimics are potent CaaX protease inhibitors that could be potentially developed as anti-cancer drugs.

Katanin Plays a Role in Microtubule Dynamics and Ciliary Assembly in *Tetrahymena thermophila*

Jessica M. Bryant – CURO SCHOLAR
Dr. Jacek Gaertig, Department of Cellular Biology, University of Georgia

The cytoskeleton is a dynamic structure that provides cell shape, motility, protection, organization, and division. Little is known about the *in vivo* regulation of the cytoskeleton, but it has been suggested that microtubule-severing proteins may play an important role in cytoskeleton dynamics. Katanin is an AAA ATPase microtubule-severing protein with a catalytic subunit, p60, and a non-catalytic subunit, p80. In order to study katanin's role in the ciliate *Tetrahymena thermophila*, a heterokaryon gene knockout was performed for each gene encoding a different subunit of katanin and the phenotypes were analyzed using immunofluorescence and electron microscopy. *Tetrahymena* has two genes that encode p60, KAT1 and KAT2, and one gene that encodes p80, KAT3. Cells lacking *Kat2p* appeared normal, while cells lacking either *Kat1p* or *Kat3p* showed multiple arrests in cytokinesis and had short, immotile cilia that lacked central pairs. This finding is supported by a previous experiment where flagella of *Chlamydomonas* lacking p80 lacked a central pair. *Kat1p* and *Kat3p* thus require each other for proper function of katanin. Cells lacking *Kat1p* or *Kat3p* also showed long, stable, acetylated microtubules in the cell body and long cortical microtubules, causing the mutants' arrest in cytokinesis, which suggests that *Kat1p* and *Kat3p* are required for microtubule-severing activity in the cell body of *Tetrahymena*. In addition, although assembly of basal bodies was normal in cells lacking *Kat1p* or *Kat3p*, assembly of cilia did not occur at every basal body, and cilia that were assembled were very short and lacked central pairs, rendering cells

immobile. This finding suggests that *Kat1p* and *Kat3p* also play a role in ciliogenesis. If further tests confirm a direct role of katanin in intraflagellar transport, this protein could be used to study ciliary diseases such as polycystic kidney disease.

Developing Synchronization Protocols in Ewes

Ashley C. Burch
Dr. William Graves, Department of Animal & Dairy Science, University of Georgia
(Ashley C. Burch, Dr. Clay Lents, Dr. William Graves, Joseph Durham)

Synchronizing estrus can increase reproductive efficiency of livestock. Information regarding estrus synchronization of sheep in the southeastern United States is lacking. The objective of this study was to compare two synchronization protocols under natural service conditions. On day -6 ewes were randomly assigned to one of the two treatment groups (n = 18 per group). Ewes in (PGF) on day -6 and -1. Ewes inαgroup 1 received 10 mg of prostaglandin F2 g of gonadotropin-releasing hormone on day -6 and on dayμgroup 2 received 100 0. Group 2 also received 10 mg of PGF on day -1. Plasma obtained from blood was collected on days -6, -1, 0 and 1. Plasma concentrations of progesterone were determined by radioimmunoassay (RIA). Treatment groups were replicated in two pastures using a single ram in each pasture. Each ram was raddled with paint crayons fitted to a harness, and estrus was determined by checking ewes daily for paint marks during the following 42 days of the breeding season. More ewes were in estrus earlier in group 1. Sixteen of the animals in group 1 became estrus during the first two weeks of the breeding season compared to 10 animals in group 2. Seven additional animals in group 2 became estrus in the third week of the breeding season. Lambing data is currently being collected. We conclude from these preliminary results that two injections of PGF 7 days apart are effective for estrus synchronization in sheep in the southeastern United States.

Construction of and Use of GAUT1 and GAUT7 Reporter Gene Constructs to Study GAUT1 and GAUT7 Transcriptional Activity in Plants

Amy J. Burrell
Dr. Debra Mohnen, Department of Biochemistry & Molecular Biology, University of Georgia

Pectin is a family of polysaccharides present in the cell wall of all plants. Pectin has many biochemical properties that contribute to plant growth and development. Homogalacturonan galacturonosyltransferases (GalATs) are enzymes that catalyze the transfer of galactosyluronic acid (GalA) residues from uridine diphosphate-GalA (UDP-GalA) to a growing pectic polysaccharide chain. One proven and one putative *Arabidopsis* GalAT, namely GAlactUronosylTransferase1 and 7 (GAUT1 and GAUT7), were recently co-identified through a proteomic approach using partially-purified, detergent-solubilized *Arabidopsis* membrane protein preparations. The objective of this project is to analyze where within the plant the GAUT1 and GAUT7 genes are expressed, with the goal of understanding the biological function of these genes in pectin synthesis. This will be accomplished through utilization of a reporter gene system known as β-Glucuronidase (GUS), which will be driven by the promoter regions of the GAUT1 and GAUT7 genes. The promoter regions of GAUT1 and GAUT7 have been amplified from genomic DNA of *Arabidopsis thaliana* suspension culture cells and inserted into the cloning vector pGEM-T-Easy. The sequences of the promoter regions are currently being verified by DNA sequencing. Upon verification of the sequences, the promoter regions will be removed from pGEM-T-Easy and inserted upstream of the GUS gene in the vector pBI101. The pBI101 vector harboring the promoter:GUS constructs will be transformed into *Arabidopsis thaliana* plants for analysis of the tissue and cell-type specific expression of each GAUT gene. The results of these studies will be reported and discussed in relation to the functions of GAUT1 and GAUT7 in pectin synthesis in *Arabidopsis*.

Sexual Selection and the Relevance of Female Choice in *Drosophila*

Charles P. Callihan
Dr. Wyatt Anderson and Dr. Yong-Kyu Kim, Department of Genetics, University of Georgia

The mate selection process depends upon the responses of females to various male cues. In this experiment, isofemale lines, wild-caught lines that have been individually maintained in captivity, of Drosophila were used to test the null hypothesis that Drosophila females randomly mate among males with the goal of understanding the process of mate selection, and in turn, the evolution of Drosophila. To test the prediction that mate selection in Drosophila is not random, virgin females were added to a clear glass cage with 14 marked males and were observed daily for five consecutive days. After copulation, the male was identified, and the number of mating events per male was scored. Prior studies have shown that 10% of males mated multiple times while 20% never mated; and that cuticular hydrocarbons were involved in selective mating. The results suggest that there is variation in mating success among males, cuticular hydrocarbon characteristics could indicate vigor and status, and that Drosophila females mate non-randomly. Beneficial genes are passed on to the next generations and, as a result, gene frequency will be changed in populations.

The Role of Hispanic Media in Athens-Clarke County

Colony C. Canady – CURO APPRENTICE
Dr. Leara Rhodes, Department of Journalism, University of Georgia

A growing Hispanic population in the Athens community raises the question of whether the Hispanic community is able to attain adequate community information in both their native Spanish language, as well as English. The Athens community's operation of only four Spanish-language sources, primarily radio stations, creates the need for a more diverse source of community information directed to this growing Hispanic community. This research presents the results of an analytic study on the importance and need for community-based media for the Hispanic media consumer in Athens-Clarke County through the analysis of local Hispanic media and the proposed development of a Spanish-language television program. To investigate the necessity of Hispanic community media in the Athens community, literature reviews were conducted, in which connections were made with previous research on related topics. Individuals participating in the proposed development of the Spanish-language television program in Athens and various members of the Athens community, including Grady College professors and community leaders, were then interviewed. Ultimately, a Hispanic newsletter was developed and disseminated to Hispanic members of the Athens community. Results suggest that community-based organizations, such as television programs and Hispanic publications, play a critical role in advancing the socioeconomic status of Hispanics and affording them the opportunity to feel included in the community, which can in turn, promote community relations and most importantly create a public sphere for information this community needs in order to make informed decisions within the community. Due to the closing of one Hispanic media source in Athens-Clarke County, Eco Latino Magazine, and the failure of the proposed television program, my research included an applied project based on the completed research of how Hispanics use media and the importance of Hispanic media. A newsletter, representing one aspect of the Hispanic community, was developed and in turn, was distributed by Sister Margarita of Oasis Católico to the Hispanic community of Athens and served as much needed source of current issues while promoting community relations.

Immobilization of Xyloglucan-specific Endo-β-1,4-Glucanase: Activity and Nectarin IV Inhibition

Kevin K. Chang
Dr. William York, Department of Biochemistry & Molecular Biology, University of Georgia

Xyloglucan is a highly branched, hemicellulosic polysaccharide present in the primary cell walls of vascular plants. Xyloglucan cross-links cellulose microfibrils in these walls, forming a dynamic network that expands in a controlled, oriented fashion, thereby regulating cell growth. Some plant pathogens secrete an enzyme known as xyloglucan-specific endo-β-1,4-glucanases (XEG) that specifically hydrolyzes xyloglucan chains. Xyloglucan-specific fungal endoglucanase inhibitor protein (XEGIP) is the only plant protein that has been shown to inhibit fungal endoglucanases and may play a key role in the plant's defense against fungal pathogens. Plant nectar contains an XEGIP ortholog called Nectarin IV (or NEC4), which binds to the fungal XEG, inhibiting its hydrolytic activity, thereby protecting the plant cell wall from enzymatic attack. The purpose of this study is to characterize immobilized XEG prepared by biotinylating the enzyme and binding it to magnetic beads. Catalytic activity of the immobilized XEG was demonstrated by the *p*-hydroxybenzoic acid hydrazide (PAHBAH) assay, which gives a colored product in the presence of reducing ends produced when the xyloglucan substrate is hydrolyzed. Reactions were also performed in the presence of NEC4 from tobacco nectar, showing that NEC4 binds to the immobilized XEG and inhibits it. The XEG-coated beads provide an experimental system for future experiments designed to bind, identify and isolate XEGIP orthologs and other plant proteins, including putative multiprotein aggregates, that are involved in the plant's resistance to microbial pathogens. Identification of such aggregates would provide invaluable insight into the mechanisms by which plant and animal cells defend themselves from pathogens.

Analyzing the Interactions of Acidic Matrix Polysaccharides with Cell Surface and Matrix Proteins Using Surface Plasmon Resonance

Chuan Cheng
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

Glycosaminoglycans (GAGs) are naturally occurring, heterogeneous, negatively charged, and N- acetylated, unbranched polysaccharides. GAGs in the extracellular matrix have been extensively studied and contribute to the general structure and permeability properties of connective tissues. Pectins are acidic polysaccharides that are primary structural elements of the matrix of the plant cell wall, serving functions similar to GAGs within their respective organisms. Surface plasmon resonance (SPR) biosensors measure the mass concentration of biomolecules close to the surface of a sensor chip that is coated with a macromolecule such as a protein or carbohydrate (the ligand). Samples containing an analyte are passed over the bound ligand and the level of interaction (translating into a biomolecular mass concentration change) is proportional to the level of refraction of laser light that shines onto the sensor surface. The laser refraction increases with the interaction between ligand and analyte and these changes are used to analyze the binding affinity and kinetics of the interaction. SPR is an ideal tool with which to measure the interactions of various cell surface and/or extracellular proteins with pectins and GAGs. Here we describe the development of an appropriate method for binding the pectin or GAG to the surface of the SPR chip to allow the study of this important class of interactions. Data from such studies will further our understanding of pectins' implications in morphogenesis, wall permeability, and plant defense, and GAGs' implications in binding of pathogens to particular target cells, maintenance of cellular activities, and development of metastasis in cancer cells.

Indigenous Use of Medicinal Plants and Herbs by the Pavacachi Community of the Ecuadorian Region of the Amazon Rainforest
Disha Chhabra – CURO SCHOLAR
Dr. James Affolter, Department of Horticulture, University of Georgia

The Pavacachi community is an indigenous settlement on the shore of the River Curaray, in the heart of the Amazon rainforest of Ecuador. The community has a long history of subsisting on herbs and plant flora for primary health care. Ethnobotanical data were gathered over a four week period in which I lived within the community and interviewed two elders of the community, Alberto and Raul. The goals of this project included the scientific identification and classification of plants used by the community through visual identification of pictures taken in the forest. Also, I recorded the local names, uses, and modes of preparation of these medicinal plants. Finally, I performed a critical survey of medicinal plants in use in Ecuador today and analyzed how the Pavacachi pharmacopoeia fits within this larger context. Through this project, I documented data on more than thirty medicinally relevant plants that have been passed down the generations of the Pavacachi community and identified their place in the literature on the medicinal plants of Ecuador as a whole.

Strength in Numbers: Parasite Transmission and Virulence in Monarch Butterflies
Jean Chi
Dr. Sonia Altizer, Institute of Ecology, University of Georgia

The protozoan parasite, Ophroycystis elektroscirrha, infects monarch butterflies (Danaus plexippus). Parasite infection reduces fitness and longevity in monarch butterfly hosts, with higher parasite loads resulting in shorter host life spans. Because high infection levels (i.e. high parasite density) cause high virulence within the host, we tested if high infection loads are also advantageous to the parasite through increased transmission. Monarch larvae were infected with various doses of parasites and reared to adulthood, and parasite spores on milkweed leaves and eggs were counted. Results showed that heavily infected monarchs transmitted more spores onto leaves and eggs than lightly infected monarchs. When females laid eggs, they also transmitted more spores onto leaves than when they did not lay eggs. Spore counts taken from two dates did not significantly differ, suggesting that once a host is infected, the parasite can be transmitted over a certain time interval without decreasing in number. These results suggest that parasites require a high level of infection to transmit most effectively, and that host health deterioration is an unavoidable cost to parasite survival. This study supports a long held theory in evolutionary biology that parasite virulence can evolve as a trade-off of parasites optimizing their fitness.

Metrical Dissonance in Robert Schumann's Op. 39
Mark J. Chilla
Dr. John Turci-Escobar, Department of Music Theory & Composition, University of Georgia

Robert Schumann’s (1810-1856) Eichendorff "Liederkreis," Opus 39, is a cycle of twelve songs rich in musical complexity particularly in regard to rhythm, but lacking in overall unifying themes. Music theorist Harald Krebs has written several scholarly articles and books concerning rhythmic complexities, which he has referred to as “metrical dissonance.” With his analyses of Schumann’s music, he often favors the metrical dissonances of his piano music to that of his vocal music. Through analysis of the songs highly syncopated areas using the techniques set forth by Krebs, the paper will highlight the metrical dissonances of Schumann’s "Liederkreis" and show how the rhythmic complexities heighten the musical and extramusical expression. According to Krebs’ theories, metrical dissonances occur either as displaced accents or as unequal grouping layered upon each other. In the "Liederkreis," the dissonances can occur without any kind of direct textual connection, as in the piano postludes for many of the songs. However, how these metrical dissonances coincide with the text is of

particular interest. A striking dissonance can occur at a crucial textual point, providing "word-painting." Also, Schumann employs dissonances that occur over the course of an entire song, which helps to reflect the overall emotional effect. Highlighting the rhythmic complexities helps to clarify the music and text relationship while unifying the entire song cycle.

National Geographic Magazine: What Gets Covered Around the World?

Katherine B. Church
Dr. Leara Rhodes, Department of Journalism, University of Georgia

Once thought to be merely marketing tools, recent research has shown that magazine covers may be cultural artifacts which record a society's values and norms. To examine the role of magazine covers, a content analysis based on Sumner's methodology was conducted on five representative European editions of the National Geographic Magazine over a four-month time period (n=24). The investigation compared the European editions to one another and to the English-language original. All of the covers were analyzed according the type (human, animals, manmade objects, landscape, or nature) and theme (political nature, geographic scope, and scientific focus). It was hypothesized that the covers of the international editions, whose circulation relies predominantly on newsstand sales, would exhibit more of Sumner's five marketing tools than the covers of the English edition, whose circulation is mainly subscription-based. It was surmised that the international editions must appeal to a broader consumer-base, demonstrating more marketing tactics, whereas, the English edition could target a more narrow subscription-base. Despite a greater dependency on newsstand sales, the investigation showed that the international covers retained a quality of cultural distinctiveness, as determined by a literature review of cross-cultural communication, and were distinct from the English original. The inconsistency in results across geography and time demonstrates that magazine covers do indeed act as cultural artifacts. Therefore, magazine covers play a more influential social role than industry professionals believe. This study's results show that magazine covers have the power to preserve individual cultures despite the globalization of the media industry.

The Role of Non-resident Indians in Promoting U.S.-India Strategic Rapprochement

Benjamin T. Cobb
Dr. Seema Gahlaut, Center for International Trade & Security, University of Georgia

On December 8, 2006, the United States House of Representatives, in an overwhelming 330-59 vote, approved Senate amendments to House Resolution 5682, solidifying the Bush administration's historic deal to legalize nuclear trade with India. This legislation represents the recent culmination of six years of rapprochement strategy pursued by the White House. Bilateral convergence has been driven by a range of issues including security/terrorism, defense relations, trade, and technology security. While the sustained political effort in recent years has attracted international media attention, little credit has been given to the Indian-American community, whose efforts have doubtlessly played a critical role in fostering U.S.-India bilateral cooperation. This study provides a critical analysis of the Indian-American community's recent organized political efforts, unveiling successes and shortcomings in promoting U.S.-India strategic rapprochement. Special attention is granted to the U.S.-India Political Action Committee and the U.S.-India Business Alliance, which represent the interests of the nearly two million Indian-Americans to decision makers in both countries. To dissect this highly organized, complex lobby, the demographics of the Indian-American community are briefly discussed before outlining the historical rise of Diaspora politics. By highlighting the causes of political mobilization, the manifestations of political organization are better understood. This study also addresses a recent shift in Indian governmental policy, whereby the diasporic community has newfound leverage and support in promoting bilateral convergence.

The Repression of Dissent: Multi-Group Dissident Responses to State Repression in Burma, 1980-2005

Lauren Coffey – CURO SUMMER RESEARCH FELLOW
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

My study seeks to explain dissident group responses to repressive governments. My study focuses on the repressive State Law and Order Restoration Committee (SLORC) or State Peace and Development Council (SPDC) regime of Burma/Myanmar and various dissident groups' responses to the regime. The SLORC regime took power in 1989 and is known for its harsh repressive policies. Numerous dissident groups including the All Burma Students Democratic Front (ABSDF), the Karen National Union (KNU) and Khun Sa's Mong Tai Army (MTA) exist in opposition to the regime. I seek to explain the behavioral relationships between the militant groups and the government by focusing on their day-to-day behavioral exchanges of conflict and cooperation. Primary data has been obtained from a search of English-language news reports through LexisNexis. The dataset generated from these news reports will be coded to generate multi-actor political event data. The project then employs several difference of means tests to determine how government repression affects the substitution of tactics by rebels over time. Specifically, the project compares the mean of each rebel group's behavior prior to repressive activities of the state and determines whether or not state repression succeeds at decreasing the mean hostile activities of each group. I expect to find that, once disaggregated, the multiple dissident groups will respond to the repressive activities of the state in a variety of ways. While some of the groups may meet state repression with increased levels of resistance, other dissident groups may offer their cooperation to the state. Traditional research on militant group responses to repressive regimes may be flawed and their statistical estimates biased since they aggregate all dissident groups' actions towards the state into a single variable. One of the aims of my research is to determine whether the practice used in previous research projects of aggregating all groups together influences the inferences we draw from statistical studies.

Flavor of Jude

Nikki Couppee
Prof. Rob Jackson and Prof. Mary Hallam Pearse, Department of Jewelry & Metalwork, University of Georgia

This piece is based on my interest in the portrayal of Catholic Saints, Byzantine mosaics and contemporary cult figures. In *Flavor of Jude,* Saint Jude is transformed into Flavor Flav with the blending of Flav's unique characteristics onto the patron saint. Jude is depicted in a blue background typical of mosaics, but capped with Flav's signature Viking hat. Jude's pendant of Jesus is replaced

with Flav's clock which also emphasizes the different time frames the two come from. The brooch is framed in a Palladian window signifying the importance of the patron saint. This piece was made using Cloisonné enameling techniques and fabricated with metals such as silver and brass.

Formulation of a Stable Acidified Dairy Beverage Containing Ellagic Acid

Rebecca Anne Creasy
Dr. Louise Wicker, Department of Food Science & Technology, University of Georgia

Acidified dairy drinks, such as Dannon® Frusion™, provide health-promoting nutrients and bacteria in a tasty, convenient product. The nutritional profile of these drinks can be further enhanced with addition of ellagic acid. Ellagic acid is a phytochemical that normalizes C-reactive protein levels linked to human inflammation. Ellagic acid is added to the dairy beverage in the form of muscadine skin. Within the beverage, skin particulates can interfere with interactions between pectin and casein micelles, decreasing beverage stability. Thus, the purpose of this research is to formulate and process a stable acidified dairy beverage containing ellagic acid. The treatment beverage will consist of yogurt made from milk, sugar, and non-fat dry milk powder fermented with a commercial *Lactobacillus bulgaricus* and *Streptococcus thermophilus* starter culture. A 0.6% pectin solution will be formulated from apple juice, sugar, and pectin. Dried muscadine skin and seed, yogurt, and pectin solution will be mixed (final pectin concentration of 0.3%) and homogenized at 5000psi. Homogenized beverage will be thermally processed at 190°F and pumped into sterile bottles. This process will be repeated for control yogurt beverage, omitting addition of muscadine skin. Stability of treatment and control yogurt drinks will be determined with a 90-day chilled storage study. During the 90-day study, particle size and sedimentation analysis, turbidity measurement, and BCA protein assay will be conducted as measurements of beverage quality. Results from the physical measurements for treatment and control beverages will be analyzed to determine if stability can be increased with formulation modifications.

Studies of Hirano Bodies and Oxidative Stress in Neuroglioma Cells

Caelin A. Cubeñas – CURO SCHOLAR
Dr. Marcus Fechheimer and Dr. Ruth Furukawa, Department of Cellular Biology, University of Georgia

Hirano bodies are paracrystalline F-actin aggregations associated with a variety of conditions including aging, Alzheimer's, Parkinson's, diabetes, and other diseases. The physiological function of Hirano bodies is unknown. An *in vitro* model for Hirano body formation was developed by expressing mutated forms of the 34 kDa actin-bundling protein (Maselli, et al., 2002, 2003). The altered forms of the protein are termed CT, the carboxyl-terminus (aa 124-295) which lacks an amino terminal inhibitory region, and ΔEF1, which has mutations that affect intramolecular domain-domain interaction. Both forms exhibit activated actin bundling that causes formation of Hirano bodies. Because Hirano bodies are associated with aging and late onset diseases in which oxidative stress is implicated as a major factor, we investigated possible relations between oxidative stress and Hirano bodies. Experiments were conducted in WT (wild-type) H4 neuroglioma cells, and H4 cells transfected with either the enhanced green fluorescence protein (EGFP) or CT-EGFP. Application of oxidative stress results in formation of numerous Hirano bodies visualized by fluorescence microscopy. The viability of cells with and without Hirano bodies was assessed 24 hours after application of oxidative stress. All cells lines showed increased cell death with either increasing H_2O_2 or menadione sodium bisulfite concentrations. The cells expressing CT-EGFP had a significantly greater level of death, indicating that Hirano bodies increased cell susceptibility to oxidative stress. Pretreatment of the cells with the anti-oxidant N'N-dimethyl-thiourea restored cell viability to control levels in all cell lines, indicating that the cell death was caused by

oxidative stress. Future experiments will investigate mechanistic details of these findings to better understand a possible relationship between Hirano bodies, oxidative stress, and late onset diseases.

Association between Infant Feeding and Body Composition
Kimberly B. Cunningham
Dr. Alex Anderson, Department of Food & Nutrition, University of Georgia

Obesity and overweight are increasingly becoming public health problems here in the US and the rest of the world. Early and long-term preventive measures are urgently needed to fight this epidemic. The purpose of the study was to examine types of infant feeding and how they affect the mother's and the infant's body composition using the "BOD POD and PEA POD body composition systems," respectively. Pregnant women were recruited in the Athens area and followed through 12 weeks postpartum. Body composition of the mother was monitored at 36 weeks gestation, and through the first 12 weeks postpartum. The infant's body composition was monitored through 12 weeks postpartum. Subjects were interviewed for information on infant feeding practices, dietary practices and food habits, and other biomedical indicators. Results indicate that exclusively breastfeeding infants had higher percent body fat than mixed fed infants at 2 weeks postpartum. Exclusively breastfed infants were significantly longer than mixed fed infants ($p<0.05$). Although exclusively breastfed infants had significantly higher percent body fat earlier in life compared to mixed fed infants, this significant difference disappeared by 3 months postpartum. This result may suggest that exclusively breastfed infants obtain more fat from breastmilk, which is then used as a source of energy needed for the rapid growth during the first few months after delivery. Continued study of infants with respect to their feeding practices into adolescence will be necessary to fully understand any long-term effects of breastfeeding in the prevention of obesity and overweight in the United States.

Awareness of Student Expenditure Patterns
Bryan P. Davis – CURO APPRENTICE
Dr. Lance Palmer, College of Family & Consumer Sciences, University of Georgia

This research focuses on student expenditure patterns at the University of Georgia. Literature on student debt and student consumption choices indicate that many college students regret consumption decisions made during college and would choose differently if they could do it over. However, many college students may not be sufficiently aware of potential spending problems, thus limiting their ability to change their spending behavior. This research model utilizes the Transtheoretical Model of Change, which provides a foundation for articulating and measuring how individuals make behavior change. This research will assess how aware students are of their consumption patterns. The sample is a 300-person elective course, which should cover many demographics, ages, and cultures of students. Since the sample size is so large, it should eliminate any size-related bias from our results. Students will complete an initial survey and questionnaire assessing their estimated spending behaviors as well as their readiness to change spending behavior. Students will keep track of their expenses regularly, using a secure website. Through this research, we hope to gain insight on how aware UGA students are of their spending behavior.

Sexuality in Israel: Birth of the Gay Rights Movement and its Struggles for Acceptance in Israeli Society
Michael W. Davis – CURO SCHOLAR
Dr. Randy Sturman, Department of Religion, University of Georgia

In 1988, the Israeli Knesset voted to repeal Israel's sodomy law. Over the following two decades, gay rights advocates succeeded in expanding gay rights within the overtly Jewish state. These successes included the Knesset vote to outlaw workplace discrimination based upon sexual orientation in 1994 and the Israeli Supreme Court decision stating that a lesbian had the right to adopt her partner's child in

2005. Such successes positioned Israel as the most progressive Middle Eastern state on gay rights issues. Yet full marriage equality has not been achieved, and questions still linger over the place of homosexuals in a society dominated by Jewish tradition, mandatory military service, and the Arab-Israeli conflict. This paper analyzes the formation of the gay rights movement in the context of Israel's unique history as a Jewish democratic state. More specifically, this paper explores the discrepancy between the advances of the movement on the one hand and the actual lives of gays and lesbians within Israel on the other. Israeli films and memoirs are examined for evidence of the alternate acceptance and discrimination that homosexual individuals, both Israeli and Palestinian, experienced as the Israeli state officially expanded rights and protections for said individuals. Special attention is focused upon the issue of homosexuals within the Israeli military and gay relationships between Israelis and Palestinians.

Mechanisms of Bromide- and Bromate-induced Kidney and Liver Cell Death
Dilhara T. De Silva – CURO APPRENTICE
Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Bromide and bromate are by-products of the ozonation water purification system and are commonly found in drinking water. The mechanisms of bromide (Br-)- and bromate (BrO3-)-induced death in Normal Rat Kidney (NRK) and liver cells (CRL1469) was investigated. Both BrO3-, (added as KBrO3) and Br- (added as NaBr) induced concentration-dependent decreases in MTT staining after 48 hours in kidney and liver cells. BrO3- reduced MTT staining at lower concentrations (0.1 to 1.6 mg/mL) than Br- (1.6 to 25.6 mg/mL). Cell morphology analysis demonstrated that 0.2 mg/mL BrO3 altered kidney cell morphology, compared to 0.8 mg/mL in liver cells. The role of the sodium iodide symporter (NIS) in cell death was investigated by treatment with the NIS inhibitor NaClO4 (20 mM) prior to BrO3- or Br- exposure. NaClO4 increased MTT staining in kidney but not liver cells. The effect of BrO3- and NIS on annexin and PI staining and cell cycle were also determined. BrO3- exposure increased both annexin V and PI staining in tandem, suggesting that cell death was primarily mediated by necrosis. Cell cycle analysis demonstrated that BrO3- exposure doubled the percentage of cells in G2-M, which was not inhibited by NaClO4. These data demonstrate that BrO3- and Br- cause concentration-dependent death in kidney and liver cells, that BrO3- is a more potent toxicant than Br-, that kidney cells are more susceptible to BrO3--induced cell death than liver cells, and suggests that the mechanisms of BrO3--induced cell death involves both a G2-M arrest and NIS.

The Rise of Political Islam in East Africa
Breonne T. DeDecker
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

The goal of this project is to explore the development of Political Islam throughout the Muslim populations of several East African states. The intent is to identify historical and cultural forces in each society that could inform the trend towards the politicization of Islam within the region over the past few decades. The central theme is the historical context in which the radicalization of Islam has taken place, and what common trends can be identified. Methodology was primarily comparative historical analysis, with emphasis on understanding the evolution of the political climate in each state from the colonial period until the present. This paper seeks to understand the common trends of ethnic divisions between Arab and African populations and the subsequent rise of Political Islam within three states: Kenya, Sudan, and Somalia. The states were chosen based on their geographic relationship, cultural relationship, susceptibility of penetration by modern terrorist organizations, and the interplay of ethnic groups within their borders. The focus is on evolutionary time periods within each state in regards to the politicalization of Islam. These evolutionary periods include Islamic revolutions against

colonial domination, increased ethnic violence along religious lines due to competing territory claims, establishment of religious hierarchies within government access and education, and failed attempts at democratization.

Analysis of the Self-serving Bias Using EEG
Vanessa N. del Valle – CURO APPRENTICE
Dr. W. Keith Campbell, Department of Psychology, University of Georgia

The self-serving bias is the tendency of individuals to attribute negative outcomes to external factors and attribute positive outcomes to internal factors. Campbell and Sedikides (1999) described self-serving attributions as a preservation technique to heighten the image of the self in one's own eyes. The current study sought to replicate past research, predicting that participants would make self-serving attributions subsequent to false feedback in an adapted working memory task. Participants completed multiple questionnaires which measured various personality components that contribute to demonstration of the self-serving bias such as narcissism, depression, locus of control, and self esteem. Participants then completed a computer task which they were told was a memory task using working memory for face recognition. False feedback was administered to create equal numbers of failure and success conditions. Participants then attributed their "failure" or "success" to a forced choice between internal or external attributions. Internal and external attributions were further classified as stable or unstable. Using electroencephalography (EEG), brain activation was measured during the working memory task, during the 500 milliseconds before the attribution responses (biased or unbiased) were made. As hypothesized, individuals made significantly more self-serving responses following both positive and negative feedback. Preliminary analyses revealed more prefrontal cortex activity after participants received negative feedback preceding unbiased responses.

The Economic Implications of a Marijuana Decriminalization Policy in the United States
William Patrick Dever – ROOSEVELT @ UGA
Dr. William Lastrapes, Department of Economics, University of Georgia

Theory dictates that "successes" in US marijuana enforcement only lead to higher revenues for marijuana dealers, who are also responsible for funding other crimes. Furthermore, Miron reports that $5.3 billion by state and local governments and $2.4 billion federally are spent on marijuana enforcement (8, 10). Nevertheless in 2005, 16.9% of all Americans admitted to using marijuana within the last year (National Household Survey on Drug Use and Health). Thus this large sum has very little effect on the demand for marijuana and actually raises the cost to society. Therefore both in theory and in practice, the United States policy of marijuana prohibition is ineffective. A policy of decriminalization, under which the penalties for the production, sale and consumption of marijuana are lifted, should be implemented. Admittedly, a decriminalization policy can be reasonably expected to result in a relatively small increase in the amount of marijuana consumed, but would increase the total economic welfare as well as open up this whole market to safer governmental regulation and tax. To estimate the amount of revenue that could be received from a marijuana tax, the total yearly amount of consumption must be found and then treated like cigarettes for tax purposes. Even if no additional consumption occurred and marijuana is taxed at a rate comparable to cigarettes, the amount of government revenue to be gained would be approximately $125 million federally and $314 million for the states. This additional tax revenue should be used for both marijuana education and treatment to help to curb drug abuse and increase public awareness of possible health risks.

The Stability of Children's Gender Toy Preference through a Two-year Longitudinal Study

Sara Douglass, Kelli Webb, Matthew Anderson, Ankita Patel & Jeramy Denton
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Children's use of gender cues is evident through socialization. At an early age, they begin to identify with a specific gender and build gender stereotypes. They further use these gender cues to guide their understanding of immediate contexts, and to build sex-typed behaviors accordingly. The socialization of gender is, in turn, often revealed by children's toy preferences. Understanding the stability of children's selections of gender-stereotyped toys would help educators and parents in understanding how children develop gender-specific behaviors. This project is aimed towards documenting the stability and changes of children's toy preferences over a two-year period. Forty-two children (girls = 30) were recruited from a county Head Start program, and were interviewed at age 3. Children were first asked to name one of their favorite toys verbally. A box containing masculine (e.g. a male firefighter as an action figure, a ball, a truck, a white stuff animal), feminine sex-typed toys (e.g. a baby doll, a Polly doll, a pink stuff animal) and neutral toys (e.g. a book, a star box which contained their favorite toy) were presented to children individually. Children were then asked to point to the toy they preferred. Two follow-up tests with the same procedure were used to document the preference changes. The preliminary results showed that boys developed gender-stereotyped behavior earlier than girls by frequently choosing toy truck and ball. In addition, the toy preference is very stable in boys earlier on, while girls do not become consistent until they turn four years of age.

Environmental and Ontogenetic Changes in Detection Probability of Pond-Breeding Salamanders in the Georgia Piedmont

Andrew M. Durso – CURO APPRENTICE
Dr. John Maerz, Department of Forestry Research, University of Georgia

Amphibian declines have prompted research into effective means to monitor amphibian populations. As estimates of species abundance are costly, presence-absence data are more frequently used for landscape-level monitoring efforts. Because aquatic salamanders are difficult to sample using opportunistic methods, the implications of using alternate sampling strategies to estimate patch occupancy must be rigorously assessed before these estimates can be considered valid. Estimates of detection probability are necessary for accurate interpretation of trends based on these data. Eight wetlands in Clarke County, Georgia were intensively sampled for pond-breeding salamanders using aquatic traps and opportunistic searches, to test effects of season, sympatry and pond permanence on detectability. Using program PRESENCE, detection probability was estimated for neotenic and adult forms of these species in fall, winter and spring. The amount of sampling effort required to infer absence with 95% confidence for each species was also estimated to obtain an index of survey quality. Inter- and intraspecific variation in detectability across wetlands were compared. Expected correlates between detection probability and wetland characteristics included a positive association between pond ephemerality and presence of neotenic forms, a negative interaction between adult *Notophthalmus* and *Ambystoma* larvae, and seasonal effects concurrent with known breeding intervals. These results emphasize that extensive effort must be employed to infer absence of cryptic species, so that their presence is not overlooked in conservation and management decisions. The importance of incorporating parameterized detection probabilities into patch occupancy estimates is crucial when species negatively impact one another or are absent in some seasons.

The Effects of Antibiotic Use in Food Animals and the Prevalence of Tetracycline Resistance in Bovine Gastrointestinal Commensal Bacteria

Jodi L. Dyer
Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia

Multi-drug resistant (MDR) bacteria are rapidly becoming a threat to medicine worldwide. The genes that confer antibiotic resistance are carried within the chromosome of bacteria or on mobile genetic elements, on which the bacteria may be capable of exchanging these genes, even interspecially. Often bacteria harboring these genes contain resistance to multiple antibiotics. *tet(A)*, a gene conferring resistance to tetracycline, is one example of a gene that is often clustered with other genes on a single conjugational plasmid within some bacterial strains. The objective of this study was to determine the prevalence of *tet(A)* in both *Salmonella* and lactose-fermenting *Enterobacteriaceae* isolated from fecal samples of dairy cattle located on three geographically separate farms, which were selected because of the therapeutic use of antibiotics that was made available on these farms. Gene-specific screening was performed, and on each farm, the lactose-fermentors demonstrated a carriage rate of 24% or higher, potentially indicative that selection of these MDR bacteria is occurring through therapeutic antibiotic use. In contrast, only a single farm contained *Salmonella* isolates carrying *tet(A)*. The similarity between the *Salmonella* and lactose fermentors on this farm, a 62% to a 64% carriage rate, respectively, suggests that gene transference may be occurring between species within the animals. Given that many food contaminants are derived from fecal material, the development of antibiotic resistant bacterial reservoirs in food animals may be contributing to the increase of resistant strains causing disease in humans, increasing the difficulties of medicinal treatment.

Plasse

Rachel Egger
Prof. Susan Roberts, Department of Graphic Design, University of Georgia

This piece of work began as a mission to come up with an idea for a restaurant that would have a particular environmental concern and to design its menu with this concern in mind. My personal interest in reducing the negative impact of the automobile developed into Plasse, a hypothetical restaurant with a casual atmosphere that would promote bike riding and alternative transportation in general. The name Plasse, which rhymes with "toss," was derived from the Norwegian word for space and ground. I chose this language because Norwegians are known to

have a deep interest in enjoying and preserving the environment. I began designing the menu with many photographic ideas in mind, but after weeding out many of them I decided to work strictly with Adobe Illustrator to create simple vector graphics from scratch. I wanted the piece's imagery to have a clean feel, which led to its white space, limited color palette, and simple representations of bikes and roads. I took the dotted line and carried it throughout the menu to draw together the text and bicycle parts. For the cover I decided to carry this road theme a step further by actually making the word Plasse abstractly create the dotted line effect over a black background. Once the menu cover and interior were finished, I designed a few promotional items for patrons to use at Plasse and possibly take home with them, including a design for a water bottle. The bottle would fit in a bicycle's bottle holder and could be filled with any drink at a discounted price. The dotted line and simple color scheme were carried throughout each piece to bring them together under the Plasse brand.

Calmodulin Activation of Estrogen Receptor α: Cloning and Expression of a Fusion Protein for Defining the Calmodulin Binding Determinants

Madeline C. Elliott, CURO SCHOLAR
Dr. Jeffrey L. Urbauer, Department of Biochemistry & Molecular Biology, University of Georgia

Estrogen dependent breast cancer, accounting for approximately 70% of all breast cancer tumors, requires estradiol-17β (E_2) bound to the estrogen receptor α (ERα) to thrive. One of the most common treatments for estrogen dependent breast cancer is antiestrogen hormone therapy using the drug tamoxifen (TAM). In breast cancer tumors, TAM binds ERα, deactivating it. Initial treatment with TAM is effective, but over time, resistance to TAM is acquired and the cancer reappears. The precise mechanism by which TAM deactivates ERα or resistance to TAM develops remains unclear. It has been demonstrated that calmodulin (CaM), an important signaling protein, binds ERα and is required for normal ERα transcriptional activity. Because TAM also binds CaM, it is possible that TAM inhibits ERα function by attenuating CaM activity. As a first step towards elucidating the mechanism of ERα activation, and the role played by CaM, it is essential to define the CaM binding site(s) on ERα. We successfully cloned a segment of the ERα gene (residues 241-320) that we believe contains the CaM binding site(s). We then overexpressed it as a thioredoxin fusion protein, purified it using column chromatography, and most importantly, demonstrated binding to CaM, confirming that our protein contains (a) CaM binding site(s). Successful production of this protein permits delineation of the precise CaM binding site(s) on ERα and allows for future studies that explore how modifications to the site(s) on ERα affect binding and activation by CaM. More effective treatments then may be devised to treat or prevent resistant tumors.

The Marriage of Expression and Design

Hsuan Ju Susan Fang – CURO SUMMER RESEARCH FELLOW
Prof. Christopher Hocking, Departments of Studio Foundations and Drawing & Painting, University of Georgia

As an art student, I have long admired the works by the great Expressionists, from Beckmann to de Kooning, and as a design student I'm deeply captivated by contemporary graphic design and illustration, yet very seldom had I combined the two worlds. The goal for the CURO Summer research was to marry two of my inspirations, expressionism and graphic illustration, creating works that incorporate elements and principles from the two styles. With the art world changing and our visual culture growing, I feel that a crossover between the two worlds is inevitable, if not already present, which makes the research that much more important in furthering my artistic ambitions. My work was achieved through the technique *pentimenti.* By layering loose and improvised curvilinear lines and then covering it with a thin layer of paint, I am able to create a ghost image from which another layer is based, and create a painterly surface. The process of building and blocking out layers allows for me to find the medium between the depth of expressionism and the flatness of graphic illustration. The act of making improvised lines forces me to think about the composition as both expression and design, in which I edit my own brushstrokes for the sake of aesthetic unity. I have a strong attraction to the chaotic canvas, with clustering bold line work and letter stencils, but in keeping with a design mentality I wanted to find a way of controlling the chaos. By limiting and controlling my color palette and adding in areas of solid color I am able to achieve an environment of controlled chaos.

Influence of Bivalves on the Persistence of Avian Influenza Virus in Water

Christina L. Faust
Dr. David Stallknecht, Department of Infectious Diseases, University of Georgia

Although the transmission of avian influenza virus (AIV) is dependent on an indirect fecal-oral route involving fecal-contaminated water, little is known about the persistence of AIV in aquatic environments. Studies have shown that the infectivity of AIV is temperature, pH and salinity dependent; however, biotic factors have not been studied. The objective of this study is to examine the influence of filter feeding bivalves on the infectivity of AIV in water. In experiments, freshwater clams, *Corbicula fluminea*, were used as model bivalves and collected locally. For each trial, clams were rinsed and individually placed in tissue culture flasks (n=20) containing distilled water that was inoculated (1:100) with a low pathogenic avian influenza virus. Water samples were taken a minimum of three times during 48 hours, and after each trial the clams were processed for microscopic examination with immunohistochemistry (IHC) and *in situ* hybridization. The virus titer of the water samples was quantified by titration in primary cultures of chicken embryo fibroblasts. The virus titer decreased (compared to control flasks) or was undetectable in all 20 flasks where clams

were present. Rapid decreases in virus titers at varying time points suggested the decrease in titer was due to water filtration by clams. The results of this study suggest that biotic factors within the environment, specifically filter feeders, impact the persistence, and thus infectivity, of AIV. Studying the impact of filter feeders on the epidemiology of AIV will help develop an understanding of the maintenance of AIV within wild aquatic bird populations.

The Interaction of Natural Killer Receptor + T-cells with *Campylobacter jejuni*
Yayne Fekadu
Dr. Joan O'Keeffe, Department of Biochemistry, National University of Ireland, Galway

Natural Killer receptor+ T cells (NKR+ T-cells) are a unique subpopulation of T-cells that share characteristics of Natural Killer cells. This subpopulation of cells recognizes self and foreign glycolipids presented by CD1d. Their ability to rapidly produce cytokines led scientists to believe that NKR+ T-cells may have a role in infection and immunity. The aim of this study was to investigate the effects of lipopolysaccharides (LPS) derived from *Campylobacter jejuni* on NKR+ T cells from human peripheral blood using flow cytometry and ELISAs. Peripheral blood mononuclear cells were stimulated with *C. jejuni* LPS fractions (HS:2, HS:3, HS:4, O:19, O:23, and HS:41) for 24, 48, and 72 hours. Activation marker expression (CD25) was studied on NKR+T cells by flow cytometry and IFNγ levels measured in culture supernatants using ELISA. The results showed that all of the LPS fractions used increased CD25 expression on NKR+T cells after 48 hours in culture. IFNγ levels were also increased upon stimulation with each of the LPS fractions tested. In conclusion, the responses of NKR+ T cells to *C. jejuni* may be important in diseases associated with infection. Further studies are warranted.

Characterization of Putative Genes that Encode the Enzymes Arabinose Kinase and Galactose Oxidase: Enzymes Involved in the Biosynthesis of Sugar Nucleotides
Zion Firew
Dr. Maor Bar-Peled, Department of Plant Biology, University of Georgia

The defining feature of plants, the cell wall, affects all aspects of plant morphology, growth and development. Cell walls surround the plant cell and provide structural support and protection. They play vital roles in our environment and society in their use as a source of food, fuel and fiber. They are complex structures made up of polysaccharides, proteins and lignin. The major polysaccharides in the primary cell walls are cellulose, hemicellulose and pectin. Pectin contains three major polysaccharides that are thought to occur in all primary cell walls, and these are homogalacturonan, rhamnogalacturonan-I and rhamnogalacturonan-II. The main objective of this ongoing project is the biochemical characterization of the enzymatic roles of several putative enzymes involved in the synthesis of nucleotide sugars and polysaccharides. Nucleotide sugars are activated monosaccharides used to synthesize polysaccharides. Some of the major identified sugars that make up this cell wall include glucose, rhamnose, galactose, xylose, arabinose, and galacturonic acids. Our lab studies candidate genes that may encode enzymes that catalyze the synthesis of sugar nucleotides. Our model plant of study is *Arabidopsis thaliana* whose genome sequence is known. However, the study of function of all the genes is still lagging behind. In this project, the identified gene Ara1, for Arabinose Kinase and novel gene, at3g5359, which is a putative galactose oxidase (GalO) are studied and characterized to understand their role in the biosynthesis of polysaccharides. Arabinose Kinase catalyzes the phosphorylation of the arabinose sugar into arabinose-1-phospate. Though this activity was studied before, it is unknown if this catalytic activity is specific only for arabinose. The putative galactose oxidase gene is going to be

characterized both *in vivo* and *in vitro* to analyze its function in the synthesis of sugar nucleotides. This project will focus on the verification of the genes, and the process of cloning and characterizing to study its function.

Mathematical Computing: Exploring the Relationship between the Critical Group and Structure of Graphs
Grant M. Fiddyment
Dr. Dino Lorenzini, Department of Mathematics, University of Georgia

In mathematics, a graph is a collection of vertices and edges between them. The number of spanning trees of a graph is a standard invariant attached to it. It turns out that this integer is, in fact, the number of elements in an algebraic structure associated with the graph called the critical group. Although this group has applications to economics and physics, the precise relationship between the algebraic structure of the group and the combinatorial properties of the graph is not yet well understood. For instance, the simplest possible group structure is the one where the group needs only one generator – that is, it is cyclic. It would be interesting to understand how often the critical group of a graph is "as simple as possible." As part of the Vertical Integration of Research and Education (VIGRE) Graph Theory Group, several approaches to this problem have been studied, including calculation of the Smith-Normal form of the graph's Laplacian as well as computer-assisted computation. In particular, using the published list of the millions of graphs with at most 11 vertices, a comprehensive list of the explicit structure of the critical group of these graphs is being created using the computer software "nauty" and Maple. This work required writing Maple procedures to compile data, later refined to take into account the sheer size of the input. A statistical analysis of this data, which will hopefully provide some insight on how often critical groups are cyclic, will be presented.

A GP-evolved Formulation for the Relative Permittivity of Water and Steam
Sergey V. Fogelson
Dr. Walter Potter, Department of Computer Science, University of Georgia

The relative permittivity (or static dielectric constant) of water and steam has been experimentally calculated at a relatively wide range of temperatures and pressures. Two separate functions for predicting the relative permittivity of water and steam in three distinct thermodynamic regions were evolved using genetic programming. A data set comprised of all of the most accurate relative permittivity values, along with temperature, pressure, and density values from the entire experimentally calculated range of these values was used for this task. The accuracy of these two functions was evaluated by comparing the values for the relative permittivity obtained using the GP-evolved functions and the values obtained using the latest dielectric constant prediction equation to the experimentally obtained data set. In all regions, the newly evolved functions outperformed the latest dielectric constant prediction equation in terms of difference between calculated and experimentally obtained values for the dielectric constant. This work heralds the successful beginning of applying AI techniques to this important scientific application area.

A Cellulosic Ethanol Plan for Athens
Zach Fox – ROOSEVELT @ UGA
Dr. Thomas Adams, Department of Biological & Agricultural Engineering, University of Georgia

The U.S. transportation sector's reliance on fossil fuels increases American dependence on foreign oil, pollutes our air, contributes to global climate change, and is generally unsustainable. An alternative to fossil fuels is cellulosic ethanol which is a cleaner-burning fuel blended with conventional gasoline and may be produced from biomass. Mixed-stream paper, consisting of newspaper, office paper, and other discarded paper products, is readily available biomass in the University of Georgia community and will

serve as the raw material for ethanol production in this proposal. This paper proposes a comprehensive plan to be implemented to increase research on and production of cellulosic ethanol. The objectives of the plan are to 1) provide University vehicles with cleaner burning ethanol-blended fuel and 2) decrease waste streams of paper to local landfills and recycling centers. The success of this plan hinges upon implementation of three interdependent plans of actions: 1) completion of a facility capable of pilot-scale ethanol production; 2) a stronger university-wide recycling initiative implemented to ensure a reliable, consistent supply of feedstock; and 3) an increase over time of the quantity of ethanol blended with gasoline corresponding to the production capabilities of the research facility. By coordinating varied parties and interdependent initiatives, this plan ultimately will provide University vehicles with a clean fuel alternative, increase campus recycling efficiency, and promote scientific and commercial advancement of cellulosic ethanol. Furthermore, using Athens and UGA as a model, we seek to demonstrate this plan's applicability to the nation.

Investigation of the Genetic Population Structure of the Canine Hookworm, *Ancylostoma caninum*

Mary B. Gassama
Dr. Ray Kaplan, Department of Infectious Diseases, University of Georgia

Hookworms are intestinal nematode parasites that feed on the blood of the host, resulting in various ailments such as iron-deficiency anemia and malnutrition causing stunted growth and mental retardation in children. Mass treatment of communities with anthelmintic drugs can greatly reduce morbidity and infection prevalence, but also bears the danger of selecting resistant alleles, which could render whole parasite populations irresponsive towards the drug. To investigate the development and spread of resistance, it is necessary to understand the population structure and genetics of hookworms. This project is focused on population genetics of canine hookworms as a model for human hookworms. In order to get a better understanding of the population genetics of hookworms, it is necessary to analyze hookworm DNA. DNA genetic markers, isolated from adult hookworms and eggs samples and amplified by PCR, are analyzed for allele changes. Parasite populations and relations between them are estimated by bioinformatics approaches. Finally, presence of resistant hookworms will indicate a need to adjust the method currently used to administer hookworm treatment drugs.

Effects of 8-2 Fluorotelomer Alcohol on Gene Expression and Pregnancy Outcome in Mice

Gabrielle D. Gay – CURO APPRENTICE
Dr. Mary Alice Smith, Department of Environmental Health Science, University of Georgia

8-2 fluorotelomer alcohol (FTOH) and its stable metabolites, perfluorooctanoic acid (PFOA) and perfluorononanoic acid (PFNA), are developmental toxins that result in early pregnancy loss as well as poor neonatal growth and survival. Previous work in our laboratory has determined that treatment with 8-2 FTOH results in neural tube defects (NTDs), manifesting as either anencephaly or exencephaly in CD-1 mice. The objective of our current study was to investigate the mechanism of NTD induction by 8-2 FTOH using the inbred LMBc mouse. These mice are highly susceptible to birth defects due to genetic alterations in sphingolipid biosynthesis, which regulates both cell growth and cell death. Pregnant LMBc mice received a single gavage dose (30 mg/kg·BW 8-2 FTOH) on gestational day (GD) 8. Mice were sacrificed on GD15 and tissues excised for analyses. Subsets of fetal and placental samples were fixed in RNAlater® for gene expression analysis with RT-PCR. Preliminary data suggest that following treatment, maternal weight gain was not affected by 8-2 FTOH. However, 8-2 FTOH resulted in both increased absolute and relative liver weight in treated dams. Treated dams had an increased number of late-stage resorptions, thus decrease in litter size (75 % incidence). Our data suggest that LMBc mice,

unlike the previously studied CD-1 mice, are more likely to abort affected fetuses. Future work will include looking at gene expression alterations in pathways governing metabolism, growth and development, as well as stress and toxicity.

Escalation or Acquiescence? An Analysis of Sequential Dissident Responses to Repression in Indonesia

Andrew I. Gladden & Patrick Bentley
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

This study evaluates the relationship between government repression and dissident tactics. It is based on statistical data collected from Indonesia through Project Civil Strife under the direction of Dr. Stephen Shellman. It is important to note that the particular country chosen is not what is being studied. Instead, the goal is to apply a new statistical test to the government-dissident data from this country. This test, known as a difference of means test, begins by assigning values to particular events based on a spectrum ranging from very hostile to very cooperative. For each instance of repression, both pre-repression and post-repression values are recorded. These values are then averaged over the 25-year period studied and the difference between the two means can then be used to determine trends in behavior. For the purposes of this study, cooperation is defined as an event that is considered positive in the context of the overall government-dissident relationship. Conversely, hostility is defined as an event that is considered negative in the context of that same relationship. This study is motivated by a desire to quantify and statistically analyze the levels of hostility and cooperation among dissidents in response to government repression. More simply, does government repression of dissident cooperation yield a substitution of tactics toward hostility? Does Government repression of dissident hostility yield a substitution of tactics toward cooperation? It is believed that dissidents will reduce their cooperation levels and increase their hostility following government repression of cooperation. Additionally, repression of hostility will cause dissidents to increase their cooperation levels and decrease their hostility levels. Statistical analysis of data from Indonesia from 1980 – 2005 corroborates both hypotheses.

Differentiation of Human Embryonic Stem Cells to a Vascular Phenotype

Elizabeth A. Godbey
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Human embryonic stem cells (hESC) from early blastocysts are self-renewing cells capable of differentiating into every cell type present in the human body. They are a promising source of cells which may help develop treatments for human heart and vascular disorders. This project attempted to derive endothelial cells, the cells lining blood vessels, from hESC using four differentiation protocols. On day zero of the experiment, undifferentiated hESC colonies were transferred to laminin-coated tissue culture dishes. After 21 days of differentiation, the cells of each protocol were harvested and tested for expression of 47 genes by real-time PCR using a low-density array card. A portion of the harvested cells were replated on microscope slides for immunostaining with hESC and endothelial markers. The undifferentiated hESC, umbilical vein endothelial cells, microvascular endothelial cells, and hepatoma cells (all of human origin) were used as controls for both gene expression and immunostaining studies. Gene expression data was procured using SDS2.2.1 software and analyzed by the SAS package. Differentiated cells on slides were detected using fluorescent microscopy. Images were acquired with an Olympus Disk Spinning Unit. Both low-density array data and immunostaining images will be considered when evaluating the efficiency of the endothelial cell production from hESC by different protocols. Further refinement of protocols will be made to find the best method. The present project will potentially bring to light new ways of studying *in vitro* human angiogenesis, and thus would have a strong impact on future cardiovascular health strategies.

An Investigation of Botulinum Neurotoxin Interactions on RhoA Activity Using *In Vitro* Assays

Courtney Grant – CURO SUMMER RESEARCH FELLOW
Dr. Julie Coffield, Department of Physiology & Pharmacology, University of Georgia

Botulinum neurotoxin, the most poisonous substance known, primarily causes paralysis. It was observed that muscles treated with botulinum neurotoxin serotype A demonstrated the emergence of active nerve sprouts (neurites) from poisoned nerve endings. We believe that this finding may actually hold the key to the identity of the receptor for this toxin serotype. Dr. Coffield's team has preliminary evidence, obtained through affinity precipitation assays using homogenates of neuromuscular tissue, that neurotoxin serotype A binds a protein receptor known as NgR2 (Nogo Receptor 2) which is known to regulate axonal growth within the central nervous system via three ligands. One of these ligands, myelin associated glycoprotein (MAG), is also found in the peripheral nervous system, where its action is not as well understood, but in the CNS MAG's binding to NgR2 has been reported to activate RhoA, a small GTPase that ultimately regulates neurogenesis. In the current study, the action of botulinum serotype A on RhoA activity on tissue homogenates of the PNS were observed. Changes in RhoA activation from treatment with MAG and from the toxin were measured with the aid of absorbance- and/or luminescence-based ELISA kits designed to selectively detect activated RhoA. If competition assays using MAG and toxin confirm that any observed effect on RhoA activation is mediated by the selective binding of serotype A to NgR2, then NgR2 is a functionally significant receptor for botulinum neurotoxin. The ultimate goal of this study is developing therapeutic countermeasures that may be used in the event of toxin exposure.

Features of Nicaraguan Spanish

Katie Griffith – CURO SUMMER RESEARCH FELLOW
Dr. Diana Ranson, Department of Romance Languages, University of Georgia

This study investigates the use of noun, pronoun and null subjects in Nicaraguan Spanish through a quantitative analysis of a corpus of natural speech recorded in Jinotepe, Nicaragua in the summer of 2005. Knowledge of Nicaraguan Spanish is scarce, yet this dialect can provide a valuable point of comparison to studies of subject expression in other dialects of Spanish. For example, a widely debated issue is the functional compensation hypothesis, whether subject pronouns tend to be used when a final /s/ is dropped from a second person singular verb form, so that a speaker who says [a-bla] for *hablas* would be more likely to add a subject pronoun and say *tú hablas* [tu-a-bla]. This claim has been made for Puerto Rican Spanish, in which final /s/ is often deleted, yet it has been disproved by studies of Andalusian Spanish, an /s/-deleting dialect in Southern Spain and by studies of non-/s/-deleting dialects in Spain and Los Angeles. It is therefore interesting to determine the status of subject expression in Nicaraguan Spanish, which is an /s/-deleting Central American dialect which belongs neither to the Caribbean nor to the Southern Spain dialect area. In addition to determining the contribution of Nicaraguan data to the functional compensation hypothesis, this research analyzes additional hypotheses as well concerning the effect on subject expression of previous reference, contextual knowledge, and pragmatic functions, such as contrast, turn initiation, topic introduction, and the speaker's personal attitude. My research entails analyzing a self gathered corpus of native speech in order to show a correlation between a lack of subject nouns and pronouns and previous subject reference, implicit contextual knowledge, and the presence of these subjects to indicate contrast, turn initiation, topic introduction and the speaker's personal attitudes to the topic of discussion.

Systematic Empirical Study: The Impact of Sri Lanka's Economy on Dissident Behavior
Susan S. Guo – CURO APPRENTICE
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

Dissident rebel behavior plays a large role in today's society. Dissident rebels' actions stem from various factors. My project focuses on the economic factor, which is debated in the literature. I am observing how the economic circumstance of Sri Lanka may affect domestic suicide terrorist acts. My project branches off of Project Civil Strife, which is headed by Dr. Stephen Shellman. Project Civil Strife furthers our battle against terrorism by conducting research to analyze the motives of domestic terrorist activities of rebel groups. Researchers working with this project are seeking to develop theories to explain and predict patterns of dissident group tactics and actions. It is essential for researchers to better explain terrorist actions so that we can develop effective techniques in combating terrorism. I chose the economy as the independent variable because it involves money, a large influence of many people's decisions. My project involves the collection of two aggregate data sets: suicide bombing events and economic statistics (monthly inflation, trade balance with the US). I will examine the evolution of Sri Lanka's economy from 1980 to 2006 and observe how the economy affects the frequency of suicide bombing attacks. I predict adverse economic conditions will increase suicide bombing while improving economic conditions will lessen it.

Intracellular Gene Transfer from the Mitochondrion to the Nucleus in *Toxoplasma gondii*
Erica M. Hall – CURO SUMMER RESEARCH FELLOW, CURO SCHOLAR
Dr. Jessica C. Kissinger, Department of Genetics, University of Georgia
(Erica M. Hall, Chih-Horng Kuo, Abhijeet A. Bakre)

Toxoplasma gondii is a unicellular, eukaryotic apicomplexan parasite that causes toxoplasmosis, a widespread disease capable of causing serious health problems in immuno-compromised individuals and pregnant women. *T. gondii* is a model protist parasite because of its genetic accessibility, ease of experimental use, and available genome sequences. *T. gondii* presents a unique opportunity to study the phenomenon of intracellular gene transfer between organellar and nuclear compartments. The *T. gondii* nuclear genome contains ~7,200 assorted fragments of its mitochondrial genome, accounting for up to 1%, depending upon the level of conservation, of the nuclear genome sequence. The focus of my research is to elucidate the mechanism(s) by which NUMTs (nuclear sequences of mitochondrial origin) arose in *T. gondii*. Our hypotheses include a mechanism of continual transfer of fragments over evolutionary time, or a few original transfers followed by subsequent fragmentation and multiplication within the nuclear genome. My computational research supports the former since NUMT sequence containing a 60-100% gradation of conservation with mitochondrial genome sequence are observed. Genomic southern blots confirmed the large number of NUMTs. My sequence analyses have discovered multiple 40-200bp repetitive elements encoded by the mitochondrial genome that may be facilitating transfer; however, this remains to be verified via analysis of the target insertion sites in the nuclear genome. The completion of this project will increase our understanding of genome evolution in this organism and the process of intracellular gene transfer.

Metal-Metal Bonds and Aluminum Clusters
Adele Handy – CURO SUMMER RESEARCH FELLOW
Dr. Gregory Robinson, Department of Chemistry, University of Georgia

Metal clusters on the atomic level provide insight into the behavior of the bulk metal. In an organometallic reaction, the ligand plays a very important role by stabilizing, protecting and influencing the resulting metal-metal bond. Upon formation of a metal-metal bond, the solution must be crystallized in order to further

study the composition of the air and moisture sensitive compound. During my summer research, I attempted to create two different crystallized compound with unique ligands attached, in order to characterize and analyze the resulting bonds. For one of the ligands, if crystallization occurred, an interesting aluminum cluster could have been the result. Two different ligands were investigated: triphenylmethyllithium and isobutylaluminumdichloride. After being synthesized, triphenylmethyllithium was reacted with the metal compound galliumtrichloride and then underwent a sodium reduction. After the reactions were performed, the conclusion was reached that the triphenylmethylgalliumtrichloride reduction failed. Although a dark reddish brown solution was obtained, crystals did not form, and the composition of the solution could not be analyzed. The second compound, a commercially made isobutylaluminumdichloride, was reduced during separate trials using potassium, sodium, and lithium. The attempted crystallization of the varying reductions of the isobutylaluminumdichloride was not successful either; no aluminum clusters formed. Through this research, I reached the conclusion that these two ligands are not good candidates for synthesizing compounds which can be crystallized for analysis.

The Face of Costa Rica

Comusina Celan Hardman – CURO SUMMER RESEARCH FELLOW
Prof. Joseph Norman, Department of Drawing & Painting, University of Georgia

In eight months, I became intertwined with the vibrant culture of Costa Rica; visitors cannot help but appreciate the subtle differences of the various regions in both the landscape and the people. Costa Rica is said to be the harmonious meeting of opposites: the meeting of flora, fauna, and bird life from both the northern and southern hemispheres, but also, a harmonious union of the ideas of different groups in Costa Rica. The population of Costa Rica is an interesting combination of old traditions and new ideas spiraling together to create a group who spends hours preparing gallo pinto for twenty unexpected extended family members, but also those who are fascinated with the microwave and the iPod. Like the United States, Costa Rica has become immune to the growing development and the booming tourism industry; they accept the necessity to learn English and the McDonald's located directly beside

historical monuments as part of their world. Through a series of journal entries, sketches, interviews and paintings, I wove together the unique personalities that represent Costa Rica, the faces who make a country whole. I captured the stories of those who are initially hidden from view in the tropical paradise. Their stories are told through pictures and words; the story of a man with a long white beard who traveled to parque central every day for thirty-five years to play games with children; the story of an unorthodox female artist who traveled the world just to return to Costa Rica to open a gallery of her own; the story of a family of Nicaraguan immigrants who took the yearly pilgrimage to Cartago to observe Costa Rican traditions. These are the people of Costa Rica who are found in a landscape trying to find a balance between development and preserving the natural beauty that brings over a million tourists a year. Each painting and sketch contains brilliant colors that reflect the animated nature of Costa Rica; the layers of circles and squares represent the many pieces that make up not only the image but also the country. My hope is to use the interest evoked by my paintings to bring awareness to the results of development in Costa Rica and keep a visual record of a previously more tranquil society. My work helps to capture and preserve pieces of Costa Rica that will continue to change and possibly disappear under the hands of outside influences within the next decade.

Creation of a Computer Game from Concept to Completion
Brian L. Harper
Dr. Mike Hussey, Department of Theatre & Film Studies, University of Georgia

The purpose of this thesis/project is to showcase my visual and audio works in one interactive multimedia application, or computer game. The concept of the game focuses on new ways for the user to interact with the computer. The standard mode of interaction with a computer involves pressing a button which translates abstractly to some action such as jumping or shooting. With the recent release of the Nintendo Wii, human-computer interaction is becoming more intuitive. For instance, swinging the Wii Remote during a tennis game will swing the racquet on screen. The goal of my project is to build on this one-to-one relationship between human action and computer reaction. Through the use of a glove and webcam, the user's hand movements are tracked and converted to digital data. A 3D model of a hand on the screen follows the movements of the user's hand by interpreting that data. The user must control the hand to defeat various enemies and obstacles before completing the level. The user is able to smash through obstacles by making a fist, shoot enemies by pointing fingers at them, and pick up items by grasping them between fingers. Through the process of creating the game, I became familiar with all aspects of producing an interactive computer game from start to finish. Additionally, I hope new modes of human-computer interaction can be applied to not only computer games, but all fields of study.

Site-mapping and Glycan Characterization of Functional Alpha-Dystroglycan
Sana Hashmi – CURO APPRENTICE & CURO SUMMER RESEARCH FELLOW
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia
(Sana Hashmi, Stephanie Hammond, Jae-Min Lim, Kazuhiro Aoki, Mindy Perlman, Gerardo Gutierrez-Sanchez, James Wheeler, James M. Ervasti, Carl Bergmann, Michael Tiemeyer, Lance Wells)

Alpha-Dystroglycan (aDG) is a highly O-mannosylated glycoprotein that in a multiprotein complex serves as a bridge between the intracellular cytoskeleton and the extracellular matrix. In several forms of congenital muscular dystrophy, mutations exist not in aDG but in the glycosyltransferases necessary for the O-mannose addition and extension of the glycan structure necessary for proper aDG function. Hypoglycosylated aDG has also been associated with oncogenesis and metastasis. Given the importance of glycosylation of aDG in disease, the work presented here is our current progress in fully site mapping and characterizing the

glycans on aDG isolated, initially, from rabbit skeletal muscle. The sites of glycosylation are being mapped using mass spectrometry techniques for O-glycosylation including neutral-loss MSn directly on the glycopeptides and beta-elimination/Michael addition approaches. Released permethylated glycans are also being characterized by MSn approaches. The project's glycan analysis and site-mapping data to date include several O-Man and O-GalNAc initiated structures on multiple residues of aDG. Furthermore, a laminin-1 binding assay using surface plasmon resonance has been developed, which has been used to show binding of the aDG preparation. Currently using a host of glycosidases, the glycans necessary for aDG interaction with laminin-1 can be elucidated. Using all of this information, the project can determine the key functional sites of modification and glycan structures on aDG for laminin-1 binding. Following mapping and characterization of the glycans of aDG from rabbit muscle, aDG glycosylation will be studied in other tissues, tumors, and mouse models of congenital muscular dystrophy. This work is supported by the Muscular Dystrophy Association (LW) and the Jane and Bill Young Summer Fellowship (SH).

A Universal Language? Translation and Cultural Imperialism in the Writings of Karl Vossler and Alphonse Daudet

Elizabeth K. Hebbard
Dr. Martin Kagel, Department of Germanic & Slavic Languages, University of Georgia

Karl Vossler, an early 20th century German humanist and philologist, had a unique appraisal of the art of translation: he considered it cultural imperialism, where a literary work is forcefully annexed by the target language community and occupied by an army of its own readers. He claimed that this is partly due to the intense connection between cultural identity and language which is disrupted or dislocated in translation. My paper explores this connection and its function in translation by analyzing a short story of Vossler's contemporary, Alphonse Daudet. I will illustrate Vossler's position on the imperialistic nature of translation, using the story to parallel its subject matter: the colonization of a language community; and to provide examples for cultural considerations in translation. I will then address Vossler's idea of a "universal language," inquiring whether translation adds to the literary value and experience of the translated work by providing another concrete facet of its realization. I will demonstrate that Vossler and Daudet's conceptualization of the language-identity relationship is not only contradictory, but also exaggerated due to the bias of personal experience. Both men represent an era when language was essential to establishing cultural identity, and I will show that their claim that this identity is constructed exclusively through language is untenable; that the relationship between language and cultural identity is more multi-faceted than they make it out to be; and that translation is a means of adding to the pool of universal knowledge rather than a form of cultural imperialism.

RGS Proteins Regulate LPA Signaling in Ovarian Cancer Cells

Paul A. Henkel
Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Ovarian cancer is the most fatal form of gynecological cancer in the world. Characterized by the uncontrolled growth and proliferation of tissue in the ovary, ovarian cancer has a five-year 70% mortality rate following preliminary detection. Most patients who are afflicted by ovarian cancer are symptomatic only in advanced stages, showing abdominal swelling caused by a build up of Ascitic Fluid. It has been found that Ascitic Fluid contains increased levels of Lysophosphatidic Acid (LPA). LPA is an intercellular lipid mediator that promotes increased stimulation of cell proliferation, cell survival, and tumor cell invasion in ovarian cancer cells. LPA has been shown to interact with specific receptors coupled to G-proteins embedded in the cellular membrane (specifically LPA1, LPA2, and LPA3). Regulators of G-

protein Signaling (RGS proteins) are inhibitors of G-protein activation that act by binding to G-proteins and stimulating GTPase activity, effectively terminating G-protein activity. The goal of this project is to gain insight into the possible effect of RGS proteins in LPA induced cellular signaling, specifically the production of cyclic adenosine monophosphate (cAMP) which is a constituent in the cellular signaling pathway that regulates proliferation. Our strategy involves the use of the cAMP assay to measure LPA effects on Gi-coupled cell signaling in the SKOV3 strain of ovarian cancer cells. Since the beginning of the project, we have successfully produced mutant cells that are resistant to regulation by RGS proteins. Preliminary data suggest that RGS proteins are involved in the physiology of ovarian cancer in the SKOV3 cell line. Our future work will include the quantification of the RGS involvement in the signaling pathways of the SKOV3 strain as well as other variations of ovarian cancer cells.

NERUDA

Carol M. Herbert
Prof. Susan Roberts, Department of Graphic Design, University of Georgia

Pablo Neruda was a Nobel Prize winner, a poet, and a champion of the "everyman". He wrote poetry for the masses so that everyone could enjoy the beauty of words. Pablo Neruda used words to unite "the community of man." This menu was designed for a restaurant modeled after the ideals of Pablo Neruda, hence the name NERUDA. The concept of the restaurant was a place where intellectuals and creatives could mingle and mix, enjoying food and drink from all over the globe. In the spirit of Pablo Neruda, this restaurant would donate a certain percentage of its proceeds to literacy foundations around the world, in the hopes of spreading the gift of words. The visual concept for this menu came simply from the pages of a book. I used photographs I took for the background visual. I

wanted the letters of the identity to reference these pages. I used the repetition of lines to bring the typography out, as well as the geometry of the letters to add color in an unexpected way. This line motif is repeated on the interior spreads, as well as the geometric shapes created by the letter forms. My hope in doing this was to have a literary feel in the design. To me design is about incorporating conceptual and visual elements—the symbols and the form—to create a balanced harmony with purpose. It's about seeing what is not there and creating anew. When I approach a design problem, I am always keeping these principles in mind. I look at the elements that need to be involved and try to create a scenario of harmony through balance. I try to look at the thing with an abstract eye and see if the composition and color are pleasing. I think of the main point I am trying to make, and then try to show it in an intelligent way. I focus on the negative space—the underlying ideas we do not actually see but which in fact communicate the message—and try to bring them to light.

Hand to Mind Coordination.
Cassie L. Hester
Prof. Susan Roberts and Prof. Alex Murawski, Department of Graphic Design, University of Georgia

Doodle, as defined by *Webster's Dictionary*, is "a rough drawing made absentmindedly." Doodling is a brain-storming methodology. The notion of churning out solutions whilst scribbling may seem like wishful thinking, but I find that it relaxes me and allows my brain creative freedom. Compositions, imagery and patterns are often the result of my "absentminded" endeavors. Other times, words and concepts are evoked through this meditative practice.

Birdsong in the Minnesang Tradition: Natural Imitation and Symbolic Association
Sojourner Hodges
Dr. David Schiller, Department of Musicology & Ethnomusicology, University of Georgia

Since the times of the ancient Greeks and Romans, the natural world and its inhabitants have been the source of endless fascination within the arts; as early as 414 B.C.E., Aristophanes utilized live bird vocalizations in his comedy *The Birds*. Perhaps because birds are the original songsters, birdsong has long held sway over composers. One of the most remarkable periods of interest in birdsong was during the Minnesang (a tradition of lyric song in Germany that flourished from the 12th century through the 14th century). Two composers of the Minnesang era, Walther von der Vogelweide and Oswald von Wolkenstein, used birdsong in dramatically different ways. In analyzing Oswald von Wolkenstein's song "Der Mai mit lieber zal" and Walther von der Vogelweide's song "Unter der Linden," I will attempt to isolate and discuss the various birds therein, their respective roles, their literal and symbolic representations, and their diverse impacts on the two composers. Furthermore, I will examine both composers' use of not only their own imaginations in assigning roles to specific birds, but also of their use of traditional folkloric portrayals of the characteristics of various birds. These two composers and their use of birds and birdsong provide a unique glimpse into the naturalistic atmosphere of music in the Minnesang era.

The Integration of Aesthetic Principles and Human Movement
Mia Holtzman
Professor Bala Sarasvati, Department of Dance, University of Georgia

My current project involves the exploration of common choreographic vocabulary while integrating the ideals of basic human movement to create a dance form of both novelty and predictability. Movement based merely on traditional technique has the potential of becoming monotonous. Therefore, my composition expands on the works and teachings of conventional choreographers by fusing ballet and modern with distinctively different human expressions and actions. I believe the non-literal story I express through my movement may portray feelings and experiences shared by many. My objective was not to dance in a way that the obvious becomes evident, but rather to perform with the passion instilled from the lyrics. The result of assimilating communal human emotion and gesture with time-honored technique is a dynamic and thought provoking display of what new age dance can accomplish.

It's lonely out here
Matt Howell
Prof. Alex Murawski and Prof. Susan Roberts, Department of Graphic Design, University of Georgia

In art, as well as life, we should all strive for clarity whether it is clarity of image on the canvas or clarity of mind when facing adversity. In artistic endeavors the final piece is what one sees as the artist's lucid vision, but it is not. It is a crystal representation of the viewer's perception. As soon as the artist completes a work for display it no longer belongs to them; it is a limpid mirror that we all own and use to look into ourselves.

Epistatic Interactions among Long-lived *Drosophila melanogaster* Mutants

Annie Huang
Dr. Daniel Promislow, Department of Genetics, University of Georgia

Several different theories exist to explain the causes of aging. One of these theories, the mitochondrial theory of aging, states that all cells naturally produce and build up harmful free radicals such as reactive oxygen species. In recent years, scientific research has discovered numerous life-extending mutations in *Drosophila melanogaster* populations, many of which exhibit a strong resistance to various stresses such as oxidative stress. The purpose of this experiment is to discover whether combinations of unique long-lived mutations affect life span and also oxidative stress resistance. We will study three distinct life-extending mutations, where each acts in a unique pathway: Indy, EcR, and Enigma. Different pathways are key because if two mutations act in the same pathway, then the resulting reaction towards a particular stress is likely to be similar to the reaction of the control population containing a single mutation. We hypothesize that the combined mutant lines will display the strongest tolerance toward oxidative stress and the greatest lifespan extension. Along with the combined mutant lines, we will create three different control lines. First, each control background will be crossed with each different control background; second, each mutant line will be crossed with its own control background; and third, each mutant line will be crossed with different genetic backgrounds. At this point, our data are still being analyzed. We chose to perform an oxidative stress assay due to the fact that all living organisms produce harmful free radicals and also to reach the ultimate goal of understanding the aging process better. With a greater understanding of genetic processes, a greater understanding of human health follows. Currently, we know much about these genes' pathways of action. Furthermore, epistatic interactions between mutations that act in the same pathway have also been elucidated; however, interactions between mutations that act in different pathways have yet to be thoroughly studied.

Magnitude of the Inverse Relationship between Nighttime Transpiration and Hydraulic Redistribution in *Quercus laevis*

Margaret A. Hubbard
Dr. Lisa A. Donovan, Department of Plant Biology, University of Georgia

C3 plants use stomatal regulation to prevent unnecessary water loss, and recent studies have shown significant nighttime stomatal conductance and water loss in C3 plants. Another process, hydraulic redistribution involves water flowing from the wettest soil layers through the plant to drier regions in the soil. Because nighttime transpiration contributes to water loss in a plant, we hypothesized that by minimizing water loss through this process, hydraulic redistribution can be maximized. This hypothesis was tested in a greenhouse study using *Quercus laevis*. Plants were grown with their root systems split between two adjacent pots. The magnitude of water hydraulically redistributed between the pots was quantified using screen cage psychrometers, which measure availability of water for plant uptake. Treatment involved bagging plant canopies on alternating nights to suppress nighttime transpiration. The results were found to be insignificant. However, a previous parallel study with *Artemesia tridentata* found significant evidence to support the same hypothesis. Because water is required for photosynthesis and the absorption of essential nutrients from the soil, a further understanding of the process of hydraulic redistribution could offer insight into how plants interact with their environments to obtain these essential materials. Also by studying different species, we can gain a better understanding of how hydraulic redistribution differs between species from similarly dry habitats.

Taking *Clostridium thermocellum* ORFans from the ORFanage and Crystallizing Them in Search of Possible Novel Folds

Justin L. Hula – CURO SCHOLAR
Dr. Claiborne Glover, Department of Biochemistry & Molecular Biology, University of Georgia

As the number of sequenced genomes increases, the number of ORFs, open-reading frames that could potentially encode a protein continues to grow. Among this collection of ORFs lies a group of singleton ORFs, cleverly deemed singleton ORFans, which have not been found in other genomes. New sequence discoveries continue to further subdivide these ORFs: non-ORFans are found to be homologous in other families, orthologous ORFans are found only in the organism's family, and paralogous ORFans are found only in the organism's species. These unique singleton ORFans may then hold an insight into why organisms are different from each other. The goal of this work is to express, purify and crystallize a protein containing novel fold from selected singleton ORFan targets. Three singleton ORFans have been cloned in Top10 *E. coli* cells, expressed in BL21 (DE3) RPX cells, and purified with Nickel columns and Gel filtration. Work is underway to crystallize the transcribed protein from these singleton ORFans, and we hope to possibly identify a novel fold from the crystal structure. Dr. B. C. Wang's lab has achieved a forty percent success rate of identifying novel folds of the proteins in these singleton ORFans via crystallography. A crystal structure of these proteins will allow research into how they interact with other proteins in vivo. In general, knowledge of novel folds will allow a fuller understanding of these interactions and may ultimately uncover cures for diseases such as HIV/ AIDS, ataxias, Alzheimer's, and cancer.

Living in Fire, Ice, and Cardboard*; *Hotter'N Hell*; *Green with a Cowboy Print*; and *Thanksgiving with the Pope, Popeye, and the Mafia

Brittney Inman
Prof. Judith Ortiz Cofer, Department of English, University of Georgia

Last semester, Fall 2006, I was privileged to participate in Dr. Judith Ortiz Cofer's intensive creative writing course, which sanded my writing into a raw, original shape. Under her expert guidance, I wrote a variety of creative non-fiction pieces that I am proud to present at the CURO 2007 Symposium. As I wrote each piece, I selected true experiences and true people from my life and entwined and expressed them in an artistic way to capture particular themes, characters, and moments. Thus, writing these works was reminiscent of putting the pieces of a puzzle together; I endeavored to connect various pieces of my life to create meaningful designs. Among these creative non-fiction works is the prose poem, "Living in Fire, Ice, and Cardboard," which is a lyrical montage of experiences, reflecting upon a family's repetitive yet progressive series of moves from state to state, told from a child's perspective. The other works presented are short, creative non-fiction prose pieces, which include: "Hotter'N Hell," a series of three scenes, each told from a different time in a girl's life, exposing her father's extreme disposition and downfall; "Green with a Cowboy Print," a depiction of a mother-daughter relationship from a teenage girl's perspective; and "Thanksgiving with the Pope, Popeye, and the Mafia," a characterization of a grandfather's rich personality through a Thanksgiving setting. My hope is that these glimpses of meaning, crafted from life's clutter will evoke a feeling or change within the reader, whether it is subtle, nameless, or ephemeral.

The Who, What, Where and Why of Georgia's 2006 Agriculture Commissioners Race: An In-depth Look at the Reasons for Tommy Irvin's Landslide Victory over Gary Black

Jennifer S. Ivey
Dr. Charles Bullock, Department of Political Science, University of Georgia

Georgia's political landscape has changed. Beginning many years ago with Republican Senator Mack Mattingly's defeat of Democratic Senator Herman Talmadge and culminating in the election of a Republican General Assembly, as well as a two-term Republican Governor, elections at most levels in Georgia have become competitive for both parties. Because of this, connected Republicans across the state assured the media that this was the year a Republican was finally going to take the office of the Agriculture Commissioner. However, election night came and delivered the Republican challenger, Gary Black, exactly 321,476 fewer votes than Tommy Irvin. The purpose of this study is to understand why Irvin was so successful in his defeat of Gary Black. Irvin's past victories will be analyzed, county by county, and compared to the counties in which Black was victorious. In addition, a comparison of the candidates' media shares will be made. A least squares regression model will be used to control for the relative Republicanism in Georgia, differences in North and South Georgia, as well as the Urban, Suburban, and Rural area differences. The results from this study can help political scientists understand what areas of Georgia have become more Republican, and those areas which are remaining staunchly Democratic. Furthermore, while other state-wide races in Georgia have been analyzed by political scientists, the Agriculture Commissioner's race is a topic that has received no attention among researchers.

Genetic and Environmental Effects on Aggressive Behavior in *Drosophila*

Jae W. Jeon, Daniel Alvarez, Jarrad Barber
Dr. Wyatt Anderson and Dr. Yong-Kyu Kim, Department of Genetics, University of Georgia

Aggression is a familiar behavior expressed by different animals, including humans. The causes of aggression are, however, not well known. We investigated the environmental and genetic effects on the formation of *Drosophila melanogaster* aggressive behavior. To test the prediction that male fly aggression is influenced by the environment and genetic make-up, we utilized two types of flies, wild type and mutant type. We also raised them in two ways, in social isolation and in group, to determine how these two factors interact on the aggression in *Drosophila*. We observed six aggressive behaviors - fencing, lunging, boxing, wing threat, holding, and chasing. The aggressive index was measured using a total amount of these behaviors and statistically analyzed using the ANOVA. Our data showed that wild types were more aggressive than mutant flies; and isolated males tend to be more aggressive than communally raised ones. We also found a sexual dimorphism in aggression: males are more aggressive than females in wild types but not in mutant types. These results confirmed that both genetic and environmental factors played important roles in the formation of aggressive behavior in *Drosophila*. This study will be useful for better understanding of human aggressive behavior. Several studies report that genes such as MAOA are involved in aggression, and maltreatment significantly increased aggression in the childhood and adolescent stages. We intend to look at the association between aggressive behavior and brain development in *Drosophila*.

Screening of Fosmid Library of Environmental Genomic DNA from Sapelo Island

Heather E. Johnson
Dr. James Hollibaugh, Department of Marine Sciences, University of Georgia

The purpose of this project was to explore the metagenome of the microbial community at Dean Creek, Sapelo Island, Georgia. A metagenomic library was constructed by splicing randomly selected pieces of DNA extracted from the microbial assemblage and inserting them into a plasmid hosted in *E. coli*. The library was screened, targeting 16S rRNA, bacterial and archaeal ammonia monooxygenase (amoA), proteorhodopsin, arsenate reductase, Rubisco, and ATP citrate-lyase genes. Successful amplifications indicating the presence of the gene of interest were identified using agarose gel electrophoresis or denaturing gradient gel electrophoresis. Draft sequences were obtained from PCR products and compared to published sequences. The presence of the 16S rRNA genes in fosmids allowed us to identify four clones that were derived from Actinobacteria, three from gamma Proteobacteria, and one from alpha Proteobacteria. One clone out of the 5,280 screened appeared to contain an arsenate reductase gene and one contained a Rubisco gene. None of the other targeted genes that were screened for were found in the fosmid library. Fosmids containing genes of interest were sent to the Broad Institute for complete sequencing. The full sequences from the fosmids may reveal novel genes from this community. They will also allow us to associate single genes with taxonomic markers providing an understanding of functional diversity.

DNA Recognition by a Novel Recombinase

Joseph P. Johnson, CURO SCHOLAR
Dr. Anna Karls, Department of Microbiology, University of Georgia

IS492 is an insertion sequence found in the marine bacterium *Pseudoalteromonas atlantica*. IS492 is inserted into the *P. atlantica* chromosome in at least five locations. Insertion and excision of IS492 from one of the locations, a putative glucosyl transferase gene, controls the production of extracellular polysaccharide (EPS). EPS is important for the biofilm formation ability of *P. atlantica*. The transposase, MooV, catalyzes the movement of IS492. In order to catalyze the excision of IS492 and its subsequent insertion, MooV must first bind site-specifically to the ends of the IS element before introducing nicks into the DNA. The goal of this project is to characterize MooV DNA binding activity using in vivo assays. Our current approach is to measure in vivo MooV binding to the junction of the ends of IS492 that is formed when IS492 excises from host DNA to give a circular intermediate; this junction sequence was previously shown to be a very strong promoter. Using a plasmid construct with the junction sequence inserted upstream of a promoterless lacZ gene, MooV binding to the element ends is detected as repression of lacZ expression (measured by beta-galactosidase assays). Interestingly, results at this juncture suggest that cleavage-defective MooV variants bind and repress the junction promoter more effectively than wild-type MooV. Further experiments are in progress to determine whether the level of MooV expression or catalytic activity of the recombinase affects the occupancy of the promoter sequence within the circle junction.

A Biotechnological Approach to Restoration of American Chestnut (*Castanea dentata*): Mass Propagation via Somatic Embryogenesis

Sara B. Johnson
Dr. Scott Merkle, Department of Forestry Research, University of Georgia

The American chestnut was one of the most important forest trees in the Appalachian Forest until the introduction of the chestnut blight fungus, which caused the death of virtually every mature American chestnut tree in the eastern United States. A system for mass propagation of blight-resistant material obtained through conventional breeding or gene transfer is still lacking. Thus, the goal of our project is to

develop a high-frequency *in vitro* propagation system for American chestnut via somatic embryogenesis, a process by which thousands of structures ("somatic embryos") resembling the embryos in seeds can be produced and germinated to form seedling-like plantlets. Two bottlenecks in this approach are the low initiation rate (<1%) of embryogenic cultures and the production of plantlets from the somatic embryos. To increase embryogenic culture initiation, we tested two plant growth regulators (2,4-D and picloram) at different concentrations and found that 2,4-D resulted in the highest frequency of embryogenesis (up to 3.5 %). To increase plantlet production, we tested variations in cold (4° C) treatment duration (12, 15, and 18 weeks) and light quality (red, red + far red, and cool white fluorescent). For some genotypes, the longer cold treatments improved plantlet production and red light improved overall plantlet production frequency (up to 80% and 69%, respectively). Thus, by manipulating the cultural treatments, we were able to increase culture initiation frequency and plantlet production efficiency. These production methods will aid in the restoration of the American chestnut in our forests.

Early Childhood Education and Family Literacy in Athens

Jimari L. Jones, Jeremy Atkins – ROOSEVELT @ UGA
Dr Elizabeth DeBray-Pelot, Department of Lifelong Education, Administration & Policy, University of Georgia

Athens, Georgia, has one of the nation's highest poverty rates. At roughly 28%, Athens has a poverty rate twice that of the state. Poverty is a humiliating phenomenon that binds and constrains families, creating communities of devastation and concentrations of despair. As a result, impoverished families are hindered from fulfilling the promises and dreams that have come to epitomize America. Therefore, we have developed a comprehensive bi-generational policy designed to combat the ill effects of poverty. Our policy initiative provides for an Athens-Clarke County-wide universal preschool program to positively impact the early childhood development among children of low-income families in the community. To complement this early-childhood initiative, an adult program would be established, empowering parents to sustain employment and create and maintain healthy learning environments at home in practical ways. It addresses the basic educational needs of low-income parents and children up to age eight by providing a unified program of: (1) adult basic or secondary education and literacy programs for parents, (2) assistance for parents to effectively promote their children's educational development, and (3) early childhood education for children. Our hope is to inspire and motivate children before even beginning elementary school. Secondly, by providing adult and family literacy, this ensures the children have the positive reinforcement necessary from parents that spurs interest and a healthy passion for an education.

Intersections

Kerry Jones
Prof. Andrea Trombetta, Department of Fabric Design, University of Georgia

These three garments serve as these three women's uniforms. They are extensions of themselves, they are explanations of themselves. Each garment was created specifically for each hand-picked woman, and fitted to her body. Exaggerated hips on the pant, the short and the skirt emphasize the importance contemporary America places on both body image and fertility. This piece relies on the investigation of discomfort within society due in part to

changing, as well as ever-present, gender roles and the impossibility of avoiding judgment throughout our lives. Photographs of steel parts in repetitive positions are the subject of the imagery, though abstracted. Grey cotton was screen-printed with these images using various shades of grey pigment. This dulled palette provides a somewhat blank, though still visually stimulating, canvas for the added details to express the personality of each individual piece and of each individual wearer. The women used as models resemble each other greatly, adding to the feeling of a blank canvas waiting to be dug into. Every garment has accents of red, orange or yellow; the colors of fire. These accents represent the inner audacity stifled by society's desire for the grey exterior; the audacity bubbling right beneath the surface of the women adorned with the pieces. The women are literally bound in a space by VHS tape, creating a visual representation of their tension due to inequality, expectations, abnormality, psychoses, whatever each woman feels, whatever any human being feels.

Sampling Ambient Air to Test for Polycyclic Aromatic Hydrocarbons

Kunal N. Kanani
Dr. Geoff Smith, Department of Chemistry, University of Georgia

The air in Athens, GA was sampled and tested for the presence and the amount of Polycyclic Aromatic Hydrocarbons (PAHs) over a period of one year. Polycyclic Aromatic Hydrocarbons (PAHs) occur widely in the environment as a result of incomplete combustion of fossil fuels and other inorganic matter. The major source of PAHs in the atmosphere are burning of wood, coal, automobiles and heat and power plants. The Environmental Protection Agency (EPA) has classified 16 PAHs as potent human carcinogens. Some of them include anthracene, benz[a]anthracene, benzo[ghi]perylene, benzo[a]pyrene, pyrene, benzo[k]fluoranthene, chrysene, and fluorine. These PAHs induce genotoxic and chronic effects in humans. It was predicted to detect the 16 EPA classified PAHs by using similar methods that have been used in the past by other researchers. Ambient air was sampled using a glass fiber filter paper attached to a pump. Then, the sample was extracted and a suitable technique for extraction was determined. Ultrasonic bath using methylenechloride as solvent was found to be an efficient technique for extraction. The different analytical methods used to detect PAHs were HPLC (high-performance liquid chromatography), GC (gas chromatography) and quadrupole mass spectrometry. The results obtained from the HPLC/GC were inconclusive because PAHs were found to be below detection limit of the HPLC/GC but a suitable result was obtained from the mass spectrometer with identification of some PAHs like fluoranthene, pyrene and other particles in the atmosphere like alpha pinene ozonolysis products. Furthermore, this paper reports the problems encountered, such as obtaining efficient extraction of the PAHs from the filter paper, lowering the detection limits of the analytical methods and measuring PAH concentrations quantitatively.

The Role of Extremism in the Arab-Israeli Conflict

Samantha E. Keyes-Blumer
Dr. Christopher Allen, Department of International Affairs, University of Georgia

Recent literature aside, diverse peoples have actually flourished together in the Middle East for hundreds of years. Under the benign neglect of the Ottomans, various cultures coexisted and even assimilated into a relatively cohesive Middle Eastern culture. Why then, have the peoples of the Middle East been caught up in an increasingly violent and intractable conflict? One explanation offered by scholars is the growth of extremism. Popular commentators, policy wonks, and serious scholars alike label everything from Iraq's civil war to peaceful student protests as "extremism" and "fundamentalism." A plethora of terminology with vastly different meanings has been co-opted in an attempt to understand the complex civil and communal conflicts of the Middle East. This presentation will attempt to unpack and differentiate among these terms. It will offer

precise definitions and focus specifically upon action as extremism: the committing of a violent, unprovoked act, as opposed to simply the threat of violence. Next, the presentation will examine various actions and events, which meet the definition of extremism, to see if they share characteristics that explain the pattern of punctuated, violent episodes that have occurred throughout the last century. For example, a pattern of violent Arab revolts might share the characteristic of being preceded by illegal land confiscations. Extremism in Israeli, Palestinian, and/or the Arab governments and citizenry will be explored: Is extremism entrenched in the actions of the Israelis, the Arabs, both, or none at all? Finally, policy proposals for possible solutions to the Arab-Israeli conflict will be suggested.

Diagnostic Assay for *Mycoplasma bovis* Using Immunohistochemistry

John R. Killey
Dr. Corrie Brown, Department of Veterinary Pathology, University of Georgia

Mycoplasma bovis is an important cause of pneumonia in cattle. Treatment of diseases resulting from *M. bovis* usually proves very difficult because *Mycoplasma* species lack cell walls, which separates them from most bacteria, and thus renders them invulnerable to many of the main categories of antibiotics. The first step in a successful treatment for *M. bovis* begins with an accurate and reliable diagnosis. The purpose of this experiment is to develop a diagnostic assay for *M. bovis* using immunohistochemistry (IHC). Using a monoclonal antibody specific for *M. bovis*, followed by application of avidin-biotin complexes (ABC) and enzyme substrates, the bacteria were effectively localized within lung tissue harvested from cattle suspected of having the disease. By honing the sensitivity and specificity of the IHC method used, the University of Georgia College of Veterinary Medicine's diagnostic laboratory hopefully will be able to improve its reliability and accuracy in making diagnoses on clinical specimens submitted for analysis. As a result, treating diseases which result from infection with *M. bovis*, such as pneumonia, will become easier and more effective.

The Influence of Muscle Length on Muscle Oxygen Saturation

Aaron K. McPherson
Dr. Kevin McCully, Department of Kinesiology, University of Georgia
(J. Michelle King, Aaron K. McPherson, Christopher P. Elder, Christopher D. Black, Kevin K. McCully)

Previous studies have suggested that chronic stretching might be able to produce an increase in the size of skeletal muscle. However, stretching might also result in restricted blood flow which might influence any stretch-training program. This study evaluated the influence of muscle position (shortened, neutral, and stretched) on muscle oxygen saturation using near infrared spectroscopy (NIRS). An 8 channel NIRS probe was placed on the calf muscles of 5 healthy adults. Measurements were made over 30 minutes in the three positions with the subjects performing 5 second maximal contractions once every minute. Oxygen saturation values were normalized with the maximum and minimum levels of oxygen saturation recorded. Oxygen saturation before (rest) and during the different conditions were measured and confirms that the stretched position significantly lowered oxygen saturation relative to the other conditions. Stretching either passively or with contractions decreased oxygen saturation, such that stretch training may also have a significant hypoxic component. A stretch-training program will have other components that will influence the development of muscle because other studies have shown that a decrease of oxygen within the muscle can also enhance muscle growth.

Tracking Continent-wide Parasite Spread in Monarch Butterflies: Launching a New Citizen Science Project, MonarchHealth

Natalie D. Kolleda
Dr. Sonia Altizer, Institute of Ecology, University of Georgia

Monarch butterflies (*Danaus plexippus*) are iconic insects that occur worldwide and are best known for undertaking a spectacular annual migration in parts of N. America. The protozoan parasite, *Ophryocystis elektroscirrha* (*OE*), infects all monarch populations examined to date and prevalence varies inversely with host migratory distances, with highest prevalence in populations that breed year round and do not migrate. To better understand how migration influences variation in parasite prevalence over space and time, in spring 2006 we launched a new citizen science monitoring project, MonarchHealth. We predicted that volunteer-collected samples across North America would show increasing prevalence of *OE* throughout the breeding season following transmission from adults to larvae. We further predicted that prevalence would be lowest among monarchs sampled at the extreme northern limits of their breeding range. After publicizing this project through environmental outreach programs, we recruited nearly 100 volunteers from across the U.S. and Canada. We developed a kit for volunteers to obtain samples from wild-caught monarchs; samples were returned to our laboratory at UGA and examined a microscope to check for the presence of *OE* spores. Results showed that about 12% of monarch butterflies were infected with *OE* during the 2006 breeding season, and that parasite prevalence increased toward the end of the breeding season, as we had originally predicted. This project enabled us to involve the public in collecting scientifically useful data at a continent-wide scale, with broader implications for understanding how monarch migratory behavior – currently classified as a "threatened phenomenon"– influences parasite infection patterns.

Synthesis and Photochemistry of 8-Cyano-7-hydroxyquinoline (CHQ): A Photolabile Protecting Group with a High Photochemical Quantum Efficiency for Biological Use

Christopher H. Kragor
Dr. Timothy Dore, Department of Chemistry, University of Georgia

8-Bromo-7-hydroxyquinoline (BHQ) is a photolabile protecting group for carboxylic acids, phosphates, diols, and phenols, which are commonly encountered functional groups in bioactive molecules such as neurotransmitters, DNA, RNA, messengers, and drugs. BHQ is stable in the dark under physiological conditions, and upon one- (1PE) or two-photon excitation (2PE); it releases the bioactive molecule in its active form. 2PE enables the tight 3-dimensional spatial release of the protected group. The light-triggered release of bioactive molecules is important because it enables many applications in research and medicine, such as the controlled inhibition of protein synthesis or the delivery and activation of drugs. Additionally, it will help further our understanding of the action of neurotransmitters and other biological messengers. An 8-cyano derivative of BHQ was successfully synthesized, 8-cyano-7-hydroxyquinoline (CHQ). The synthesis involved addition of dichlorocarbene to the C-8 position of quinaldine to generate an aldehyde, which was converted to an oxime. Dehydration provided the nitrile. The cyano group, which does not promote intersystem crossing (ISC) to the triplet excited state, like bromine does, improved the light sensitivity of CHQ. ISC competes with photochemical processes, lowering the quantum efficiency of carboxylate release. CHQ shows increased absorptivity when compared to BHQ, but the quantum efficiency is similar because of increased levels of fluorescence, which competes with the photochemistry. CHQ demonstrated a lower 2PE cross-section than BHQ, which might be explained by the increase in fluorescence.

Healthcare Coverage among Latinos in an Emerging-Gateway Southern State

Joseph T. Lariscy – CURO SCHOLAR
Dr. Leigh Willis, Department of Sociology, University of Georgia

This study examines the disparity in healthcare coverage between Georgia's new Latino population and the state's non-Latino, white residents. Between 1990 and 2000, the Latino population in Georgia tripled (Census Bureau 1990 and 2000). This influx to Georgia, and several other southern states, was a result of a growing demand for low-wage, unskilled workers in local economies. Georgia's healthcare system had to respond to the rapid arrival of a population that possessed a language and culture different from that of the mainstream native-born residents and lacked familiarity with Georgia's healthcare policies. This lack of knowledge of the medical practices of the dominant culture may impair the ability of Latino immigrants to obtain health insurance for themselves and their families. Analyses are based on the 2005 Behavioral Risk Factor Surveillance System (BRFSS), collected by the Centers for Disease Control and Prevention. Logistic regression was performed to show the effect of various demographic factors, including race/ethnicity, age, education, and income, on likelihood of possessing health insurance. The results show that, in Georgia, non-Latino whites are more likely to have health insurance than are members of the state's increasing Latino population. This conclusion suggests that in emerging-gateway southern states, Latinos may be assimilating into the underclass, where adequate healthcare is difficult to obtain. The research is important because it may assist Georgia's healthcare professionals as they work to solve the state's healthcare disparities.

Functional Analysis of the *Magnaporthe grisea* Secretome

Brian T. Laughlin
Dr. Alan Darvill, Departments of Biochemistry & Molecular Biology, Plant Pathology, University of Georgia

Magnaporthe grisea is the causal fungal agent of rice blast disease responsible for the annual loss of 200 million tons of rice output worldwide. Under various growth conditions, *M. grisea* secretes a large number of extracellular proteins (ECPs) presumably required for growth, development, pathogenicity, maceration of host cell walls, and molecular signaling. Many ECPs have been identified, but their exact biological functions remain to be determined. Among these extracellular proteins, two *M. grisea* ECPs, MgEcp22 and MgEcp23, are exclusively secreted during infection of the plant host, thus may be pathogenicity factors or signal-molecules involved in the regulation of interactions between the fungal pathogen and plant host. To better understand the roles of MgEcp22 and MgEcp23, *M. grisea* expression systems capable of over-expressing the ECPs are being developed. Initially the traditional, though laborious, restriction-ligation technique was used to clone *MgEcp22* and *MgEcp23* into an expression vector. In an effort to reduce labor, I also tested, though not yet successfully, a high-throughput technique to clone the ECP genes using the yeast gap-repairing protocol, which takes advantage of the high rate of homologous recombination in yeast. One finished expression construct, pWH102, which carries the *MgEcp22* gene, has been transformed into *M. grisea*, and the over-expression of the MgEcp22 is being examined using antibodies against epitope tags fused to the ECP. The probable formation of protein complexes between MgEcp22 and a host protein or proteins during infection will also be investigated. Such complexes, if purified, may then be characterized using current proteomics technology.

Soldier Series Fall 2006
Chandler Leathers
Prof. Michael Marshall and Prof. Stephen Scheer, Department of Photography, University of Georgia

The images are photographed using a 4x5 toyo field camera. I have been photographing UGA's Army ROTC members since the Spring of 2006 in an effort to put a face on our armed services. I feel that too often with media coverage that we forget that the UNITS and branches often casually discussed contain individuals who have chosen to put their lives on the line for causes sometimes that are not seen as black and white. Also, these individuals are not just in a day-to-day job; it is a lifestyle that requires a 24-hour commitment, whether to training or to picking up roots at the drop of a hat. I realize that it is a personal choice and there are a lot of benefits, but there are only a select few who have the discipline and will power to do the things they do.

The English-only Movement: A Critical Analysis through Comparative Study of French Language Regulation
Brian Levy – CURO SUMMER RESEARCH FELLOW, CURO SCHOLAR
Dr. Larry Nackerud, School of Social Work, University of Georgia

Within the increasingly polarized American political debate on immigration, the English-only movement continues to gain prominence. Recently, the US Senate passed two language bills, declaring English the common, official, and unifying language of America. These regulatory acts come as the Hispanic population within the United States continues to burgeon—approximated at 14.1 percent in 2004. Governmental regulation of language is not a phenomenon unique to America. France, Spain, and other worldwide nations have also undergone varying degrees of language management. The first part of this paper is an ethnographic case study that utilizes France as a model for potential American language regulation. France offers the most promising source of exploration due to its long regulatory tradition, as well as strong national culture. To effectively examine the nature and consequences of French lexicon management, a phenomenological-explanation model—with semi-structured interviews of linguists, media workers, and a French Culture Ministry Official being the primary method of data gathering—was used. The rationale, structure, and effects of French regulations are highlighted. The second half of the study is a policy analysis that employs this data to argue against the feasibility of language regulation in the United States. National and multinational cultural implications are also underscored.

A Field Guide to English/Spanish Medical Translation
Robert B. Lindell
Dr. David S. Williams, Honors Program, University of Georgia

Given the steady increase in the Hispanic population in the US, the need for Spanish-

speaking medical professionals is growing. In light of the current lack of bilingual physicians, our healthcare system relies on medical translators to bridge the language gap that hinders patient care. However, due to sheer patient volume and the economic burden of highly-skilled, full-time translators, hospitals are struggling to effectively treat Hispanic patients. In response to this current limitation of our medical system, I authored *A Field Guide to English/Spanish Medical Translation*. This forty-page booklet is designed as an active reference for physicians and volunteers with limited exposure to Spanish. Organized by body systems and organs, the booklet emphasizes technical vocabulary, important verbs, and practical diagnostic questions for each section. After nearly six months in Peru and Spain studying medical Spanish, the challenge of authoring this guide was to identify the terminology essential to patient care. Drawing on my own clinical experiences, I have included only vocabulary with direct clinical significance. Technical jargon has been discarded in favor of accessible layman's terms. In all possible cases, I have selected widely accepted medical terms, minimizing the effect of regional language variations. Though many exhaustive guides to medical Spanish exist, this booklet is unique for its incredibly brief and highly targeted treatment of the entire body of medical Spanish. Due to its unique approach, this booklet has the potential to achieve widespread acceptance and impact the quality and nature of medical care for the Hispanic population.

The Effect of Cognitively Challenging Talk on Oral Language Development in Low-income Preschool Children

Christopher MacLean
Dr. Paula Schwanenflugel, Department of Educational Psychology, University of Georgia

Preschool children growing up in poverty have fewer opportunities to practice complex language skills. These students begin kindergarten academically disadvantaged because language development is closely tied to early literacy and later school achievement. To learn how to enhance verbal ability within this population, a ten-week intervention was employed throughout multiple lottery-funded preschools serving low-income communities in Northeast-Georgia. Experimenters met twice a week with pairs of students to complete 500 minutes of Cognitively Challenging Conversation. Results were compared with a control group matched on EVT scores that did not partake in the intervention. Various techniques were used to elaborate on child speech including imitation, extension, expansion, recast, repetition, clarification and open-ended questions. Pre- and posttest language sampling included the use of guided conversation, speech stems and the narration of a word-less picture book. Mean Length of Utterance (MLU) was used as a measure of oral language ability. Relationships between Cognitively Challenging Conversation, MLU, academic learning and early literacy are discussed.

Under the Rug Swept: Rural Punjab Women in the Ecotone of Urbanization

Aqsa Mahmud
Dr. Fausto Sarmiento, Department of Geography, University of Georgia

The case study examines urban expansion in traditionally agricultural areas of Pakistan and its effects on the functions of rural Punjab women. Expansion of industrial activity into peripheral areas of Pakistan's Punjab creates a buffering zone which resides between two economically different regions. This mediating area features an inter-mixed economy, in a continuum inclusive of traditional farming practices and industrial employment. Hitherto, rural Punjab women exist as an invisible factor to family income, functioning in domestic roles and as farming aides. This role is changing with the introduction of inner-city norms and an industrial climate. Industrial expansion promotes alternate economic opportunities for women and urban growth increases awareness in health and education sectors. Data collected through house call surveys shows female participation primarily in the informal economy. Industrial

presence and the growth of urban housing offers work options for women and allows for multiple income-earners within a household. Interviews with health personnel stress the importance of women's role in health education of rural areas. Women are the primary patients at Basic Health Unit facilities and are important in community awareness campaigns. As more schools open in the area, effort is exhibited to obtain formal education for both genders and provide female teachers, one of the few formal economic activities with female participation. This study concludes the alteration of gender-role activities among rural Punjab women as a reaction to urban expansion; the Punjab women case study can also be applied to better understand the dynamics of farmscape transformation in peripheral regions of developing countries.

Expression and Renaturation of Recombinant HL-1, a Lectin-like Protein That May Function as a Type II Diabetes Therapeutic

Anant Mandawat & Bradley Allen
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

Recent studies have found that human lectin-1 (HL-1, omentin, intelectin) is a secretory protein released from adipose tissue. It has been reported to function as an adipokine that when used in conjunction with insulin, improves glucose uptake in adipocytes. In addition to its previously theorized immune function, the adipokine results may link HL-1 to a function in type II diabetes. Our research hopes to elucidate the role or roles of HL-1 via its expression in bacteria and analysis. The HL-1 DNA sequence with an added 6-His tag was cloned into a pET vector using restriction enzyme sites. The vector was then transformed into BL-21 cells, and the HL-1 insert was expressed using IPTG induction. The BL-21 cell components were retrieved and stained for HL-1. After several washes to isolate the protein, the sample was subjected to refolding to solubilize the protein. The presence of isolated HL-1 was confirmed using Commassie staining and Western blotting. Purified HL-1 will be used with radiolabeled glucose to assay glucose uptake in adipocytes. If successful, HL-1 would be an important treatment to combat insulin resistance, the cause of type II diabetes. In addition, experiments on a carbohydrate microarray will be performed on the lectin to determine its binding specificity. The binding specificity will provide clues to the immune function of HL-1 as well as its mechanism of action in adipose tissue.

Gone but not – Making Dance through Improvisation

Mary Mattmann
Prof. Rebecca Enghauser, Department of Dance, University of Georgia
(Laura Burgamy, Leah Chapman, Marie Danielle Clark, Emily Crate, Caitlin Cunningham, Leslie Gibson, Cara O'Grady)

Gone but not is a study in using words rather than music to develop movement vocabulary. The poetry, by Pablo Neruda, was used to create an atmosphere as well as a theme for the movement, which is the desire by the human race to leave a trace and not be forgotten by the world when they have left it. The goal of the work is to create an emotional reaction to the theme as well as create a connection between the audience and dancers, who use both their voice and their bodies to communicate the theme. The piece uses modern and contemporary movement vocabulary that was developed both as a direct response to the words of the poem as well as an indirect response to the literary theme of the piece. Although much of the choreography is set, the dancers have the freedom in many areas to improvise their movement, creating a more genuine representation of the theme from each dancer. The dancers were also given verses of the poem and created their own movement in response to those excerpts, which was later set as part of the choreography. The ability of the dancers to self-determine much of the piece was a critical part of the creation of this work. Each performer draws upon her own dreams, goals, and desires, and in order to communicate that idea, in hopes that the individual voices of the dancers shines through. This universal notion could be portrayed in movement in a number of

ways; communicating this idea serves as our central inspiration.

Models of Diversity
Dakia McCray – CURO APPRENTICE
Dr. Victoria Plaut, Department of Psychology, University of Georgia

To address the problem of interracial and intergroup tension, scholars have made efforts to promote different ideologies. The major of these are multiculturalism and colorblindness. Colorblindness says that people of varying races/ethnicities hold essential similarities and should therefore be treated as individuals rather than identified with a social group. This position often leads to pressure to assimilate as well as loss of cultural identity. Multiculturalism, as it is generally understood, is the advocacy of a society that is inclusive of distinctive cultural groups equal in status. Previous research has examined the prevalence of these two models and their popularity among majority and minority groups (Plaut and Markus, 2005). In the current research we are interested in how these models of diversity relate to social status. In one experiment, we exposed participants to either multiculturalist or colorblind ideologies in addition to a control group. After the experimental manipulation, participants completed two dependent measures: the Social Dominance Orientation (SDO) scale and a resource allocation task that assessed their willingness to support diversity-related organizations. We found that these ideologies did indeed affect attempts to preserve status. In a second experiment, we exposed participants to two different status levels. These levels were represented by a CEO and a bank teller. Following the manipulation, the participants completed two measures of diversity attitude in the workplace. Through this experiment, we are looking to see whether status influences people's attitudes toward diversity. We will seek to find a way that these models can minimize threat and decrease intercultural conflict and hostility.

Determining Cost of Medical Sharps Disposal at a Local Health Center in Uganda
Andrew C. McKown
Dr. Robert T. Chen, Centers for Disease Control & Prevention

In the recent decades, single-use disposable syringes have replaced sterilizable syringes in health care settings in order to curb disease transmission through reuse of sharps. However, the consequent generation of infectious medical sharps waste also poses health risks if the waste is not properly contained. In resource-scarce developing countries, health systems often under-budget for health care waste disposal because of lack of knowledge of expenses, necessitating an easy tool by which to measure and plan for actual disposal costs of medical sharps. This study field-tested a preliminary spreadsheet tool for costing of medical sharps disposal in developing countries, including all labor, capitol, and operating expenses. Over a six-week period all medical sharps were inventoried and tracked through usage and disposal at a rural health center in eastern Uganda, during which time the health center changed from simple open pit burning of waste to encapsulation of sharps waste. The cost of disposal via open pit burning and encapsulation were measured at US$0.027 and US$0.029 per syringe, respectively. The cost of the introduction of a more appropriate system of medical waste pits was also estimated, at US$0.036 per syringe. The study experience demonstrates that proper budgeting for waste disposal is feasible because the cost of disposal is measurable with a simple tool. Furthermore, the measured costs of sharps disposal approach the purchase price of syringes, thus confirming the importance of budgeting for sharps disposal. The spreadsheet tool is being developed for widespread use in the future.

The Path Less Taken: A Progressive Approach to Stem Cell Extraction and Grading

William Colter McWhorter & Naseem Esteghamat – ROOSEVELT @ UGA
Dr. J. David Puett, Department of Biochemistry & Molecular Biology, University of Georgia

Human embryonic stem cell (hESC) research has ascended to the forefront of national controversy in the past decade. Despite further research and developments in other stem cell sources, hESC research is still the most effective method for deriving stem cell lines and potential disease treatments. An alternative method, which may appeal to those traditionally against hESC research, must be considered by the U.S. Congress. This method promotes utilizing nonviable embryos generated by in-vitro fertilization (IVF) clinics that would normally be discarded because of their low potential for developing into a fetus and likelihood of endangering the mother. Although unfit for implantation, these embryos would be ideal for research and generation of stem cell lines. As a preliminary step in supporting this method, the federal government must support developing a nationally recognized and federally regulated method for grading IVF–generated embryos in order to assuage political doubts and foster basic medical and scientific research developments. Federal scoring of embryos, through statistically-based biological aspects such as cleavage abnormality, structural inconsistency, and time frozen, along with federal oversight and funding would provide a solid foundation for hESC research. Under the supervision of the National Institutes of Health, unfit embryos would be transported from IVF clinics and passed to researchers. Derived embryos would require written consent through the IVF donor couple. Implementing these policies at the clinical level is essential to show the real value of alternative derivation. It will be a key measure on the road to full government support of hESC applications.

Egyptian Life, As Represented in *Adrift on the Nile* and *Zaat*

Yael Miller
Dr. Sherry Lowrance, Department of International Affairs, University of Georgia

The period of Nasser and Sadat in Egyptian history is a complex and fascinating time. Novels, plays, and non-fiction work abound concerning the era, as writers attempt to signify the importance of nationalism and modernization during the time. Sonallah Ibrahim and Naguib Mahfouz, in respective novels, tell the story of different sectors of society during the period. Two novels were analyzed in order to develop theories regarding Egyptian life during the period, while taking into account historical background. While Ibrahim attempts to convey the struggle of the "common" Egyptian woman during the Nasser, Sadat, and Mubarek's reigns, Mahfouz writes concerning a group of bourgeois intellectuals during the later years of Nasser. Nationalism, economic reform, and the status of various groups in Egyptian society at the time all influenced the lives of Egyptians. Class relations and Egyptian politics are both subjects of Sonallah Ibrahim's *Zaat* and Naguib Mahfouz's *Adrift on the Nile*. Egypt's political situation in both novels shows the process of change, with Mahfouz beginning with the time of Nasser and Ibrahim concentrating more on Sadat. Ibrahim specifically underscores the suffering and the isolation of the middle and lower class Egyptians, while Mahfouz demonstrates the boredom and eventual downfall of the upper class. In both novels, class interaction is close to nonexistent, and while, both novels may not be universal examples of Egyptian life, it is possible to ascertain important information from both regarding Egyptian life and its complexities.

US Involvement in the Reconstruction of Lebanon

Yael Miller – ROOSEVELT @ UGA
Dr. Sherry Lowrance, Department of International Affairs, University of Georgia
(Yael Miller, Jonathan Pride – ROOSEVELT @ UGA)

Once called the "Paris of the Middle East," Lebanon was known for its tolerance and diversity among its Christian, Muslim, and Druze factions. Its democratic traditions, its widely-publicized "Cedar Revolution," and its history of diverse tradition stemming from years of foreign rule and intervention, have given Lebanon a unique standing amongst Arab nations. Lebanon has sustained one of the region's few functioning, though fragile, democracies and the only Arab democracy to date. A secure Lebanon would provide the United States a solid, moderate ally, in a region where the United States needs another. Lebanon's recent conflict with Israel has highlighted weaknesses in the Lebanese government; Hezbollah poses a serious threat to the Lebanese government's sovereignty. In order to determine a course of action regarding US involvement in the reconstruction of the state, data were gathered concerning Lebanese history, historical records of other conflicts where the US has supported reconstruction efforts, and other positive, economy-building initiatives in other war-torn areas. A public works program supported by US aid will enforce a collective civil identity and promote community in war-damaged regions and throughout Lebanon; furthermore, those who once turned to militias for financial and community support will find new opportunities in the public works system. In addition, by strengthening the Lebanese military, the country of Lebanon may physically improve the slow process of dismantling all interior militias, including the military wing of Hezbollah, that threaten the very existence of the fragile government. A reconstruction effort beginning with a public works program will provide an innovative start to strengthening Lebanese sovereignty.

An Empirical Study of Government and Dissident Interactions in Cambodia and Indonesia, 1980-2005

Maggie Mills – CURO APPRENTICE & CURO SUMMER RESEARCH FELLOW
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

There is an abundance of literature which deals with the way governments react to the dissident groups within their borders. However, the majority of this material analyzes the relationship quantifiably through the two variables of government and dissidents in a two-actor model. The literature fails to take into account the fact that multiple dissident groups have different goals, ideologies, and behave in different manners, and they should not be analyzed as a single actor or coalition of groups, especially if a coalition fails to exist. My research will act as a case study using the results from a conference paper on disaggregating dissident groups I have worked on with Dr. Shellman. My research will take into account the number of dissident groups and will analyze the relationships between the government and the groups through a multivariate vector auto-regression test, as well as through the difference of means test. These tests will show whether a dissident group's actions are dependent upon different types of cooperation and repression coming from the government, as well as the success or failure of tactics used by other dissident groups. To perform these tests I will use the Project Civil Strife data for Cambodia and Indonesia. In the future, this project will include other countries in order to validate the results coming from Cambodia and Indonesia or show how situations and the dynamics of different countries affect these interactions. Eventually I would like to look at my results and deduce whether certain governmental actions deter more action from dissident groups than other policies and actions; these conclusions can provide me with the information I would need to make viable policy prescriptions based upon my research.

Differential Modulation of Anxiety-like Behavior in Syrian Hamsters by Endocannabinoids and Benzodiazepines

Anna M. Moise – CURO SUMMER RESEARCH FELLOW
Dr. Andrea G. Hohmann, Department of Psychology, University of Georgia

We tested the hypothesis that endogenous cannabinoids would suppress anxiety-like behavior in Syrian hamsters through activation of cannabinoid CB_1 receptors. Animals were evaluated in one of two distinct behavioral paradigms − a conventional model of anxiety (the elevated plus maze) or a naturalistic model of social stress (social defeat). Hamsters received an inhibitor of endocannabinoid deactivation (URB597), a cannabinoid CB_1 antagonist (rimonabant), a benzodiazepine anxiolytic (diazepam) or vehicle. Inhibition of endocannabinoid metabolism with URB597 induced a CB_1-mediated suppression of anxiety in the elevated plus maze. Blockade of CB_1 with rimonabant increased anxiety-like behavior. URB597 and diazepam decreased entries into closed arms of the maze, consistent with anxiolytic effects. By contrast, rimonabant decreased entries into open arms of the maze, consistent with anxiogenic effects. We used a naturalistic model of social anxiety to evaluate the effects of the same pharmacological manipulations on social defeat. Following exposure to a larger dominant hamster, subordinate hamsters display submissive behavior even in the presence of a smaller, nonaggressive hamster. We tested the hypothesis that this conditioned defeat would be suppressed by conventional anxiolytics such as diazepam and inhibitors of endocannabinoid deactivation such as URB597. Diazepam suppressed the expression, but not the acquisition, of conditioned defeat. By contrast, URB597 and rimonabant, administered at doses that modulated anxiety-like behavior in the elevated plus maze, did not alter conditioned defeat. Our data demonstrate that URB597 and diazepam differentially modulate anxiety-like behavior in male Syrian hamsters. Moreover, conditioned defeat is not dependent upon cannabinoid CB_1 receptor activation.

Gene Knockout Analysis of Two Putative Xylanase-regulating Transcription Factors in the Rice Blast Fungus

Lamar H. Moree – CURO SUMMER RESEARCH FELLOW
Dr. Alan Darvill, Departments of Biochemistry & Molecular Biology, Plant Pathology, University of Georgia
Dr. Sheng-Cheng Wu, Complex Carbohydrate Research Center, University of Georgia

Magnaporthe grisea is the causal fungal agent of rice blast disease, which is responsible for the annual loss of about 200 million tons of rice output worldwide. Under various growth conditions, *M. grisea* secretes numerous extracellular proteins important for growth, development, pathogenicity, and molecular signaling. Among these proteins are many hydrolytic enzymes that macerate the host plant cell walls. In the industrial fungus *Aspergillus niger*, production of cell wall-degrading enzymes is regulated by a transcription factor, XlnR, which has two homologs in the *M. grisea* genome (*MgXR1* and *MgXR2*). To determine the biological function of *MgXR1* and *MgXR2*, gene knockout analysis was performed on each gene. One Δ*mgxr1* and two Δ*mgxr2* mutants were confirmed by Southern Blot analysis. Both mutants were cultured on minimal media with rice cell walls as the sole carbon source. Mycelia weight, xylanase activity, and RNA transcripts of the cultures were quantified and compared to those of the wild-type strain. On Day 5 post-inoculation, both mutants out-grew the wild-type by 20-30% in terms of fresh fungal mass; however, the mutants secreted only about 5% as much xylanase as the wild-type. Surprisingly, the RNA concentration for each of the six xylanase genes measured appeared to vary from gene to gene and culture time to culture time, ranging from severe reduction to enhancement in expression level. The radial growth of both mutants on monosaccharides, particularly on xylose, exceeded that of the wild-type by over three fold. These results indicate that MgXR1

and MgXR2 are functionally similar to XlnR, but neither positively nor directly regulates the transcription of a set of individual xylanase genes.

Zeolites of Eastern Uganda and Their Scientific, Social, and Economic Potential
Mia Catherine Morgan
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

In an ongoing study at the University of Georgia, the mineral zeolite is being used in the development of a cooling system, which would provide milk cooling for small dairy farmers who do not have access to electricity. The zeolite in the system plays a crucial role in the vacuum adsorption technology used in the cooler. There are over two million farmers in Uganda alone who greatly need this technology, and the discovery of zeolite in Uganda would not only lower the cost of the cooler, making it more affordable, but will also open up possibilities for other applications. Some of these applications include liquid purification and clarification, deodorizers, desiccants, construction materials, etc. The goal of this research is to determine whether rock samples collected during an eight week, on-site research project in Uganda, East Africa, are one of the more than 40 naturally occurring zeolite species. A natural zeolite is a framework alumino-silicate whose structure contains channels filled with water and exchangeable cations. Rocks are currently being tested using Thermogravimetric Analysis (TGA) as well as Nuclear Magnetic Resonance (NMR). Results of these tests will be presented. Also, this research will examine the potential social and economic impact of discovering zeolite in Uganda.

African Immigrant Integration in Post-industrial Western Societies
Yannick Morgan
Dr. Abdulahi Osman, Department of International Affairs, University of Georgia

Immigration issues have recently become especially important since several Western countries have experienced major acts of violence involving their immigrant populations. What are the factors that affect the way African immigrants are integrated into the Western societies of France, the Netherlands, and the United States? Demographic information about the immigrant populations, relevant news reports, and reviews of the national legal, political, and social attitudes about immigration all contribute to the conclusion reached here. That is to say, the factors that arise from this analysis include the following: first, while European majority populations are focused on their growing Muslim populations (much of which originate from African states) due to the recent increased visibility of political Islam, in the United States, the immigrant group more prevalent in the national discourse is the illegal Hispanic population coming from Mexico and Central America. Second, African immigrants to France and the Netherlands include a greater number of individuals with lower incomes than the national average and of Muslim descent, while in the United States, African populations are drawn more from sub-Saharan Africa and represent one of the more wealthy immigrant groups in the States. These factors – social domestic focus and characteristics of incoming immigrants – affect how African immigrants are able to integrate into these western societies. While in the United States, African immigrants are able to integrate more fully, flying under the Nativist radar, whereas in the Western European countries of France and the Netherlands African populations have had greater difficulty integrating into the majority populations.

Evaluation of Direct Plating Methods to Enumerate *Alicyclobacillus* in Beverages

Melinda B. Murray – CURO SCHOLAR
Dr. Larry R. Beuchat, Department of Food Science & Technology, University of Georgia

The development of a standard direct plating method to enumerate *Alicyclobacillus*, a spoilage bacteria known to survive heat pasteurization processes applied to fruit, vegetable, and fruit/vegetable-based beverages, has been difficult because of varying pH and temperature optima for growth of some strains of *Alicyclobacillus* species. Ten agar media were evaluated for their suitability to support spore germination and colony development by six strains of *Alicyclobacillus acidoterrestris*, three strains of *Alicyclobacillus acidocaldarius*, and one strain of *Alicyclobacillus cycloheptanicus*. The influence of plating method, incubation temperature, and incubation time on colony development were determined. K agar, *Alicyclobacillus* medium (ALI agar), and *Bacillus acidoterrestris* thermophilic (BAT) agar recovered the highest numbers of spores. Orange serum agar and Hiraishi glucose yeast extract agar were the least suitable. Overall, surface plating was superior to pour plating and, with the exception of one strain of *A. acidocaldarius* which grew better at 50°C, incubation of K agar, ALI agar, and BAT agar plates at 43°C or 50°C resulted in recovery of equivalent numbers of spores. Essentially all viable spores were detected on media incubated for three days at 43°C. The ability of one strain of each *Alicyclobacillus* species to grow in ten non-carbonated commercially manufactured beverages at 30°C and 43°C was markedly affected by the composition of the beverages. Results show that surface plating samples on BAT agar, followed by incubating plates at 43°C for three days provide suitable conditions to enumerate ten strains of three species of *Alicyclobacillus* most commonly responsible for spoilage of beverages.

Annotation of Cuticular Protein Genes in *Anopheles gambiae*

John Nagao
Dr. Judith Willis, Department of Cellular Biology, University of Georgia

Cuticular proteins make up the exoskeleton of insects. Their genes are excellent targets for research because they are developmentally regulated and abundantly expressed. The largest family of cuticular protein genes can be identified by the R&R Consensus, a highly conserved short amino acid sequence. *Anopheles gambiae* is an ideal candidate for research on cuticular protein genes because its genome has recently been sequenced. There are over 150 cuticular protein genes with the R&R Consensus in *A. gambiae*; although they belong to the same gene family, the temporal pattern of expression of these genes varies. Studying the genes for these proteins may provide significant insights into how genes are regulated. Genes for six cuticular proteins are located on the X chromosome of *A. gambiae*, but are not closely linked as are many other cuticular protein genes. There was no supporting evidence for the annotation of four of the genes. To verify the annotations, selected cDNAs was inserted into a plasmid vector and amplified in bacteria. The plasmids were then purified and sequenced. Sequences were obtained for two of these genes and I am working on the others. Temporal expression patterns for all six genes have been determined using real-time PCR, with each gene showing a distinct pattern of expression.

Effects of Glycerol on Processing of Kit Ligand Mutants in Mammalian Cells

Nithya M. Natrajan – CURO APPRENTICE
Dr. Mary Bedell, Department of Genetics, University of Georgia

Kit ligand (Kitl) is the ligand for the receptor tyrosine kinase Kit and is required for the development and proliferation of germ cells, melanocytes, and hematopoietic cells in multiple animals. In humans, abnormal Kit signaling pathways are involved in several diseases, including tumor development and pigmentation

disorders. Additionally, Kitl is used clinically to increase peripheral blood progenitor cells prior to autologous transplantation. Despite numerous studies, many aspects of the molecular mechanisms of Kitl function remain unknown. In order to obtain more information on Kitl, we are studying a series of mouse Kitl mutants. Preliminary studies suggested that some mutant Kitl proteins become misfolded and trapped intracellularly, preventing them from reaching the cell surface. Other studies revealed that glycerol acts as a chemical chaperone to stabilize misfolded proteins, thus allowing their transport to the cell surface. This project will test whether treatment of cells with glycerol will restore transport of Kitl mutant proteins to the cell surface. If glycerol does not act as a chemical chaperone for Kitl mutants, studies with other common chemical chaperones will be conducted. Once a chemical chaperone for Kitl mutants is identified, the functionality of the mutant proteins on the cell surface will be studied. The results of this experiment will contribute to knowledge on structural aspects of Kitl function and will be applicable to other growth factors with similar structures. In addition, further understanding of the actions of chemical chaperones will aid in the development of pharmacological chaperones that can be used therapeutically.

HESX1 Mutations in Idiopathic Hypogonadotropic Hypogonadism
Nithya M. Natrajan – CURO APPRENTICE
Dr. Lawrence Layman, Department of Obstetrics & Gynecology, Medical College of Georgia

Idiopathic hypogonadotropic hypogonadism (IHH) is characterized by the absence of puberty and low serum levels of the gonadotropins follicle-stimulating hormone (FSH) and luteinizing hormone (LH). Homeobox expressed in embryonic stem cells-1 (Hesx1) is involved in the early differentiation of the anterior pituitary into five cell types. Mutations in Hesx1 have been associated with Septo-optic dysplasia (SOD), isolated growth hormone deficiency (IGHD), and combined pituitary hormone deficiency (CPHD). Panhypopituitarism, midline brain abnormalities, and optic nerve hypoplasia are the characteristics associated with SOD. Human HESX1 is a good candidate gene to study in patients with IHH because of the role it plays in SOD, IGHD, CPHD, and pituitary development. To determine if HESX1 mutations occur in IHH patients, DNAs were subjected to PCR for exons 3 and/or 4. These PCR products were sequenced and analyzed to find potential mutations. Sorting Intolerant from Tolerant (SIFT) was used to determine if missense mutations in the coding region might affect the protein. In this study, three potential heterozygous mutations were identified; one was a missense mutation (Q143E) and two mutations were identified together in the 3' untranslated region (UTR) (2043A>C and 2105G>C). These potential mutations must be studied further to determine if they affect the function of the protein. If these mutations are shown to affect protein function, then mutations in HESX1 may be a cause of IHH.

Curbing Private Forestland Divestment: Research into Georgia's Private Forests
Jesse N. Oakley – CURO APPRENTICE & CURO SUMMER RESEARCH FELLOW
Dr. Dr Laurie Fowler, Institute of Ecology, University of Georgia

Approximately 66% of Georgia's land is forested. Recently, divestment trends in the timber industry led to a massive sell-off of over three million acres. We want to understand why this is occurring, what affect it has on the environment of Georgia, and what tools can be implemented and utilized to curb forest loss. The lands were sold to developers who cut the forests and further subdivided acreage for homes or commercial growth. These forests provide society with benefits such as improved air and water quality, and habitat for wildlife. The consequences of this development include storm water discharge due to increased impervious surfaces, habitat fragmentation, altered air quality, and increased loss of biodiversity. Data collected will establish the detrimental affects divestment has on the environment and the tools available to landowners that aid in conservation.

The data will be collected through normative research, interviewing experts of the timber field and reading examples of conservation purchases around the state of Georgia and around the United States. Collected will be evidence of forest conservation and how the people conserved the land by the use of easements, leases, and other forms of Joint Purchase Agreements. We want to comprehend how some Joint Purchase Agreements were successful while others failed; also, we seek to understand different economic and social interests in these agreements. The research will have bearing on land development and the future of Georgia's forests. The study will illuminate the need for action and the availability of conservation that is both economically and ecologically rewarding.

Brief – Solo Study Utilizing Crafting Devices in Dance Choreography

Cara O'Grady
Prof. Bala Sarasvati, Department of Dance, University of Georgia

Brief arose as a solo study while learning and practicing the use of crafting devices to develop choreography in a dance composition course. The vocabulary chosen was simple and selected from the modern dance genre. The project began as a chance to utilize different forms, speed, levels, and perception of eight different movements. These actions were chosen by physically and internally exploring how the ideas of vulnerability, detachment, abandonment, regret, and reaction as expressed in human body language. The movements were then modified to be only an abstract interpretation. This abstraction created potential for broader viewer and performer interpretation and experience. After selecting and honing appropriate vocabulary, I set about examining how many different ways the movement could be performed in a repetitious manner. Augmentation, both of space and time; together and separate, were first used. Then the perception and angle of the movement was varied to vary audience perception and possible reaction. Likewise speed, body parts, transposing, effort, loco-motor and non-locomotor elements were shifted, rearranged and added. Finally, with the developmentally structured new arrangement, the elements of music and personal performance were added as layers to morph the attitude and overall effort quality of the work. Peers, and mentor faculty member Bala Sarasvati, for clarification and precision of intent, reviewed the work.

Gender Meaning Parity and the Gay Movement: A Cross-cultural Study of Developing Movements

Noona Oh
Dr. Dawn Robinson, Department of Sociology, University of Georgia

The development of the gay movement is increasingly visible on the international stage with the multi-national emergence of gay and lesbian rights movements. This research examines the role of gender parity in the development of gay and lesbian movements in Canada, China, Germany, Japan, and United States. It compares the cultural meanings associated with gendered and sexual identities in the five nations to ascertain the relative favorability of social environments conducive to gay and lesbian movement success. Variations along the Evaluation, Potency, and Activity (EPA) meanings of these identities revealed the social and cultural basis from which a gay movement operates and also predicted the probability of a mature or undeveloped movement. Country rankings were derived from calculations of EPA disparities between man and woman identities and formed the predictions for movement maturity. These predictions were tested with a qualitative analysis of movement development using a coding scheme indexed along six dimensions of movement success. Observed rankings based on movement success largely reflect the initial rankings derived from EPA measures of gender meaning differences. Countries with greater gender meaning equality have mature gay and lesbian movements while countries with greater disparities in gender meanings tend to have less developed gay and lesbian movements. In addition, the relative affective meanings of homosexual identities

closely reflect the actual development trends in the gay movements and capture important differences between them.

Characterizing PGMRC1, an Enzyme Suspected in the Regulation of the Cytochrome P450 CYP51A1

Ezinne A. Okwandu
Dr. William Lanzilotta, Department of Biochemistry & Molecular Biology, University of Georgia

Cytochrome P450s are ubiquitous heme-containing proteins that play crucial roles in several biosynthetic and drug metabolism pathways in humans. My research focuses on a novel regulation mechanism for the human P450 enzyme, CYP51A1, by the progesterone receptor membrane component-1 protein (PGMRC1p). CYP51A1 is required for lanosterol demethylation during ergosterol synthesis in humans. The PGMRC1 protein is a member of the membrane associated progesterone receptor binding proteins and has been proposed to regulate cytochrome P450 activity in the biosynthesis of cholesterol by directly activating and/or inhibiting the lanosterol 14α- demethylase enzyme. These observations have fostered the hypothesis that PGMRC1 may have a broader role in activation of P450 enzymes involved in the degradation of cancer drugs. Given the diverse functions of P450s in general, it is important to understand how heme interacts with PGMRC1 and how the heme-PGMRC1 complex alters cytochrome P450 activity. At the present time research has focused on characterizing the biophysical properties of the yeast homolog (with and without heme bound). In order to characterize the human enzyme, we have initiated a study to express PGMRC1 successfully, optimize purification of the protein and begin to analyze the biophysical properties of the protein. In addition, the heme concentration was also measured and crystallization trials have been initiated in order to eventually determine the structure of protein using X-ray crystallography. NMR spectroscopy shows that in the current buffer conditions the purified protein exists predominantly as a molten globule and therefore a search for new buffers has been initiated.

Tax Binding to Various CBP Domains

Ezinne A. Okwandu
Dr. Jennifer Nyborg, Department of Biochemistry & Molecular Biology, Colorado State University

The Tax protein is a potent transcriptional activator that stimulates the expression of the Human T-cell Leukemia Virus type 1 (HTLV-1) provirus. HTLV-1 is a retrovirus that causes human T-cell leukemia. Previous studies have shown that Tax interacts with the cellular transcription factor CREB and viral cyclic AMP response elements (vCREs) in the viral promoter to recruit the pleiotropic coactivators CBP and p300. The interaction of Tax, vCREs, CREB and the CBP/p300 proteins recruits transcriptional machinery beginning the transcription of viral DNA inside the host cell. Although the mechanisms behind Tax's role as a transcriptional activator are not fully understood, Tax binding to various CBP domains has been explored in detail. Previous research indicated that the interaction between Tax and the KIX and C/H1 domains on CBP is believed to be responsible for the recruitment of the coactivators to the HTLV-1 promoter. More recent research studies show that Tax interacts with a domain located towards the carboxy-terminus of CBP, known as CR2. This study compares Tax interaction with the, KIX domain, C/H1 domain, KIX and C/H1 fusion domain and the CR2 domain in the presence of vCREs and CREB *in vitro* using western blots. The bands were quantified using Imagequant application software. The experiments showed strong Tax binding to the CH1/KIX and KIX domains and some Tax binding to the CR2 binding. Unraveling the mechanisms of Tax binding to the viral promoter may help solve the mystery surrounding the reproductive cycle of retroviruses such as HIV and the HTLV-1.

Kinetics of Inhibition of Polygalacturonases and Polygalacturonase-inhibiting Proteins
Victor M. Orellana – CURO APPRENTICE
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

*Endo*polygalacturonases (EPGs) are important fungal pathogenicity factors, and are among the first enzymes secreted when fungi are grown on isolated plant cell walls as a sole carbon source. EPGs hydrolyze deesterified regions of wall-bound homogalacturonans, opening up the wall to the action of other *exo*- and *endo*glycanases. During pathogenesis, interactions between fungal EPGs and plant-derived polygalacturonase-inhibiting proteins (PGIPs) may alter the hydrolytic activity of the EPG**.** EPGs from a single strain of fungus may exist in a variety of isoforms and may vary in their mode of action as well as in their ability to interact with, and be inhibited by, PGIPs. In addition, the PGIPs of a single species may be present as a set of isoforms. The mode of action of a particular fungal EPG and its inhibition by PGIPs may be critical factors in determining whether the fungus is a viable pathogen. In the last few years, work by our lab and others have begun to unravel the mechanism of action and of inhibition. We have used mass spectrometry, surface plasmon resonance spectrometry (SPR), and molecular modeling to study the binding site of the EPG for its homogalacturonan substrate and the mechanism of substrate cleavage. We have also used these same techniques to investigate the binding of EPG to PGIP and the interaction between these two proteins. The literature on the kinetics of inhibition is, however, somewhat contradictory. In response to this problem, the work presented here is part of a detailed kinetic analysis of *Aspergillus niger* EPG-PGIP interactions.

Gentrification in Athens, Georgia: A Two-sided Coin in a County with the Fifth Highest Poverty Rate in the Nation[1]
Katie Orlemanski – CURO SUMMER RESEARCH FELLOW, CURO SCHOLAR
Dr. Patricia Richards, Department of Sociology, University of Georgia

The purpose of this thesis is to clarify the concept of gentrification. I examine a range of definitions and theories that have been explored since the coining of the term by Ruth Glass in 1964. I outline why the study of gentrification is important to anyone interested in the physical, economic, social, and/or cultural aspects of urban space. Because I argue that there is no single coherent vision of the meanings, causes, and experiences of gentrification, the latter part of this paper examines a specific gentrification encounter through a case study of development in Athens, Georgia. Within the methodology section, I discuss the meaning and importance of my actor-oriented approach to research based in interviews with community members and some of the benefits and difficulties it posed. An analysis of my research from Athens follows that applies the theoretical concepts of gentrification introduced earlier. The conclusion of this thesis offers suggestions for confronting gentrification issues in Athens, Georgia while also posing questions that need further examination. It is my hope that this thesis will help shed light on the various experiences of gentrification in Athens in order to promote a more comprehensive development policy for the city.

The Effects of Heat Shock on the Lethality of Subsequent Infection in *Drosophila melanogaster*
Katharine A. Owers, CURO SCHOLAR
Dr. Daniel Promislow, Department of Genetics, University of Georgia

When an organism receives a heat shock, heat shock proteins (HSPs) are synthesized, conditioning the organism and making it more

[1] For counties with populations 100,000 or more

resistant to later heat shocks. Infection, like heat shock, is a stress that releases HSPs, but the relationship between heat shock and infection has so far been studied little. Because heat-induced HSPs help organisms deal with later heat stress, I predict that they also help fight stress from infection and thereby decrease the lethality of disease. I also predict that the effects of heat-shock on lethality are temperature-dependent. These hypotheses are being tested with *Drosophila melanogaster*. One group of flies is heat shocked prior to infection, while the other is only infected. Flies were infected with *Lactococcus lactis,* a gram-positive (toxin-releasing) bacterium, at a dose causing death of between 50 and 60 percent of infected flies. Post-infection, flies were incubated at various temperatures. The effects of heat shock were measured by comparing mortalities of the different treatment groups. Preliminary results are inconclusive, but if heat shock affects susceptibility to disease in *D. melanogaster*, then increased temperatures, such as those under global warming, might constitute a heat stress that could change the lethality of disease. Because *D. melanogaster* is a model for ectotherms, including many economically important organisms, these results could have broader implications.

Infectious Plant Pathogen: *Botrytis cinerea*
Shreyal C. Patel
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

Botrytis cinerea is a widespread plant pathogen that causes grey mold or soft rot on the host tissues and is responsible for significant economic losses. *B. cinerea* must breach the cell wall during the infection process and accordingly secretes multiple enzymes that can degrade cell walls. Among these cell wall-degrading enzymes are endopolygalacturonases (EPGs), which are some of the first enzymes secreted. Thirteen EPG isoforms have been described in *B. cinerea*, although the possible functions for each in pathogenesis have not been fully elucidated. Six *B. cinerea* genes encoding EPGs have been studied and the results indicate that each gene is differentially expressed depending on factors such as the stage of infection, the plant species and the temperature. A focus of my research is the interaction during pathogenesis between fungal EPGs and plant cell wall derived inhibitors of EPGs known as polygalacturonase-inhibiting proteins (PGIPs). The mode of action of a particular fungal EPG and its inhibition by PGIPs may be critical factors in determining whether the fungus is a viable pathogen. The glycosylation patterns on the EPGs and PGIPs have been implicated in the way these two classes of proteins interact, and there is some evidence that glycosylation may change during pathogenesis. In this research, we undertook a complete mapping of the patterns of glycosylation on the EPG BcPG3. These results will serve as the basis for future site-mutations in order to dissect the role the different carbohydrate side chains play in pathogenesis and EPG-PGIP interactions.

Developing a Biocontrol Agent for Chinese Privet, *Ligustrum sinense*
Tulsi Patel – CURO APPRENTICE
Dr. Scott Gold, Department of Plant Pathology, University of Georgia

Ligustrum sinense, commonly known as Chinese Privet, is an exotic weed that currently invades millions of acres of land in the southeastern United States. The weed has the potential to outcompete many native species because it grows in various climatic conditions, and birds and small animals rapidly disseminate its seeds by consuming Privet fruits. Although privet is one of the most harmful weeds in the southeastern United States, there is no efficient mechanism to control its growth. The purpose of this project is to develop a cost effective biocontrol agent for *L. sinense*. This goal may be achieved by using a fungal pathogen that secretes large amounts of an amino acid that is detrimental to privet. The first step in finding such a fungal pathogen is to identify an amino acid that is toxic to Chinese privet. Preliminary tests in which Privet plantlets were treated with nine amino acids have shown that Lysine, Methionine, and Valine are three amino acids

that are most toxic to the plants. Next, we will create a mutant fungal pathogen that secretes large amounts of one of these inhibitory amino acids and test it for host specificity. If successful, this project will provide an effective biocontrol agent for Chinese privet and a model that could be used to control other exotic weeds.

Media Development, Journalism and Democratization in Croatia
Danielle L. Pearl – CURO SUMMER RESEARCH FELLOW
Dr. Keith Langston, Department of Germanic & Slavic Languages, University of Georgia

Since declaring its independence from the former Yugoslavia in 1991, Croatia has made significant social and institutional advances toward building a truly democratic polity. Nevertheless, the independence and legitimacy of the news media pose a continuing challenge to Croatia's democratic aspirations. This project constitutes a qualitative analysis of the current state of development of the news media in Croatia, assessing what factors and conditions prevent the media there from fulfilling their role as the "fourth estate" in this young democracy. This project examined the nature and causes of constraints on a legitimate, professional and effective media in Croatia through a series of moderately structured interviews with Croatian journalists and other media practitioners associated with a variety of print and broadcast news media. An analysis of these interviews was used to identify a set of specific policy options available to the Croatian media, government, publics, and concerned non-governmental organizations to improve media independence and legitimacy in Croatia. It is hoped that the results of this research will be of further use to scholars and policymakers in fields including media studies, democratic, post-communist and post-conflict development, and contemporary Croatian politics and society.

Metropolis Monte Carlo Simulations of Thin Ferromagnetic/Antiferromagnetic Bilayers
Daniel Perry – CURO SUMMER RESEARCH FELLOW, CURO SCHOLAR
Dr. David Landau, Department of Physics & Astronomy, University of Georgia

Ferro/Antiferromagnetic bilayers exhibit several interesting properties. One such property is called Exchange Bias (EB), which is a shifting of the hysteresis loop so that it is not symmetry about zero applied magnetic field. A hysteresis loop can be observed through quantitative analysis of ferromagnets by sweeping a magnetic field from a positive value to a negative and then from a negative value back to a positive. With the addition of an antiferromagnetic layer to the ferromagnetic layer, EB is observed in the laboratory. EB effectively stabilizes a system, making it useful in hard drives and potentially other nanotechnologies. A fundamental understanding of EB is important for the field of nanotechnology, but to date, the interactions that drive EB are not fully understood. This research aims to obtain a general understanding of the interactions that produce EB by using a simple atomistic model. Metropolis Monte Carlo simulations were used on a Body-Centered Cubic lattice. The parameters that were used to explore the properties of the model were temperature, lattice size, and the interface interactions between the two films. There are 3 types of interactions: exchange, crystal field and dipole-dipole. The dipole-dipole interactions are long range and simulated using effective anisotropy in the model. The resulting data revealed phase transition temperatures, phase transition fields, and hysteresis loops. These results differed slightly with temperature, but more so with interface types. The uniform interface was found to be useful for understanding the model. The random and step interfaces were used to mimic more realistic interfaces. Thus far, none of the interactions produce EB in the model, so it can be concluded that this model does not sufficiently describe a bilayer system. These results show that

current theory concerning EB is either incomplete or incorrect.

Polygalacturonase-inhibiting Proteins and Their Relationship to Polygalacturonases
Aaron C. Petrey
Dr Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

The plant cell wall is a major barrier against attempted invasions by phytopathogenic fungi, therefore the plant cell wall-degrading enzymes produced by fungi play an important role in their pathogenicity. Endopolygalacturonases (EPGs) are responsible for much of the pectin-degrading activity of plant pathogenic fungi and are among the first molecules secreted upon fungal infection of plants. EPGs cleave the linkages between D-galacturonic acid residues in non-methylated homogalacturonan. Polygalacturonase-inhibiting proteins, or PGIPs, are important defensive proteins which exist within plant cell walls. PGIP proteins inhibit the activity of fungal polygalacturonases (PGs) which are part of the primary method of cellular invasion by fungi such as *Fusarium moniliforme*. Until recently, little was known about the mechanism of action of EPGs. There has been an equal lack of information regarding the mechanism of interaction between EPGs and PGIPs. Previous results have demonstrated that the relationship is pH dependent. Here the relationship of fungal EPGs, plant PGIPs, and PGA (polygalacturonic acid, the pectic substrate) is examined in order to determine kinetically if the inhibition of *Fusarium moniliforme* EPG by snap bean PGIP is competitive or noncompetitive. The mechanism of inhibition has been widely debated and the results of this research fit nicely with our model that the PG binds on the underside of the EPG-complex in a noncompetitive fashion. These data are in contradiction with analysis performed by other researchers and suggest the need to perform further kinetic experiments to evaluate the relationship of many PGIP glycoproteins with their EPG enzyme counterparts.

Effects of Alcohol Use on Cognitive Ability
Natalie M. Picchetti
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Inhibition allows inappropriate responses to be suppressed and appropriate responses to be made. A simple model of inhibition is based on antisaccade performance, which is presumably mediated by the pre-frontal cortex. During an antisaccade trial, participants are required to move their eyes as quickly and accurately as possible to the mirror image (opposite side; same amplitude) of a target presented in the periphery. Alcohol decreases activity in the pre-frontal cortex, and might be expected to affect antisaccade performance. Previous research has shown that individuals with alcohol dependence have increased antisaccade errors. A high percentage of errors can also be a predictor for potential susceptibility to alcohol dependence. Young adults with a family history of alcoholism make increased errors compared to those who do not. From these results it was hypothesized that normal undergraduates with heavy alcohol use will make more antisaccade errors compared to individuals with light alcohol use and that a positive relationship will exist between the number of antisaccade direction errors and extent of alcohol use. Anti-saccade performance was measured in 100 undergraduate students who were screened for alcohol and drug use. Eye movements were recorded with the infrared oculography and the data were evaluated for percentage of direction errors. Relationships between antisaccade errors and alcohol use were calculated using correlations and T-tests were used to determine any possible relationships between the two extreme groups from the entire distribution, heavy and light drinkers. The results of this experiment will be presented.

My Neighbor's Keeper: Social Capital as a Means of Mediating Extremist Activity

Andrew W. Pierce – CURO SUMMER RESEARCH FELLOW
Dr. Tom McNulty, Department of Sociology, University of Georgia

Among the benefits created by social capital, defined as the resources embedded in social networks, is reportedly a decline in extremist activity. Previous research states that isolated members of society are the most likely to join extremist movements, and that high levels of bridging social capital, which is the type of social capital that includes the most people, bring isolated individuals into society thereby precluding their involvement in extremist movements. To investigate the interaction between social capital and extremist activity, social capital indicators and hate crime data were collected for all fifty states. The social capital indicators were compiled into a social capital index at the state level which, when compared to hate crime rates at the state level, can explain patterns of extremist behavior. Regression analysis was used to measure the relationship between several social capital indicators and hate crime rates. The analysis showed that bridging social capital indicators are negatively correlated with hate crime rates to a significant degree. These results imply that strategies important to growing social capital can be viewed as strategies to decrease current extremism in the Middle East or curb the growing extremist movements in Europe.

Expression, Optimization and Crystallization of Cystathionine β-Synthase and Cystathionine γ-Lyase

Richard C. Piercy – CURO SUMMER RESEARCH FELLOW
Dr. Cory Momany, Department of Biomedical & Pharmaceutical Sciences, University of Georgia

An elevated homocysteine level in blood serum has been determined to be a significant risk factor for arteriosclerosis. In the reverse transsulfuration pathway two Pyridoxal 5-Phosphate (PLP) dependent enzymes metabolize homocysteine to the end product of cysteine. Cystathionine β-synthase(CBS) metabolizes homocysteine into cystathionine which is then metabolized into cysteine by cystathionine γ-lyase(CGL). This research is of the basic type that has the goal to develop a reproducible process to yield crystals of CBS and CGL which will be studied in order to solve the full-length structures of each. The hypothesis is that a defect in either CBS or CGL could be a leading cause of arteriosclerosis. Full structures could help confirm or deny this claim and possibly lead an alternative treatment. Modifications were made to previous protocols to crystallize CGL and CBS. Those attempted with CGL include expression in auto-induction media, French-Pressure cell press for cell bursting, and Fast-Flow Crude columns to quickly and efficiently remove cellular material from enzyme supernatant. After purifying using High Performance Liquid Chromatography (HPLC) the enzyme was then dialyzed, concentrated and added to a crystallization buffer. Concentration of purified CGL failed to yield a concentration above 10.6mg/L. Crystallization attempts to date have failed both in the lab and at the Hauptman-Woodward high-throughput facility. CBS, a heme and PLP dependent protein requires an excessive amount of heme for proper expression. The expression of CBS without a heme transport mechanism has seen mixed results in protein quality in the past so the pHEX-2 plasmid was selected for transformation along with CBS. This plasmid provides a heme-transport system for the *E. coli* host as CBS needs an excessive amount of heme to be fully translated. Double transformations into Rosetta-2 (DE3) pLysS cells have failed all double antibiotic platings to date. Further attempts will be made with different transformation techniques as well as alternative plasmids to more effectively express CBS.

Public Space in a New Urbanist Development: A Case Study of Atlantic Station

Emily Powers – CURO SUMMER RESEARCH FELLOW
Dr. Steven Holloway and Dr. Katherine Hankins, Department of Geography, University of Georgia

Situated on the 138-acre site of the former Atlantic Steel Mill in midtown Atlanta, Atlantic Station is an example of a new urbanist "mixed-use" development. The "live, work, play" design of Atlantic Station is a worthy replacement to the abandoned industrial eyesore; it has benefited the city of Atlanta and state of Georgia with its new jobs and favorable press. At the same time, questions remain about the nature of the public space available in Atlantic Station. The case study investigates the intended and the realized spaces produced by Atlantic Station as well as reveals the multiple definitions of the term "public," which are underexamined in contemporary geography literature about public space. Through qualitative investigation including interviews with Atlantic Station residents, consumers, and employees in addition to participant observation, this research reveals the degree to which Atlantic Station developers and retailers provide highly regulated spaces that emphasize walkability and shopping convenience, which are celebrated by residents and consumers alike. Atlantic Station's public is utilizing the regulated spaces, but it is not challenging the democratic spaces in question; the consumerist citizens are not searching for more representation. This "well-behaved" public is not claiming space for active citizenship but rather it is participating in the spaces so carefully designed for its consumption. It is a public space that, by all appearances, has been severed from the state.

American Investment in a Post-Castro Cuba

Lucas L. Puente
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

Cuba represents a potential American investment market that is currently untapped. Currently, the U.S. imposes an embargo, banning trade with Cuba, but a repeal of this economic boycott would reap large benefits for Americans and Cubans. The presence of political resistance, economic uncertainties, and current trade alliances all pose as a threat to the opening of trade. However, significant trade and economic data from the U.S. Department of Commerce will demonstrate the objective of this research: the enormous financial potential of open trade with Cuba. Furthermore, data will be analyzed in order to show the advantages of trade liberalization for Cuba, given certain American incentives. The future of Cuban-American relations is now: the implementation of liberalized trade will catalyze Cuban-American relations for the years to come.

Effects of Mg/HA on Growth and Differentiation of Osteoblast Cells (Bone Cells) in a Hydroxy Apatite Scaffold

Crystal Rapier
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

Biodegradable polymer scaffolds are currently being widely investigated in the effort to create both a reliable and efficient support mechanism to promote the growth of new bone tissue. Many of the current metal, synthetic cement and bioceramic materials being used have numerous limitations. There is an imminent need for alternative bone biomaterial therapies that promote natural, rapid, controlled, and healthy cell growth that will improve the quality of life for the thousands of people who go through joint or dental bone replacements. In the current study, we examine the addition of magnesium mineral deposits (Mg+) on biodegradable ceramic polymer nano-hydroxyapatite (HA)/ pol(L-lactic acid) (PLLA) scaffolds. Osteoblast

growth on the novel nano-HA/PLLA/Mg^+ scaffolds are being compared to growth on nano-HA/PLLA scaffolds to observe possible improvement in bone development. The objectives of this study are to determine and compare the proliferation rate and differentiation proficiency of osteoblast cells between scaffolds. Currently, cell proliferation (doubling time) is being compared utilizing a 3-(4,5-Dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay. MTT assays determine the amount of viable cells in a given sample by quantifying cellular mitochondrial dehydrogenase activity. Bicinchoninic acid protein assays will be utilized to measure the amount of collagen made by differentiated osteoblast cells. Analyzing the amount of collagen will determine if the incorporation of magnesium enhanced the health and functionality of osteoblasts on the scaffolds. Results have shown that both nano-HA/PLLA scaffolds and Mg^+ incorporated nano-HA/PLLA scaffolds are biocompatible and osteoconductive to osteoblast cells *in vitro*. Initial MTT experiments have shown that an increase in osteoblast cell growth has occurred in the scaffolds containing magnesium. So far, we conclude that the addition of magnesium to the scaffolds has increased osteoblast proliferation. However, further testing will be required to assess the overall consequence of magnesium addition to nano-HA/PLLA scaffolds.

Migration Reduces Parasite Prevalence in Monarch Butterflies

Rachel M. Rarick
Dr. Sonia Altizer, Institute of Ecology, University of Georgia

The protozoan parasite *Ophyrocystis elektroscirrha* commonly infects monarch butterflies (*Danaus plexippus*) and causes reduced longevity and flight ability of their hosts. Monarchs occur worldwide in non-migrating populations but are best known for the population in eastern North America that migrates annually to overwinter in Mexico. Parasite prevalence is lower in migratory versus non-migratory populations. One reason for this could be that harsher conditions in migratory populations – including the strenuous migration itself – reduce the number of infected individuals. To test this prediction, we compared infection rates of successfully migrated monarchs in Mexico with those caught in Georgia and Florida en route to their overwintering sites. We also compared monarchs at two different overwintering sites in Mexico, one of which (Sierra Chincua) has harsher microclimatic conditions than the other (Cerro Pelon). To determine infection status, we pressed pieces of clear tape on monarchs' abdomens and counted parasites on these using a microscope. At the overwintering sites we also measured butterfly forewing length, wing damage and abdominal fat. We found that infection rates of monarchs wintering in Mexico were lower than among monarchs caught during their migration. Also, monarchs at Sierra Chincua had lower fat reserves and higher infection rates than those at Cerro Pelon. These results support the hypothesis that harsher conditions and the migration process itself can reduce parasite prevalence in migratory populations. Monarch migration is currently threatened by human activities; our results have implications for understanding how this could alter parasite prevalence.

Towards a More Effective Delivery System for Anti-cancer Drugs

Mandy Redden – CURO SUMMER RESEARCH FELLOW
Dr. Robert Arnold, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Sterically-stabilized liposomes (SSLs) have been used to encapsulate camptothecins (e.g. topotecan). These potent anticancer agents have a broad spectrum of activity, but their clinical utility is limited by poor aqueous solubility, reversible pH-dependent metabolism, and rapid release, which limits tumor exposure to the drug. Encapsulating the inactive, water-soluble form of topotecan in SSLs is hypothesized to maximize drug retention and produce a sustained release at tumor and/or metastatic sites

of disease, while minimizing toxicity. Small (90 nm) liposomes with a composition of DSPC, cholesterol and PEG-DSPE in a 9:5:1 mole ratio were prepared, and their performance, drug stability and release in different buffering systems over time were determined. Lipid composition was determined spectrophotometrically using a modified inorganic phosphorus assay, and topotecan content was determined using a spectrophotometric microplate reader at an absorbance of 384nm. Preparation of SSLs in 5.4 pH buffered ammonium sulfate (250 mM) with basic topotecan loaded at drug:lipid ratio of .25 achieved an 87% loading efficiency, while SSLs in 7.4 pH buffered solution with acidic topotecan loaded at a drug:lipid ratio of 0.25 resulted in a loading efficiency of 81%. Both SSLs showed fairly stable lipid compositions after dialysis over a 102 hour time period at 20°C with gradually decreasing concentrations of drug. These data suggest that SSLs can be used to efficiently encapsulate and slowly release drug over time. Further examination under *ex vivo* conditions are ongoing and will be used to support future in vivo studies with the goal of improving treatment of prostate and breast cancer while limiting drug toxicity.

Development and Evaluation of a Coping Skills Training Program for Adolescents with Inflammatory Bowel Disease (IBD)

Eva Bonney Reed – CURO SUMMER RESEARCH FELLOW, CURO SCHOLAR
Dr. Ronald Blount, Department of Psychology, University of Georgia

The current study is a skills-based, psychological intervention for adolescent girls and their families aimed at reducing the pain associated with Inflammatory Bowel Disease (IBD) and at increasing quality of life. Inflammatory bowel disease refers to Ulcerative Colitis and Crohn's Disease, chronic gastrointestinal diseases. In general, studies investigating the psychological health of children and adolescents with IBD have shown that they demonstrate higher levels of psychological problems than do healthy controls (Engstrom, 1992; Engstrom & Lindquist, 1991; Mackner, Sisson, & Crandall, 2004). To decrease negative symptoms and improve daily functioning, skills such as problem solving, pain management, communication, and relaxation will be taught in the one-day program. Following the intervention, all participants will complete a web component to reinforce the skills learned in session. The first intervention is scheduled for winter 2007, and the paired wait-list control group intervention will take place six weeks following. All participants in the intervention (N=32) will be recruited from Children's Center for Digestive Healthcare in Atlanta, Georgia. Participating families will answer psychological questionnaires before and after the intervention program including the web component, and six months following the intervention to assess changes. We predict that the adolescents will report a reduction in abdominal pain, functional disability, and also in symptoms of depression and anxiety. Further, we expect parents to report a reduction in their daughters' abdominal pain, functional disability, and other somatic symptoms. Data will be assessed using both within group (pre-, post-, and follow-up for all subjects) as well as between group (treatment vs. wait-list control) analyses.

Conversations with God
Patricia Lynn Rhudy
Prof. Ted Saupe and Prof. Sun Koo Yuh,
Department of Ceramics, University of Georgia

I make small figures out of clay. When I start working on a piece, I only have a very rough concept about what it is going to look like or even what emotion I choose to evoke. I work quickly and responsively with the figures, using my eyes and then my mind. If I like the placement of an arm, a leg, or the tilt of a neck, I keep it. If I do not, I change it. I make art that I relate to. If I like it, if it somehow speaks about something real inside of me, then maybe someone else can relate to it as well.

Ceramic
2006

Determining the Affinity of Perchlorate for Albumin in Rat Serum Using Equilibrium Dialysis and Ion Chromatography
Lisa Rivard – CURO SUMMER RESEARCH FELLOW
Dr. Jeffrey Fisher and Dr. Jerry Campbell,
Department of Environmental Health Science,
University of Georgia

Perchlorate (ClO_4-) is a prospective health concern and is currently listed on EPA's Contaminant Candidate List. Upon ingestion from drinking water and other sources, ClO_4- enters the bloodstream, inhibits iodide uptake in the thyroid gland, and in turn decreases the body's ability to produce the thyroid hormones T3 and T4. This study was performed to determine the binding affinity of ClO_4- to serum proteins and to determine if iodide is a competitive inhibitor in this process. Laboratory conditions were developed to simulate body conditions. An equilibrium dialysis system was set up by loading 10 Teflon® cells. Each cell had a semipermeable membrane to separate rat serum from saline spiked with ClO_4- in concentrations from 195 to 100,000 ng/ml. The cells were rotated in a 37°C water bath for four hours to equilibrate and allow ClO_4- to bind to serum proteins. The cells' contents were removed via syringe and then further prepared for ion chromatograph analysis. The equation $C_{bound} + C_{free} = C_{total}$ was used to determine the amount of ClO_4- bound to serum proteins, where C represents concentration of ClO_4-. An overall trend of approximately 11.0-24.0% of ClO_4- was bound to serum proteins. When the experiment was repeated with the addition of 6250 ng/ml iodide to the saline solution, the approximate percentages of ClO_4- bound did not change. These data suggest that ClO_4- binds to serum proteins at approximately 11.0-24.0% of its total concentration and that iodide is not a competitive inhibitor in this process at iodide levels of 6250 ng/ml. Perchlorate travels to the thyroid gland, these data suggesting probably by means of nonspecific attachment to serum proteins, and can decrease the body's production of T3 and T4. The length of time ClO_4- remains bound to serum proteins and is thus able to remain in the bloodstream and reach the thyroid is left to be determined; a future study would be applicable in this area.

Applying Koch's Postulates of *Mycobacterium shottsii* Infections in Fish
Rebecca L. Satterfield
Dr. Frederick Quinn and Dr. Russell Karls,
Department of Infectious Diseases, University of Georgia

Striped bass (*Morone saxatilis*) from the Chesapeake Bay experienced an epizootic outbreak of mycobacteria beginning in the year 2000. A newly-identified bacterial species *Mycobacterium shottsii* was detected in a large

percentage of the diseased fish. The infected fish exhibited ulcerative lesions on the skin and granulomas in the kidney and spleen. In this case, Koch's postulates require that a pure culture of the bacterial agent can cause the granulomatous lesions and skin ulcers in experimentally infected fish and that the organism can be re-isolated. The goal of this project is to demonstrate Koch's postulates with *M. shottsii* using zebrafish as a model system. Thus, our hypothesis is that *M. shottsii* will infect zebrafish and produce lesions similar to those detected in infected striped bass. In this study, either *M. shottsii* bacteria or sterile saline was injected into the coelomic cavity of individual zebrafish. Both groups of fish were monitored for 25 days after which pathological analyses of euthanized fish revealed the presence of granulomas in the kidneys and liver of only the *M. shottsii*-infected group. Thus the first half of Koch's postulates has been completed. Re-isolation and culture of *M. shottsii* is ongoing due to the extremely slow growth rate of this bacterium and an abundance of faster growing commensal bacteria in the zebrafish. Long term infection experiments are in progress to demonstrate ulcer formation.

North Korea: Options for Dealing with a Nuclear Armed State

Aaron M. Sayama – ROOSEVELT @ UGA
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

North Korea's recent nuclear test is an unsettling and worrisome act of aggression to global security and to the nuclear nonproliferation status of nations around the world. The perceived regional threat accompanying North Korea's declaration of nuclear capability could serve as a catalyst for a dangerous game of East Asian nuclear armament. Convincing North Korea to surrender its nuclear weapons program should be a top strategic priority for the United States. However, current US policy would have the world drive North Korea into further isolation. By pushing North Korea further out of global politics it will only exacerbate the problem. This paper will explore the proposed options for dealing with the North Korean nuclear crisis, assessing the advantages and disadvantages of each solution. A comprehensive, multilateral incentives package aimed at bringing North Korea out of its deep isolation is the most efficient and direct way of handling the issue of nuclear engagement. Such a package, negotiated in talks led by China, should include increased economic support from Japan, agricultural reform through South Korea, and a new and updated agreed framework previously laid out by the Clinton administration. This new agreed framework and multilateral action by neighbors to North Korea would provide the best basis for nuclear disarmament.

Femininity as a Continuum: From Battered Victim, to Self-Defense Aggressor, to Lesbian and to Barbarian

Kathryn L. Scheffel – CURO SCHOLAR
Dr. Dean Rojek, Department of Sociology, University of Georgia

It has been estimated that 1 in 10 persons arrested for murder is a woman, 1 in 50 death sentences imposed at the trial level is for a woman, 1 in 70 death row inmates is a woman, and 1 in 97 persons executed in the current era is a woman (Streib 2006). Due to this disproportionate representation, it is believed that there is a discriminating factor that greatly influences female murder trials more than the details of their crime. A contention has been made that a woman's degree of femininity is the ultimate deciding factor in determining the type of charges brought against her and, most often, the verdict of her criminal trial. This study will examine the implications of the degrees of femininity which are exemplified by the distinct types of women currently found within the criminal justice system: women who claim Battered Woman's Syndrome as a self-defense plea, women who defend themselves against their abusers, lesbians involved in capital cases, and women whose offenses aid in their categorization as being part of The Evil Woman Theory. Inherently these offenders share the same gender, but how their gender is portrayed

during their trial is disparate of one another. The issue of femininity is not only a case of discrimination against homosexual women, but also evidence of gender inequity occurring within the criminal justice system. Understanding the factors that influence a female offender's trial aids in arguing that the process for determining which offender receives a death penalty sentence is arbitrary and capricious.

Identifying the Source of an Introduction of Yellowfin Shiner
Clare H. Scott
Dr John Wares, Department of Genetics, University of Georgia

The introduction of a species into an environment where it is not native can have profound effects on that habitat such as a loss of native species and changes in the habitat where the organism was introduced. These events can also have a profound effect on the evolution of the introduced species, depending on the source and size of the introduction. Often determining the source of the introduction can be difficult due to the large native range of the species and the amount of time that has elapsed since the introduction. However, the Yellowfin shiner has recently been introduced to the Little Tennessee River (fewer than 10 generations ago). Also its range (with populations in the Chattahoochee and Altamaha basins in Georgia, and the Savannah, Broad, and Santee basins in South Carolina) is contained within the southeast US in close proximity to Athens, GA. Given these factors this study will be attempting to identify the source of the introduction and the initial size of the introduced group using genetic markers. I amplified mitochondrial and nuclear DNA gene regions, along with microsatellite markers, from each native population of Yellowfin shiner. These markers represent different portions of the genome and undergo different forms of selection and inheritance, which makes them useful in identifying the source population. By identifying the source it will be possible to observe the rate of evolution of a species that is adapting to a new habitat. Our results will also provide information about the dynamics of species introductions that can be used to manage other freshwater introductions.

Unsuspecting Targets – Preparing America's College Towns for a Bioterrorism Attack
Deep J. Shah – ROOSEVELT @ UGA
Dr. Loch Johnson, Department of International Affairs, University of Georgia

Review of biosecurity literature, analysis of federal documents, and original interviews with public health leaders reveals that football stadiums in small to medium-sized college towns, often distant from hub cities, are among the ideal targets for bioterrorism attacks. Such an attack could have devastating consequences similar to those following Hurricane Katrina. This paper assesses Athens, Georgia, using it as an example for comparable communities across the nation. Based on statistical data from the United States Department of Health and Human Services, Athens-Clarke County (ACC) regularly lacks adequate medical resources and personnel. Following a game day "BioKatrina" attack, the United States Department of Homeland Security estimates that 70 percent of stadium-goers will need medical treatment – 64,922 for Sanford Stadium. Such a strike would drastically overwhelm ACC's healthcare resources. In the event a contagious or extremely virulent bioweapon is used, it will be incumbent upon ACC leaders to contain and facilitate treating every potential victim. Moreover, physicians nationwide are unprepared to diagnose and treat bioterrorism victims without additional training. In order to expedite the clinical management of a stadium attack, Athens' leaders must do more than rely on mutual aid agreements. Printing evacuation routes on ticket stubs and fortifying potential treatment will create more organization within the healthcare response. Furthermore, every ACC official should be familiarized with the biological agent used, likely smallpox or anthrax, and its required treatment through Continuing Medical Education (CME) programs and other required educational curricula. The federal government should fund committees in

all communities like Athens to develop tailored curricula for these sessions. Enacting these measures will tremendously increase confidence and response capability at both the site of disaster and treatment facilities.

Construction of Plasmids for Deletion of the Polyphosphate Kinase Gene in *Mycobacterium tuberculosis*

Neel N. Shah
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

The causative agent of tuberculosis, *Mycobacterium tuberculosis*, exists in the latent phase in over one-third of the world's population. Annually, 8-10 million people suffer from the active disease leading to 2-3 million deaths. *In vitro*, *M. tuberculosis* can enter an antibiotic-resistant state of dormancy. Individuals cured of active TB disease typically remain latently infected and carry a 10% lifetime risk of reactivation of TB. Although the source of energy that this pathogen uses to emerge from latency is unknown, polyphosphates (polymers of high energy phosphate units) may be the source. To investigate whether polyphosphates participate in *M. tuberculosis* dormancy, we are constructing plasmid-based systems that will facilitate deletion of the *ppk* gene encoding polyphosphate kinase in this pathogen. Approximately 500 bp of chromosomal DNA on each side of *ppk* were obtained by PCR and cloned adjacently onto an *E. coli* plasmid to create a deletion cassette. These 500 bp flanking regions are required to direct homologous recombination/deletion of the *ppk* gene upon introduction of the recombinant plasmid into *M. tuberculosis*. Various derivatives of the deletion cassette plasmid have been created to help overcome the low homologous recombination frequency. Progress toward the construction of these plasmids will be presented along with a model for how these plasmids can be used to delete the *ppk* gene in *M. tuberculosis*.

Development of Leptin Resistance through High-fructose Diet

Christopher S. Sharp
Dr. Ruth Harris, Department of Food & Nutrition, University of Georgia

Over 60% of the American adult population is overweight or obese, with obesity becoming a critical health problem. Some studies have demonstrated a possible link between the consumption of high fructose corn syrup and obesity. Between 1970 and 1990 the consumption of corn syrup increased 1000%. The hormone leptin has been shown to inhibit food intake and increase energy expenditure in rodents and humans resulting in weight loss. It accomplishes this inhibition by signaling the hypothalamus, an area of the brain involved in food intake regulation, to change the expression of peptides known to regulate food intake and energy expenditure. Leptin must cross the blood-brain barrier to enter the hypothalamus; however, this transport can be inhibited by high concentrations of triglycerides in the blood. Studies have shown that diets high in fructose raise triglyceride concentrations; therefore we tested whether a high fructose diet could inhibit leptin function in rodents. In this study Sprague Dawley rats were fed either a 60% kcal high fructose diet or a control fructose free diet. After three weeks post-prandial serum triglycerides were approximately 175% those of the controls. The rats were infused with 60 μg/day rat leptin for two weeks. Leptin decreased body fat in the control rats but not those fed the high fructose diet. This experiment shows that high fructose diets impair leptin function, suggesting that the increase in consumption of high fructose corn syrup can potentially cause leptin resistance by raising serum triglycerides and thus may contribute to development of obesity.

Short-term Storage of MDBK Cells

Karin K. Sheehan
Dr. Jeremiah Saliki, Athens Diagnostic Laboratory, University of Georgia

Research involving the use of mammalian cell lines faces the difficulty of storing and preparing

cell cultures for experiments. Cell lines can be stored indefinitely in liquid nitrogen (-197°C), but must be properly thawed, grown, and trypsinized before use for research and diagnostic tests. The need for fresh cells results in high costs that would be reduced if cell suspensions could be stored over a period of days and remain viable for tests. For this study, Madin Darby Bovine Kidney cells (MDBKs) were stored for up to eight days in refrigerator temperature to determine if they maintained their sensitivity to bovine viral diarrhea virus (BVDV) infection. Twenty-four flasks of MDBKs were trypsinized and the cell suspension from each flask divided into nine aliquots. The aliquots were stored at 4°C, and one set of 24 suspensions was used each day for cell counting, titration of BVDV, and the serum neutralization test. Over the nine days (0 to 8), there were significant differences between cell counts but not virus titers or antibody titers. Days 0 and 1 had higher counts than Days 5-8, and Day 2 had a higher count than Days 6-8, with a statistical level of significance of 0.05. These findings suggest that MDBK cell suspensions can be stored at 4°C for a period of nine days and maintain their sensitivity to BVDV infection. These conditions are easy to maintain in a laboratory and can increase efficiency of maintaining cell lines by decreasing the costs of storage.

The Interaction between Culture, Poverty, and Educational Achievement: How Policy Can Better Impact the Graduation Rates of Georgia's Latino and African American Youth

Nari Shin, Celina Correa & Yuliya Kuzovkova – ROOSEVELT @ UGA
Dr. Larry Nackerud, School of Social Work, University of Georgia

The population of Georgia consists of various cultures, economic standings, and education levels. Research and statistical data show Latinos and African Americans in the state of Georgia consistently with a lower high school graduation rate. Georgia's Latino and African American populations have poverty rates that are higher compared to Caucasians. The factors of cultural background and economic standings are significant contributing variables. Decreased earnings are one of the important negative results on the adult lives for these youth groups. Analysis of data accessed from Emory University, the U.S. Census Bureau, and the Georgia Department of Education reveals the positive and powerful correlation between educational progression and economic standing among Latinos and African Americans. The purpose of this paper is to help understand the interaction of the complex variables of culture and economic standing affecting Latino and African American youths' educational progression. In order to combat this issue, various policies after investigation show positive results, such as the membership in the MSAN, the Minority Student Achievement Network, as well as Charter school options, and governmental aide through certain welfare programs. Another effective economic policy is the "Robin Hood Act" used in Texas to distribute equal state and local funds to school districts. Also, an increase in the federal budget for the study of national dropout rates will develop even more effective policies. These policies will help the development and execution of effective educational policies to decrease dropout rates for the Latino and African American students in the state of Georgia.

Determining Appropriate Social Assistance Models for Children Living in Communities Affected by HIV/AIDS in Sub-Saharan Africa

Helen C. Smith
Dr. Christopher Allen, Department of International Affairs, University of Georgia

The HIV/AIDS epidemic is particularly harsh in sub-Saharan Africa, where approximately 25.4 percent of people are infected with the virus. Children are often the most affected by the epidemic, frequently losing family members and access to resources early on. Appropriate policy responses to protect children from the shocks of HIV/AIDS have developed slowly, but the epidemic's scale requires comprehensive

solutions to strengthen communities and prevent new infections. A fundamental question is how resources should be disbursed in order to build the capacity and capital of households and communities in order to benefit vulnerable children. Currently, however, there are no comparative studies of social protection models that focus on children in communities affected by HIV/AIDS. This paper addresses some of these gaps through comparing targeted but unconditional payments, targeted and conditional transfers, cash for work programs and in-kind transfers. Case studies in South Africa were analyzed to see how well each performs as a family- and community-centered approach that is universal in its treatment of children, has long-term development potential, can be sustained by the government, and does minimal harm with regards to established community safety nets. The paper found that unconditional cash transfer payments offer the most potential, but more robust evaluation of current programs is needed.

The CO-H2 Variation in Translucent Clouds at Small Scales

Myra J. Stone
Dr. Loris Magnani, Department of Physics & Astronomy, University of Georgia

It is important to study interstellar molecular clouds, the sites of all galactic star formation, in order to understand the evolution of our galaxy. Because most of our knowledge of molecular clouds is tied to a determination of their mass, it is of fundamental importance to develop methods which lead to accurate mass estimates. One method is to calibrate the CO – H2 conversion factor known as X(CO). X(CO) is defined as the molecular hydrogen column density divided by the CO(1-0) velocity-integrated antenna temperature. There is a relationship between the integrated antenna temperature of CH and the amount of molecular hydrogen in a cloud which, in turn, can yield X(CO). It is via this CH-H2 relationship that we have re-examined the three interstellar molecular clouds MBM03, MBM16, and MBM40 in order to calculate how X(CO) varies over the clouds on scales of two arcminutes. Previous analyses measured changes on scales of nine arcminutes, so our objective is to explore variations in X(CO) at smaller scales. We present the analysis of new data taken at the Arecibo radiotelescope of MBM40, MBM16, and MBM03.

Characterization of the *vgat* Expression Pattern in the Developing Mouse Brain

Ryan J. Summers, CURO SCHOLAR
Dr. Brian Condie, Department of Genetics, University of Georgia

GABA (γ-aminobutyric acid) is the primary inhibitory neurotransmitter in the mammalian nervous system. The vesicular GABA transporter (VGAT or VIAAT) is a key component in the release of GABA as a neurotransmitter in the mammalian nervous system. It is responsible for loading GABA into synaptic vesicles for release at the neuronal synapse. Until now, the expression pattern of the *vgat* gene in the developing mouse brain had not been characterized. In order to address this question mouse brains at incremental stages from embryonic day 14.5 to embryonic day 17.5 were examined for *vgat* expression. This procedure was accomplished using a mouse line containing an insertion of the *lacZ* reporter gene into the *vgat* coding sequence. Visualization of the reporter gene expression has enabled characterization of the expression pattern of *vgat* in the mouse brain over the course of development. The results obtained indicate that *vgat* is expressed in regions previously identified as containing GABAergic neurons, including the striatum, ganglionic eminence, and cortex. These data indicate that *vgat* is a marker for GABAergic neurons. This characterization of the *vgat* expression pattern over the course of development has expanded our knowledge of the GABA neurotransmitter pathway. The data obtained shows where GABAergic neurons are located spatially as well as what neural circuits they are interacting with at different developmental stages; this information is crucial to understanding the role of GABAergic neurons in brain development.

Calcium-independent Phospholipase A_2 Are Novel Targets for Inhibition of Prostate Cancer Cell Growth

Sonia Talathi – CURO APPRENTICE & CURO SUMMER RESEARCH FELLOW
Dr. Brian S. Cummings, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Current treatments for prostate cancer include cisplatin and vincristine. Although these chemotherapeutics are somewhat effective, current strategies have focused on combinatorial dosing. This study tested the ability of the Ca2+-independent phospholipase A2 (iPLA2) inhibitor bromonenol lactone (BEL) to alter cell growth and death of human prostate cancer cell cultures (PC-3) in combination with commonly used chemotherapeutics cisplatin (0-50 μM) and vincristine (0-2 μM). Exposure of PC-3 cells to cisplatin for 48 hours resulted in concentration-dependent decreases in growth with an IC50 of 25 μM. Exposure of cells to BEL prior to cisplatin treatment lowered the IC50 to 6.25 μM. Similar results were seen for vincristine. These data suggested that treatment of cells with BEL potentiated the ability of cisplatin and vincristine to decrease cell growth. To study the mechanisms involve in this process, the effect of BEL, in the presence and absence of chemotherapeutics, on cell cycle and annexin and PI binding was studied. Exposure of cells to BEL increased the amount of cells in G1 while decreasing the amount of cells in S-Phase. Incubation with cisplatin or vincristine induced a G2-M arrest. However, pretreatment with BEL inhibited this arrest and increased the amount of cells in G1 and sub-G1. These data suggest that iPLA2 inhibition decreases cell growth by decreasing the progression of cells from the G1 to the S-phase of the cell cycle, that the effect of iPLA2 inhibitors and chemotherapeutics on cancer cell growth are additive, and that iPLA2 is a novel target for the inhibition of cancer cell growth.

Gene Expression Profiles of Neuronal Cells Derived from Human Embryonic Stem Cells

Christine E. Tarleton – CURO APPRENTICE
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Human embryonic stem (hES) cells are a potential source for generating large quantities of neuronal cells for use in cell therapy treatments for neurodegenerative diseases such as Parkinson's. A major goal in stem cell research is to fully understand and to reliably and specifically differentiate hES cells into the specific subtypes of neuronal cells. Our lab has derived an intermediate between hES cells and neuronal cells, the neuronal progenitor (NP) cell. NP cells have the ability to become several types of neuronal cells such as neurons, astrocytes, and oligodendrocytes. Although it is currently possible to differentiate neuronal cells from NP cells, this process is not fully understood in part because these cells have not been fully characterized. By isolating mRNA from the cells at different stages of differentiation (hES cells, NP cells, and neuronal cells) and using a low density array to perform simultaneous real-time PCR reactions of 95 genes known to play a role in neuronal development, it may be possible to determine which genes are expressed at each stage of the differentiation process as well as their relative quantification at these stages. Relative quantification will be determined by comparing the expression of the genes known to play a role in neuronal development to a housekeeping gene, a gene that is transcribed at a relatively constant level regardless of experimental conditions. It is our hope that these gene expression profiles will provide insight into the differentiation of hES cells into various neuronal cell types. We expect the derived NP cells to have similar gene expression profiles to neuronal epithelial cells; likewise, we believe that the derived neuronal cells' gene expression profile will be consistent with that of neurons.

Peyton Wall's Impact on Racial Relations in 1960s Atlanta, Georgia

Courtney M. Thomas – CURO APPRENTICE
Dr. Barbara McCaskill, Department of English, University of Georgia

In the 1960s, the city of Atlanta, Georgia was a booming metropolis that constantly added new businesses and residents. Americans considered Atlanta "The City too Busy to Hate," since many of the city's public and private areas were desegregated. However, much racial segregation existed among residential areas. One such neighborhood was Peyton Forest, an all-white subdivision located in southwest Atlanta. In the fall of 1962, the subdivision's developer grew dissatisfied with the rate of development and threatened to start selling homes in Peyton Forest to African Americans, since many blacks were currently moving into adjoining neighborhoods. Enraged by his threat, the white homeowners of Peyton Forest formed the Southwest Citizens Association, whose purpose was to maintain the neighborhood's racial homogeneity. Ivan Allen, Atlanta's mayor at the time, decided to stop the panic of these white homeowners by designating an area of unused commercial land to the north of Peyton Forest as a place to house low-to-middle income African Americans. On December 17, 1962, Mayor Allen further met the desires of Peyton Forest's white homeowners when he signed a proposal to build a 2-foot, 10-inch-high, steel and wood barrier that separated Peyton Forest from Collier Heights, a middle-class African American neighborhood. My presentation focuses on Peyton Wall's impact on Atlanta's reputation as a racially progressive city during the 1960s. I will also discuss how Peyton Wall and other racial buffers led to "white flight" in the city and the racial disparities between metro and suburban Atlanta that currently exist.

A Study of Site Formation Processes for the Northwestern Hawaiian Islands

Lindsey Thomas, CURO SCHOLAR
Dr. Ervan Garrison, Department of Anthropology, University of Georgia

The Northwestern Hawaiian Islands is the most remote archipelago of distant atolls in the world. Despite their small size, these islands have harbored shipwrecks for hundreds of years. Site formation process is the study of how a ship goes from being a highly organized machine whose purpose is to stay afloat to a scatter of artifacts on the bottom of the ocean. Every environment and type of ship undergoes a different site formation process. Site formation process is crucial to understanding the archaeological site, and can help archaeologists determine the path that a ship took as it wrecked. This is an ongoing study aimed at determining the unique characteristics of a wooden shipwreck in the Northwestern Hawaiian Islands. This paper is based on fieldwork conducted during a 2006 NOAA Hollings Program scholarship and research conducted through University of Georgia CURO Independent Research courses. The scholarship allowed the author to join the annual field research cruise to the Northwestern Hawaiian Islands on board the NOAA ship *Hi'ialakai.* To develop/apply a site formation theory to any particular region, it is necessary to use information about both the environmental conditions of the area and information about shipwrecks themselves. Information about environmental conditions in the Northwestern Hawaiian Islands was obtained from oceanographers that study the region, and the historical information about four shipwrecks (the *Pearl*, the *Parker*, and the USS *Saginaw,* and an unidentified fishing vessel) was obtained through fieldwork conducted by the author. Each site was mapped in as much detail as possible, and by combining this information with historical details about the shipwrecks and information about the environment, it was possible to gain a better understanding of site formation processes for wooden shipwrecks in the Northwestern Hawaiian Islands.

The Caddo Bateau

Lindsey Thomas, CURO SCHOLAR
Prof. R. G. Brown, Departments of Sculpture and Studio Foundations, University of Georgia

I am not an artist in the traditional sense. I study Maritime Archaeology, which could be considered a different type of art. The construction of the Caddo Bateau, a flat bottom fishing boat from Lake Caddo in Texas, was built so that I could gain a better understanding of small boat construction. This process will help me analyze future archaeological sites with a better understanding of the subject matter. The Caddo Bateau that is currently under construction will likely be built of cypress and mulberry, though that is dependent upon the availability of materials. The first step in constructing the boat was to draw the plans. Those plans were then converted into a scale model. The fifteen-foot boat was shrunk down to a thirty-inch cypress model. This model was built as a way to prepare for the construction of the larger boat and to work out any issues with the directions in advance. The Caddo Bateau was chosen as the type of boat to be built because it was small enough and simple enough to be feasible for a first-time boat builder to complete, while still offering several characteristics found in larger boats, such as plank construction and supporting knees. Ideally, by the end of construction I will be able to analyze shipwreck sites with a builder's eye rather than just a student's.

The Analysis of Synthetic Neoglycolipids by FTICR Tandem Mass Spectrometry

Laura A. Thornsberry
Dr. Jon Amster, Department of Chemistry, University of Georgia

Synthetic neoglycolipids are used as stabilizing agents in cationic liposomes, which are one of the most important nonviral gene carriers used in cancer gene therapy. A series of synthetic neoglycolipids, consisting of a sugar linked to a steroid by a polyethylene glycol (PEG) chain, were analyzed using Fourier Transform Ion Cyclotron Resonance mass spectrometry. Recently, synthetic neoglycolipids were observed to form a unique product ion, called the [C-glycoside]+, as the result of the excision of the PEG chain from the molecule. The purpose of this work is to confirm the structure of this novel product by tandem mass spectrometry, as well as study the conditions in which it is formed. Mass spectra of the samples were acquired in positive and negative ion modes, and collisionally assisted dissociation and infrared multiphoton dissociation were used to further fragment the ions. Initial fragmentation of the protonated species of the synthetic neoglycolipid samples resulted in the formation of the [C-glycoside]+ product ion. Further fragmentation of the [C-glycoside]+ ¬resulted in two peaks, which were assigned as the sugar and the steroid, thereby confirming the *in situ* formation of this ion-molecule product. In many cases, substantial amounts of formic acid were used to strengthen the intensity of the [M+H]+ peak. Some neoglycolipids were only observed as [M+Na]+, due to their inherent acidity, and did not form the [C-glycoside]+ product. The samples were also studied under negative ion mode, however, the novel product

did not occur under these conditions. The presence of acetylated groups on the sugar moiety of the molecule also proved unsuccessful in the generation of the novel product ion.

Glycosyl Composition Analysis of *Rhizobium leguminosarum* 3841 Bacteroids

Prince Tieku
Dr. Russell Carlson, Department of Biochemistry & Molecular Biology , University of Georgia

The legume-nodulating bacterium, *Rhizobium leguminosarum*, forms symbiosis with leguminous plants while other bacteria can not co-exist with these plants. Once inside the root cortical cells, the bacteria's surface membrane differentiates morphologically and functionally yielding bacteroids; the active form of the bacteria which carry out nitrogen fixation. The aim of this project was to study the biochemistry of the bacteroid surface lipopolysaccharides. Pea plants were infected with the *Rhizobium* and the bacteroids were isolated. The bacteroid lipopolysaccharides (LPSs) were extracted by a phenol-water method, and analyzed by polyacrylamide gel electrophoresis in deoxycholate (DOC-PAGE). DOC-PAGE revealed that a majority of the bacteroid LPS was recovered in the phenol layer. In contrast, free-living forms of the bacteria yielded LPS that partition primarily into the water layer. The extracts were analyzed by preparing TMS-methyl glycoside and alditol acetate derivatives with GC-mass spectrometry analysis. The phenol layer extract contained unusual, endogenously methylated glycosyl residues, having a higher degree of methylation than those derived from free-living Rhizobial LPS. These results indicated that the bacteroid LPS are altered compared to LPS from the free-living *Rhizobia*, indicating a shift toward greater hydrophobicity for the bacteroid LPS. These changes may contribute to long term bacteroid survival within the plant cell. This project seeks to further understand the molecular basis of the many stages of symbiotic infection. This in turn can result in the development (through molecular biological construction) of improved strains of *Rhizobia* that can broaden their host-range specificity, increase their competitiveness, and thus maximize legume growth rates and yields.

Trade for Humanity: A Proposal for Viet Nam

Anh V. Trieu & Ashley Bowen – ROOSEVELT @ UGA
Dr. Maurits Van der Veen, Department of International Affairs, University of Georgia

Despite pressure from the United Nations and the constraints of international law, the Vietnamese government continues to deny its citizens basic political freedoms. Fundamental rights like freedom of speech, press, and religion are routinely restricted in Viet Nam, which blatantly violates the United Nations' Universal Declaration of Human Rights. The United States, Viet Nam's largest trade partner with 21.2 percent of Viet Nam's trade activity, normalized trade with Viet Nam in 2006. The United States is in a unique position to create incentives for the Vietnamese government to improve its substandard human rights record. The United States, using reports from international human rights organizations, should prepare a series of human rights goals that Viet Nam must implement. For each year that goals are met, the United States would decrease tariffs on imported goods from Viet Nam by a percent. Offering phased incentives, a continued decrease in tariffs for each year, the policy should produce measurable improvement in Vietnamese human rights without the stigma and backlash of applying direct pressure. The incentive system would penalize Viet Nam for human rights violations and reward good behavior with increased participation in the global market. This policy would further the United States' commitment to promoting democracy and freedom in southeast Asia.

Genetic Systems for the Elimination of Polyphosphate Synthesis in *Mycobacterium avium* Subspecies *paratuberculosis*
Blake M. Troiani, CURO SCHOLAR
Dr. Russell Karls and Dr. Frederick Quinn, Department of Infectious Diseases, University of Georgia

Mycobacterium avium subspecies *paratuberculosis* (*M.a.p.*), a slow-growing pathogen of ruminants and the cause of Johne's disease, colonizes the distal ileum of the small intestines. As antimycobacterial treatment for *M.a.p.* infection is not feasible, a live-attenuated vaccine strain of *M.a.p.* may provide a better solution to Johne's disease. The goal of this research is to explore a new avenue for the creation of a suitable vaccine strain of *M.a.p.* Previous research has implicated the polyphosphate kinase gene (*ppk*) as essential to the survival of *Salmonella enterica* in acidic environments. Because *M.a.p.* similarly endures typically lethal pH environments and contains a putative *ppk* region, it is hypothesized that *ppk* serves an equivalent purpose in *M.a.p.* A *ppk* deletion mutant will be created by homologous recombination. Regions adjacent to *ppk* on the *M.a.p.* chromosome will be amplified by polymerase chain reaction (PCR) and cloned adjoining one another on an *E. coli* plasmid. Genes necessary to facilitate the isolation and screening of deletion candidates will subsequently be incorporated into the plasmids. The newly created vectors will serve as a suicide delivery vector for facilitating the deletion of *ppk* in *M.a.p.* via homologous-recombination mediated replacement of *ppk*. If the mutation causes the expected effect, diminished growth should be observed in situations that mimic the low pH *M.a.p* would encounter in infection conditions.

An Affect Control Model of Attribution
Traci N. Tucker
Dr. Dawn Robinson, Department of Sociology, University of Georgia

Past research has suggested that attributions are made on the basis of perception; however, more recent research suggests that attributions are generated when a conclusion is inconsistent with an individual's expectation. This study aims to answer the question of what drives individuals to make different types of attributions and how those attributions can be predicted for in any given situation. Two experiments examined the relationship between attribution and deflection, where deflection is conceptually defined as how unlikely a particular occurrence is, to see if high deflection rates would predict situational attributions and vice versa. Study 1 made use of self report data to assess the attribution outcomes of high and low self-esteem individuals when they were presented with either positive or negative feedback themselves. Study 2 then used computer simulations to calculate the expected deflection for the events of study 1. Results indicated that high deflection rates do indeed lead to situational attributions while low deflection rates lead to dispositional attributions.

Parasite Strain-dependent Cariation in CD8+ T Cell Responses Is a General Characteristic of Experimental *Trypanosoma cruzi* Infection
Jake E. Turrentine, CURO SCHOLAR
Dr. Rick L. Tarleton, Department of Cellular Biology, University of Georgia

The genome of *Trypanosoma cruzi*, the causative agent of Chagas' disease, contains a large number of *trans*-sialidase (ts) genes that encode for peptides recognized by $CD8^+$ T cells in mice and humans. In previous studies, experimental infection of C57BL/6 mice yielded dominant $CD8^+$ T cell responses against ts peptides TSKB20 and TSKB18. However, the kinetics and magnitude of the ts-specific $CD8^+$ T cell responses varied depending on the infecting parasite strain. The studies presented here sought to determine whether parasite strain-dependent differences in ts-specific $CD8^+$ T cell responses are a general phenomenon of experimental infection. Therefore, Balb/c mice were infected with different strains of *T. cruzi* (Brazil, CL or Y strain), and $CD8^+$ T cell responses to the previously identified ts epitope TSKD14 were

examined. $CD8^+$ T cells from Brazil-infected mice produced the pro-inflammatory cytokine IFN-gamma at higher frequencies following TSKD14 stimulation than did $CD8^+$ T cells from mice infected with CL strain. However, TSKD14-specific $CD8^+$ T cell responses were observed earlier following CL infection than following Brazil infection. TSKD14-specific recall responses were considerably lower from splenocytes of Y strain-infected mice. *In vivo* cytotoxic activity against TSKD14-pulsed cells also varied in mice infected with different parasite strains. Thus, as predicted, the kinetics and magnitude of TSKD14-specific immune responses show parasite strain-dependent variation in Balb/c mice. These results suggest that infection of humans by different strains may lead to substantially different immune responses and could contribute to different disease outcomes.

The Role of CD8+ T Cell Responses to Immunodominant Trans-sialidase Epitopes in Control of Experimental *Trypanosoma cruzi* Infection

Jake E. Turrentine, CURO SCHOLAR
Dr. Rick L. Tarleton, Department of Cellular Biology, University of Georgia

Trypanosoma cruzi, the causative agent of Chagas' disease, afflicts approximately 18 million people in Central and South America. In both humans and mice, the $CD8^+$ T cell response is critical for management of *T. cruzi* infection. Depletion of $CD8^+$ T cells during infection leads to elevated parasitemia, and mice deficient in $CD8^+$ T cells are unable to control the infection. In *T. cruzi* infection of Balb/C mice, dominant $CD8^+$ T cell responses against a single *trans*-sialidase (ts)-derived peptide (TSKD14) have been identified. This study examines the role of TSKD14-specific $CD8^+$ T cell responses in the control of *T. cruzi* infection. To this end, mice vaccinated to induce potent TSKD14-specific $CD8^+$ T cell responses, or tolerized to prevent the induction of TSKD14-specific responses during infection, have been generated. These mice will be challenge infected with *T. cruzi*, and the ability to control the infection will be determined. We predict that vaccination to induce TSKD14-specific responses will protect mice from lethal infection and that tolerization of this response will make mice highly susceptible to challenge infection. The possibility that responses to alternative ts or non-ts epitopes may be able to compensate for the absence of the dominant $CD8^+$ T cell response against TSKD14 will also be investigated. Results from these experiments will reveal the importance of the ts-specific $CD8^+$ T cell response and will provide guidance for the formulation of vaccines for *T. cruzi* infection.

The Effect of Women as Candidates in Congressional Campaigns

Anna Tyler
Dr. Ruthann Lariscy, Department of Advertising & Public Relations, University of Georgia

Each election cycle, more women are elected into the US House and Senate. Women are also increasing their numbers in leadership roles within the political sphere and constantly expanding opportunities for future generations of women in politics. The fight to be elected to a national office is one that women of all ages, races and beliefs have struggled with for decades. Six races for the House of Representatives were examined during the 2006 Election Cycle in order to shed light on the dynamics of campaigns in relation to gender. The races were broken into three subgroups: two races featuring men only, two races featuring men and women, and two races in which just women ran. The data are drawn from a variety of local and national news publications from across the country as well as several previously conducted research studies on women and political campaigns. Previous studies suggest support for the idea that women who assume offensive positions in policy areas that are considered traditionally male receive increased support and higher approval ratings. However, gender was shown to have no real effect on negativity or attack ads during the campaigns. Rather, as more and more women enter politics at the national level, races are focusing less on gender and more on other aspects of the

candidate's life such as their party affiliation and previous political experience. This expansion of women into the political arena creates a new and exciting dynamic, especially as the playing fields appear to level and gender is taken out of the equation, by opening the door to more viewpoints and a variety of backgrounds and opinions.

Music and Identity among Mexican Immigrants in Atlanta, 1985-2006
Karen C. Usselman
Dr. Pamela Voekel, Department of History, University of Georgia

Mexican immigrants to the United States have used music to cope with the struggles of living in a new society, to maintain a connection with their homeland, and to create unified immigrant enclaves for as long as the border between the two countries has existed. But just as trends in immigration fluctuated, so too have the styles, content, and popularity of music in immigrant communities. Studying the changes in the music of Mexican immigrants reveals varying degrees of cultural mixing and assimilation, evolving economic and social struggles, attempts at establishing a cohesive immigrant community, and even the development of a new Mexican-American identity. The city of Atlanta, with its exploding Mexican immigrant population, vibrant musical tradition, and historically active minority population, provides a unique and relatively unstudied locale for exploring the effects of music on Mexican immigrant identities in a rapidly globalizing society. My three primary methods of conducting such research are to examine the styles and content of popular song lyrics from the late 1980's onward, to read the Atlanta newspaper Mundo Hispánico from the same period, and to interview music industry professionals in Atlanta, such as record store owners and radio station managers, about the evolution of Mexican music and changes in the listening audience. This approach reveals a multi-faceted and dynamic Mexican-American identity, rooted in a sense of shared history and developed through shared experiences, that reflects the changes of a globalizing culture.

Chicken Water*, *What Are We?*, and *We Are Nothing But the Scraps
Kacie Versaci
Prof. Judith Ortiz Cofer, Department of English, University of Georgia

I began writing as soon as I could form words on pages, transferring images from my brain to the paper. Time has brought me to the ripe old age of 20, where I have been finding many more outlets for my writing than just journals and private scribbling. In the spring of my sophomore year of college, my writing focused on poetry and prose-poetry, then shifted the fall of my junior year to more essays and creative non-fiction. I am at a phase now where I am experimenting with ruination, by blending other works into new poems and crossing genre lines to create new media. I am also working on a series of short, creative non-fiction pieces about various relationships in my life and experimenting with different forms of stream-of-consciousness fiction. I draw a great deal of influence from Judith Budnitz, trying to blend imaginative story telling with fresher takes on prose. My current area of study is magazine journalism, so more of my writing style is drawn from the writing skills learned in that field.

The Effectiveness of Teaching Expressive Arts Activities Based in the Methods of Art and Drama Therapy to Educators to Improve Student Welfare
Erika B. Vinson – CURO SUMMER RESEARCH FELLOW
Dr. Richard Siegesmund, Department of Art Education, University of Georgia

The purpose of this mixed-methods study is to determine the effectiveness of The ArtReach Foundation's Train the Trainers workshops in preparing teachers and community leaders to use art and drama therapy-based activities with their children to help them express themselves. Data were collected through surveys, interviews, follow-up interviews, and visual journals. The participants were Arkansas educators, counselors, and administrators, some of whom have received Gulf Coast evacuees in their

classrooms. Six school counselors, five art instructors, one preschool multicultural specialist, one social worker, one incarcerated-parent educator, and one school administrator completed two surveys. The first survey inquired about the participants' first experience in the five-day workshop in October of 2005 and how it has affected their work with children. The second survey pertained to the second phase of training conducted during a week in June 2006. Eleven counselors and teachers participated in thirty-minute semi-structured interviews. All participants were also provided a visual journal in which to document their personal reflections and reactions to the workshop curriculum by means of text and images (Grauer & Naths, 1998). Starting with the daily goals and objectives used by the ArtReach professionals to organize instruction, the data is thematically reviewed with a focus on discursive, metaphoric, and visual symbolic meaning in the participants' visual journals. Preliminary findings suggest that visual journals aid in sustaining and expanding important metaphors utilized during instruction, help to organize thoughts, and clarify points emphasized during instruction, and show complexity of thought leading to more robust understandings of the participant.

Initial Sequencing and Tissue Distribution of Toll-like Receptor 3 mRNA in White-tailed Deer

Seychelle M. Vos
Dr. Elizabeth Howerth, Department of Veterinary Pathology, University of Georgia

Hemorrhagic disease is a fatal disease in white-tailed deer (WTD) caused by two closely related double stranded RNA orbiviruses, bluetongue and epizootic hemorrhagic disease. Susceptibility to these viruses varies among populations of WTD, and results from experimental studies suggest that innate immunity may contribute to these differences. It is hypothesized that the Toll-like receptor 3 (TLR3), an important cell surface receptor in innate immunity that recognizes double stranded RNA (dsRNA), may be involved in differences in innate immunity in WTD populations. However, little is known about TLRs in WTD, and rudimentary information is needed before the potential effect of TLR3s on disease susceptibility can be evaluated. Therefore, the objectives of this study were to perform initial sequencing and determine tissue distribution of the mRNA of TLR3 in normal WTD. A 209bp portion of WTD TLR3 mRNA was sequenced using primers designed originally for the TLR3 in cattle. Primers were then designed specifically for deer using the newly sequenced fragment. A northern blot was performed to confirm that the sequenced mRNA fragment was the TLR3 receptor. Quantitative analysis of TLR3 mRNA in various WTD tissues from non-infected WTD was performed using real time-polymerase chain reaction (RT-PCR). The results suggest that the TLR3 is expressed in skin, small intestine, brain, lung, and spleen tissues at levels that may prove useful in future research. These initial results will allow further investigation into the overall significance of the TLR3 in variation of susceptibility to disease among WTD populations.

Identification of L-PHA Reactive Glycoproteins from Invasive Breast Carcinoma Tissue: Potential Biomarkers for Early Detection

Rachelle W. Wallace, CURO SCHOLAR
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

There is an urgent need for the research and development of biomarkers for breast cancer to aid in diagnosis. The focus of this project is the use of new glycoproteomic techniques to discover biomarkers for breast cancer. Glycoproteomics will allow the identification of specific glycoproteins that have been reported to contain an identified carbohydrate structure attached to an asparagine residue on glycoproteins known as the β (1,6) N-linked glycan. The presence of this glycan is altered throughout the progression of breast carcinoma. Recent studies have found that the lectin L-PHA binds to and enriches for glycoproteins expressing the β (1,6) N-linked glycan, which is present on glycoproteins expressed in breast

carcinoma, but is absent in non-diseased tissue. The goal of this study was to detect the glycoproteins that contain the β (1,6) N-linked glycan in the tissue of patients with breast carcinoma. The binding of this lectin indicates the expression of the β (1,6) N-linked glycan. Analysis of the tissue was performed by means of lectin-affinity chromatography and liquid chromatography/mass spectrometry in order to identify glycoproteins or glycopeptides that show this specific β (1,6) N-linked glycan in breast carcinoma and to show the ability of this lectin L-PHA to enrich for these proteins. Several glycoproteins identified as a result of L-PHA enrichment have been previously linked to cancer in recent literature, specifically within the TGF-β signaling pathway. With further research, one of these identified proteins could potentially become a biomarker for breast cancer diagnosis.

The Price of Victory: Influences on the Conduct of War

Joshua J. Watkins – CURO SUMMER RESEARCH FELLOW, CURO SCHOLAR
Dr. Patricia Lynne Sullivan, Department of International Affairs, University of Georgia

The deployment of military forces abroad is one of the most difficult and profound decisions national leaders face because of the daunting task of determining the potential human and material costs of attaining a state's political objectives. But there have been no attempts to collect systematic data on leaders' pre-war expectations about the duration, casualty rates, or troop and resource requirements of military operations. In addition, extant literature does not explore the connection between leaders' pre-war expectations and public support for sustaining military operations once they are underway. I used military records, government documents, archival material, newspaper articles, secondary historical accounts, and chronologies of international events to collect data on both anticipated and actual troop deployments, conflict escalation, casualty rates, assistance from allies, and public support for sustaining British, French, and U.S. military interventions since World War II. My research suggests that leaders' pre-war expectations are often misguided and, in some cases, completely wrong. I also found that public support for sustaining military operations tends to decrease over the course of a conflict, although not as dramatically as previous case studies would cause one to believe. Levels of support vary according to the objectives of a military intervention, the human cost, and public perceptions of progress. This research provides insight regarding the ability of nations to bear the costs of future conflicts.

Sexual Orientation as a Diffuse Status Characteristic: The Effects of Sexual Orientation on Expectations in Interaction

Alexander W. Watts – CURO SCHOLAR
Dr. Dawn Robinson, Department of Sociology, University of Georgia

Status characteristics theory attempts to model how groups working together to complete a task act according to a shared hierarchy of expectations based on group members' expectations for each other's competency. This hierarchy is based on group members' characteristics that are both unrelated (diffuse status characteristics) and immediately related (specific status characteristics) to the task at hand. Despite the wealth of literature providing evidence for gender, age, and occupation operating as diffuse status characteristics, no experimental research has tested the operation of sexual orientation as a diffuse status characteristic, though the implications of discovering the effects of sexual orientation are profound. For example, what effect does the perception of a jury member's sexual orientation have on the rest of the jury's tendency to value his/her input? Would a heterosexual U.S. soldier be less likely to obey the commands of an openly gay officer? In this paper, I provide evidence for the need to empirically test the effects of sexual orientation on expectations in interaction through an experimental design. I find that survey data, past research, and theoretical reasoning illustrate that sexual orientation likely influences expectations in task settings. Furthermore, based on survey data and

the results of a computer simulation of affect control theory, I provide evidence that the effects of sexual orientation on the group's shared hierarchy of expectations are conditional upon the gender of the group members. Last, I will make more general conclusions about the real-world and theoretical implications of my findings and suggestions for future research.

The Legacy of AQ Khan: An Analysis of Illicit Trade Patterns in the Pre-enlargement European Union since the Exposure of the Khan Network and Recommendations for Preventing Future Catastrophe

Daniel Weitz – CURO SUMMER RESEARCH FELLOW & ROOSEVELT @ UGA
Dr. Gary Bertsch, Center for International Trade & Security, University of Georgia

Illicit trade of items that pose severe threats to international security has surfaced noticeably in recent years. The ever-increasing volume of global trade, the availability of assorted dangerous goods on the open market, and circumvention of international trade law have created an ideal environment for traffickers to procure and supply illicit goods. Consequently, illicit trafficking has become a subject of much international concern amongst academics, policymakers, and government officials alike. The term illicit trade encompasses numerous aspects of unlawful trafficking, including the types of goods being trafficked, the countries used as points of transit, and other variables. This paper focuses specifically on the trafficking of nuclear dual-use goods, defined as equipment and technologies with legitimate civilian and non-military uses that are exploitable for the construction of nuclear weapons. This topic is of critical importance because illicit transfers of nuclear dual-use items have already contributed to at least one nation's procurement of nuclear weapons, and future nuclear weapons developments by such means remains largely open unless effective measures are taken to deter proliferators. This paper seeks to analyze existing trends in the trafficking of nuclear dual-use equipment and technology throughout the pre-enlargement European Union since the 2003 procurement of nuclear weapons by the Pakistani national Abdul Qadeer Khan's illicit trafficking network. Through the creation of a database documenting cases of illicit trade based upon extensive open source research, this paper will offer an intensive analysis of trafficking trends in the countries most heavily linked to illicit trade. Furthermore, this paper will analyze the export and border controls of these countries and offer policy recommendations based on perceived deficiencies with the hope of curbing means of illicit trade currently available to traffickers.

The Effect of Age on Subject Doubling in French

Melissa E. Whatley
Dr. Diana Ranson, Department of Romance Languages, University of Georgia

Native speakers of French often produce utterances, such as "la grammaire c'est difficile", which exhibit Subject Doubling (SD), a noun, which alone could serve as a subject and a corresponding subject pronoun. While most examples of SD serve a pragmatic function, such as topic identification or comparison, others appear to serve no function. This fact has led several researchers to propose that the subject pronoun in spoken French is agglutinating to the verb, and that eventually every verb will be preceded by a pronoun despite its pragmatic function. The finding that younger speakers produce more SD than their older counterparts would support this hypothesis. This study is based on an aural analysis of 1,390 utterances with noun subjects in spontaneous conversations with 32 native speakers of French, recorded in Southern France in 2005 and 2006. The 16 younger speakers, 24 to 40 years old, produced a slightly higher percentage of SD than their 16 older counterparts, 43 to 78 years old (40% vs. 33%). These speakers also produced more pronouns lacking pragmatic functions (29 examples or 10% of the total number of pronouns) than the older speakers who produced only 16 such pronouns (8%). This 2% difference is not statistically significant. Even though younger speakers produced a higher percentage

of utterances with SD and a higher percentage of doubled pronouns with no pragmatic function, the finding that 63% of the utterances with noun subjects in the corpus do not exhibit subject doubling argues against the hypothesis that the subject pronoun is agglutinating to the verb. According to this research, French is not changing in this aspect of its verbal morphology.

Investigation of the Horizontal Transfer of Virulence Factors of *Staphylococcus aureus* between Humans and Companion Animals

Brooke L. Wheeler
Dr. Susan Sanchez, Athens Diagnostic Laboratory, University of Georgia

Staphylococcus aureus is part of human's transient microflora, found on approximately 20% of people at any time, occasionally causing opportunistic infection. Methicillin resistant *Staphylococcus aureus*, MRSA, emerged following the introduction of antibiotics to healthcare. Previously there has been a distinction between "hospital acquired" MRSA with resistance to multiple antibiotics and a "community acquired" MRSA that seemed unrelated to the healthcare settings, had fewer resistances, and sometimes had a leukocidin toxin that was especially virulent. A major concern is that companion animals are also reservoirs of the organism suggesting a greater potential of transmission. These animals have been insinuated as the sources of strains causing infections in their owners. To test the prediction that the MRSA strains found on companion animals are actually different from the ones that cause infections in humans, samples were taken from canines at the small animal teaching hospital. These were tested by PCR, all confirmed *mecA* positive, which shows the organism carries antibiotic resistance, and *nucA,* which is specific to *Staphylococcus aureus*. The positive samples were then tested by PCR for superantigens including SEA-SEE, SEG-SEJ, ETA, ETB and TSST-1. The strains were also typed and found to be genetically similar to the human strains USA900 and USA100, one seemingly identical to USA300. Though the strains found on humans and non-human animals came from a common original strain, the difference in the virulence factors found in the human versus the companion animal strain suggest that animals are being wrongfully blamed as the infection source.

Mothers' Parenting Styles and Their Toddlers' Compliance

Lionel (Leo) White
Dr. Hui-Chin Hsu, Department of Child & Family Development, University of Georgia

During the second year of life, toddlers develop their first sense of autonomy. Due to this dramatic change and the resulting difficult interactions with parents, this age period is typically referred as the "Terrible Twos." Parents may use different strategies to deal with their two year olds' misbehaviors. Within a larger longitudinal study from infancy to early childhood, an experiment of "Toys on Shelf" was designed to target toddlers' compliance following maternal orders. Children were instructed not to play with toys on the shelf by their mothers. The social interaction between a total of 73 two-and-a half-year-olds and their mothers were observed and videotaped. Previous research showed that young children's compliant behavior is related to their motivation to learn (Kochanska, Tjebkes, Forman 1998). This study will focus on the examination of whether and how mothers' parenting styles relate to different degrees of compliance with the child. The observation of child compliance, which varies from committed compliance (full endorsement of maternal agenda), to situational compliance (compliance is sustained by continuous maternal prompting), passive noncompliance (child ignores maternal directives without overt negativity), overt resistance (refusal or negotiation of maternal agenda), and to defiance (overt rejection of maternal agenda), is based on the system developed by Kochanska et al (1998). It is expected that maternal guidance (e.g. request, reason, positive evaluation, verbal/nonverbal empathy) contributes to toddlers' committed compliance, whereas maternal control (which includes negation, power assertion, reprimand, and bargaining)

contributes to the children's overt resistance and defiance. The detailed results and implications of mother-child interaction on the emotional development of the toddler will be discussed at the conference.

Investigation of State-controlled Media Outlets and Their Reports on Internal Conflict: A Xinjiang Province Case Study
Ashley A. Wilkinson
Dr. Stephen Shellman, Department of International Affairs, University of Georgia

My research concerns how state-run media depict internal conflict to the outside world, and whether foreign media report the situation differently or merely repeat the state-run media's viewpoint. In researching state-owned media reports of conflict I will perform a quantitative case study of the media coverage of the Xinjiang province of China. This study will consist of developing a scheme to codify the frequency, scope, magnitude, and political slant of several newspapers' coverage of the conflict in the Xinjiang province between Uighur nationalists and the Chinese government. I will code the frequency of reports and the frequency of particular terms used across different media sources, and I will code how the coverage differs in scope and magnitude, and how media sources on the left and right cover the conflict. Since the Chinese established the northwest territory known as the Xinjiang province, the native ethnic Uighurs have believed that the Chinese Han majority has infiltrated and repressed their culture. While some Uighur groups have tried to re-establish their sovereignty through protests, other groups such as the East Turkestan Liberation Front have gone as far as bombing buildings. China has taken a strong stance against Uighur nationalism, and since the Chinese government has great influence over its newspapers, I hypothesize that the Chinese media have an anti-Uighur bias. I also hypothesize that many Western papers have used state-run media sources in their reports without using other sources, and thus may be promulgating Chinese government opinions. This project is part of a growing body of research on both the influence of state-run media bias and the conflict in the Xinjiang province. I hope that this study contributes to future research on these topics.

The Broken Bridge: Discovering Why Alpha-Dystroglycan Loses Its Function
Jasmaine D. Williams – CURO SCHOLAR
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia

Alpha-Dystroglycan (aDG) is a protein heavily glycosylated with N and O-linked sugar molecules that plays a key role in the function of muscles and neurons. Together with other proteins in a multiprotein complex, aDG establishes a necessary connection between the cytoskeleton within the cell and the extracellular matrix. Improper glycosylation of aDG has been associated with metastasis in certain cancers and genetic defects in the enzymes that add a particular type of glycosylation, known as O-mannosylation, to aDG result in improper function of the protein and congenital muscular dystrophy. The severity of the hypoglycosylation correlates with the severity of the resulting disease. The purpose of this project is to identify the key residues that cause aDG to lose its function. Chinese Hamster ovary (CHO) cells will be used to express the protein for these experiments since several existing CHO cell lines have known defects in specific glycosylation pathways. An epitope-tagged aDG expression plasmid and transient transfection conditions have been generated. We are currently in the process of purifying the wildtype protein taking advantage of the epitope tag and will be monitoring purification via Western blotting and silver staining of SDS-PAGE gels. Purified protein will be assessed for function via binding to laminin using surface plasmon resonance. Future work will focus on analyzing site-directed mutants of aDG that are defective in glycosylation as well as expressing the wildtype protein in CHO cells that are defective in specific glycosylation pathways. By doing so, we expect to discover the key residues and glycosylation types that are essential for proper

aDG function. This research is supported by the Muscular Dystrophy Association.

Titanium Carbide Nanocrystals: A Storage Medium for the Coming Hydrogen Economy?

Kathryn E. Williamson
Dr. Steven Lewis, Department of Physics & Astronomy, University of Georgia

As energy consumption continues to rise, the need for an alternative fuel supply has become ever more prevalent. The hydrogen economy offers great potential as the next source of energy delivery. Hydrogen is nonpolluting and abundant; however, more research needs to be done in the technology of production, storage, and use. Our research focuses on the storage issue. Nanocrystals are good candidates for hydrogen storage due to their high surface to volume ratios. Hydrogen atoms could be stored by binding to the surface or within the interiors of nanocrystals, and could later be extracted for use. We have concentrated on the class of nanocrystals called metal carbides, specifically titanium carbide. Titanium is a lightweight metal and, when compounded with carbon, the structure offers several good candidate sites for binding hydrogen. We have treated interatomic interactions quantum mechanically to understand accurately how hydrogen interacts with the titanium carbide nanocrystal and where it is likely to bind. This has been done using the Vienna Ab-initio Simulation Package (VASP), which is a robust, widely used program for solving the quantum mechanical equations numerically on supercomputers. These simulations reveal detailed microscopic information about the electronic structure and bonding energetics of the hydrogen/titanium carbide system. By comparing results for different configurations, we have determined likely locations for atomic and molecular hydrogen to bind and the strengths of these binding interactions.

Political and Social Foundations for Environmental Sustainability

Karen C. Wong
Dr. Andrew Whitford, Department of Public Administration & Policy, University of Georgia

Environmental sustainability is the long-term preservation of our environment for the future. The purpose of our essay is to quantitatively investigate several possible foundations for environmental sustainability, as measured across countries with varying geography, development patterns, social customs, and political arrangements. We first test two central hypotheses about the roles of democracy and federalism. Our study asks if democracy increases environmental sustainability and if federalism reduces sustainability. We also assess the roles of organized groups representing different kinds of environmental interests, development paths, and religious orientations. To measure sustainability, we use three measures of sustainability (environmental systems, environmental stresses, and human vulnerability) from the 2002 Environmental Sustainability Index (ESI). We find little evidence for variation in sustainability levels given variation in either democracy or federalism. However, we find that the effect of economic development (both current and historical) depends on the measurement of sustainability. Stress and vulnerability are affected by business practices and international environmental organizations (but environmental systems are not), and the effect of Protestant religious affiliations depends on our measurement of sustainability. Although these findings show no clear political foundation, they portray a complex and varied set of foundations for environmental sustainability.

Poppy Reliquaries* and *Tissue Ring
Laura Wood
Prof. Rob Jackson and Prof. Mary Hallam Pearse, Department of Jewelry & Metalwork, University of Georgia

My recent works reflect themes of memory and preciousness. Containment of the memory is a way for me to exemplify the importance of the object within. I pull inspiration for my work largely from my surroundings. *Poppy Reliquaries* were inspired by the poppy plant that grows throughout Italy. While living in Tuscany over the summer of 2006 I noticed the life cycle of these plants. While the plants were alive they were bright blooms and as they began to die their brightness would subside and they would eventually loose their petals, stiffen and turn beautiful colors of brown. The fragile poppies would remain until the weather took its toll. I wanted to give these plants a home for which I could protect and cherish them. The poppies remain a lasting memory of Italy. *Tissue Ring* also alludes to a memory. This piece was created to embody the characteristics of my mother and grandmother who often carried tissues on hand. The tissues were used for anything from blotting lips to blowing noses. I chose to honor this childhood memory. The tissue housed inside this piece evokes the memory and the ring is a means to contain a precious moment in time.

Molecular Regulation of Parathyroid Organogenesis in the Mouse
Shannon F. Yu – CURO SUMMER RESEARCH FELLOW, CURO SCHOLAR
Dr. Nancy R. Manley, Department of Genetics, University of Georgia

In mice, the parathyroid and thymus glands develop from shared primordia that form from the third pharyngeal pouch. The parathyroid glands are the most important endocrine regulator in maintaining calcium homeostasis in order to achieve the proper functioning of the nervous and muscular systems. At E 11.5, the parathyroid and thymus are morphologically indistinguishable, but can be marked with two organ-specific transcription factors: Gcm2 and Foxn1, respectively. Consistent with its expression pattern, $Gcm2^{-/-}$ mutant mice are aparathyroid. Analysis of the third pouch-derived primordium in $Gcm2^{-/-}$ mutants showed that the parathyroid gland was present prior to E12.5 and was lost due to apoptosis between E12-12.5. Additional gene marker analysis excluded the possibility that Gcm2 is required for pouch patterning or for the establishment of the parathyroid domain, but did find evidence for a requirement for *Gcm2* in differentiation and subsequent survival of parathyroid cells. Previous research from our lab has implicated Shh in the regulation of *Gcm2*, which is undetectable in $Shh^{-/-}$ mutant mice. Changes in the expression of *Gcm2* suggest that a Shh gradient is responsible for establishing the location of *Gcm2* expression. *In situ hybridization* analysis of the $Shh^{flx/flx}$ allele, which exhibits a reduced range of diffusion, did not reveal any phenotypic change at E11.5, and

demonstrated *PTH* expression at E12.5, indicating normal parathyroid differentiation. Analysis of the *ShhN* allele, which demonstrates an extended range of diffusion, revealed concurrent expansion of *Gcm2* and *Tbx1* expression, supporting a role for Shh in regulating parathyroid organogenesis. Thus, the data support our model in which Shh regulates *Gcm2* expression in a concentration-dependent manner.

The Effects of Colostral Leukocytes on TNFα Levels in Neonatal Calves
Leilah D. Zahedi – CURO APPRENTICE
Dr. David Hurley, Department of Large Animal Medicine, University of Georgia

Colostrum, the "first milk" produced by all mammals, contains many immunological components, including immunoglobulin, cytokines, and maternal leukocytes that help protect the neonate in the first days after birth. Tumor necrosis factor alpha (TNFalpha) is a cytokine associated with immune function and an activator of inflammatory responses in the body. It is not clear, however, how colostral leukocytes affect TNFalpha levels in the neonate. The purpose of this project is to determine the effects of maternal cells in colostrum on serum concentrations of TNFalpha in neonatal calves. Calves were fed either whole colostrum (C), frozen colostrum (FC), or cell-free colostrum (CFC) within 6 hours of birth. Blood samples were collected before the calves were fed colostrum, 1 day, 2 days, and 7 days after feeding. TNFalpha levels were measured using a TNFalpha specific ELISA assay, and samples were compared to a standard curve using recombinant bovine TNFalpha protein. Preliminary results indicate that at birth all calves have levels of TNFalpha below 2 ng/mL. At 24 hours, the calves receiving CFC had the highest level of circulating TNFalpha (mean 29 ng/mL), the calves receiving FC had moderate TNFalpha concentrations (mean 16 ng/mL) and the calves receiving C had the lowest TNFalpha concentrations (mean 12 ng/mL). By 48 hours, serum concentrations of TNFalpha were similar in all groups (mean 13 ng/mL). The results for samples collected 7 days after feeding are being determined. These results are consistent with the concept that transfer of maternal leukocytes reduces early inflammatory activation in he neonate.

Lectin Histochemistry of Cell-surface Glycoproteins of the Non-pathogenic Ciliate *Tetrahymena thermophila* and the Pathogenic Ciliate *Ichthyophthirius multifiliis*
Jessica Zaleon – CURO APPRENTICE
Dr. Thomas Krunkosky, Department of Veterinary Anatomy & Radiology, University of Georgia

The non-pathogenic ciliated protozoan, *Tetrahymena thermophila*, is a suitable candidate for the expression of heterologous surface proteins from a pathogenic ciliated protozoan, *Ichthyophthirius multifiliis*. *I. multifiliis* expresses abundant membrane proteins known as immobilization antigens, or i-antigens. These proteins elicit an immune response in the infected host and are the focus of vaccine development. *I. multifiliis* theronts and *T. thermophila* cells will be analyzed using a panel of highly purified lectins. These biotinylated proteins bind to cell-surface glycoproteins and will be utilized in immunohistochemical methods to detect them. In addition, cell-surface glycoproteins of *T. thermophila* expressing *I. multifiliis* i-antigens will also be analyzed with these lectins. Of particular interest will be the detection of any differences in the lectin staining as a result of the i-antigen expression in *T. thermophila*. The results of this study will elucidate the effectiveness of utilizing lectin histochemistry as a detector of changes that might occur in the staining pattern of cell-surface carbohydrates when a heterologous surface protein is expressed in a non-pathogenic host. With the findings of this study, the potential effectiveness of *T. thermophila* as a vaccine expression vector will be elucidated.

The Center for Undergraduate Research Opportuntities is grateful to the following sponsors for underwriting the 2007 Symposium.

Symposium 2009

University of Georgia
Classic Center, 300 N. Thomas Street
March 30, 2009

CALL FOR ABSTRACTS

The Center for Undergraduate Research Opportunities at the University of Georgia provides a forum for all undergraduates to present original research and creative works sponsored by faculty members. Undergraduate students from all disciplines are encouraged to participate. Representatives of public and private higher education institutions in Georgia are encouraged to apply.

Presentations may be in the form of an oral presentation, poster session, exhibition, performance, or work of art. Students can also present a tutorial about a research methodology or new technology. Undergraduate researchers who are at various stages of the research process are encouraged to submit abstracts describing where they are in the research process and the issues they face. Those who wish to present their work should submit an application and an abstract of a maximum of 250 words and a brief supporting letter from the sponsoring faculty member via the CURO web site no later than January 16, 2009. Group research projects should be submitted with one application and one letter of faculty support. All abstracts will receive graduate student peer review with faculty guidance. All participants accepted into the Symposium will be notified by February 27, 2009, and their abstracts will be published in a book of abstracts. Sponsoring faculty will be invited to preside at their students' sessions.

Best Paper Awards
Papers on work being presented at the CURO Symposium submitted by March 13, 2009 will be considered for Best Paper awards in the categories of humanities, social sciences, civic responsibility focus, international focus, and sciences. Papers must be submitted electronically to curo@uga.edu. Maximum length is 20 pages, double spaced.

Purpose of the Symposium:
- To highlight excellence in research by undergraduate students
- To enrich the undergraduate experience by promoting communication and cooperation between faculty and students
- To provide a forum for undergraduates to communicate and disseminate their research findings and creative works
- To provide an opportunity for undergraduate researchers in the state of Georgia to engage with their peer researchers

Criteria for Selection:
- Originality and quality of research
- Quality of written abstract
- Ethical and responsible research
- Extent of the undergraduate student's involvement in development of the research design and execution of the project. Research presented at the Symposium should go beyond work completed for a class paper or project
- A letter of support from supervising faculty

This event will be free and open to the public. All interested faculty and students are encouraged to attend the CURO 2008 Symposium. For more information, contact curo@uga.edu, (706) 542-5871.

Monday, March 31, 2008

Concurrent Oral Sessions

Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

10:10 – 11:00 a.m. First Concurrent Session

Room A	**Rachel Dolan**	Two Faced Politicians: Political Supply versus Constituent Demand in Health Rationing Policy
	Faculty Mentor	Dr. Anthony Bertelli, Department of Public Administration & Policy
	Amy K. Winter	HIV/AIDS in India: A Case Study on the Influence of Traditional and Modern Indian Characteristics on the HIV/AIDS Epidemic among Indian Youth
	Faculty Mentor	Dr. Dr. Nan McMurry, Department of History
	Catherine P. Mencher	The Case for Minor Access to Emergency Contraceptive
	Faculty Mentor	Dr. Monica Gaughan, Department of Health Policy & Management
Room B	**Cain Harrelson**	The Diplomatic Face of America: Promoting Diversity in the U.S. Foreign Service
	Faculty Mentor	Dr. Kaye Sweetser, Department of Advertising & Public Relations
	Rachel A. Spencer & Sarah Vaughn	"In the Shadows of Espionage": Extraordinary Rendition as a Threat to American National Security
	Faculty Mentor	Dr. Loch Johnson, Department of International Affairs
	Alexander B. Johnson	The U.S. Intelligence Community Must Become Centralized
	Faculty Mentor	Dr. Loch Johnson, Department of International Affairs
Room C	**Ashley A. Wilkinson**	Determining the Truth: The War on Terror and Repression in China
	Faculty Mentor	Dr. David S. Williams, Honors Program
	John T. Dixon	U.S.-China Energy Cooperation: A Step toward Greater Environmental Cooperation
	Faculty Mentor	Dr. Rhett Jackson, Department of Forestry
	Aaron M. Sayama	A Feasible Trilateral Agreement: A Convergence of Interests
	Faculty Mentor	Dr. Dr. Seema Gahlaut, Center for International Trade & Security

Room D	**Robert Rosenbleeth & Rocky T. Cole**	Avoiding Overcorrection: Solving the Army's Readiness Crisis
	Faculty Mentor	Dr. Patricia Sullivan, Department of International Affairs
	William Patrick Dever	Reforming Subsidies in the Federal Budget
	Faculty Mentor	Dr. William Lastrapes, Department of Economics
	Karen E. Tanenbaum	Diversity and State-Building: A Cross-Country Analysis of the U.S. and Canada
	Faculty Mentor	Dr. Christopher Allen, Department of International Affairs
Room G	**Lillie Ann M. Madali**	The Joys of Hunting: Analyzing the Relationship between the Small Hunt Mosaic of Piazza Armerina in the Architectural Space of the Hiemale Triclinium
	Faculty Mentor	Dr. Asen Kirin, Department of Art History
	Jason E. Dyer	A Domitianic Predecessor to the Arch of Constantine?
	Faculty Mentor	Prof. James Anderson, Jr., Department of Classics
	Stefann S. Plishka	George Washington and Abraham Lincoln: Relic Veneration and "Saint" Commemoration in Contemporary America
	Faculty Mentor	Dr. Asen Kirin, Department of Art History
Room H	**Cleveland A. Piggott**	The Role of Microtubules in the Formation and Degradation of Hirano Bodies
	Faculty Mentors	Dr. Marcus Fechheimer, Department of Cellular Biology Dr. Ruth Furukawa, Department of Cellular Biology
	Tulsi Patel	Generating Uniform Proliferation of Neuroprogenitor Cells
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
	Neil T. Pfister	Characterizing RNA-Protein Complexes in *Pyrococcus furiosus*
	Faculty Mentor	Dr. Michael Terns, Department of Biochemistry & Molecular Biology
Room I	**Joshua A. Dunn**	Roswell Voices: Oral History and Linguistics in Roswell, Georgia
	Faculty Mentor	Dr. Dr. William Kretzschmar, Department of English and Department of Linguistics
	Jana M. Hanchett	Hispanic Music in Athens, Georgia
	Faculty Mentor	Dr. David Schiller, Department of Musicology & Ethnomusicology
	Andrew C. Clark	French Dislocation: The Syntax of Power
	Faculty Mentor	Dr. Diana Ranson, Department of Romance Languages

Room J	**Darryl Tricksey & Dakia McCray**	African-American Models of Success
	Faculty Mentors	Dr. Victoria Plaut, Department of Psychology Dr. Larry Nackerud, School of Social Work
	Erica Holland	The N-Word and Its Implications on a Predominately White Campus
	Faculty Mentor	Dr. Robert Pratt, Department of History
	Jennifer L. Barr	Examining Parenting Stress for Mothers of Young Children with Autism Spectrum Disorders
	Faculty Mentor	Dr. Dr. Jonathon Campbell, Department of Educational Psychology & Instructional Technology

11:15 a.m. – 12:05 p.m. Second Concurrent Session

Room B	**Shelby R. Carlson, Holly Chandler, Heather Smith & Rebecca Lewis**	Emotional and Behavioral Problems Displayed in Preschoolers Raised by Biological Grandchildren
	Faculty Mentor	Dr. Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University
	Nicole M. Fenton & Emily Osborn	The Impact of Family Relations, Health Perceptions, and Parental Functioning on Adherence and Medical Outcomes in Adolescent Transplant Recipients
	Faculty Mentor	Dr. Ronald Blount, Department of Psychology
	Ashley A. Wilkinson	Ending the Waiting List Crisis: Increasing Child Care Subsidy Funds
	Faculty Mentor	Dr. Thomas McNulty, Department of Sociology
Room C	**Halina Maladtsova**	Eliminating the Road Test in License Renewal Programs
	Faculty Mentor	Dr. Christopher Cornwell, Department of Economics
	Lila E. Tedesco	Mixed Income Housing: A Comprehensive Reconstruction Plan for New Orleans
	Faculty Mentor	Dr. Andrew Carswell, Department of Housing & Consumer Economics
	Terry L. Palmer	Reducing and Rethinking Recidivism
	Faculty Mentor	Dr. Mark Cooney, Department of Sociology
Room D	**Lauren F. Kelly**	*Eres un Universo de Universos:* Reconnecting With the Human Aspects of Medicine Through Field Experiences on *La Isla de Ometepe*
	Faculty Mentor	Dr. Pamela B. Kleiber, Honors Program

	Lee Ellen Carter	Otavaleños and Cotacacheños: Local Perceptions of Sacred Sites for Farmscape Conservation in Highland Ecuador
	Faculty Mentor	Dr. Fausto Sarmiento, Department of Geography
	Adam Thomas	Perceptions of Puerto Rican Women and Their Impact on Public Health Policy in the Early 20th Century
	Faculty Mentor	Dr. Reinaldo Román, Department of History
Room G	**Brian T. Laughlin**	Functional Analysis of the *Magnaporthe grisea* Secretome
	Faculty Mentor	Dr. Sheng-Cheng Wu, Complex Carbohydrate Research Center
	Matthew C. Agan	Epistasis for Fitness among Biosynthesis Genes in Yeast
	Faculty Mentor	Dr. David Hall, Department of Genetics
	Amy J. Burrell	Transcriptional Expression of Arabidopsis GAUT Genes: 15 Proven and Putative Plant Cell Wall Biosynthetic Galacturonosyltransferases
	Faculty Mentor	Dr. Debra Mohnen, Complex Carbohydrate Research Center
Room H	**Erika D. Frank**	La Voz de los Sin Voz: The Use of Radio by the Zapatista Movement in Mexico
	Faculty Mentor	Dr. Pamela Voekel, Department of History
	Lucas L. Puente	The Importance of American Development Aid in Nicaragua
	Faculty Mentor	Dr. Santanu Chatterjee, Department of Economics
	Clare J. Hatfield & Maggie Mills	The Road to Violence: Nonviolent v. Violent Actors in Bangladesh
	Faculty Mentor	Dr. Mia Bloom, Department of International Affairs
Room I	**Prashant Monian**	Expression of Glycerophospholipids in Rat Brain after Cocaine Withdrawal
	Faculty Mentor	Dr. Brian Cummings, Department of Pharmaceutical & Biomedical Sciences
	Steven P. Trau	IS492 Movement on the *Pseudoalteromonas atalantica* Chromosome
	Faculty Mentor	Dr. Anna Karls, Department of Microbiology
Room J	**Jessica N. Van Parys**	Does Writing Ability Predict Academic Achievement? Evidence from the New SAT Writing (SATW) Section
	Faculty Mentor	Prof. David Mustard, Department of Economics
	Ashley A. Babcock	The Engineering Learning Environment
	Faculty Mentor	Dr. Nadia Kellam, Department of Biological & Agricultural Engineering

	Mary K. Holder, Marcia A. Cole, Bette' S. Ford & Destiny L. Murray	Solving Rubik's Cube: Artificial Selection in Higher Education
	Faculty Mentor	Dr. Farooq Khan, Department of Chemistry, University of West Georgia

12:20 – 1:10 p.m. Third Concurrent Session

Room C	**Mia Catherine Morgan**	Potential Economic Impact from Zeolite Use in Uganda
	Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
	Ellyn A. Echols & Jeremy Akin	Rethinking the U.S.'s Relationship with the Global Poor: A Restructuring of USAID's Microfinance Efforts in Africa
	Faculty Mentor	Dr. Glenn Ames, Department of International Public Service & Outreach
	Alex Kazer	Hope for the Horn: The Case for the Recognition of Somaliland
	Faculty Mentor	Dr. Abdulahi Osman, Department of International Affairs
Room D	**Sharanya Raghunath**	Characterization of Human Stem Cells Using Quantitative RT-PCR
	Faculty Mentor	Dr. Kelley Moremen, Department of Biochemistry & Molecular Biology
	Laura J. Simpson	The Naturally Attenuated TCC Strain of *Trypanosoma cruzi* Induces a Specific CD8+T Central Memory Response
	Faculty Mentor	Dr. Rick Tarleton, Department of Cellular Biology
Room G	**Rebecca I. Lunceford**	Tort Cases in Georgia in the Early 2000s: Tort Abuse Not as Prominent as Portrayed
	Faculty Mentor	Prof. David Mustard, Department of Economics
	Karen C. Wong	Regional Comparison of the Legal Basis of Venture Philanthropy
	Faculty Mentor	Dr. Andrew Whitford, Department of Public Administration & Policy
	Meghan A. Royal	The Impact of Chinese Product Fraud and Lack of Quality Control on U.S. Commercial Trade Laws and Regulations
	Faculty Mentor	Prof. Marisa Pagnattaro, Department of Legal Studies
Room H	**James T. Gordy**	Characterizing the Small Proteome in the Hyperthermophilic Archaeon *Pyrococcus furiosus*
	Faculty Mentor	Dr. Michael Adams, Department of Biochemistry & Molecular Biology

	Kathryn S. Flake	Cloning, *E. coli* expression, and HPLC Enzymatic Assay Analysis of Putative Domains of Arabinose Kinase
	Faculty Mentor	Dr. Maor Bar-Peled, Complex Carbohydrate Research Center
Room I	**Delila D. Wilburn**	Black Women and the Movements: Using Art to Re-Define Beauty
	Faculty Mentor	Dr. Barbara McCaskill, Department of English
	Traci N. Tucker	A Cross-Cultural Comparison of Gender and Role-Identities in China and the United States
	Faculty Mentor	Dr. Dawn Robinson, Department of Sociology
	Matthew G. Anderson, Lindsay Bailey, Christopher Newberry & Jimmie Flower	The Influence of Family Structure on Aggression Displayed in Young Head Start Children
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University
Room J	**Laura C. Patterson**	The Application and Adaptability of N.A. Rimsky-Korsakov's Orchestration Techniques Across National Styles in Orchestral Program Music
	Faculty Mentor	Dr. David Haas, Department of Musicology & Ethnomusicology
	Tyler L. Kelly	Usage of Linear Subspaces with Varieties
	Faculty Mentor	Dr. Elham Izadi, Department of Mathematics
	Caroline M. Anderson	A Psychological View of Wolf/ Mörike's Peregrina Songs
	Faculty Mentor	Dr. Max Reinhart, Department of Germanic & Slavic Languages

1:25 – 2:15 p.m. Fourth Concurrent Session

Room C	**Robert M. Truan**	Antonio Vivaldi's Contribution to the Evolution of Program Music
	Faculty Mentor	Dr. Susan Thomas, Department of Musicology & Ethnomusicology and Institute for Women's Studies
	Victor M. Orellana	The Homeric Lineage of Lautaro in Ercilla's *La Araucana*
	Faculty Mentor	Dr. Nicolás Lucero, Department of Romance Languages
Room D	**Kevin K. Chang**	Improving the Health of Georgia Youth: An Incentive Program for Nutritional Standards in Georgia Schools
	Faculty Mentor	Dr. Phaedra Corso, Department of Health Administration, Biostatistics & Epidemiology

	Lauren M. Lesso, Susan Hulteen, Christopher Newberry, Kim Mears, Christina Borne & Alex Carson	The Impact of Low Income Families on the Development of Literacy
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University
Room G	**Tyler B. Pratt**	The Global Arms Bazaar: Lessons from the 2006 Hezbollah-Israel War
	Faculty Mentor	Dr. Michael Jasinski, Department of International Affairs
	Nathaniel T. Edwards	Increasing Trade Security: United States-Venezuelan Trade Incentives
	Faculty Mentor	Dr. Christopher Allen, Department of International Affairs
	Chris Chiego	Managing U.S. Aid to Egypt: A Reorientation of Current Support
	Faculty Mentor	Dr. Brock Tessman, Department of International Affairs
Room H	**Jessica L. Mobley**	Is a Hepatitis E-Like Virus Found In Cats and Does It Cause Hepatitis?
	Faculty Mentor	Dr. Elizabeth Howerth, Department of Pathology
	Jessica L. Buday	Charcoal-Powered Vacuum-Zeolite Adsorption Cooler Regenerator for the Preservation of Milk, Vaccines, and Other Perishables
	Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
	Natasha A. James	The Ecology of Enteric Bacterial Isolates in San Luis, Costa Rica
	Faculty Mentor	Dr. Susan Sanchez, Department of Infectious Diseases
Room I	**Sarah R. Breevoort**	Towards the Discovery of Ras-Converting Enzyme Inhibitors-A Novel Anti-Cancer Target
	Faculty Mentor	Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology
	Claire M. Rice	In Vitro Assay to Measure Cell Growth and Invasion
	Faculty Mentor	Dr. Bruce LeRoy, Department of Pathology
	Nithya M. Natrajan	The Roles of Non-homologous End Joining Repair Proteins in Non-B-DNA Structure Induced Genetic Instability
	Faculty Mentors	Dr. Karen Vasquez, Department of Carcinogenesis, University of Texas Dr. Mary Bedell, Department of Genetics

Room J	**Anna E. Hudson**	Using Surface Enhanced Raman Spectroscopy for the Detection of Pathogens
	Faculty Mentor	Dr. Richard Dluhy, Department of Chemistry
	Matthew Logan Davis	Long-Range Retrograde Transduction of Survival Signals in Neurons
	Faculty Mentor	Dr. James Franklin, Department of Pharmaceutical & Biomedical Sciences
	Anita C. Randolph	Functionality of Glutamate Receptors in hESC-derived Neural Progenitors vs. Matured Neurons
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science

1:25 – 3:20 p.m. Creative Writing & Music

Classic Center, Athena Ballroom E

Jordan A. Dalton	*Room–Poem*
Faculty Mentor	Prof. Andrew Zawacki, Department of English
Soujourner Hodges	*Book of Trees* (selections)
Faculty Mentor	Dr. Adrian P. Childs, Department of Music Theory & Composition
Brandon Kaufman & Kim Nogi	*Duet of Soprano and Bass Clarinet*
Faculty Mentor	Dr. Roger Vogel, Department of Music Theory & Composition
Brian Graiser	*Sketches in Noir* (selections)
Faculty Mentor	Dr. Leonard V. Ball, Jr., Department of Music Theory & Composition
Bulldog Brass Quintet: Tommy Cox, Josh Cutchin, Cathy Kilroe-Smith, Chris Probst, Aaron Ritter & Brad Whitfield	*Contemporary Brass Sounds* (selections)
Faculty Mentor	Prof. Fred Mills, Director & Department of Brass
Opera Ensemble: Jason Blanton, Ben Dawkins, Andrew Frazier, John Ford, Danielle Granati, Kathryn Sabol, Ronaldo Steiner, Megan Tucker, Kristen Vanderoef, Brett Vogel, Katherine Walters & Chloe Zeitounian	*From Page to Stage*
Faculty Mentors	Prof. Frederick Burchinal, Director & Department of Voice Prof. Gary DiPasquasio, Pianist/Music Director & Department of Voice

2:30 – 3:45 p.m. Fifth Concurrent Session

Room G	**Ashley A. Bowen**	Are We Really Ready? The Need for National Standards and the Creation of the Cycle of Emergency Planning
	Faculty Mentor	Dr. Brock Tessman, Department of International Affairs
	Nicole C. DeMarco & Aqsa Mahmud	Emergency Response: Bringing it to Georgia
	Faculty Mentor	Dr. Michael Beck, International Center for Democratic Governance
	Kelsey A. Jones	You Are What You Eat: Mandating Point-of-Purchase Nutrition Information in Georgia Restaurants
	Faculty Mentor	Dr. Marsha Davis, Department of Health Promotion & Behavior
Room H	**Michael D. Mogill**	Oxygen Delivery After Ischemia in Active and Inactive Subjects
	Faculty Mentor	Dr. Kevin McCully, Department of Kinesiology
	Yen Tran	Comparison of the Acute Toxicity of Selective Serotonin Reuptake Inhibitors (SSRIs) and St. John's Wort (*Hypercium perforatum*) to *Ceriodaphnia dubia*
	Faculty Mentor	Dr. Marsha Black, Department of Environmental & Health Sciences
	Kimberley L. DeLisi	The Effect of Sample Handling and Storage on the Accuracy and Repeatability of Fecal Worm Egg Counts in Horses
	Faculty Mentor	Dr. Ray Kaplan, Department of Infectious Diseases
	Christina L. Faust	Environmental Factors Affecting the Persistence of Avian Influenza Virus in Water
	Faculty Mentor	Dr. David Stallknecht, Department of Wildlife Disease Study
Room I	**Leilah D. Zahedi**	Permeability of Intestinal Cells Exposed to Black Walnut Extract
	Faculty Mentor	Dr. David Hurley, Department of Population Health
	Seychelle M. Vos	Sequencing and Tissue Distribution of Toll-Like Receptor 3 in White-tailed Deer
	Faculty Mentor	Dr. Elizabeth Howerth, Department of Pathology
	Robert D. Bennett	Can Smallholder Dairy Farmers of Southwestern Uganda Save Their Evening Milk?
	Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering

	Aaron O. Watwood	Design Evolution of Non-Electric Evaporative-Cooling Milk Container for Smallholder Farmers in East Africa
	Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
Room J	**Sean P. Durning**	Antibody Extraction
	Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology
	Ashley L. Foster	Voltage-Dependent Anion Conductance (VDAC) Porin: A Possible Channel for Cytochrome c Release in Apoptosis
	Faculty Mentor	Dr. James Franklin, Department of Pharmaceutical & Biomedical Science
	Purvi S. Sheth	Characterization of *Mycobacterium shottsii*
	Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases

4:00 p.m. Welcome and Opening Session

Classic Center, Athena Ballroom E

Welcome	Dr. David S. Williams, Director, Honors Program
The Value of Undergraduate Research	Dr. David C. Lee, Vice President for Research
Recognition of CURO Promising Scholars	Dr. Pamela B. Kleiber, Associate Director, Honors Program
Introduction of Keynote Speaker	Ashley L. Foster, Honors Program student and CURO Scholar
Keynote Address ***Global Climate Change and Georgia: The Challenges Are Mounting***	Dr. James Porter Josiah Meigs Distinguished Teaching Professor, Eugene Odum School of Ecology
Excellence in Undergraduate Research Mentoring Awards	Prof. Jere Morehead, Vice President for Instruction

5:00 p.m. Poster Presentations and Reception

Classic Center, Athena Ballroom F

Kyle F. Abramowicz	Aggressive Behavior and Prezygotic Isolation in *Drosophila persimilis* and *D. pseudoobscura*
Faculty Mentor	Dr. Wyatt Anderson, Department of Genetics

Ashley A. Babcock	The Engineering Learning Environment
Faculty Mentor	Dr. Nadia Kellam, Department of Biological & Agricultural Engineering
Robert D. Bennett	Can Smallholder Dairy Farmers of Southwestern Uganda Save Their Evening Milk?
Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
Andrew D. Bosson	The Role of Rif1 in *Kluyveromyces lactis* Telomere Maintenance
Faculty Mentor	Dr. Michael McEachern, Department of Genetics
Emily Dale Broder	Forced Copulation and Offspring Viability in *Drosophila melanogaster*
Faculty Mentors	Dr. Wyatt Anderson, Department of Genetics Dr. Yong-Kyu Kim, Department of Genetics
Nancy D. Brynteson	"I Want My Credits!": The Impact of Procedural and Interactional Injustice on Participants' Evaluations of an Experimenter
Faculty Mentor	Dr Alicia Bembenek, Department of Psychology, Georgia College & State University
Jessica L. Buday	Charcoal-Powered Vacuum-Zeolite Adsorption Cooler Regenerator for the Preservation of Milk, Vaccines, and Other Perishables
Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering
Joseph S. Burch	Characterization of Mitoferrin and Its Interactions with Ferrochelatase
Faculty Mentor	Dr. Harry Dailey, Biomedical & Health Sciences Institute
Jean Chi	Evaluating Protocols for Measuring Immune Defenses in Larval Monarch Butterflies
Faculty Mentor	Dr. Sonia Altizer, Eugene Odum School of Ecology
Eric P. Cho	Contours and Melting Crystals
Faculty Mentor	Dr. Robert Varley, Department of Mathematics
Caroline G. Colden	Nipah Virus and Apoptosis in Cells
Faculty Mentor	Dr. Corrie Brown, Department of Pathology
Benjamin P. Crane	Physical and Structural Basis for pH Dependence of Transcription Regulation by the Anti-Sigma Factor AsiA
Faculty Mentor	Dr. Jeffrey Urbauer, Department of Biochemistry & Molecular Biology
Vanessa N. del Valle	The Role of Insulin-Induced Tyrosine Phosphorylation on O-GlcNAc Transferase (OGT)
Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology

Melissa D. Docampo	Metabolic Studies in *Toxoplasma gondii*
Faculty Mentor	Dr. Boris Striepen, Department of Cellular Biology
Andrew M. Durso	Cataloging Biodiversity: Filling in the Gaps for Coastal Ecuadorian Herpetofauna
Faculty Mentor	Dr. Paul Hamilton, Department of Biological Sciences
Jessica E. Dyke	Sex-Related Differences in Pain Experience in Marathon Runners
Faculty Mentor	Dr. Patrick O'Connor, Department of Kinesiology and Department of Exercise Psychology
Ryan M. Friday	Vesicular Stomatitis in Cattle
Faculty Mentor	Dr. Corrie Brown, Department of Pathology
Steven A. Gay	Potential Novel O-N-acetylglucosamine Transferase (OGT) Downregulation Technique for *D. rerio*
Faculty Mentor	Dr. Scott Dougan, Department of Cellular Biology
Elizabeth K. George	Association Between Infant Feeding and Overweight/Obesity in Ghana, West Africa
Faculty Mentor	Dr. Alex Anderson, Department of Food & Nutrition
Samantha J. Haring	Corticosterone and Its Effects on Stress-Induced Weight Loss
Faculty Mentor	Dr. Ruth Harris, Department of Food & Nutrition
Laura M. Harrison	Newcastle Disease Pathogenesis
Faculty Mentor	Dr. Corrie Brown, Department of Pathology
Lauren F. Kelly	*Eres un Universo de Universos:* Reconnecting with the Human Aspects of Medicine Through Field Experiences on *La Isla de Ometepe*
Faculty Mentor	Dr. Pamela B. Kleiber, Honors Program
Lauren F. Kelly	The Role of Plasminogen Activator Inhibitor-1 (PAI-1) in the Immunopathogenesis of *Plasmodium falciparum*-mediated Placental Malaria
Faculty Mentor	Dr. Julie Moore, Department of Infectious Diseases
Christine M. Kendrick	Evaluation of Potential Inhalation Hazards of Petroleum-, Synthetic- and Bio-Fuels Using GC/MS Analysis of Vapors under Equilibrium Conditions
Faculty Mentor	Dr. Jeffrey Fisher, Department of Environmental & Health Sciences
Karen S. Kenner	Finding the Best Protocol to Homogenize Carbon Nanotubes
Faculty Mentor	Dr. Marcus Lay, Department of Chemistry

Noah A. Koon	Mutagenesis Analysis of the Chain Length Determination Domain of the *Toxoplasma gondii* Farnesyl Diphosphate Synthase
Faculty Mentor	Dr. Silvia Moreno, Department of Cellular Biology
Andrew F. Kragor	Unbiased Isolation of Alpha-Dystroglycan
Faculty Mentor	Dr. Carl Bergmann, Complex Carbohydrate Research Center
James P. MacNamara	Inhibition of the CaaX Proteases Rce1p and Ste24p with Peptidyl (Acyloxy)Methyl Ketones (AOMK) and Quinolinol Based Molecules
Faculty Mentor	Dr. Timothy Dore, Department of Chemistry
Margaret C. Madean & Sohyun Kwon	Female Choice and Male Mating Success in *Drosophila* Sexual Selection
Faculty Mentor	Dr. Wyatt Anderson, Department of Genetics
Sharon A. McCoy	Dialect Perceptions of Spanish Speakers in Georgia
Faculty Mentor	Dr. Chad Howe, Department of Romance Languages
Amy M. McGoff & Harold Jackson	Polyphenolic Antioxidants in Unprocessed Traditional Diets: Wild-Crafted Acorn Flour as a Dietary Staple
Faculty Mentor	Dr. James Hargrove, Department of Food & Nutrition
David T. Mitchell	Effects of Social Environment on Women's Participation in Computer Science
Faculty Mentor	Dr. Victoria Plaut, Department of Psychology
Jessica L. Mobley	Is a Hepatitis E-Like Virus Found In Cats and Does It Cause Hepatitis?
Faculty Mentor	Dr. Elizabeth Howerth, Department of Pathology
Michael D. Mogill	Oxygen Delivery After Ischemia in Active and Inactive Subjects
Faculty Mentor	Dr. Kevin McCully, Department of Kinesiology
Prashant Monian	Expression of Glycerophospholipids in Rat Brain after Cocaine Withdrawal
Faculty Mentor	Dr. Brian Cummings, Department of Pharmaceutical & Biomedical Sciences
Diana Murro	Creation of a Transposon Library in *Francisella tularensis* Strain LVS
Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases
Neil D. Naik	Investigating the Role of Corticotrophin Releasing Factor 1 Receptors (CRFR1) in Stress-Induced Weight Loss
Faculty Mentor	Dr. Ruth Harris, Department of Food & Nutrition

Muktha S. Natrajan	The Role of KIT-Ligand in Enrichment and Differentiation of Germ-Like Cells in Human Embryonic Stem Cell Cultures
Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
Natalie A. Nesmith	Genetic Studies on the Roles of KITL in Regulating Germ Cells in Mice
Faculty Mentor	Dr. Mary Bedell, Department of Genetics
William T. Oliver	The Effects of Alcohol Abuse on Antisaccade Performance
Faculty Mentor	Dr. Jennifer McDowell, Department of Psychology
Tulsi Patel	Development of a Biocontrol Agent for Chinese Privet, *Ligustrum sinense*
Faculty Mentor	Dr. Scott Gold, Department of Plant Pathology
Amanda C. Perofsky	Behavioral Effects of Navigate® on Paedomorphic Mole Salamanders, *Ambystoma talpoideum*
Faculty Mentor	Dr. John Maerz, Department of Wildlife
Tomas Pickering	Measuring Proficiency of Palm Nut (*Attalea sp.*) Cracking in Wild Bearded Capuchin Monkeys (*Cebus libidinosus*)
Faculty Mentor	Dr. Dorothy Fragaszy, Department of Psychology
Cleveland A. Piggott	The Role of Microtubules in the Formation and Degradation of Hirano Bodies
Faculty Mentors	Dr. Marcus Fechheimer, Department of Cellular Biology Dr. Ruth Furukawa, Department of Cellular Biology
Adam Pyrzak	Acidocalcisome-like Granules of Chicken Egg Yolk – Polyphosphate Content and Its Relationship to Development
Faculty Mentors	Dr. Roberto Docampo, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases Dr. Paul Ulrich, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases
Anita C. Randolph	Functionality of Glutamate Receptors in hESC-derived Neural Progenitors vs. Matured Neurons
Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
Amanda N. Rinehart	Identity Achievement as a Function of Age, Gender, and Ethnicity
Faculty Mentors	Dr. Douglas Kleiber, Department of Counseling & Human Development Dr. Pedro Portes, Center for Latino Achievement & Success in Education
Jarrad W. Rowse	Understanding M16A Metalloprotease Enzymology
Faculty Mentor	Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology

Julia R. Schuchard	Relationships Between Psychosis Risk Scales and Antisaccade Performance
Faculty Mentor	Dr. Jennifer McDowell, Department of Psychology
Jeff Shapiro	Effects of Initial Population Size and Food Quality on Stochastic Population Persistence
Faculty Mentor	Dr. John Drake, Eugene Odum School of Ecology
Edgar A. Shartilov	Functional Characterization of a Putative Inositol-1,4,5-Triphosphate Receptor in the Parasite *Trypanosoma brucei*
Faculty Mentors	Dr. Silvia Moreno, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases Dr. Paul Ulrich, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases
Lindsay T. Stein	The Distribution of Rabies Antigen by Immunohistochemistry in the Brains of Different Mammalian Species
Faculty Mentor	Dr. Corrie Brown, Department of Pathology
Yen Tran	Comparison of the Acute Toxicity of Selective Serotonin Reuptake Inhibitors (SSRIs) and St. John's Wort (*Hypericum perforatum*) to *Ceriodaphnia dubia*
Faculty Mentor	Dr. Marsha Black, Department of Environmental & Health Sciences
Kathryn L. Turner	RGS Regulation of the LPA Signaling Pathway in Prostate Cancer Cells
Faculty Mentor	Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Sciences
Matthew A. Turner	An Investigation of the Relationship between the Existence of Inc A/C Plasmids and the Prevalence of Multiple Therapeutic Antibiotic Resistances
Faculty Mentor	Dr. Susan Sanchez, Department of Pathology
Manouela V. Valtcheva	SPQ-Identified Schizotypy and Antisaccade Performance in a Normal Population
Faculty Mentor	Dr. Jennifer McDowell, Department of Psychology
Dana Wagshal	Source Memory and Picture Location in Relation to Working Memory
Faculty Mentor	Dr. Nash Unsworth, Department of Psychology
Wei Wang	Is Elevation of O-GlcNAc Levels Both Necessary and Sufficient to Extend Median Lifespan?
Faculty Mentor	Dr. Lance Wells, Department of Biochemistry & Molecular Biology

Aaron O. Watwood	Design Evolution of a Non-Electric Evaporative-Cooling Milk Container for Smallholder Farmers in East Africa
Faculty Mentor	Dr. William Kisaalita, Department of Biological & Agricultural Engineering

6:15 p.m. Art Gallery Talks

Classic Center, Fire Hall

Introductions	Dr. Pamela B. Kleiber, Associate Director, Honors Program Prof. Georgia Strange, Director, Lamar Dodd School of Art Ms. Nora Wendl, Gallery Director, Lamar Dodd School of Art

Visual Arts Presenters

Meghan Boling, Talia Bromstad, David Broughton, Kathryn Burne, Bryan Hilley, Corey Jameson, Lauren Kesler, Ivy Lane, Eric Lotzer, Katherine Osbum, Lauren Ramsey & Ivy Williams	*Collaborative Print Project: Prada Shoes*
Faculty Mentor	Prof. Shelly DiCello, Department of Printmaking
Gabrielle Bratton, Maddie Edwards & Miriam Rowe	*Project Runway: Consume*
Faculty Mentors	Prof. Clay McLaurin, Department of Fabric Design Prof. Mary Pearse, Department of Jewelry/Metalsmithing
Jenny Bryant, Julie Givens & Marilyn Zapf	*Project Runway: Cyborg*
Faculty Mentors	Prof. Clay McLaurin, Department of Fabric Design Prof. Mary Pearse, Department of Jewelry/Metalsmithing
Ashley Buchanan, Lindsey Bartell, Eleanor Simmons & Jenny Moore	*Project Runway: The Defense of Intimacy*
Faculty Mentors	Prof. Clay McLaurin, Department of Fabric Design Prof. Mary Pearse, Department of Jewelry/Metalsmithing
Adam Gruszynski	*The People* *The Tower* *Nancy*
Faculty Mentors	Prof. Ted Saupe, Department of Ceramics Prof. Sunkoo Yuh, Department of Ceramics
Kathleen Janvier	*Residue Brooch*
Faculty Mentor	Prof. Mary Pearse, Department of Jewelry/Metalsmithing

Lindsay MacLean Ruderman, Susan Kent & Rachel Huggins	*Project Runway: Untitled*
Faculty Mentors	Prof. Clay McLaurin, Department of Fabric Design Prof. Mary Pearse, Department of Jewelry/Metalsmithing
Marie Tetzlaff, Allison Sheats & Kathleen Janvier	*Project Runway: Screen Study*
Faculty Mentors	Prof. Clay McLaurin, Department of Fabric Design Prof. Mary Pearse, Department of Jewelry/Metalsmithing
Marilyn Zapf	*Simulacrum Ring*
Faculty Mentor	Prof. Robert Jackson, Department of Jewelry/Metalsmithing

Art exhibit arranged by Ms. Nora Wendl, Gallery Director, Lamar Dodd School of Art

8:00 p.m. Awards Ceremony

Classic Center, Fire Hall

Presentation of CURO Summer Research Fellows, CURO Scholars, UGA Libraries Undergraduate Research Awards, and Best Paper Awards	Dr. David S. Williams, Director, Honors Program Ms. Florence E. King, Assistant University Librarian for Human Resources and Director, Student Learning Center Ms. Deborah Dietzler, Executive Director, UGA Alumni Association

The office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2001. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students. In 2006, the Graduate School and the Honors Program established a new award that recognizes graduate students devoted to the research mentorship of undergraduate students. Awards will be presented at the CURO Symposium Opening Session on Monday, March 31, 2008 at 4:00 p.m. in the Classic Center, Athena Ballroom E.

2008 Awards

Master Level Faculty Award
Dr. John J. Maurer, Professor of Population Health
Early Career Faculty Award
Dr. Walter K. Schmidt, Assistant Professor of Biochemistry & Molecular Biology
Program Award
Biomedical and Health Sciences Institute

2007 Awards

Master Level Faculty Award
Dr. Timothy Hoover, Associate Professor of Microbiology
Early Career Faculty Award
Dr. Steven Stice, Professor of Animal & Dairy Science

2006 Awards

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Associate Professor of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Professor of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD student in Plant Biology

2005 Awards

Faculty Awards
Dr. Gary Barrett, Odum Professor of Ecology
Dr. Sidney Kushner, Professor of Genetics
Department Award
Department of Cellular Biology

2004 Award

Faculty Award
Dr. William S. Kisaalita, Associate Professor of Biological & Agricultural Engineering

2003 Awards

Faculty Award
Dr. Jody Clay-Warner, Assistant Professor of Sociology

Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator

Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Professor
Dr. Marie-Michèle Cordonnier-Pratt, Senior Research Scientist

2002 Awards

Faculty Awards
Professor William D. Paul, Jr., Professor of Art
Dr. Katherine Kipp, Associate Professor of Psychology

Faculty Recognition
Dr. Susan Sanchez, Assistant Professor of Veterinary Medicine

Department Award
Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head

Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Professor of Physics and Astronomy
Dr. Heinz-Bernd Schuttler, Professor and Department Head of Physics and Astronomy
Dr. Jonathan Arnold, Professor of Genetics
Dr. Susmita Datta, Professor, Georgia State University
Dr. David Logan, Professor, Clark Atlanta University
Dr. William Steffans, Professor, Clark Atlanta University

2001 Awards

Faculty Award
Dr. Marcus Fechheimer, Professor of Cellular Biology

Faculty Recognition
Dr. David MacIntosh, Associate Professor of Environmental Health Sciences
Dr. Dean Rojek, Associate Professor of Sociology

Department Award

Aggressive Behavior and Prezygotic Isolation in *Drosophila persimilis* and *D. pseudoobscura*

Kyle F. Abramowicz
Dr. Wyatt Anderson, Department of Genetics, University of Georgia

The two species *Drosophila persimilis* and *Drosophila pseudoobscura* are ideal models for the study of speciation. They are of particular interest because of their natural distribution - the range of *D. persimilis* is entirely within that of *D. pseudoobscura*. Sympatric speciation is a divergence in the same geographic area, whereas allopatric speciation involves a geographic separation. In this experiment, aggressive behaviors of different *Drosophila* strains were observed to investigate the possible effects of aggressive behavior on the sympatric speciation of *D. persimilis*. An acrylic variant of Elens-Wattieau mating chambers were used to observe *D. persimilis* paired with *D. pseudoobscura* from populations that exist naturally in sympatry or allopatry with *D. persimilis*. Six aggressive behaviors were observed - wing threat, fencing, lunging, boxing, holding, and chasing. Aggressive behavior was totaled for each encounter. Means and standard errors were calculated and analyzed for significance. The collected data showed a significantly higher incidence of aggressive behavior in *D. persimilis* when paired with the allopatric strain of *D. pseudoobscura*. There were no meaningful differences in aggressive behavior between the two strains of *D. pseudoobscura*. The higher aggressive behavior observed in the allopatric pairing indicates that while aggressive behavior is not a significant source of prezygotic isolation in sympatric populations, it is impacted to greater levels in allopatry. A possible cause is that there is a cost to aggressive behavior, thus reducing the fitness of constantly aggressive individuals. Further studies on the interacting behavior of closely-related species may reveal a behavioral influence on speciation.

Epistasis for Fitness among Biosynthesis Genes in Yeast

Matthew C. Agan, CURO Scholar
Dr. David Hall, Department of Genetics, University of Georgia

Understanding the evolution of sexual reproduction is a central question in evolutionary biology. Deleterious mutations play an important role in theories for the evolution of sex. Specifically, if different deleterious mutations interact so that their combined effect is greater than the sum of their individual effects, sexual reproduction is more likely to evolve. This phenomenon is termed synergistic epistasis. I generated yeast strains with all possible combinations of six different mutations (zero mutations, six different single mutations, etc.) and scored their fitness to test for evidence of synergistic epistasis. The results and analysis of patterns of fitness from four different tests will be presented: haploid mating efficiency, diploid sporulation efficiency, and both haploid and diploid growth rate. Each test will estimate the fitness of every genotype using a different component of fitness, so that all four together will encompass the entire life cycle of the yeast. Evidence of synergistic epistasis in any of the assays would provide support for current theories for the evolution of sexual reproduction

A Psychological View of Wolf/ Mörike's Peregrina Songs

Caroline M. Anderson, CURO Summer Fellow, CURO Scholar
Dr. Max Reinhart, Department of Germanic & Slavic Languages, University of Georgia

Hugo Wolf's (1860-1903) and Eduard Mörike's (1804-1875) Peregrina I and II (1888) are songs rich in harmonic and rhythmic complexities that do not always hold a clear relationship with the texts. Unfortunately, the considerable body of scholarship on German art songs has generally taken an analytical approach that focuses primarily on texts. As a result, the musical layers of these songs are often only explored superficially. Deborah Stein and Susan Youens are the only scholars to come close to touching

on the issue of psychological distress and tension within these art songs, though her research is still limited to minimal songs. My research incorporates a combination of text analysis, music theory, and psychology; this approach in particular allows one to more closely examine the relationship between the text, which represents the conscious mind, and the music, which represents the subconscious mind. The established literature does cover the basics of art songs by discussing musical symbolism and mood representation, but Wolf's choice to portray the deeper meaning of the poem, rather than the surface value, is scarcely discussed. Through my research, I realized that two areas of conflict are within the songs; the struggle between fantasy and reality, and desire for love and the disappointment that ensued, the latter being very personal for Mörike. The conflicts result in a shift of functionality of the underlying harmonies, in which the nature of harmonic function is a psychological parallel to the text. The harmonic shift is therefore a reflection of the conflicts. The musical representation of developing insanity is that of unusual chord inversions and desires is represented by jarring syncopation. With these findings, I provide a new model for analyzing the German art song tradition that allows for a greater understanding of the interaction between the music and text.

The Influence of Family Structure on Aggression Displayed in Young Head Start Children

Matthew G. Anderson, Lindsay Bailey, Christopher Newberry, and Jimmie Flower
Dr Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Current research of childhood aggression has shown significant relationships exist between the quality of mother-child relationships and their children's external aggression. However, the majority of these studies of childhood aggression were limited to study how aggression is displayed in middle class families. Few studies examined the influence of social variables, such as lower social economic status and/or single parent background, have on children's aggression. The need to examine how diverse family dynamics are related to children's social development is evident. The present study thus designed to examine the relationship between the reported parental child-rearing beliefs and their children's aggressive behaviors observed in the classroom from a local head start program. Many children in these samples do not have residential fathers. Some children even frequently lack any paternal guardian. Fifty two children with ages range from 35 months to 48 months old in two waves of data were used to document how various types of demographic background related to children's displays of aggressive behaviors. Guardians of these children were asked to fill out a survey (Chiang, 2006) regarding their observations of children's hurting and helping behaviors and disciplinary practices. Teachers were given Social Competence Behavior Evaluations (by LaFreniere) to rate children's social behaviors in school. Although children from single parent households did not show more aggressive behaviors, children from father present families tend to have better social skills. Further results and implications will be discussed at the conference to address whether children are universally better with two parents in social development.

The Engineering Learning Environment

Ashley A. Babcock
Dr. Nadia Kellam, Department of Biological & Agricultural Engineering, University of Georgia

Previous studies have indicated that the engineering learning environment strongly influences a lack of diversity among students as well as harboring a "chilly" environment for students, both male and female. This "chilly" environment harbors competitiveness, loneliness, and separation of students and professors, culminating in the limited spectrum of surviving students, particularly females, who comprise only 20% of those who graduate. While there is much literature focusing on learning environments, little has been directly extended to the engineering learning

environment and its impact on women. Because the learning environment can empower or marginalize people, this research aims to not only understand the learning environment but also the connection between the learning environment and attraction and retention of diverse people, specifically women. A set of semi-structured interviews employ biographic and linguistic analysis methodologies to elicit female students' accounts of their learning environment in engineering. The interview questions elicit narratives from the female students describing their decision to major in engineering, a typical day in the classroom, the topics in their courses, the building's aesthetics, and any reluctance to continue in engineering. Qualitative research methodologies are used to elicit greater, contextual understanding of women's experiences since quantitative research tends toward marginalization of subjects, seeking broad generalizations. These accounts highlight environmental attributes and detriments, indicating that the engineering learning environment is "chilly." Graduate-bound students indicate that their success is accredited to support groups via club involvement and undergraduate research that helped dissipate this "chilly" environment.

Examining Parenting Stress for Mothers of Young Children with Autism Spectrum Disorders

Jennifer L. Barr
Dr. Jonathon Campbell, Department of Education Psychology & Institutional Technology, University of Georgia

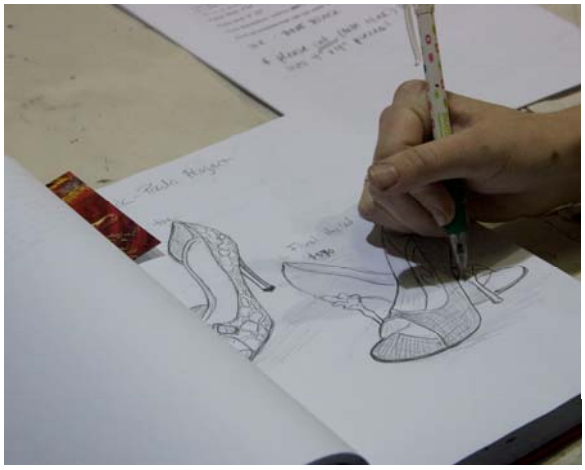
Parents of children with an Autism Spectrum Disorder (ASD) report higher stress levels than parents of typically developing children and parents of children with Down syndrome. Research has shown that parents of children with ASD attribute the highest degree of parenting stress to their child's: embarrassing disruptive behavior, lack of prosocial behaviors, and inability to function independently. This study examined Parenting Stress Index (PSI) scores of six families with children with ASDs (50% male, M = 4 years, 2 months) participating in the Parent-Child Interaction Therapy (PCIT) Clinic at the University of Georgia. Participant PSI scores were compared to literature documenting specific stress profiles of parents of children with ASDs. Based on the published literature, the author predicts that parents of children with ASDs will score higher on certain subscales of the PSI. In the child domain, participants should score highest on the distractibility/hyperactivity, reinforces parent, and acceptability subscales. In the parent domain, participants are predicted to score highest on attachment, role restriction, and depression. Further, recommendations will be made as to whether PSI Total Stress scores or PSI subscale scores should be utilized when examining the effect of treatment on parenting stress in families of children with ASD.

Can Smallholder Dairy Farmers of Southwestern Uganda Save Their Evening Milk?

Robert D. Bennett
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

Due to the poor infrastructure of the milk trade of Uganda, smallholder dairy farmers of Southwestern Uganda have no way of selling the evening milk which constitutes thirty-five percent of the total milk harvested. A cooler is being created to save this milk until it can be taken to market the following morning; however, it still stands to be determined if the cost of the design can be repaid by the farmer. The purpose of this paper is to determine the affordable cost of the cooler to guide the design and fabrication processes. The average smallholder farmer has 5 cows which produce a total of 50 liters of milk daily, 17.5 liters of which are produced in the evening. The current market price for the farmer is 200 Uganda Shillings (USh) per liter while the cooler design currently costs 170,000 USh. It will be shown that there is need for the manufactured cost to be lowered to allow the farmer to repay the initial cost in two years. However, expeditious repayment is shown to be a possibility with the supplement in income that the evening milk

provides. Also, the above calculation is considered conservative; it is speculated that the current price of milk will rise due to demand rising as the infrastructure of transporting and storing processed milk, which is relatively new in Uganda, becomes refined. With a rise in price and therefore profits for the farmer, the repayment period would be shortened allowing more farmers to obtain the product without a debilitating debt.



Collaborative Print Project: Prada Shoes
Meghan Boling, Talia Bromstad, David Broughton, Kathryn Burne, Bryan Hilley, Corey Jameson, Lauren Kesler, Ivy Lane, Eric Lotzer, Katherine Osbum, Lauren Ramsey & Ivy Williams
Prof. Shelly DiCello, Department of Printmaking, University of Georgia

In this collaborative project, Lamar Dodd School of Art Visiting Assistant Professor Shelly DiCello, Visiting Artist Libby Black, and twenty undergraduate, graduate and faculty artists (selected by artist Libby Black after an application process) each created a print corresponding to a narrative penned by Black, "Prada Shoes." The parameters of the project asked that each participant draw and etch a pair of Prada shoes that they desire to own. Each participant then created an edition of 25 prints from their matrix, as well as one paper box that housed this portfolio.

The Role of Rif1 in *Kluyveromyces lactis* Telomere Maintenance
Andrew D. Bosson, CURO Scholar
Dr. Michael McEachern, Department of Genetics

Linear chromosomes present two major problems to a cell. The first is that every round of replication slightly shortens the chromosome ends because initiation requires a primer, and the second is that the ends can be confused with damaged DNA and therefore be degraded by the cell. To prevent the loss of genetic information at the chromosome terminus during each round of replication, eukaryotic chromosomes have structures on their ends, called telomeres, consisting of multiple repeats of a short non-coding DNA sequence capped with telomeric proteins. The enzyme telomerase maintains the functional telomeric structure by adding more DNA repeats when the telomeres get too short. Since most adult human somatic cells do not need to divide any more, they do not express telomerase, and replication eventually leads to senescence. In most carcinogenic cells, however, telomerase is expressed at high levels, allowing the cells to divide indefinitely. Basic knowledge of telomerase and telomerase-related proteins is therefore of great importance to cancer research. This project details the involvement in telomere maintenance of a telomerase-associated protein, Rif1, in the model yeast *Kluyveromyces lactis*. Rif1 knockout mutants were grown in different genetic backgrounds and analyzed for phenotypic effects, including telomere length, in order to determine how Rif1 affects telomerase activity and the capping of telomeres. The results of this study provide a better understanding of the function of Rif1 on the telomerase complex and the alternative telomere elongation process of recombination.

Are We Really Ready? The Need for National Standards and the Creation of the Cycle of Emergency Planning

Ashley A. Bowen, Roosevelt @ UGA
Dr. Brock Tessman, Department of International Affairs, University of Georgia

After witnessing the September 11th attacks and the aftermath of Hurricane Katrina, Americans have become increasingly concerned about the safety and security of the United States. A review of the Department of Homeland Security's (DHS) policies and recent performance reveals major weaknesses in the nation's preparedness for protecting against and responding to terrorist attacks and natural disasters. Research has shown that the DHS currently lacks any national standards for the review and maintenance of emergency plans, the frequency of emergency drills, and the review of results from such drills. This policy proposes the standardization of emergency exercises across the nation and the creation of the Cycle of Emergency Planning (CEP), with DHS funding contingent on the implementation of these national standards. This paper addresses how the implementation of the CEP would provide a method for testing, revising, and maintaining emergency preparedness through review, exercises, and revision. The CEP is designed to resolve many of the current breakdowns in planning at the state and local level. Holding emergency exercises at least every two years and reviewing their results will help keep plans current and grounded in feasibility. Reviews of emergency plans and capabilities, conducted every five years by a third party, will help maintain objectivity in the reviewing process. These exercises and reviews should be used to update and maintain emergency plans as part of the CEP. Enforcing these new standards will remedy the failures in the current emergency preparedness system and improve the general safety and security of the nation.

Project Runway: Consume

Gabrielle Bratton, Maddie Edwards & Miriam Rowe
Prof. Clay McLaurin, Department of Fabric Design, University of Georgia
Prof. Mary Pearse, Department of Jewelry/Metalsmithing, University of Georgia

In this collaborative project and runway exhibition by Jewelry/Metalsmithing students of Professor Mary Pearse and Fibers students of Professor Clay McLaurin, material, adornment and body as site are examined and performed, taking cues from Visiting Artist Anya Kivarkis, and the publication "Fashion at the Edge." For one week, these students worked in teams of five with non-traditional materials, manipulating paper towels, hosiery, window screening and roofing shingles into performative, and in some cases spectacular, wearable art.

This piece explores the concept of restriction. We chose physically light weight materials,

nylon and polyester batting, to create the illusion of something heavy that would weigh down the body. The decision to use nylons was also important because nylons are physically restrictive to the body. We wanted this piece to restrict the body's movement both by adding weight and tension.

Materials: Paper, cupcake liners, paper towels

Towards the Discovery of Ras-Converting Enzyme Inhibitors - A Novel Anti-Cancer Target

Sarah R. Breevoort, CURO Scholar
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

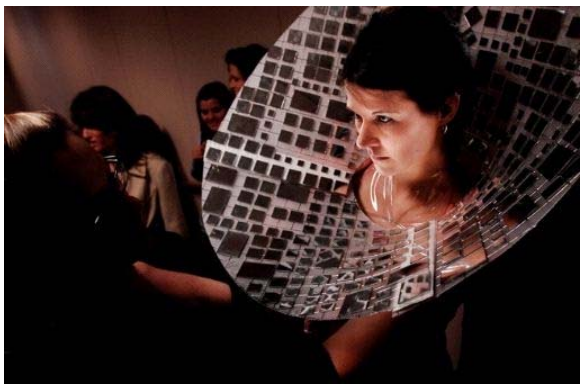
The proteases Rce1p and Ste24p promote a proteolytic step associated with the maturation of proteins containing a C-terminally localized *CaaX* motif, (*C* = cysteine, *a* = small aliphatic amino acid, *X* = one of several amino acids). Rce1p is considered a chemotherapeutic target because of its crucial role in the maturation of Ras proteins. Hyperactive forms of Ras are associated with 30% of human cancer tumors, including more than 90% of pancreatic cancers and 50% of lung cancers. Inhibiting Ras maturation is proposed to disable, or at least moderate, its cancer-causing activity. Because of the critical role Rce1p has in Ras maturation, compounds that inhibit Rce1p are being considered as anti-cancer therapeutics. In this study we compared the inhibitory profiles of the Rce1p and Ste24p *CaaX* proteases using peptidyl(acyloxy) methyl ketones (AOMKs) and inhibitors identified by high throughput screening (HTS). We conclude that AOMKs, although displaying better inhibitory properties than certain previously reported Rce1p inhibitors, are unlikely therapeutic candidates partially because of the inability to significantly enhance their potency. Nevertheless, we did observe instances of selectivity among the *CaaX* proteases, which makes these compounds effective tools for investigating *CaaX* protease enzymology. The inhibitory profiles of compounds identified by HTS and their analogs were also evaluated, and several compounds appear to be potent and specific Rce1p inhibitors. The compounds identified represent new tools for understanding the enzymology of post-isoprenylation modifying enzymes and provide new insight for the future development of Rce1p inhibitors that could be developed as anti-cancer drugs.

Forced Copulation and Offspring Viability in *Drosophila melanogaster*

Emily Dale Broder, CURO Scholar
Dr. Wyatt Anderson, Department of Genetics, University of Georgia
Dr. Yong-Kyu Kim, Department of Genetics, University of Georgia

The compensation hypothesis predicts that males and females mated with non-preferred partners attempt to make up for viability deficits in their surviving offspring by increasing reproductive investment. Consistent with the hypothesis of reproductive compensation, previous studies show that fewer offspring resulted from non-preferred matings in *Drosophila pseudoobscura* though males transferred more sperm when constrained to mate with a non-preferred partner. Using *Drosophila melanogaster*, I tested the compensation hypothesis by measuring offspring viability when females were constrained to mate with non-preferred partners. I employed natural phenomenon to create non-preferred matings: forced copulation and familiarity. Mature males forcibly copulate teneral females (very young immature flies) in nature. Following protocols from previous studies, I placed teneral females in vials with two mature males, but I observed no matings in over 60 trials. In previous experiments, flies avoided mating with each other when either non-siblings or siblings were raised together (familiarity); therefore matings between non-siblings raised together in the same vial are considered non-preferred. I raised non-siblings together in the same environment and crossed mature flies under one of two treatments: non-siblings raised together (NSRT) or non-siblings raised apart (NSRA). Fecundity and fertility will be a measured for offspring viability. Preferred

matings (NSRA) and non-preferred matings (NSRT) will be compared to test the compensation hypothesis. I expect matings between NSRT to yield more eggs but an equal number of offspring as NSRA. The results of these experiments will shed light on the components of reproduction that underline natural selection.



Project Runway: Cyborg
Jenny Bryant, Julie Givens & Marilyn Zapf
Prof. Clay McLaurin, Department of Fabric Design, University of Georgia
Prof. Mary Pearse, Department of Jewelry/Metalsmithing, University of Georgia

In this collaborative project and runway exhibition by Jewelry/Metalsmithing students of Professor Mary Pearse and Fibers students of Professor Clay McLaurin, material, adornment and body as site are examined and performed, taking cues from Visiting Artist Anya Kivarkis, and the publication "Fashion at the Edge." For one week, these students worked in teams of five with non-traditional materials, manipulating paper towels, hosiery, window screening and roofing shingles into performative, and in some cases spectacular, wearable art.

In our age of cyber-technology, identity and personality can exist apart from the body. Is it the moral nature of our bodies that drive us to create potentially immortal and forever youthful online personas, or is it technology that is suffocating our physical presence? As our minds become more disconnected from our body, will the current hybrid nature of technology and humanity remain? "Cyborg" questions the function of the body in this transitional time of being "plugged-in."

Materials: Electrical Cord, Mirror, Plastic, Vellum

"I Want My Credits!": The Impact of Procedural and Interactional Injustice on Participants' Evaluations of an Experimenter
Nancy D. Brynteson
Dr Alicia Bembenek, Department of Psychology, Georgia College & State University

It is difficult to determine precisely how a person may react when one experiences an injustice. Theory states that people will react negatively to any occurrence of injustice; however, a person experiencing an injustice may react differently depending upon the type of injustice experienced (e.g., procedural or interactional). This study was conducted to determine how participants would react to an experimenter who committed a procedural and/or interactional injustice against them. Undergraduates (N = 37) were provided with a cover story that they were completing a "student lifestyle" survey for research credit. Prior to the survey being completed, some participants experienced an interactional injustice (represented by a disrespectful, unrelated phone call made by the experimenter during the session). After the survey was completed some participants experienced a procedural injustice (represented by denial of research credit). Responses to the injustices were thereafter obtained with an "experimenter evaluation" which measured participants' thoughts (e.g., perceptions of respect), feelings (e.g., anger, disappointment), and behaviors (e.g., intentions to participate again with same experimenter) on 1 = *not at all* to 10 = *very much* scales. The results indicated that participants did perceive both types of injustices as unfair. However, participants responded negatively only after the procedural injustice was committed (i.e., when they were denied research credit), and did not appear to be affected by the interactional injustice (i.e., the inappropriate phone call).

Questions remain as to whether a non-student population would react similarly, as reactions to an injustice may depend strongly on *expectations* of social interactions.

Project Runway: The Defense of Intimacy
Ashley Buchanan, Lindsey Bartell, Eleanor Simmons & Jenny Moore
Prof. Clay McLaurin, Department of Fabric Design, University of Georgia
Prof. Mary Pearse, Department of Jewelry/Metalsmithing, University of Georgia

In this collaborative project and runway exhibition by Jewelry/Metalsmithing students of Professor Mary Pearse and Fibers students of Professor Clay McLaurin, material, adornment and body as site are examined and performed, taking cues from Visiting Artist Anya Kivarkis, and the publication "Fashion at the Edge." For one week, these students worked in teams of five with non-traditional materials, manipulating paper towels, hosiery, window screening and roofing shingles into performative, and in some cases spectacular, wearable art.

The Defense of Intimacy deals with an individual's prerogative to protect the aspects with which they feel most uncomfortable. By juxtaposing a hard, coarse outer shell with a pure, soft, and tactile interior the wearer can choose how she wishes to express her vulnerability.

Materials: Textured Poster Board, Satin, Organza, Yard Tubing

Charcoal-Powered Vacuum-Zeolite Adsorption Cooler Regenerator for the Preservation of Milk, Vaccines, and Other Perishables
Jessica L. Buday
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

Smallholder dairy farmers in Sub-Saharan Africa are not able to sell their evening milk to dairy processing centers because of the lack of appropriate equipment and electricity sources to cool the milk during transport. Through another undergraduate engineering design and research program, a cooler previously designed for alcoholic beverages (CoolKeg) is being adapted to meet this need. The cooler uses a vacuum-zeolite adsorption system and requires no electricity, but it is necessary to recharge it after each use by using heat exposure to regenerate the wet zeolite. The goal of this research is to develop a system that has the capacity to effectively "recharge" the cooler by regenerating (water desorption) the spent zeolite. A charcoal-powered brick oven has been designed using locally-available materials. The CoolKeg was filled with water to act as a milk-substitute, and a cooling curve was generated after every regeneration to indirectly assess the effectiveness of the oven and the stability of the zeolite. Preliminary results presented in terms of Coefficient of Performance (COP) approach those achieved in refrigeration devices employing similar technology, suggesting that

there is room for further optimization of the regeneration process. The success of this project is expected to have impact beyond milk; other preservation applications include vaccines and perishables such as non-alcoholic beverages.

Contemporary Brass Sounds
Bulldog Brass Quintet
Prof. Fred Mills, Director and Department of Academic & Performance Areas (Brass), University of Georgia

If J.S. Bach were alive today, he would love the sound of modern brass playing his compositions. The evolution and development of brass instruments over the last 150 years infuses 21st-century performances of Bach's 18th-century compositions with new life—a new set of clothes, so to speak. It is exciting to hear centuries-old masterworks performed in new styles to reach a modern audience. It is also exciting that American musical styles—jazz, country and western, bluegrass, and rock—have also donned new clothes and are welcomed into concert halls traditionally reserved for serious music of the 18th and 19th centuries. For the CURO Symposium, the Bulldog Brass Quintet will present a selection of "crossover" music—a phenomenon started in the 1960s by Jean-Pierre Rampal, Maurice André, and Itzhak Perlman and continued today by Mark O'Connor and Béla Fleck.

Characterization of Mitoferrin and Its Interactions with Ferrochelatase
Joseph S. Burch, CURO Summer Fellow, CURO Scholar
Dr. Harry Dailey, Biomedical & Health Sciences Institute, University of Georgia

Iron is an important cofactor in many biological reactions. Due to its high redox nature, iron availability is highly regulated. Heme synthesis requires iron and is essential for life in almost all organisms. Iron is inserted in protoporphyrin IX during the last step of the heme biosynthesis pathway by ferrochelatase. Since ferrochelatase is associated with the inner-mitochondrial membrane, mitoferrin transports iron into the mitochondria. Little is known about mitoferrin except that it is membrane bound and it is necessary for erythroid iron assimilation into the mitochondria. The goal of this project was to clone, express, purify, and describe different mitoferrin orthologs and any interaction between mitoferrin and ferrochelatase. Five different mitoferrins genes have been isolated: zebra fish mitoferrin 1 (Z1), zebra fish mitoferrin 2 (Z2), human mitoferrin 1(H1), mouse mitoferrin 1 (M1), and mouse mitoferrin 2 (M2). Thus far, Z1, Z2, H1, and M2 have been cloned into multiple vectors and been expressed in *Escherichia coli*. Talon chromatography was used for purification and western analysis for detection. Small amounts of Z1, H1, and M2 have been detected with western blots. The small quantity of protein has limited further study. Immunoprecipitation reactions with mitoferrin and ferrochelatase have been inconclusive and failed to show any interaction. In further tests, Z1, H1, and M2 will be cloned into a modified pET vector which may provide better yields. With higher yields of the mitoferrins, an interaction between it and ferrochelatase may be shown.

Transcriptional Expression of *Arabidopsis* GAUT Genes: 15 Proven and Putative Plant Cell Wall Biosynthetic Galacturonosyltransferases
Amy J. Burrell, CURO Summer Fellow, CURO Scholar
Dr. Debra Mohnen, Complex Carbohydrate Research Center, University of Georgia

Pectin is a family of plant cell wall polysaccharides that have multiple functions in growth and development and are used for diverse industrial and biomedical products. A family of pectin biosynthetic enzymes known as galacturonosyltransferases catalyze the transfer

of galactosyluronic acid (GalA) residues from uridine diphosphate-GalA to growing polysaccharide chains. The first gene encoding a pectin galacturonosyltransferase, *Arabidopsis thaliana* GAlactUronosylTransferase1 (GAUT1), was recently identified. BLAST analyses indicate the existence of 14 additional genes (GAUTs 2-15) with sequence similarity to GAUT1. To understand the biological significance of these genes in pectin synthesis, it is important to understand where and when the genes are expressed. My research goal was to analyze the expression of each GAUT gene in *Arabidopsis* through utilization of a β-Glucuronidase (GUS) reporter gene system. The promoter regions of 13 GAUT genes were determined, amplified, and inserted into cloning vectors. The DNA sequence of the 13 promoter sequences were verified and the remaining two promoter sequences will be amplified soon. Using restriction digestion, the promoter regions of GAUT1 and GAUT7 were removed from the cloning vectors and inserted upstream of the GUS gene in a transformation vector. The GAUT1 and 7 promoter:GUS constructs were transformed into *Arabidopsis* plants using an *Agrobacterium*-mediated method. Transformed plants have been recovered and histochemically stained to detect GUS activity. The results indicating the cell-type and tissue-specific expression of the GAUT1 and GAUT7 genes will be reported and discussed in relation to the functions of the GAUT genes in pectin synthesis.

Emotional and Behavioral Problems Displayed in Preschoolers Raised by Biological Grandparents

Shelby R. Carlson, Holly Chandler, Heather Smith, Rebecca Lewis
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Grandparents often assume the responsibility of raising their grandchildren, commonly to avoid placing children in foster care. There is an increasing 3.6 million grandchildren under the age of 18 being raised by grandparents in the United States. Children raised by grandparents tend to display more problematic emotional and behavioral development. The most common reason for children to be placed in the care of grandparents has been found to be drug use. Stressful events leading up to the transition of living with grandparents and the transition itself contributed to many emotional fluctuations in the child. Solomon and Marx (1995) found that children raised nontraditionally by grandparents are less successful in school than the children of the traditional, two-parent family. The present study examines a focus group of fifty-two 3-year old and 4-year old preschoolers with emotional and behavioral issues that were collected in a larger intervention study. Guardians of these children were given a parenting survey, and teachers were asked to rate these children's behaviors at school using Social Emotional Behavior Evaluation (SCBE, by LaFreniere). From the data, five returned surveys were from grandparents. The results showed grandparents reported that children less frequently engaged in hurting and aggressive behaviors. However, they were observed to display more disruptive behaviors in class. All five children were the youngest child in the family, with two children being the only child. Therefore, the results can be interpreted in various ways. Detailed results from these cases and their implications will be discussed.

Otavaleños and Cotacacheños: Local Perceptions of Sacred Sites for Farmscape Conservation in Highland Ecuador

Lee Ellen Carter, CURO Summer Fellow, CURO Scholar
Dr. Fausto Sarmiento, Department of Geography, University of Georgia

Indigenous communities around the world are facing pressure from tourism practices. Otavalo, Ecuador, provides one example of how local spiritual values can enhance the conservation efforts of ecotourism. The Imbakucha watershed includes mountain landscapes that numerous indigenous communities hold sacred. In this case, the increased pressure of globalization affects local natural, cultural, and economic values as the watershed undergoes a shift from

traditional to contemporary ecotourism practices. Through ethnographic and qualitative research, the study investigates the relationship between the indigenous people and their sacred land, by way of local understanding of identity and cultural values. The data was collected through 30 interviews conducted with indigenous community leaders, indigenous peoples, nonprofit organization workers, government officials, and academics in Quito, Otavalo, and Cotacachi, Ecuador. The study concludes that there is a general outlook among the interviewees that a stronger influence of environmental ideals can and should be instilled into the livelihood of indigenous communities, in order to promote sacred sites' conservation. We recommend the implementation of a Sacred Site conservation category with six principles, including: recognizing sacred natural sites; integrating these sites into protected area management; promoting participation, inclusion, and collaboration in the community; encouraging improved knowledge of sacred natural sites; protecting sacred natural sites with appropriate management access and use; and respecting the rights of sacred natural sites in national policy. These principles would allow the indigenous communities to preserve their ancestral beliefs and values, while also providing an economic influx through ecotourism.

Improving the Health of Georgia Youth: An Incentive Program for Nutritional Standards in Georgia Schools

Kevin K. Chang, Roosevelt @ UGA
Dr. Phaedra Corso, Department of Health Administration, Biostatistics & Epidemiology, University of Georgia

Since 1980, the prevalence of overweight among children in the United States has tripled. A recent 2007 report identifies the state of Georgia as having the twelfth highest rate of overweight youth in the United States. In Georgia's nearly 2700 schools, there are currently no nutritional standards for competitive foods, or foods sold outside the federal school meal programs, such as food items from vending machines. Furthermore, Georgia does not require higher nutritional standards than the federal requirements in breakfast and lunches, resulting in only minimal amounts of healthy foods in a student's diet. In order to improve the overall health of Georgia's youth, Georgia's Department of Education should offer an incentive program for all elementary and secondary schools currently lacking nutritional standards. Through a supplemental state reimbursement offered to schools that implement the standards, the program encourages schools to adopt nutritional standards for all competitive foods sold during the school day. These standards include limitations on calories and fat, sugar, sodium, and caffeine content. Schools participating in the program must also provide greater fruit and vegetable options during meal times. Participating schools will receive an increased reimbursement rate for each lunch served through the National School Lunch Program. The state can sustain funding for the program through a special state tax on foods of minimal nutritional value and foods deemed "unhealthy." Allowing schools to phase in implementations over a three-year period, the program promotes a sustained and practical effort in improving the health of Georgia's youth.

Evaluating Protocols for Measuring Immune Defenses in Larval Monarch Butterflies

Jean Chi
Dr. Sonia Altizer, Eugene Odum School of Ecology, University of Georgia

Insects are known to employ various immune defenses to protect against injuries and infections. Hemocytes are insect immune cells that differentiate into granulocytes, plasmatocytes, spheroid cells and oenocytoids. They respond to foreign invasive organisms through a wide range of mechanisms, including encapsulation and phagocytosis. Additionally, infection and injury activate a phenoloxidase (PO) enzyme cascade that produces the compound melanin, which binds to foreign bodies. A study system of monarch butterfly larvae (*Danaus plexippus*) was used to evaluate

and refine current protocols of measuring these two types of defenses by comparing different methods for hemocyte collection, and to investigate the relationship between PO activity, hemocyte counts, and the proportion of differentiated cells to establish baseline values for healthy monarch individuals. Results show that the two methods for collecting hemocytes produced different hemocyte counts, and also show positive correlations between PO activity and hemocyte counts. This study demonstrates that consistent methods for hemocyte collection are necessary for accurate counts, and validates techniques used in studies of monarch immune system responses to infections and environmental stress.

Managing U.S. Aid to Egypt: A Reorientation of Current Support

Chris Chiego, Roosevelt @ UGA
Dr. Brock Tessman, Department of International Affairs, University of Georgia

The Middle East region (excluding Iraq) receives the largest share of the United States' foreign aid at an estimated 38 percent annually. Since 1979, Congress has sent approximately 2 billion dollars a year to Egypt, placing Egypt second only to Israel in total foreign aid. Currently, Congress allocates the majority of aid ($1.3 billion) for military purposes and $500 million earmarked for economic aid, though both allocations are essentially unsupervised. With political change looming on the horizon and discontent rising within Egypt, the United States must shift its foreign aid to help ensure Egypt's long-term stability through economic prosperity and political moderation. This paper assesses the current state of Egypt using economic data, current academic scholarship from journals, and newspaper reports and suggests incentive-based changes in the structure of U.S. aid. As Egypt is a bellwether for much of the Arab world, establishing long-term stability in the region, improving overall economic and social conditions in Egypt, and cultivating a favorable impression of the U.S. would all be benefits of such action. Furthermore, the United States should swiftly pass the free-trade agreement it has already negotiated with Egypt to assuage the Egyptian government and promote Egyptian economic growth. All these interconnected efforts are crucial for the United States to retain its strategic interests in Egypt and ensure a stable, prosperous future for a valuable Middle Eastern ally.

Contours and Melting Crystals

Eric P. Cho
Dr. Robert Varley, Department of Mathematics, University of Georgia

The topic concerns the shape of a particular boundary contour related to a melted crystal. One of the main results from the literature recently set forth by Kenyon and Okounkov is that the projection of the outer contour to the plane is an algebraic curve, to which one naturally assigns a degree. The case when the plane curve is a cardioid of degree 4, already considered by Kenyon-Okounkov, will be discussed to lay the foundation. My research involves exploring other cases of different degrees and visualizing the corresponding curves in 3-dimensional space. This report will analyze other examples, degree formulas and geometric pictures about the projection of these melted crystal contours. Since phase transitions, such as melting or freezing, are rather complex phenomena in nature, any approximate model whose phase transitions can be examined analytically is valuable. The crystal is modeled by a configuration of little cubes, called a stepped surface, so the outer contour projects to a polygon in the plane. By taking the limit of random stepped surfaces, several known rational algebraic curves are produced as a result. With further study in the plane, counting problems arise naturally with implications to better understanding the contour model.

French Dislocation: The Syntax of Power

Andrew C. Clark
Dr. Diana Ranson, Department of Romance Languages, University of Georgia

Dislocation in French occurs when a speaker produces an element of a sentence before or

after that sentence, typically employing within the sentence a pronoun to repeat the dislocated element and to fulfill its normal syntactic position. One might say, for example, *Le chien, je le vois*, "The dog, I see it," or *Je le vois moi,* "I see it, me." Previous studies of dislocation assumed that use does not vary according to social factors such as age, sex or class, but according to the speaker's message and the pragmatic function desired. These studies focused on dislocation's function in topic shifting and comparison. In a preliminary study of corpora from two French films, *Marius et Jeanette* and *La Boum*, I used the principles of conversational analysis to link dislocation to power and solidarity among speakers. The present study will extend this analysis to the Montpellier-Rognes corpus of spontaneous French recorded in 2005 and 2006. First, I will measure the average frequency of dislocation and determine the deviation from this average for individual speakers and social groups of speakers. If the individuals deviate from the average more than social groups, this would indicate that individual stylistic choice influences dislocation more than social factors. I will then analyze the dislocations within the framework of conversational power and solidarity; a consistent link to these concepts would indicate that speakers employ dislocation to provide stylistic emphasis. This study seeks then to use the distribution of dislocation to illuminate its pragmatic functions.

Nipah Virus and Apoptosis in Cells
Caroline G. Colden
Dr. Corrie Brown, Department of Pathology, University of Georgia

Nipah virus (NiV) is a zoonotic disease that recently emerged in Malaysia. This zoonosis, or disease that can be transmitted from animals to humans, causes lethal febrile encephalitis in humans. Understanding the pathogenesis of Nipah virus infection and the role the host immune system plays during this event is critical to devising effective control measures and therapeutics. In this research, we are examining the relationship between apoptosis, or programmed cell death, during NiV infection in the guinea pig model. Apoptosis, a normal process of the immune response to control infections, is often altered by viruses to facilitate infection and spread. We hypothesized that NiV blocks the apoptosis pathway early during infection allowing for its systemic spread and massive infection of cells. To test this hypothesis we are examining histologic sections from guinea pigs experimentally infected with NiV, using an immunohistochemical assay that employs an anti-active caspase 3 antibody. Caspase 3 is an early indicator of apoptosis activation. We expect to see the same or less apoptosis signaling in tissue sections of infected animals than in those of our non-infected controls.

Physical and Structural Basis for pH Dependence of Transcription Regulation by the Anti-Sigma Factor AsiA
Benjamin P. Crane, CURO Scholar
Dr. Jeffrey Urbauer, Department of Biochemistry & Molecular Biology, University of Georgia

Anti-sigma factor proteins inhibit bacterial transcription by binding the sigma subunit of the RNA polymerase. A unique anti-sigma factor is T4 bacteriophage AsiA protein. In *E. coli*, AsiA interacts tightly with the polymerase sigma-70 subunit, and, like other anti-sigma factors, inhibits transcriptional activities. Specifically, AsiA inhibits transcription from bacterial and early phage promoters. Additionally, AsiA assists in transcription activation from phage middle promoters. Thus, AsiA is a unique molecular switch for transcription regulation. Moreover, excess AsiA kills bacteria, suggesting AsiA could serve as an antibiotic development model. Most AsiA studies have been performed at relatively low pH (6.2-7.0). Through concurrent studies, we have determined that AsiA undergoes a substantial, pH-dependent structural reorganization across the range of physiological pH. Using nuclear magnetic resonance (NMR) spectroscopy, we monitored AsiA structure as a function of pH. As pH increases to 7.8 (pK for the transition), spectra

indicate increasing structural heterogeneity. Further increasing pH to 8.2 decreases heterogeneity. At pH 8.2, spectra indicate a stable, single species, structurally distinct from that at low pH. Comparison of the NMR chemical shifts of the low and high pH forms indicates clear, localized structural changes. We have also performed experiments to determine a structure of AsiA at pH 8.1 using residual dipolar couplings (RDCs) from additional NMR experiments. At physiological pH, our results indicate an equilibrium mixture of two distinct structural AsiA forms, and that functional differences between these forms permit pH-dependent regulation. Inclusion of pH-dependent regulation in the antibiotic model could improve antibiotic efficacy.

Room–Poem

Jordan A. Dalton
Prof. Andrew Zawacki, Department of English, University of Georgia

When the echoes of our words die away, does something of them remain, pressed by the force of sound into the walls themselves? How can we read these word-fossils? Can we halt this rapid dispersion, turn temporary speech into lasting print? If the walls could tell us what they understood of our conversation, what would they say? In this piece, a room has been granted the ability to comprehend language by being given a vocabulary carved from a different, virtual space. (The room of an archive, walled off by a query.) What is then displayed here is the poem carved out of this physical space, the poem created from the (mis)understandings of the hall, the walls themselves. Software is set up in a space, and as the space lives its daily life, the software jots down some of the things it hears. From this arises a poem, to be read or displayed. Voice recognition, one of the most problematic of computer science's algorithms, can yield fascinating results in its failures. Some rudimentary voice recognition software is loaded with a predetermined vocabulary and then run in the symposium space, yielding a poem created from the space's (mis)recognitions of the language used within it. Language's collision with digital technology might leave something resembling a car crash to those used to its more conventional applications, but with a bit of work, the wreck can become something wonderful.

Long-range Retrograde Transduction of Survival and Trophic Signals in Neurons

Matthew Logan Davis
Dr. James Franklin, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Developing vertebrate neurons depend on target-derived growth factors for survival and neurotrophic support. The precise molecular mechanisms underlying long-range transduction of survival and trophic signals remain unclear. When nerve growth factor (NGF) is withdrawn from sympathetic neurons *in vitro*, a complex intracellular molecular cascade results, leading to caspase-mediated protein degradation and death. A dramatic increase in reactive oxygen species (ROS) that is a critical component of the apoptotic cascade takes place in these cells soon after withdrawal. Neurons can be rescued by late re-addition of NGF which rapidly suppresses ROS production. This suppression is evidence of a rapid survival signal. I will plate mouse superior cervical ganglion (SCG) neurons in novel microfluidic chambers developed at the University of California, Irvine, in which soma are separated from their distal axons. Cells will be deprived of NGF in both somal and distal axon compartments. Somatic ROS levels will be determined by confocal microscopic imaging of neurons loaded with CM-H_2DCFDA, a cell-permeant indicator of ROS that is non-fluorescent until oxidation occurs. An immediate decrease in somatic ROS production after re-addition of NGF to the distal axon compartment would offer evidence that *long-distance* rapid survival signals take place in sympathetic neurons. The rate of movement of the signal may allude to underlying mechanisms. Many neuropathologies will be better understood by the clarification of mechanisms underlying survival signaling, and this research could have important clinical ramifications.

The Role of Insulin-Induced Tyrosine Phosphorylation on O-GlcNAc Transferase (OGT)

Vanessa N. del Valle
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia

Posttranslational *O*-GlcNAc modification is a dynamic process that occurs on a myriad of intracellular proteins throughout eukaryotic cells. *O*-linked *N*-acetyl glucoaminyltransferase (OGT) is the enzyme responsible for the addition of the *O*-GlcNAc moiety to serine and threonine residues of target proteins. Elevation in *O*-GlcNAc levels induces insulin resistance in cell culture models, and OGT overexpression leads to glucose disposal defects in rodents. Both of these outcomes are diagnostic of type II diabetes. Therefore, greater understanding of OGT and the *O*-GlcNAc modification is paramount to gaining further insight into the steps that lead to insulin resistance, an early feature of type II diabetes. In this study, we investigate the presence of tyrosine phosphorylation on OGT and its importance to the structure and function of the enzyme. OGT has previously been shown to be tyrosine phosphorylated in response to insulin stimulation though the site and impact of modification has not been elucidated. A point mutation was performed in which tyrosine 988 was substituted by phenylalanine on entry and expression vectors. Tyrosine 988 was chosen because it is the only in-silico predicted site for tyrosine phosphorylation. The point mutation was confirmed using restriction digestion analysis and DNA sequencing. An *E. coli* protein expression system showed the mutant OGT could be expressed after induction with IPTG. Mammalian protein expression systems as well as OGT activity assay analysis will soon follow. These studies will determine if tyrosine 988 is the site of phosphorylation and determine the impact of this modification on properties of OGT.

The Effect of Sample Handling and Storage on the Accuracy and Repeatability of Fecal Worm Egg Counts in Horses

Kimberly L. DeLisi, CURO Summer Fellow, CURO Scholar
Dr. Ray Kaplan, Department of Infectious Diseases, University of Georgia

Drug resistance in parasites is a major threat to the health and well-being of horses. Consequently, it is critical that veterinarians regularly evaluate deworming programs to determine if parasites are becoming drug resistant. Currently, the only means available to diagnose drug resistance in equine parasites is the fecal egg count reduction test (FECRT). However, the lack of any accepted standards for sample handling and storage hamper interpretation of results. The purpose of this investigation was to determine the effects of sample handling and storage on fecal egg count (FEC) data. Two parameters were examined: sample storage temperature, and length of time between defecation and sample collection. In a first set of experiments, fresh feces were collected and stored anaerobically at -10°C, 4°C, 24°C, and 38°C for five days. Fresh feces were then stored aerobically at room temperature, and sub-samples were removed for analysis at 0, 3, 6, 12, and 24 hours. FEC were performed using the modified Stoll technique. After five days at -10°C and 38°C, FEC decreased by 59% and 96%, respectively, whereas at 4°C and 24°C, FEC only changed by 17% and 14%, respectively. FEC in samples collected 12 hours after defecation decreased by only 15% whereas by 24 hours, FEC decreased by 78%. These data suggest that feces less than 12 hours old are suitable for collection, and samples can be stored either anaerobically or in the refrigerator up to five days. These results provide a scientific basis for new recommendations to standardize methods used for FECRT.

Emergency Response: Bringing It to Georgia

Nicole C. DeMarco & Aqsa Mahmud, Roosevelt @ UGA
Dr. Michael Beck, International Center for Democratic Governance, University of Georgia

The events on 9/11 in New York City and Washington, DC stress the role of local governments as the first line of response to terrorist threat. Therefore, it is necessary to act in a manner guaranteeing optimal level of cooperation amongst the various entities of first-responders. At the federal level, the Department of Homeland Security acknowledges the importance of local emergency response and thus, has created a system by which it allocates funds for the construction and maintenance of emergency response services. Federal money is designated to the state and then filtered to local governments. The state's main function is administration and fund allocation; primary responsibility of implementing emergency response programs falls on local governments. However, once received, local governments vary on their spending. This allows individual jurisdictions to invest in a manner that maintains low operability with neighboring municipalities. In such instances, response efficiency is lost. For example, adjacent local governments may invest in identical emergency programs to prepare for biological attack. However, this duplication is a) a misuse of funds, and b) may decrease response time due to miscommunication amongst first responders. In order to combat obstacles associated with the current methodology in the state of Georgia, our proposal establishes a system that ties funding to the adoption of mutual aid legislation. In order for municipalities to receive funding, they must administer measures of local cooperation to ensure a maximum level of efficiency in response to terrorist attacks.

Reforming Subsidies in the Federal Budget

William Patrick Dever, Roosevelt @ UGA
Dr. William Lastrapes, Department of Economics, University of Georgia

The U.S. government allocated approximately $52.52 billion in subsidies in 2006, accounting for 3 percent of total government expenditure. Many of these subsidies, though, actually reduce social welfare because of a lack of information and political lobbying. The U.S. government fails to properly assess the costs and benefits of every subsidy because the information required to do so often is too costly to obtain. In addition, subsidies greatly benefit a small group, giving them an incentive to lobby and provide campaign contributions to politicians, which can often influence the outcome of a vote, regardless of the social benefits or costs of the subsidy. Through detailed analysis of economic markets, this report illustrates the economic effects of both proper and improper subsidies and proposes the creation of an independent Subsidy Review Board (SRB). A twelve-person panel, with one member representing each of the twelve Federal Reserve districts, will lead the organization. All subsidies will be evaluated on the regional and national level under the specific criteria established in this report. This proposal will eliminate information asymmetries, because firms wishing to obtain a subsidy will have to present a detailed report on the societal benefit of the subsidy to the SRB, which will shift the information costs from the government. Furthermore, an independent Board will not be as susceptible to political or socio-economic pressures as individual legislators. A reformation of the federal subsidy process will eliminate billions of dollars from the federal budget each year and direct better allocation of the remaining funds.

U.S.-China Energy Cooperation: A Step toward Greater Environmental Cooperation
John T. Dixon, Roosevelt @ UGA
Dr. Rhett Jackson, Department of Forestry, University of Georgia

Even as global warming receives an increasing share of public debate, the world's largest contributors to greenhouse gases, the United States and China, are also two of the most reluctant countries to take action against climate change. The United States has long been the global leader in energy consumption, but China's stunning growth requires that it consume ever-increasing amounts of oil and coal. Unfortunately these sources of energy are some of the worst sources of greenhouse gases. Reviewing current policies and research in the field exposes the lack of effort and ability to factor climate change into energy plans. Any serious attempt to conquer the energy challenges of our time will require serious effort, cooperation, and leadership from both of these countries. To remedy the stark inadequacies in current climate change policy, the United States and China must enact policies to increase nuclear power cooperation and improve clean coal technology. Both governments should support these technologies, as they will require government investment to reach an adequate scale. The two countries will also have to consult each other to shape laws and build government agencies tasked with managing the push for a cleaner environment. Understanding institutions and trends in both countries allows us to create better policies to encourage cleaner growth through nuclear power. Cooperative efforts can build trust and solidarity between the United States and China, and both countries will benefit from technological improvements that will allow them to wean themselves off of oil and coal.

Metabolic Studies in *Toxoplasma gondii*
Melissa D. Docampo
Dr. Boris Striepen, Department of Cellular Biology, University of Georgia

Toxoplasma gondii is a protozoan parasite causing severe disease in immunocompromised patients and fetal disease during pregnancy. This pathogen harbors a chloroplast-like organelle named the apicoplast. We are interested in the metabolic functions of this organelle as targets for parasite specific drug development, because the organelle is absent in human cells. The route we have taken to analyze the value of individual targets is to construct genetic mutants. In this study we have begun to analyze how mutants deficient in apicoplast metabolism and protein import are affecting the metabolic state of the parasite. The gene chosen for the pilot study encodes acyl carrier protein (ACP), which is important for fatty acid synthesis. This is essential for the parasite's growth. We grew the mutants and parental strains for six days, and then extracted the cells with chloroform and methanol and separated the extract into organic and aqueous phases to perform metabolomic studies. These studies were performed by mass spectrometry. A decrease in fatty acids was observed in the ACP mutants. One of the most interesting changes was the presence of very high levels of gamma aminobutyric acid (GABA), which is known to be involved in a stress pathway in plants. Based on our metabolomic studies, we are also building a larger and more representative model to fully understand the contributions that different synthesis routes make to the overall fatty acid metabolism of the parasite.

Two Faced Politicians: Political Supply versus Constituent Demand in Health Rationing Policy
Rachel M. Dolan
Dr. Anthony Bertelli, Department of Public Administration & Policy, University of Georgia

Recently the policy of the National Healthcare Service (NHS) in the United Kingdom has created controversy as well as increased public

interest and concern in its efforts to cut costs and increase efficiency through so-called "health rationing," deciding objectively the recipients of health care. With an increase in concern also comes an increase in demand for representation pertaining to health and the NHS by constituents concerned with the state of their healthcare. However, demand for representation of interest by constituents does not always mean that their Members of Parliament (MPs) will supply it because MPs juggle conflicting interests: those of universal benefit versus particular benefit, those of the political party as well as those of the constituency (Norton and Wood 1993). This paper explores the "two faces," the face of the party as well as that of the constituents, in relation to the topic of health rationing, a topic with political implications, to determine the consequences and possible ramifications caused by these competing interests. This paper proposes constituents' interests are represented by MPs asking questions and that those of greater risk of rationing get questions asked on their behalf. Furthermore, per Norton and Wood (1993), newer MPs are more likely to represent the interests of their constituents in an effort to build electoral support. By examining questions put to the Secretary of State for Health from 1998-2005, the attention to the issue by MPs can be determined because the questions are a public forum in which backbench MPs, those without leadership positions, can easily claim credit for addressing issues of importance. Using the number of health rationing mentions in the questions asked by MPs to the Minister as the dependent variable and juxtaposing a number of factors, including constituency demographics and political factors such as seniority, this paper endeavors to discover the effect of each on Parliamentary attention to health rationing.

Roswell Voices: Oral History and Linguistics in Roswell, Georgia

Joshua A. Dunn, CURO Summer Fellow
Dr. William Kretzschmar, Department of Linguistics, University of Georgia

The Roswell Voices project emerged as a joint project of oral history and linguistics between the Folk and Heritage Bureau of Roswell, Georgia, and faculty and students of the University of Georgia. The stage of research presented here is a continuation of this program and focuses solely on the language of the youth of Roswell, those within the 18 to 35 year old demographic bracket. I examined the question of how the language of a speaker contributes to his cultural identity in relation to Roswell, a localized question but one whose methods and results can be applied to study a broader scale. I implemented a three part interview, a method inherited from the existing study. Part one entailed a one hour conversation-style interview; part two consisted of the speaker reading certain words from index cards; and the third part involved the interviewer asking questions aimed at a certain lexical response. I conducted, transcribed, and analyzed four interviews by counting features generally associated with Roswell's geographic location. After performing feature counts on data collected previously on two older age brackets, results suggest that the data collected not only characterize generation specific speech, but also define the youth of Roswell as being definite "southern" speakers, as can be determined from the prevalence of accepted "general southern" speech characteristics, despite the lack of further regional specificity. My plans for future study include tracing the history of certain recorded pronunciations and lexical responses, both in previous data and that collected for this project.

Antibody Extraction

Sean P. Durning
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia

The post-translational modification of cytosolic proteins at serine and theronine residues with the sugar N-acetyl glucosamine (GlcNAc) has been demonstrated to play a major role in regulatory processes. For example, elevated levels of O-GlcNAc have been directly correlated in humans and mice with insulin resistance, the hallmark of Type II diabetes, while in the model system *C. elegans* it has been tied to an extended lifespan. This dynamic process referred to as "O-

GlcNAcylation" occurs via the addition and removal of GlcNAc molecules on target proteins by the enzymes O-GlcNAc transferase (OGT) and O-GlcNAcase (OGA), respectively. Successful antibody recognition of OGA and OGT is a powerful tool for understanding the mechanism of O-GlcNAc structural alteration within a cell. My work has focused on purifying and characterizing antibodies that recognize either OGA or OGT. These IgY antibodies are generated in chicken egg yolks against synthetic peptides whose sequence was derived from the primary structure of either OGA or OGT. This approach was used in order to minimize the possibility of non-specific recognition to other proteins and potentially allows us to generate very large amounts of the antibodies, which can be used in a wide variety of tissues and cells from various species. Antibody extraction is performed through IgY Eggpress Purification Kit protocol, in which separate reagents are used for delipidization and protein precipitation. Following successful enrichment of antibody 352, Western Blot analysis confirms specific recognition towards over-expressed OGA lysate. Endogenous recognition of extracted 352 has not yet been confirmed, potentially requiring additional antibody purification. Antibody 470 that is proven to successfully recognize OGT remains in preliminary extraction and Western Blot efficiency stages. Once extraction and enhancement for OGA and OGT is complete, antibodies 352 and 470 will be used for further scientific research involving O-GlcNAc post-translational modifications that play major roles in intracellular behavior.

Cataloging Biodiversity: Filling in the Gaps for Coastal Ecuadorian Herpetofauna

Andrew M. Durso
Dr. Paul Hamilton, Department of Biological Sciences, University of Georgia
Jonathan M. Pahlas, Department of Biological Sciences, University of Georgia

The coastal forests of Ecuador are some of the most diverse ecosystems on Earth. Identified as a Global Biodiversity Hotspot by Conservation International in 1999, the Chocó region has suffered reductions in area of over 90% since aboriginal times. Concern for reptiles and amphibians which depend on these habitats has prompted efforts to collect data on their biodiversity, life history and interactions with other species and the environment. We provide data on community composition of herpetofauna in these imperiled habitats, and examine phenotypic variation in reptiles and amphibians for future studies of systematics and taxonomy, contributing to a five year data set. By building species accumulation curves for each site, we provide a measure of survey quality and to illustrate the potential difficulty of sampling rare and cryptic species in diverse tropical forest ecosystems. Such surveys are critical for conservation of biodiversity.

A Domitianic Predecessor to the Arch of Constantine?

Jason E. Dyer
Prof. James Anderson, Jr., Department of Classics, University of Georgia

Originally believed to be a product of Late Antiquity, the Arch of Constantine in Rome poses a unique set of problems regarding Roman topography. Though A. L. Frothingham's controversial theories regarding a predecessor to the Arch of Constantine were initially rejected, recent evidence suggests that while re-appropriated and dedicated by Constantine, the arch bearing his name may have had a predecessor centuries earlier. This predecessor was likely Domitianic, and corresponds with this emperor's grandiose building program and Roman topography during the Flavian dynasty. Isotopic analysis, the measurement of carbon and oxygen isotopes in marble samples, evidences that much of the Arch of Constantine's exterior decoration was gleaned from early monuments, a common practice during the 4th century C.E., and indicates rapid construction. Such brevity could only be achieved, however, if a structure were already present. Furthermore, the Haterii relief, which is noted as providing an accurate depiction of Roman topography, features an earlier triumphal arch where the Arch of Constantine now stands.

When considered with field of view analyses and Roman topography, the numismatic evidence, once used to counter the theory of such a predecessor, has proven to be flawed. Indeed, the presence of such an arch under Domitian in this location would correspond with the Triumphal Route and larger Flavian building program. Taken as a whole, evidence indicates that the possibility of a Domitianic predecessor to the Arch of Constantine requires further consideration.

Sex-Related Differences in Pain Experience in Marathon Runners

Jessica E. Dyke
Dr. Patrick O'Connor, Department of Kinesiology and Department of Exercise Psychology, University of Georgia

The purpose of this study was to compare women and men on their pain experiences caused by a marathon run. Over 1000 marathon runners completed an online survey. The data base was examined for pairs of men and women who could be matched on four pain-related variables: the average number of days per week the participant trained for the marathon, the marathon course run (e.g., Boston marathon course), the relative intensity at which the marathon was run as indexed by the overall rating of perceived exertion and the highest intensity of pain ever experienced. Marathon related pain reports from 31 men and 31 women were compared using t-tests. Women reporting experiencing pain significantly earlier during the marathon (mean pain threshold was at 14.3 miles for women and 17.9 miles for the men, $p < .01$). Women reported experiencing significantly higher intensity pain 1 to 3 days after the marathon using a 0 to 10 pain intensity scale (female mean: 6.1; male mean: 5.1, $p < .05$). These findings are generally consistent with prior research on sex-related differences in laboratory pain showing that compared to men women report on average a lower pain threshold and a higher pain intensity in response to the same noxious stimulus. This study is among the first to analyze sex-related differences in pain experienced during the extreme conditions that are self-imposed during a marathon. Sex-related differences in pain during and after a marathon have potential relevance for optimizing the training, performance and treatment of marathon runners.

Rethinking the U.S.'s Relationship with the Global Poor: A Restructuring of USAID's Microfinance Efforts in Africa

Ellyn A. Echols & Jeremy Akin, Roosevelt @ UGA
Dr. Glenn Ames, Department of International Public Service and Outreach, University of Georgia

As Africa's strategic importance on the global stage increases and other major powers such as China take notice, it is time for the United States to consider the future of its own economic role in the continent. We examine USAID's current partnership with Africa in its support of microfinance institutions that are locally operated and intended to reach the very poor. Microfinance techniques can be powerful catalysts of development in third-world countries because they economically equip households by giving small, low-interest loans to entrepreneurs in order to establish and maintain small businesses—strengthening the very base of a stable economic system. We assert that it is in the best interest of the United States to reevaluate and enhance its anti-poverty measures via a more effective implementation of microfinance in a continent that has traditionally been overlooked. By renewing its emphasis on partnerships with existing organizations, restructuring its loan system, and by significantly improving representation of Africa in its microfinance efforts, USAID will more effectively move toward its goal of poverty eradication. These reforms will also foster a better environment for global trade, a more stable continent, and the potential for greater democratic cooperation among U.S. and African governments.

Increasing Trade Security: United States-Venezuelan Trade Incentives

Nathaniel T. Edwards, Roosevelt @ UGA
Dr. Christopher Allen, Department of International Affairs, University of Georgia

Trade with Venezuela has risen to the top 15 nations with which the United States conducts trade; it has also become the fourth largest provider of American crude oil and petroleum products, topping over a million barrels every day. While trade with Venezuela has steadily increased, diplomatic relations have steadily declined due to open antagonism and criticism by both sides. In juxtaposition, there is a significant national security threat as Venezuela becomes a prime locale by which to load a weapon on a boat intended for American ports and Venezuela offers little domestic protection of exports to America. This risk is becoming even greater as Chavez continues to increase relations with American adversaries and openly critiques American capitalism. As trade relations increase, each state can demand a greater level of security be met and maintained in order for trade to continue. Therefore, this paper proposes the creation of a system of economic incentives in exchange for meeting and maintaining security standards at ports. Because there is a risk of Venezuelan hesitance to participate, the policy aims to appeal exclusively to the economic sector of Venezuela and avoid political confrontation. Furthermore, it aims to avoid Chavez' criticism of capitalism by establishing a controlled economic system between the United States and Venezuela. This policy will be rationalized by comparing similar case studies as well as noting inherent benefits of trade systems.

Environmental Factors Affecting the Persistence of Avian Influenza Virus in Water

Christina L. Faust
Dr. David Stallknecht, Department of Wildlife Disease Study, University of Georgia

Transmission of avian influenza virus (AIV) is dependent on an indirect fecal-oral route involving fecal-contaminated water; however, little is known about the persistence of AIV in aquatic environments. Although studies have shown that temperature, pH and salinity affect the infectivity of AIV in water, biological factors have not been considered. The objective of this study is to examine the influence of filter feeding bivalves on the persistence of AIV in water. Freshwater clams, *Corbicula fluminea*, were used as model organisms and placed into individual tissue culture flasks (n=42) filled with distilled water that was inoculated (1:100) with low pathogenic AIV. Water samples were taken a minimum of three times during 48 hours, and after each trial the clams were processed for in situ hybridization. The virus titer (amount of virus) of the water samples was quantified using microtiter endpoint titration. Over the 48 hours, the virus titer decreased (compared to control flasks) or was undetectable in water samples from flasks with filter feeders. The preliminary results of this study suggest that filter feeders, reduce the persistence, and thus infectivity, of AIV. In situ hybridization will be used to determine the location and status of AIV within clam tissue after filtration from the water column. Studying impacts of environmental factors, such as filter feeders, on the epidemiology of AIV will help develop an understanding of the maintenance of AIV within wild aquatic bird populations and aid in the management of AIV.

The Impact of Family Relations, Health Perceptions, and Parental Functioning on Adherence and Medical Outcomes in Adolescent Transplant Recipients

Nicole M. Fenton & Emily Osborn
Dr. Ronald Blount, Department of Psychology, University of Georgia

While organ transplantation was once a last resort for terminally ill children, it has become the treatment of choice for individuals with a number of illnesses. Although the survival rate is high for transplant patients, their long term prognosis deteriorates due to patients not taking their medication in accordance with doctor's instructions (medication nonadherence). High

rates of nonadherence have been reported in pediatric populations, particularly during adolescence (Shaw et al., 2003). Not taking the prescribed immunosuppressant medications may result in a patient's body rejecting the transplanted organ. This study seeks to examine how psychosocial factors such as family relations, health perceptions and parental functioning relate to medication nonadherence and therefore medical outcomes. The present study was an 18-month longitudinal investigation of adolescent transplant recipients and their families. Participants in the initial cohort were 68 adolescents who had received a kidney, liver, or heart transplant and their parents. Each of these participants were re-contacted and measures of physical and psychosocial functioning, as well as medical records, were obtained. Based on the literature and findings from our initial cross-sectional evaluation, it is expected that high levels of family cohesion, low levels of family conflict and healthy parental emotional functioning will positively influence medication adherence and therefore medical outcomes 18 months later. The relationship between parent functioning and adolescent health outcomes is expected to be partially mediated by adherence. This study will identify risk and protective factors for health outcomes in adolescent transplant recipients, and help guide the development of interventions to improve health in this vulnerable population.

Cloning, *E. coli* Expression, and HPLC Enzymatic Assay Analysis of Putative Domains of Arabinose Kinase

Kathryn S. Flake, CURO Summer Fellow
Dr. Maor Bar-Peled, Complex Carbohydrate Research Center, University of Georgia

Nucleotide sugars are produced by three pathways: the sucrose, interconversion, and salvage pathways. The salvage pathway recycles monosaccharides released from either seed storage polysaccharides, wall reconstruction, glycoproteins, or glycolipids and converts them back into activated nucleotide sugars by means of over 20 differing sugar-1-phosphate intermediates. Identifying and characterizing all salvage pathway enzymes are therefore critical steps in determining the contribution this pathway makes towards the nucleotide sugar reservoir. Arabinose kinase is an enzyme in the salvage pathway responsible for phosphorylating arabinose to arabinose-1-phosphate. There are discrepancies regarding the biochemical properties of the kinase, its subcellular localization, and its biological function, which must be resolved. The gene encoding arabinose kinase (*arak*) consists of two domains: a galactokinase-like domain, speculated to have kinase function, and a large N-terminus domain whose function is unknown. Therefore, using RT-PCR, we constructed and cloned several gene constructs expressing either the N- or C-terminal domains in addition to two versions of the protein (full-length or truncated Δ50) linked at their C-terminus to an EGFP reporter protein. The expression of the galactokinase-like domain and the truncated version of the N-terminus (Δ50) in *E. coli* were verified by SDS PAGE. Current study is aimed at defining the enzymatic properties of the various constructs using HPLC enzymatic assays. Additionally, biochemical analysis and determination of the subcellular localization will help in elucidating the activity of arabinose kinase.

Voltage-Dependent Anion Conductance (VDAC) Porin: A Possible Channel for Cytochrome c Release in Apoptosis

Ashley L. Foster, CURO Scholar
Dr. James Franklin, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Apoptosis, a type of programmed cell death, has been identified as a key component in several biological processes, including embryological development and neurological disease. Apoptosis is necessary for maintaining tissue homeostasis by regulating the balance between cell growth and death. While unchecked apoptosis leads to degeneration, the inhibition of apoptosis leads to cancer. Determining the molecular mechanism of apoptosis will aid in understanding cellular processes and in future treatments of disease. The mammalian intrinsic

apoptotic pathway involves the release of apoptogenic factors, such as cytochrome *c*, from the mitochondrion into the cytoplasm through an unknown porin. This release activates a cascade of caspase proteases, DNA fragmentation, and ultimately cell death. A proposed mitochondrial channel for cytochrome *c* release is the Voltage-Dependent Anion Conductance (VDAC) porin that spans the outer mitochondrial membrane. Preventing the release of cytochrome *c* halts the apoptotic process. Thus, inhibition of the VDAC porin could potentially prevent cytochrome *c* release into the cytoplasm and the activation of the apoptotic cascade. The present study primarily used the non-specific inhibitor, DIDS (4, 4'-diisothiocyanatostilbene-2, 2'-disulfonic acid disodium salt hydrate), to block the VDAC porin. By fluorescence microscopy, fluorescence spectroscopy, survival experimentation, and immunocytochemistry, the activity of the VDAC porin in the apoptotic cascade was analyzed. My research, found that the VDAC porin is not the channel through which cytochrome *c* is released.

La Voz de los Sin Voz: The Use of Radio by the Zapatista Movement in Mexico

Erika D. Frank
Dr. Pamela Voekel, Department of History, University of Georgia

This paper will explore the use of media by the Zapatista movement, focusing particularly on radio and internet radio. It will seek to explain exactly why these mediums were so effective and what impact they had on the movement from its beginnings in 1994 to the present. The Zapatista Army of National Liberation is a revolutionary indigenous group in Chiapas, Mexico. Their uprising in 1994 has been called the first "post-modern revolution" and has set itself apart from rebellions of the past. Since the uprising, the world has been watching the region and rebel leaders for clues as to what pattern revolution will take in our globalized society. The Zapatistas set themselves apart from other indigenous uprisings through their use of local and foreign media, particularly radio, to gain international visibility and to inform and organize their supporters efficiently. Radio is a uniquely suited medium for this type of rebellion because it is accessible to their largely illiterate target audience, is inexpensive, and is elusive to government control. The paper will explore their media strategy through analysis of the audio archives of Radio Insurgente, the dominant station in Chiapas, and Radio Zapatista, a weekly Pacifica program recorded in Berkley, CA as well as interviews with station personnel and secondary sources. This analysis demonstrates the importance of radio to the strength and success of the Zapatista movement.

Vesicular Stomatitis in Cattle

Ryan M. Friday
Dr. Corrie Brown, Department of Pathology, University of Georgia

Vesicular stomatitis virus (VSV) causes blistering in many large animals with lesions at specific sites. Outbreaks of VSV result in severe restrictions on movement and production. As such, the virus mostly poses a threat to the food animal industry. VSV is believed to spread via contact as well as through the bite of infected insects. It is believed that the black fly's salivary gland extract (SGE) facilitates viral uptake and replication. Preliminary evidence for this theory lies in the difference in the number of virus particles lesion formation requires when cattle are artificially infected versus the amount required when the black fly is involved. When researchers set out to create a lesion, doing so requires the application of approximately 10,000 times as much virus as the fly carries. The objective of this study is to determine whether it is the presence of SGE or some other factor that allows the virus carried by the flies to be so much more effective. Reaching conclusions about the natural spread of VSV is important to veterinarians and farmers who must contend with it, as evidenced by the fact that this study is funded in part by the USDA. To test the possible magnifying effects of SGE, seven cows were infected along the coronary band with differing concentrations of VSV and SGE. Tissues were collected at varying intervals postinfection. Immunohistochemistry, a technique to detect the amount of virus within fixed tissue, was used to

assess the amount of replicating virus within the inoculated tissue.

Potential Novel O-N-acetylglucosamine Transferase (OGT) Downregulation Technique for *D. rerio*

Steven A. Gay, CURO Apprentice
Dr. Scott Dougan, Department of Cellular Biology, University of Georgia

The role of post-translational modifications such as phosphorylation in regulating developmental pathways has been studied extensively. However, little is known about the role of the post-translational modification O-N-acteylglucosamine (O-GlcNAc). Although studied extensively in plants and mammalian cell culture, the role of O-GlcNAc in animal development is not fully understood. Unlike other post-translational modifications occurring in the Golgi and the Endoplasmic Reticulum (ER), O-GlcNAc modification of nuclear and cytoplasmic proteins allows for its potential involvement in multiple developmental pathways. The addition of O-GlcNAc to a wide variety of nuclear and cytoplasmic proteins occurs by the enzyme O-N-acetylglucosamine transferase (OGT). In zebrafish, OGT is expressed ubiquitously in the first 24 hours post-fertilization before restricting to the head. Structurally, the OGT protein contains a C-terminus catalytic domain connected by a flexible connector to an N-terminus protein-binding domain. Tetratricopeptide repeats (TPRs) exist within the N-terminus domain of OGT, which in rats allows OGT to act catalytically as a homodimer. Due to the very high degree of OGT sequence conservation between species, we utilized the N-terminus TPR domain to design a dominant negative construct, zNOGT, to examine the role of OGT during zebrafish embryogenesis. When zNOGT mRNA was injected into embryos before the eight-cell stage, the embryos' development were delayed and displayed a wide variety of defects including severe growth retardation of the tail and head that we are currently characterizing. In the future, zNOGT will be a tool to assess OGT function in later stages of zebrafish development such as development of the head.

Association Between Infant Feeding and Overweight/Obesity in Ghana, West Africa

Elizabeth K. George
Dr. Alex Anderson, Department of Food & Nutrition, University of Georgia

Obesity has rapidly become a leading public health issue around the world, including developing countries. A number of studies have shown an association between the type of infant feeding and overweight/obesity among mothers and their children, especially in the developed countries with limited data from developing countries. This data was generated from a needs assessment study conducted by UGA students participating in a service-learning program in Ghana, West Africa during the summer of 2007. The purpose of the study was to assess breast feeding and infant/child nutrition practices in relation to overweight/obesity. Mothers with a child five years or younger participated in the study. The mean age of the mothers was 27.39 years with an average of 9.56 years of formal education. Majority of the mothers exclusively breast fed the index child for six months or less. Mothers with more years (> 10 years) of formal education exclusively formula fed their children. Further analysis of the data showed a relationship between the type of infant feeding and maternal BMI with those who exclusively formula fed having a higher BMI. There was an inverse relationship between years of maternal education and both maternal and child BMIs. The data also shows that children who exclusively breastfed had a lower BMI. In conclusion, our results show that mothers who practice exclusive breastfeeding have a lower postpartum BMI compared to their counterparts who practice mix feeding or exclusive formula feeding. A similar trend was found among the children.

Characterizing the 'Small Proteome' in the Hyperthermophilic Archaeon *Pyrococcus furiosus*
James T. Gordy, CURO Summer Fellow, CURO Scholar
Dr. Michael Adams, Department of Biochemistry & Molecular Biology, University of Georgia

The archaeon *Pyrococcus furiosus* (*Pf*) is an anaerobic hyperthermophile originally isolated from a geothermal vent on a seabed near Italy. It grows optimally at 100°C, the normal boiling point, and as a consequence its enzymes have a lot of potential for high temperature applications. Many of them have been characterized, but due to inherent difficulties in extraction and isolation, little data is available from the low molecular weight proteome (under 15 kDa) of this organism. The goal of this project was to create a method that could generate small proteins in high enough yield for further analyses. All steps were performed anaerobically to preserve the integrity of oxygen-sensitive proteins. The cytosolic fraction of *Pf*, prepared by high-speed centrifugation of sonicated cells, was analyzed by gel filtration chromatography. The fractions were analyzed for protein and metal contents, and by native and SDS-denaturing gel electrophoresis. Using a Superdex 75 column, which fractionates in the molecular weight range from 3 - 70 kDa, the small proteins (< 15 kDa) were separated from the larger proteins. Anion-exchange chromatography (Bioscale Q2) was used for further separation. In order to yield sufficient amounts of the so-called small proteome for further analysis, a larger amount of cell paste (>10g) needs to be used as the starting material. The optimized procedure for obtaining the small proteome for further analysis will be presented and discussed.

Sketches in Noir
Brian Graiser
Dr. Leonard V. Ball, Jr., Department of Music Theory & Composition, University of Georgia

Sketches in Noire, written in 2007, is a multi-movement work akin in spirit to the "film noir" genre, representing in sound a dramatic and somewhat bleak story. The names of the seven movements supply the storyline: The Twilight Fog Rolls In; The Heist; The P.I.'s Office (Some Snappy Dialogue); The Woman by the Docks; The Social Club; The Cement Overcoat; and On the Lam/Fin. The CURO Symposium program will feature three of the movements.

Brian Graiser, Vibraphone

The People
Adam Gruszynski
Prof. Ted Saupe, Department of Ceramics, University of Georgia
Prof. Sunkoo Yuh, Department of Ceramics, University of Georgia

Lately I have been exploring different ways to express myself through clay. I build each sculpture quickly to create a gesture. Later I carve, scratch or throw thin slabs of clay on the surface. It is important to have every part of the process make its own visual mark on my work. To enhance the texture I use multiple amounts of stains and apply glazes in specific areas to contrast the rawness of the clay. I work mainly with stoneware and use multiple firing techniques such as salt, raku, electric, and gas.

The People, 2007. Porcelain glazed.
The Tower, 2007. Stoneware and porcelain glazed.
Nancy, 2007. Stoneware and gas reduction.

Hispanic Music in Athens, Georgia
Jana M. Hanchett, CURO Summer Fellow
Dr. David Schiller, Department of Musicology & Ethnomusicology, University of Georgia

The Athens-Clarke County police department estimates that 5% of the Athens population is Hispanic or Latino. This 5% consists of 20,000 individuals who are often marginalized from the Athens community due to language barriers and immigration statuses. I propose that musical experiences shared between Hispanic/Latino musicians and the Athens community will encourage social cohesion. Athens already accepts the sounds of Latin music (for example, Grogus, Cachaça, Moyuba, and salsa nights at downtown venues), but these groups consist primarily of Caucasian musicians and do not represent the voice of Athens' Hispanic/Latino immigrants. Consequently, my research centered on discovering what and where Hispanic musicians are playing in Athens. My initiation into fieldwork began on June 3, 2007, at a fiesta celebrating the Feast of the Trinity at Pinewoods Estates. Here I met IncaTepec, a music group made of two Mexican brothers, Noe and Humberto Mendoza. From them I also learned of Banda Kazador, another music band who practices popular Mexican music behind a community tienda. My fieldwork included interviewing these Mexican musicians, video recording and transcribing examples of these musicians' works, photographing the musicians within their musical environment, and playing their music with them. My objectives were threefold: 1. describe the music of IncaTepec and its function in Athens 2. describe the music of Banda Kazador and its function in Athens 3. compare and contrast IncaTepec with Banda Kazador. As cultural mediators, both groups combine American elements with Mexican music, but their music reveals two very different concepts of bridging cultural boundaries.

Corticosterone and Its Effects on Stress-Induced Weight Loss
Samantha J. Haring
Dr. Ruth Harris, Department of Food & Nutrition, University of Georgia

Rats exposed to repeated restraint (RR) stress, which is placement in a tube for three hours on three consecutive days, show a prolonged reduction in body weight. One hormonal response to stress is an increase in circulating corticosterone, a steroid hormone released from the adrenal glands. To determine if weight loss caused by RR is dependent on corticosterone, we performed a study with rats in which adrenal glands had been removed (adrenalectomized) eliminating their normal production of corticosterone. Adrenalectomized rats were separated into both RR and control groups, and the RR rats were divided into those that received corticosterone versus saline injections. The rats with intact adrenals were separated into two groups, RR and control. Blood samples were collected during stress to ensure that corticosterone injections replicated stress-induced corticosterone release. Adrenalectomized RR and control rats that received corticosterone maintained a reduced body weight after stress. The adrenalectomized RR rats that received saline lost less weight than the other groups of RR rats and regained the weight loss after stress. The adrenalectomized control rats that received saline showed little weight change. These results suggest that corticosterone is effective in resetting body weight without RR and also that RR-induced weight loss requires corticosterone release. We

now suggest that corticosterone, during RR, is important for the rats to achieve and maintain a reduced weight.

The Diplomatic Face of America: Promoting Diversity in the U.S. Foreign Service
Cain Harrelson, Roosevelt @ UGA
Dr. Kaye Sweetser, Department of Advertising & Public Relations, University of Georgia

The United States has long been represented abroad by socio-political elites, uncharacteristic of this country's richly diverse population. While legislation mandates active minority recruitment and retention across federal agencies, these efforts rarely produce substantial results. In fact, only 13 percent of the diplomatic corps comes from a minority background, while 40 percent of the overall American workforce is comprised of racial minorities; such trends are indicative of continually declining minority employment in crucial diplomatic roles. This work confirms prior research on diversifying the U.S. Foreign Service, with particular emphasis on how the lack of minority representation distorts policymaking; how diverse backgrounds and experiences translate into innovative foreign policy; and how racial diversity may positively shape the image of America abroad. In extending previous research, this work evaluates the impact of racial composition in influencing public opinion in volatile regions of the world, particularly since the beginning of U.S. involvement in Afghanistan and Iraq. Making use of Allan Goodman's initial model in addition to formative theory of diversity in public relations, the resulting policy proposal seeks to build a more representative diplomatic corps, incorporate broader ideological diversity, and improve public affairs abroad. Accordingly, the Department of State policy must expand its efforts in the recruitment of qualified racial minorities, and senior leadership must enhance the overall organizational culture by actively supporting underrepresented groups pursuing leadership positions in order to advance foreign policy objectives and public diplomacy strategies.

Newcastle Disease Pathogenesis
Laura M. Harrison, CURO Summer Fellow
Dr. Corrie Brown, Department of Pathology, University of Georgia

Exotic Newcastle Disease Virus (ENDV) is one of the foremost threats to the poultry industry. Virulent viruses can quickly sicken and kill an entire house of chickens. Presence of any virulent viruses within our country will seriously damage our abilities to export chicken meat or live birds. The last outbreak of Newcastle disease in the US happened in California in 2002-2003. That outbreak claimed the lives of 4 million birds, required 8 months to eradicate the virus, and cost over $300 million dollars to the industry. An enhanced understanding of the pathogenesis of the disease, that is, which organs are predominantly infected, and how that damage occurs, would help greatly in devising better vaccines and overall control procedures. With this study, immunohistochemistry for the viral nucleoprotein was performed on tissues of experimentally infected animals with the viral strain from the 2002 ENDV outbreak in Australia. Further analysis of pathogenesis was done through immunohistochemistry for inducible nitric oxide synthase, a key component in inflammation, and active caspase 3, an indicator of apoptosis. Viral nucleoprotein was detected in brain, intestines, cecal tonsils and spleen. Lymphoid tissue in the intestine had greatest nitric oxide synthase and active caspase 3 expression, as compared to negative controls. These preliminary results will be helpful in leading to a better understanding of the host response to the NDV infection.

The Road to Violence: Nonviolent v. Violent Actors in Bangladesh
Clare J. Hatfield, CURO Summer Fellow & Maggie Mills
Dr. Mia Bloom, Department of International Affairs, University of Georgia

This project explores behavioral relationships among state, violent nonstate, and nonviolent nonstate actors in Bangladesh from 1980-2005. The authors ask whether government policies

directed towards violent and nonviolent dissident groups result in different responses by various nonstate actors. To answer the question, they develop several hypotheses. To begin, if the government targets nonviolent social actors with the same repressive policies it employs against violent dissident groups, the otherwise nonviolent actors should respond with increasingly hostile behavior. Second, the theoretical model suggests that the wider population mobilizes into both violent and nonviolent dissident groups. The authors will disaggregate dissident groups into violent and non-violent groups, separating social actors such as labor and student unions from rebel and terrorist groups. Previous studies largely ignore such non-violent group interactions or aggregate such groups' tactics together with rebel and terrorist groups' tactics. Others explore how violent groups' interactions or competition over resources can lead terrorist organizations to ramp up the use of violent tactics (Bloom, 2005). This study is the first to examine whether the same types of state policies directed at violent groups similarly affect or even provoke violent responses from otherwise nonviolent actors. Preliminary findings reveal that government interactions with nonviolent groups oftentimes serve to mobilize the wider population into both violent and nonviolent groups and movements. If the final data supports the authors' hypotheses, the results will imply that the government's use of equally repressive policies across all groups inspires increased violence within the state, and that the government needs to both tailor its policies towards the type of group it wishes to target and accommodate forms of nonviolent protest.

Book of Trees
Soujourner Hodges
Dr. Adrian P. Childs, Department of Music Theory & Composition, University of Georgia

Book of Trees is a five-movement work, each movement bearing the name of a tree: Juniper, Oak, Elm, Cottonwood, and Maple. It is an attempt to capture the natural and folkloric characteristics of specific trees. I will perform Juniper and Maple at the Symposium because of their energy and vibrancy. With Juniper, I tried to represent a dark evergreen, simultaneously mysterious and filled with life. With Maple, I simply tried to convey the slightly chilly, yet brilliantly colorful atmosphere of the maple tree.

Soujourner Hodges, Piano

Solving Rubik's Cube: Artificial Selection in Higher Education
Mary K. Holder, Marcia A. Cole, Bette' S. Ford, Destiny L. Murray
Dr. Farooq Khan, Department of Chemistry, University of West Georgia

Rising education costs have increased demand for a formula for student success, but prior research has taken a retrospective view, examining successful students and looking back for common characteristics. In contrast, the purpose of this study is to find determinants for cognition, the mental process necessary for learning, in order to predict and forecast a student's propensity for future success. Our study asks: in higher education, might genetic, environmental or socioeconomic factors exist that could provide a student with a relative fitness advantage and are any of them intrinsic or unchangeable? Using the Rubik's cube as a test of student success allowed us to quantify cognition as a percent of the cube correctly solved. Random samplings of the 10,000+ University of West Georgia student body were taught a specific solution method by our interdisciplinary research team of science, social science and business majors. Approximately 200 students participated in our study which consisted of completing surveys, undergoing instruction and timed pre- and post-assessments. Ordinary least squares multivariate regression analysis will determine if our variable of interest, cognition, varies with any determinants at a statistically significant level. Previously, a small pilot study indicated that learning style, evaluated via questionnaire, may be the best predictor of student cognition which is supported by other research studies. However, learning style inventories are highly

controversial in the field of educational psychology and settling this debate is outside the scope of this project. What we do hope to provide is additional evidence of the amount of correlation between learning style and student success. Regardless of the findings, the uniqueness of this study is in the measurement tools used, the types of information collected, and the research team involved which lends a different perspective on student cognition and success.

The N-Word and Its Implications on a Predominately White Campus

Erica Holland, CURO Apprentice
Dr. Robert Pratt, Department of History, University of Georgia

Since the arrival of Africans into Jamestown, Virginia in 1619, one word has evolved over time to be used as a derogatory term for African-Americans: nigger. Today the word "nigger" which has been represented as a term of hatred and bigotry, has penetrated the worlds of hip hop and mainstream media, with racial incidents being more prevalent than ever. Even with its disparaging connotation, African Americans today continue to use this word as a term of endearment amongst other African-Americans in the form of "nigga" causing unspoken confusion within the African-American community and the non-African American communities. College students are perceived to be educated people. But are these college students truly educated on the word "nigger"? How do college students, both African-American and non African-American, use this word? Who taught these college students the definition/connotation of what this word really means? Was the formal burial of the word "nigger" truly effective in banishing this ugly term? How do these various racial groups on campus view this offensive word? Are there racial incidents on campus in which African-Americans are being called nigger" and are not reporting it? Through the dissemination of surveys to African-Americans, these questions of what this word means to African-Americans will be answered. The results may show that African-Americans do not want others of different ethnic origins to use this word, yet they still want to use it.

Using Surface Enhanced Raman Spectroscopy for the Detection of Pathogens

Anna E. Hudson, CURO Summer Fellow
Dr. Richard Dluhy, Department of Chemistry, University of Georgia

A rapid and sensitive method for detecting pathogens is greatly needed. Surface Enhanced Raman Spectroscopy (SERS) has emerged as a powerful analytical technique because the scattered Raman signal is characteristic of the composition and structure of the pathogen. In SERS, the incoming laser interacts with metallic nanorods on a substrate to enhance the signal of the molecules adsorbed to the surface by an observed factor of $\sim 10^9$. Previous studies demonstrated the sensitivity and specificity of SERS, but the method has been limited by the reproducibility of highly ordered nanorod arrays and the complexity of the spectra. In response to these limitations, oblique angle vapor deposition (OAD) has been used to fabricate reproducibly sensitive silver substrates and chemometrics has been used to analyze the complex Raman spectra. To demonstrate the use of SERS as a bioanalytical technique, the OAD prepared substrates and chemometrics were used to identify and classify three strains of *Mycoplasma pneumoniae*, which is a major cause of respiratory disease in humans. Using principal component analysis and hierarchical cluster analysis, 95% of samples were correctly identified and classified by strain. This study has shown that OAD is capable of fabricating reproducible SERS substrates with high enhancement factors that can be used as biosensors. It has also shown chemometrics can correctly classify the strains of mycoplasma suspended in water with high accuracy. These results suggest SERS can be used as an inexpensive, rapid, and accurate method for detecting low levels of pathogens in water and possibly in media.

The Ecology of Enteric Bacterial Isolates in San Luis, Costa Rica

Natasha A. James, CURO Apprentice
Dr. Susan Sanchez, Department of Infectious Diseases, University of Georgia

The importance of ecotourism in Costa Rica has led to conservation efforts such as sustainable agriculture that will promote avian diversity. The development of sustainable agriculture in the form of shade grown coffee plantations has presented a unique interface between domestic and wild animals, which is an unknown frontier in disease ecology. However, these shade grown coffee plantations are being inhabited by humans and their domestic animals which include free-roaming chickens. It is known that free roaming chickens have been found to have a high prevalence of common poultry pathogens, however little information exists on the health risk that these plantations pose for free roaming birds. This study was conducted to investigate the antimicrobial resistance profiles of *E. coli* isolates of wild bird and free-roaming chickens living in coffee plantations and wild birds living in forested habitat. We hypothesized that *E. coli* isolated from chickens and birds living in human-impacted areas would have a higher prevalence of antimicrobial resistance due to horizontal transfers of bacterial genetic material from human waste and chickens. Fecal samples were collected and cultured. Bacterial isolates were identified and their resistance to a variety of antibiotics was determined. PCR was utilized to identify the genes that would confer this resistance. The general trend showed that *E. coli* isolated from chickens display a higher prevalence of antimicrobial resistance. Our data however, indicate there is no significant difference between antimicrobial resistance of the wild birds in the coffee plantations and those from the forest, thus disproving our hypothesis.

Residue Brooch

Kathleen Janvier
Prof. Mary Pearse, Department of Jewelry/Metalsmithing, University of Georgia

My present work stems from the intersection between an alternative materials study and an investigation into the tradition of historical reinterpretation. Simultaneous research into the formal qualities of plastics coupled with an interest in the aesthetic and conceptual functions of Edwardian jewelry quickly lead to the combination of both in this contemporary analysis of jewelry as image. The Edwardian period, or la Belle Époque, was known for its commitment to elegance and fashion. As industry began to rise, so too did the extravagance of the upper and middle classes who soon turned to fashion, especially jewelry, for visual suggestions of their opulent lifestyles. Elegance was associated with a delicacy of materials, a monochromatic white on white aesthetic, and an airy weightlessness. White

diamonds in barely perceptible platinum white settings surrounded by intricately laced decorative motifs became the dominant elements of acceptable Edwardian adornment and still remains a popular aesthetic choice for those wishing to call attention to their wealth and social status. The notion that this aesthetic can and does relate the same set of values today that it did one hundred years ago begs an investigation into the function of jewelry as an image of opulence and elegance. By using sterling silver chain as the drawing medium in creating loose ephemeral silhouettes of actual Edwardian artifacts, I attempt to expose the transient qualities of the image, which captures only a single instant in time that cannot be recreated but whose record remains locked in the physical presence of the visually experienced image. The frame surrounding these chain-drawings works to emphasize the function of these pieces as images of jewelry before they are seen as wearable pieces themselves. Lastly, the decision to use a lightweight, white plastic stemmed from a desire to recreate the white on white aesthetic of Edwardian jewelry while at the same time encasing and freezing the chain drawing in its transitive state of being so that the loose thin edges of the plastic relate a freshly torn feeling from some jeweler's sketchbook of a piece yet to be created.

Materials: Plastic, Sterling and Fine Silver

The U.S. Intelligence Community Must Become Centralized

Alexander B. Johnson, Roosevelt @ UGA
Dr. Loch Johnson, Department of International Affairs, University of Georgia

Preventing intelligence failures like the Pearl Harbor and al Qaeda attacks on American soil is the major motivation for bringing cohesion to the United States' intelligence community (IC). As the Soviet Union mounted a new threat against America, President Harry Truman sought to organize and unify the nation's intelligence with the creation of the CIA in the National Security Act of 1947 in order to better protect its citizens. The terrorist attacks of September 11, 2001 illuminated for lawmakers the continuation of the same problems and served as an impetus for IC reorganization in order for America to counter its new threat. Consequently, President Bush signed the Intelligence Reform and Terrorist Prevention Act (IRTPA) into law on December 17, 2004, thus creating the Office of the Director of National Intelligence (ODNI). Unfortunately, this legislation has failed in its purpose to increase efficiency and only added a layer to the already large bureaucracy. The Department of Defense and its supporters in Congress exercised its formidable power and provided the politics responsible for the [less effective] ODNI. Therefore, this policy proposal will address the shortcomings of the IRTPA through proposing IC reorganization legislation that enables cooperation among agencies. Under the amended law, an empowered DNI would have full budget and appointment powers and, therefore, the ability to manage and lead the entire IC. To support the merits of this policy, analysis will be presented from texts written by intelligence and military experts, former intelligence officials, congressional research, and contemporary media outlets.

You Are What You Eat: Mandating Point-of-Purchase Nutrition Information in Georgia Restaurants

Kelsey A. Jones, Roosevelt @ UGA
Dr. Marsha Davis, Department of Health Promotion & Behavior, University of Georgia

The prevalence of obesity in the United States has prompted the U.S. Surgeon General to declare it an epidemic. This alarming trend relates to changing consumption patterns, as Americans increasingly eat restaurant foods that contain more calories, fat, and sodium than at-home alternatives. Georgia—a state with one of the highest levels of obesity-related morbidity—has yet to enact policies to prevent obesity among its citizens. The Georgia Assembly should mandate that restaurants place nutrition information on all menus to improve Georgia consumers' ability to make healthy meal decisions. In addition, the Georgia Division of

Public Health should create a complementary educational initiative; this advocacy program will encourage healthier diets and instruct consumers on how to use this new information effectively. Even health-oriented consumers have difficulty assessing the nutritional value of a restaurant meal, often vastly underestimating its contents. Moreover, this lack of information fails to hold restaurants accountable for the calorie-dense materials they use to prepare foods. Enacting point-of-purchase nutrition labeling legislation would enable individuals to make healthier food choices and compel restaurants to offer meals of greater nutritional value. The motivation for the Georgia legislature lies in the potential annual savings of $2.1 billion spent on the obesity health burden and the favorable public response to similar proposals in other states. Research could examine the relationship between the successful implementation of the policy and weight trends in Georgia. If the policy is found to be effective, the nation could benefit from Georgia's efforts to discourage an obesogenic environment.

Duet of Soprano and Bass Clarinets
Brandon Kaufman
Dr. Roger Vogel, Department of Music Theory & Composition, University of Georgia

Duet for Soprano and Bass Clarinets was written in February 2008 to provide the composer and clarinetist Kim Nogi with a new composition to premiere on their joint recital in April. The mood is cheerful and contrapuntal with the main themes elaborated by both the high and low instruments.

Brandon Kaufman, Soprano Clarinet
Kim Nogi, Bass Clarinet

Hope for the Horn: The Case for the Recognition of Somaliland
Alex Kazer, Roosevelt @ UGA
Dr. Abdulahi Osman, Department of International Affairs, University of Georgia

Since 1991, Somalia has been plagued by famine, civil war, and a complete lack of governance. However, in Somaliland, the autonomous northern region of Somalia, there is peace. Not only has Somaliland avoided the brutal history of tribal warfare that has characterized Somalia, but it has been democratically governed as an independent state since 1991, complete with tribal cooperation and peaceful transfers of power. While Somaliland declared its independence in 1991, it has yet to be recognized by any other state, precluding it from receiving foreign aid and investment and from forging security partnerships with other states. The United States should lead the international community in recognizing Somaliland as an independent state. This paper will demonstrate that recognizing Somaliland will not only yield tangible security improvements and economic benefits to the United States, but it will legitimize Somaliland's style of democracy as a model for the rest of East Africa. The international community continues to place its faith in the Transitional Federal Government, the current Somali administration, in the hopes of maintaining one Somali state, but the TFG has not even been capable of governing Mogadishu. An examination of Somali history will reveal the stark divisions between both states and the impossibility of reconciliation. Several African case studies indicate that Somaliland will not, as many African leaders fear, lead to the Balkanization of Africa and that a strong legal precedence for the division of the Somali state exists.

The Role of Plasminogen Activator Inhibitor-1 (PAI-1) in the Immunopathogenesis of *Plasmodium falciparum*-mediated Placental Malaria
Lauren F. Kelly
Dr. Julie Moore, Department of Infectious Diseases, University of Georgia

Placental malaria (PM) is characterized by accumulation of *Plasmodium falciparum*-infected red blood cells in the human placenta. This leads to maternal anemia and poor fetal outcome including low birth weight and possibly perinatal death. Primigravidae are more

susceptible to the devastating consequences of PM, suggesting the presence of gravity-dependent immunological resistance among malaria-exposed women. PM has been associated with damaging local maternal immune responses, including monocyte infiltration to the maternal placental blood space. An additional common feature of PM is excessive fibrin deposition, an end-product of blood coagulation. The immune factors that are involved in the recruitment and activation of maternal immune cells to the placenta and how this may relate to local hyper-coagulation are poorly understood. It is hypothesized that syntiotrophoblasts, fetal cells facing the maternal blood circulation, secrete these cell mediators as well as pro-coagulants or anti-fibrinolytics, resulting in the influx of maternal immune cells and clotting/fibrin accumulation. To address this hypothesis, placental plasma samples were collected in malaria-endemic western Kenya from parturient women and were stratified according to PM status and gravidity, with other parameters considered, such as the histopathological state of the placenta. The results reveal higher levels of soluble immune factor expression in PM+ primigravidae compared to multigravidae. The levels of plasminogen activator inhibitor (PAI)-1, which is responsible for fibrinolytic inhibition and thus may contribute to the excessive placental fibrin accumulation in PM, are currently under investigation. Furthermore, the relationship of PAI-1 to levels of local soluble immune factors is also of interest.

Eres un Universo de Universos:* Reconnecting With the Human Aspects of Medicine Through Field Experiences on *La Isla de Ometepe

Lauren F. Kelly
Dr. Pamela B. Kleiber, Honors Program, University of Georgia

As an undergraduate premed student preparing for a career in global infectious diseases prevention and management, I lived with and helped administer medical services to Nicaraguan residents on *La Isla de Ometepe* for two weeks in summer 2007. Reconnecting with the most essential and human aspects of medicine, I worked intimately with a Nicaraguan clinical physician as we visited four remote villages. I used qualitative research methods, specifically, heuristics (Moustakas), to interpret my experiences with the *Ometepe* people. Heuristics, a holistic process rooted in identifying with one's surroundings and creating an environment of continual questioning and self-dialogue, deepens self-awareness and illuminates one's connection with the world. My bilingual and visual journal documents my experience on the island, questions my prior assumptions, and details questions I developed in the field. During the four months after I returned, I iteratively reread and analyzed my journal and crafted *Eres un Universo de Universos*, a compilation of developed ideas and specific awakenings that transpired from the resonating themes of my documentation in Nicaragua. The process allowed me to identify particular moments marking personal transformations: the ferry boat ride when I left the world I knew; my severe illness when the people whom I intended to care for took care of me; and the post-trip reflection when I realized the unrivaled values of the experience. In my findings, I describe through my newly developed heuristics lens the persons, places and events as I experienced them during this intensive field experience on *La Isla de Ometepe*.

Usage of Linear Subspaces with Varieties

Tyler L. Kelly
Dr. Elham Izadi, Department of Mathematics, University of Georgia

Algebraic geometry can be defined as the study of solutions of systems of polynomials in an affine or projective space. This discipline has many applications in fields such as Physics, Robotics, and Coding theory. The n-dimensional complex projective space, $\mathbb{P}^n$, can be defined as the set of lines in $\mathbb{C}^{n+1}$, or $n+1$-dimensional complex space. A hypersurface X in $\mathbb{P}^n$ is an irreducible homogeneous polynomial f of degree d, i.e. a polynomial of $n+1$ projective coordinates where each monomial of f has

degree d. Our goal is to classify these hypersurfaces and describe what they look like and what properties they have. To do this, we define the Fano variety associated to X, $F_k(X)$, as the set of k-dimensional linear spaces contained in X. For example, if $k = 1$, we will be looking at projective lines in X. This Fano variety is a subspace of the Grassmannian $\mathbb{G}(k, n)$, the set of k-dimensional planes in $\mathbb{P}^n$. Through a geometric argument, we can cover the Grassmannian with open sets of itself that are equivalent to the complex space $\mathbb{C}^{(k+1)(n-k)}$. This means that the Grassmannian is smooth; hence its tangent bundle of the Grassmannian as well as the Fano variety is well-defined. Analogously, this implies that it also has a well-defined normal bundle and many other properties mathematically make sense in the context of the Fano variety. This lets us classify the original hypersurface X according to these properties. We will investigate these properties and focus on the case of lines in cubics and quartics (degrees three and four, respectively).

Evaluation of Potential Inhalation Hazards of Petroleum-, Synthetic- and Bio-Fuels Using GC/MS Analysis of Vapors under Equilibrium Conditions

Christine M. Kendrick
Dr. Jeffrey Fisher, Department of Environmental & Health Sciences, University of Georgia

The increasing attention and evolving policies concerning future energy supplies necessitates understanding the composition of alternative fuels. Fuels are complex chemical mixtures and with the possibility of switching to unconventional fuels the effects vapors may have on humans need to be known. A comparison of headspace vapor components, the vapor trapped above the liquid fuel in a sealed vial, of five fuel types was carried out using gas chromatography and mass spectrometry. Samples of Jet Propulsion Fuel (JP-8), a Fischer-Tropsch (FT) Synthetic Fuel (S-8), a 50/50 mixture of JP-8 and S-8, a commercial biodiesel, and a conventional diesel fuel were compared. Synthetic or FT fuel is produced in a catalytic reaction in which hydrocarbons are synthesized from hydrogen and carbon monoxide. This process allows petroleum products, synthetic oil and fuel, to be produced from carbon sources other than oil. A preliminary inhalation study of aerosolized JP-8 and S-8 revealed important differences in the hydrocarbon composition of the droplets and vapor phases in the chamber atmospheres. Aromatic hydrocarbons found in JP-8 were replaced with methyl branched isoparaffins and lighter hydrocarbons (C8 - C10) in FT fuel. Headspace vapor results showed a bio-fuel blend of biodiesel and a bio-oil derived from wood chips contained toluene and benzene and some components specific to wood such as Alpha pinene, 2-beta pinene, Limonene, beta-Terpinene, Camphene, 2-methyl furan, and 2,5-dimethyl furan. Such components derived from oils and polymers of plant species may lead to unique exposures compared to petroleum based diesel fuels. These differences in composition mean humans would be exposed to different molecules from each fuel resulting in distinctive health effects. Understanding the composition of each fuel leads to understanding the subsequent exposures which allows appropriate treatment of human health effects and helps create safe occupational exposure levels. Headspace samples of the five fuel types are currently under analysis using Total Ion Content to make a final comparison. Research focusing on JP-8 and diesel exists, providing extensive data from animals and modeling about their exposures. Comparing the composition of various fuel types in the context of inhalation exposures is a new endeavor however. There is data beginning to be collected on emissions of biodiesel and alternative fuels, but there is minimal data on direct vapor exposure which is what workers and producers would be in contact with. Initial results indicate more research is needed to describe the significant molecules in each fuel, the pathways and metabolism of such molecules in the human body, and ultimately the health effects. To gather that data for the various fuel types, these fuels should undergo standardized toxicological evaluations.

Finding the Best Protocol to Homogenize Carbon Nanotubes

Karen S. Kenner
Dr. Marcus Lay, Department of Chemistry, University of Georgia

Carbon nanotubes (CNTs) have many unique physical and chemical characteristics that have made them the focus of intense research in various areas of materials research. These nano-scaled molecular wires are the strongest known material. Furthermore, they also exhibit enhanced electronic properties, enabling new technologies that require lightweight and transparent electronic materials. CNTs are revolutionizing technology in the scientific community, from making stronger combat material for uniforms, to a potential space elevator that would go into outer space. Therefore, the past decade has seen an exponential increase in publications related to CNTs. Although CNTs exhibit many important qualities that make them versatile enough to serve in many different capacities, they have some significant problems that must be overcome before they are ready for widespread use. One major problem with CNT material is that when it is formed, large bundles of CNTs are formed (similar to a bundle of straws stuck together). These bundles must be separated in order for the CNTs to exhibit their desired semiconductive behavior. Sodium dodecyl sulfate (SDS) is a surfactant (soap) that can be used to suspend individual CNTs in aqueous solution, with the aid of sonication. The purpose of this study was to develop a protocol for homogenizing CNTs in 1.0 % sodium dodecyl sulfate (SDS) and investigate the length of individual CNTs while using various sonication powers (watts). Various solutions were mixed, using a sonicator, in increments of 4 watts ranging from 4-24 watts. UV-vis spectroscopy was then used to verify the effectiveness of dispersion. Next, the solution was centrifuged for 30 minutes at 1800 rpm, to remove any remaining bundles. The UV-vis data was collected again and the solution, containing CNTs, was deposited on silane-coated glass. An image was obtained from the deposits on the glass with the use of Atomic Force Microscopy (AFM). The images were used to determine that the best sonication power to homogenize CNTs would be 6 watts. Excessive Sonication was found to damage the CNTs, while insufficient sonication resulted in bundles remaining. Knowing the best sonication power is important to the overall science community because it will ensure that networks are being made to function at the maximum capacity. By sonicating too long or too little the length will vary.

Mutagenesis Analysis of the Chain Length Determination Domain of the *Toxoplasma gondii* Farnesyl Diphosphate Synthase

Noah A. Koon
Dr. Silvia Moreno, Department of Cellular Biology, University of Georgia

Toxoplasma gondii is a protozoan parasite and a major opportunistic pathogen of immuno-compromised patients and of fetuses from recently infected mothers. Drugs used for chemotherapy of toxoplasmosis are not ideal because of their side effects. Farnesyl diphosphate synthase (FPPS) is a key enzyme in the synthesis of isoprenoids and appears to be a potential drug target for chemotherapy. *T. gondii* FPPS (TgFPPS) is inhibited by bisphosphonates, which are pyrophosphate analogs used clinically for the treatment of bone disorders. These compounds also show inhibition of *T. gondii* growth *in vitro* and *in vivo*. Recent work has shown that TgFPPS is a bifunctional enzyme as it can synthesize both the 15-carbon isoprenoid farnesyl diphosphate (FPP), and the 20-carbon isoprenoid geranylgeranyl diphosphate (GGPP). This is different from other FPPSs, which can only synthesize FPP. Because of this functional difference, bisphosphonates with a long side chain are more active against this enzyme than against other FPPSs. The Moreno-Docampo lab has investigated the mechanism by which TgFPPS is able to act as a bifunctional enzyme by using site-directed mutagenesis of the amino acid residues present in the chain-length determination domain of the enzyme. Ten mutant enzymes were produced, expressed and purified. The kinetic characteristics of these

mutants were analyzed revealing that the fourth amino acid upstream to the first aspartic acid-rich domain (FARM) region is essential for activity. Other mutations changed the products formed. These results will help to develop more efficient anti-toxoplasmosis drugs in the future.

Unbiased Isolation of Alpha-Dystroglycan

Andrew F. Kragor, CURO Summer Fellow, CURO Scholar
Dr. Carl Bergmann, Complex Carbohydrate Research Center, University of Georgia

The majority of proteins on the surface of cells are decorated with carbohydrate sidechains, which have been repeatedly demonstrated to effect protein structure, stability, and activity. A specific class of sugar modifications, the O-linked sugars, have been demonstrated to play a significant role in diabetes, muscular dystrophy, leprosy, and most recently, cancer. α-dystroglycan (α-DG) is critical for many interactions of the cell with its environment. As such, it is an outstanding candidate for affecting cellular movement and adhesion, which are central in the development and spread of cancer. The isolation of α-dystroglycan from mouse muscle tissue was accomplished by a non-biased method, using conventional column chromatography that does not differentiate based on glycan structures. The protocol for mouse muscle α -DG was also applied to mouse brain α-DG isolation. α-DG has been previously isolated at the University of Minnesota, but by methods which were specific to certain glycosylations. The method we formulated is proposed to work generally for all species and organ types within those species, regardless of their glycosylation. The protocol is currently being streamlined to create better yields. Another option started is to create an antibody that selects for the peptide backbone of α-DG, again regardless of its glycosylation, and therefore independent of its functionality and tissue source. This is required prior to mapping and structural determination of all the carbohydrate structures on α-dystroglycan. It also sets up a protocol for isolation of α-dystroglycan from mice that have altered forms of O-mannosylation, which seems to be the key carbohydrate chain for functionality, and therefore disease state.

Functional Analysis of the *Magnaporthe grisea* Secretome

Brian T. Laughlin, CURO Summer Fellow, CURO Scholar
Dr. Sheng-Cheng Wu, Complex Carbohydrate Research Center, University of Georgia

Magnaporthe grisea is the causal fungal agent of rice blast disease responsible for the annual loss of 200 million tons of rice output worldwide. Under various growth conditions, *M. grisea* secretes a large number of extracellular proteins (ECPs) that have been proteomically identified. Among these, MgEcp22 and MgEcp23 are exclusively secreted during infection of the plant host, thus may be pathogenicity factors or signal-molecules involved in interactions between the fungus and its plant host. To better understand their roles, the *MgEcp22* and *MgEcp23* genes were cloned into *M. grisea* expression vectors under strong and constitutive promoters. Three completed expression constructs, each carrying the *MgEcp22* or *MgEcp23* gene, were successfully transformed into *M. grisea*. The $(His)_6$- and Myc-tagged MgEcp22H and MgEcp23H presumably secreted into the culture media were examined by Western-blotting, but the results were inconclusive. Additionally, infection analysis of several MgEcp22H- and MgEcp23H-transformed *M. grisea* strains on rice seedlings showed a consistent and significant reduction in total number of infection lesions comparing to those caused by wild-type *M. grisea*. It is possible that constitutive over-secretion of MgEcp22H or MgEcp23H resulted in a stronger immune response by the plant host. Future work will involve quantitative infection assays and microscopic examination of detached rice leaves. The probable formation of protein complexes between MgEcp22H/MgEcp23H, and plant host protein(s) during infection will also be investigated. Such complexes may then be characterized using current proteomics technology. Ultimately, my work aims to reveal

the function of such ECPs so that novel fungicides may be engineered.

The Impact of Low Income Families on the Development of Literacy

Lauren M. Lesso, Susan Hulteen, Christopher Newberry, Kim Mears, Christina Borne, Alex Carson
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

The development of emergent literacy is essential to the learning foundation of reading. Emergent literacy is reading and writing skills acquired during the preschool years that serve as a gateway to comprehensive reading in continuing grades. Research has shown that lack of emergent literacy skills places children at a higher risk of developing reading disabilities. Social and cultural contexts are highly influential on the attainment of emergent literacy. Teachers and parents are the ones who provide the ideal reading environment in school setting and at home. The present study, part of a larger study examining children's social development, focused on documenting children's preference in various objects through toy selection. Two hundred and eighty-four children, with ages ranging from 3 to 4, were collected in 3 waves of data from the local head start program during the past 4 years. Children were asked to report their favorite object verbally, followed by pointing at a favorite object from a box containing a book and various toys. The results showed that very few children (girls, 5.1%, 16.7%, 0% and boys 8.3%, 3.2% and 0% respectively) selected books as their favorite object at both ages 3 and 4. The significantly low percentage of children interested in books may indicate a drastic need for reading programs to be implemented as early as preschool to aid in the development of emergent literacy. The implications of how to foster needed literacy programs at the head start programs and gender effects will be discussed at the conference.

Tort Cases in Georgia in the Early 2000s: Tort Abuse Not as Prominent as Portrayed

Rebecca I. Lunceford
Prof. David Mustard, Department of Economics, University of Georgia

A tort is the unlawful violation of a private legal right other than a mere breach of contract. Many have feared recently that tort reform is a necessary action to repair the current system of unreasonably high and frequent punitive damages awarded to greedy plaintiffs. These high damages create incentive for more filings of tort cases and possible abuse of the legal system. Research from data collected through the University of Georgia Law School shows that this is not necessarily the case. The data contain tort information from all the cases filed from the years 2004 to 2006 in both Superior and State courts for several counties in Georgia including Bibb, Cobb, Fulton, and Gwinnett. The data collected consists of many elements from the case files including length of time it took to dispose of the case, the type of tort filed, the type of damages requested (punitive or compensatory), how the case was disposed of, and if the case did go to trial, what type of damages, if any, were awarded. The data show that at least in Georgia, the popular belief of unjustifiably high damage awards and a strong upsurge in cases filed is not the reality. The large majority of tort cases filed are simple automobile collisions. The percentage of tort cases that actually go to trial are extremely low, and out of the small amount of cases that do go to trial, a small portion of those are awarded punitive damages. Georgia's current tort system appears to operate well with little need for powerful and immediate reform.

Inhibition of the CaaX Proteases Rce1p and Ste24p with Peptidyl (Acyloxy)Methyl Ketones (AOMK) and Quinolinol Based Molecules

James P. MacNamara, CURO Summer Fellow
Dr. Timothy Dore, Department of Chemistry, University of Georgia

Ras is a GTPase involved in growth pathways and a common proto-oncogene with a CaaX motif, where "C" is cysteine, "a" is an aliphatic amino acid and "X" can be a variety of amino acids. Rce1p participates in a three-step activation of Ras by cleaving the -aaX amino acids from the C-terminus. By inhibiting Rce1p, mutated Ras activation could be halted in cancer cells, preventing any further growth. Two series of molecules are being synthesized with the intention of inhibiting Rce1p and a yeast equivalent Ste24p: peptidyl (acyloxy)methyl ketones (AOMKs) with analogs of five dipeptide backbones and quinolinol based analogs. By synthesizing and assaying these compounds against Rce1p and Ste24p, the inhibitory profile of the molecules can be gained and more information about the active site of Rce1p can be established. Ste24p is a zinc-metalloprotease with a known active site, and therefore molecules with similar inhibitory abilities for both enzymes may reveal Rce1p proteolysis mechanism. By varying the second amino acid and the benzoate, these analogs could inhibit RCE1p and ste24p more effectively. Of the AOMKs, Z-Phe-Arg was the most potent backbone, with the most potent molecule inhibiting 69% activity of Rce1p and 97% of Ste24p. Because the leaving group ability does not correlate with inhibitory abilities, it is more likely that the AOMKs work through non-covalent inhibition. The quinolinol based compound strongly inhibited both Rce1p and Ste24p and analogs are currently being synthesized and tested to improve its inhibitory ability and determine its mechanism.

The Joys of Hunting: Analyzing the Relationship Between the Small Hunt Mosaic of Piazza Armerina in the Architectural Space of the Hiemale Triclinium

Lillie Ann M. Madali
Dr. Asen Kirin, Department of Art History, University of Georgia

The Villa Filosofiana at Piazza Armerina is an early 4th Century Roman estate on the island of Sicily which houses a Small Hunt floor pavement in the hiemale triclinium or winter dining room. This floor pavement highlights the most important moments of a hunting excursion, among them a scene of sacrifice to Diana the goddess of hunting, a banquet scene, a stag hunt and a boar hunt. A reconstruction of the relationship between the Small Hunt floor pavement and the hiemale triclinium promotes a new art historical understanding. A comparative analysis of the iconography associated with hunting in other art works like the Sevso Treasury and the Dunbabin Oaks Hunt floor pavement redefines its ritual significance and its relationship with the architectural space of the hiemale triclinium. The Small Hunt floor pavement exhibits the evolution of the visual culture associated with the civic ritual of dining. What is significant is the progression and transformation of triclinium iconography from the Second Century to the Fourth Century as it becomes more abstracted. Here we see the creation of the notion of the triclinium arrangement since it has become integrated so deeply within the visual culture related to dining. By highlighting similarities with past mosaics and relating it to the philosophical ideals contemporary to the Villa, there surfaces an understanding of the triclinium arrangement's significance as it promotes the structure's purpose as a true Villa Filosofiana conducive to the intellectual pursuits of the wealthy.

Female Choice and Male Mating Success in *Drosophila* Sexual Selection

Margaret C. Madean & Sohyun Kwon
Dr. Wyatt Anderson, Department of Genetics, University of Georgia

Sexual selection is widely observed in nature. Females choose their mates based on courtship displays and sensory signals. In *Drosophila melanogaster* sensory information is exchanged during courtship. We hypothesized that (1) there is variation in male mating success; (2) males with a higher mating frequency will mate more quickly; and (3) pheromone levels will be greater in males with high mating frequencies. The following experiments were conducted to test these hypotheses. Female choice was observed by placing fourteen *Drosophila melanogaster* virgin males in a glass chamber, adding single virgin females, and then recording female mate choice. Males who mated the most and males who did not mate were collected for further analysis. Each male was placed with a virgin female in a vial. The mating speed of these couples was measured, and the males were individually analyzed for pheromone levels. The data showed high female selectivity, with females mating with certain males multiple times, while choosing not to mate with some males at all; this constitutes non-random mating. Mating frequency and mating speed show a negative correlation, so that males with a short mating speed mated more frequently. We are currently comparing pheromone levels in males with low and high mating frequencies, and we are also comparing *Drosophila melanogaster* with *Drosophila pseudoobscura*. This data will help us to understand the interplay between female mate choice, male mating speed, and pheromone levels—and to reach a fuller understanding of sexual selection in *Drosophila*, which is a key element of evolution.

Eliminating the Road Test in License Renewal Programs

Halina Maladtsova, Roosevelt @ UGA
Dr. Christopher Cornwell, Department of Economics, University of Georgia

While elderly drivers and teenagers are the two demographics most susceptible to automobile crashes, state and federal driving laws have focused primarily on curbing the dangers of teenage driving. Economists expect the number of drivers ages 75 and older to triple to 33 million by 2050, an increase deserving the attention of lawmakers. Efficient license renewal programs will prevent poor drivers from harming themselves and others on the road. Some states have passed laws that affect license renewal procedures and aim to prevent senior citizens from driving if they are no longer physically or mentally capable. A careful analysis of data provided by the Fatality Analysis Reporting System reveals that the road test requirement implemented in Illinois and New Hampshire is an ineffective deterrent to elderly crashes and fatalities. Analyses of the effects of implementing a road test in Illinois and repealing it in Indiana confirm the ineffectiveness of the test as part of the two states' license renewal programs. In order to make sure that no other state implements the ineffective road test and wastes valuable resources, this policy proposes making Department of Transportation funding contingent upon states not implementing the road test as part of their license renewal programs. The paper also calls for increased funding to states that implement vision tests and in-person renewal requirements, both of which have been shown to identify poor drivers. Such laws may be criticized as discriminatory, but their purpose is not to prevent the elderly from driving, but to promote safety.

Dialect Perceptions of Spanish Speakers in Georgia

Sharon A. McCoy, CURO Apprentice
Dr. Chad Howe, Department of Romance Languages, University of Georgia

Since the 2000 census, the Spanish speaking population in Georgia has increased by over 300 percent, creating a unique bilingual environment within the state. In order to investigate this language setting, I am collecting data regarding social factors such as age, amount of time spent in the United States, country of origin, and social networks, that affect the use and perceptions of Spanish held by native Spanish speakers within Georgia. A questionnaire will first be distributed to the Hispanic populations in the cities of Athens and Roswell, Georgia. It asks respondents to rate their views of Spanish by evaluating the Spanish spoken by their elders, peers, and by themselves on scales of "correctness" and "pleasantness." In addition, respondents provide information regarding the use of Spanish in comparison to the use of English by Hispanics and by themselves in specific social situations, such as the home, church, work, or school. The results of the questionnaire will later be statistically analyzed to observe the effects of these social and demographic factors on the perceptions of the Spanish language and the development of Georgia's bilingual climate. I hypothesize that, of these factors, the most influential are the age and community networks of respondents, followed closely by their duration of stay in the U.S. In the future, I wish to continue this investigation among other cities and regions of Georgia to analyze how these perceptions and social variables are affecting not only the speakers, but also the preservation of the languages themselves.

Polyphenolic Antioxidants in Unprocessed Traditional Diets: Wild-Crafted Acorn Flour as a Dietary Staple

Amy M. McGoff & Harold Jackson
Dr. James Hargrove, Department of Food & Nutrition, University of Georgia

Polyphenolic phytochemicals are antioxidants that confer health benefits including reduced risk for cardiovascular disease, metabolic syndrome and certain cancers. The hypothesis was tested that acorn flour, a staple in many unrefined, traditional diets, contains higher polyphenolic levels than most modern foods. Acorns from 15 oak species found in the UGA Campus Arboretum were surveyed for polyphenolic and tannin content to estimate the unknown upper range of human polyphenolic consumption. Acorns from the black oak (*Quercus velutina*) and white oak (*Quercus alba*) were selected for further study. Initial total phenolic content and antioxidant capacity of the white and black oak acorns were measured. Due to high tannin content, acorns are normally leached with water and dried prior to consumption to remove the protein precipitating capacity. Thus, a radial diffusion assay was applied to quantify loss of tannins during leaching. Dried flour made from black and white oak acorns contained 40 mg/g and 15 mg/g of polyphenolic compounds, respectively, a substantial amount compared to a 1-12 mg/g range for whole wheat flour, berries and several nuts. Pomo Indians of California obtain 25-50% of their calories from acorns, thus approximately 200-400 g acorns/d. If the acorns consumed by the Pomo people contain similar amounts of polyphenols as the studied samples, diets in some traditional cultures provide more than 3,000 – 16,000 mg phenolics/d, demonstrating the upper range for human consumption of polyphenols. In comparison, the average present US dietary intake of polyphenolic antioxidants is less than 1/6 the amount consumed by some traditional cultures.

The Case for Minor Access to Emergency Contraceptive

Catherine P. Mencher, Roosevelt @ UGA
Dr. Monica Gaughan, Department of Health Policy & Management, University of Georgia

In 2006, 82% of all teen pregnancies were unplanned, and among all age groups, teens have the largest proportion of pregnancies ending in abortion. Despite such indicting statistics, the FDA still requires minors to have a prescription for Emergency Contraceptive (EC), the only contraceptive effective after unprotected sex. In 2003 the FDA banned minor over-the-counter (OTC) access to EC, and last year teenage birth rates rose for the first time in fifteen years. A section of the FDA ban; however, reserves the right of states to allow minor access to EC. This paper will evaluate the accuracy of FDA reasoning behind limiting minor access and propose the creation of a Georgia law allowing minors OTC access to EC along with a concurrent ad campaign to address the major issues surrounding this law. A case study will be preformed to evaluate minor's access to EC in Athens-Clarke County and generalize the found results to the entire state of Georgia. The policy calls for expanding funding to the Georgia Health and Human Services subcommittee to fund an EC task force. The task force will conduct a comprehensive study establishing both the availability and knowledge of EC to teenagers. Following the study, vigorous public campaigns throughout Georgia will explain to teens how to use and access EC and highlight the general public's misconceptions about EC—specifically that EC causes an abortion and would increase teen sex.

Effects of Social Environment on Women's Participation in Computer Science

David T. Mitchell, CURO Apprentice
Dr. Victoria Plaut, Department of Psychology, University of Georgia

For decades women have fought to become more active members in many areas of employment and higher education. Whereas women have achieved successful integration in fields of study including law and medicine, there still exists a noticeable gender gap in other fields, such as computer science. According to the National Science Foundation, in 2004 women only earned 25% of all computer science BAs, a number that has been consistently decreasing. How do we explain why females at every level of our schooling are less attracted to computer science than their male peers? The goal of our research was to gauge the effects the *environment* plays on women's perception of computer science by exposing them to certain "masculine" characteristics of computer science (e.g. geeky objects such as Star Trek posters, soda, comic books) in a work environment vs. more neutral characteristics (e.g. non-geeky objects such as art posters, water bottles, general interest magazines). Following exposure, men and women were asked multiple-choice and open-ended questions about their interest in computer science and feelings of social fit. The results illustrated, for example, that jobs with more "masculine" characteristics were more frequently associated with computer science and more preferred by men than women. Results also suggest these effects are due largely to women's lack of perceived fit with masculine environments. Importantly, the research conveys the implicit effects of the environment on decision-making, although further studies (some in process) will be needed to better decipher the influence of varying deterrents on women concerning the field of computer science.

Is A Hepatitis E-Like Virus Found In Cats and Does It Cause Hepatitis?

Jessica L. Mobley
Dr. Elizabeth Howerth, Department of Pathology, University of Georgia

Hepatitis E virus (HEV) is an enterically transmitted non-enveloped, positive single stranded RNA virus in the new virus family Hepeviridae. The virus has only been identified in humans, chickens, and pigs. It is endemic in humans in developing countries with sporadic disease occurring in developed countries. Hepatitis seen in endemic cases in humans is similar histologically to an entity of unknown

cause in cats known as chronic lymphocytic cholangitis. Clinical signs in cats with this condition are very similar to those seen in HEV positive humans and swine. The objective of this study is to screen cats for the presence of a HEV and correlate viral presence to histopathologic evidence of cholangiohepatitis. We hypothesize that cats have a HEV that causes cholangiohepatitis. Bile and intestinal contents from cats submitted for necropsy at the College of Veterinary Medicine are being screened for HEV using a nested PCR technique that uses degenerate primers designed to amplify HEV from humans, pigs, and chickens. Any positive results will be correlated with liver histopathology in the same cat to assess the potential of the virus causing hepatitis. To date, there have been no PCR positive samples. Expansion of this project to include serologic detection of infected cats may be beneficial, as serology has been found to be more sensitive in detecting HEV infected humans due to transient viral shedding.

Oxygen Delivery After Ischemia in Active and Inactive Subjects

Michael D. Mogill
Dr. Kevin McCully, Department of Kinesiology, University of Georgia

Recovery of oxygen saturation after ischemia has been used as an index of oxygen delivery in patient populations. The purpose of this study was to test whether active healthy subjects have faster rates of oxygen delivery compared to inactive healthy subjects. Active subjects (21.8 $\pm$ 1.9 yrs, mean $\pm$ SD, n=8), who participate in aerobic exercise three or more times a week, were compared with inactive subjects (20.8 $\pm$ 2.4 yrs, n=5), who participated in aerobic exercise one day a week or less. Oxygen-heme saturation was measured in the medial gastrocnemius using the continuous light dual-wavelength near infrared spectroscopy (NIRS) device. Ischemia was produced by rapidly inflating a cuff (1-2s) to suprastolic pressures (>220mmHg) for four minutes. Subjects were allowed to recover for three minutes following cuff deflation. The time to ½ recovery of oxygen saturation was measured, assuming an exponential recovery. Active subjects had a shorter recovery time (9.8 $\pm$ 1.8 s) following ischemia compared to inactive subjects (13.6 $\pm$ 4.9 s). The difference between groups was statistically significant with P=0.045. The data supported the hypothesis that recovery of oxygen saturation was ~40% faster in active versus inactive young healthy subjects, consistent with known metabolic and vascular adaptations to endurance training. This suggests that the NIRS ischemic recovery test is capable of detecting training induced changes in a healthy population.

Expression of Glycerophospholipids in Rat Brain after Cocaine Withdrawal

Prashant Monian, CURO Summer Fellow
Dr. Brian Cummings, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

The purpose of this study was to investigate the effects of cocaine withdrawal on glycerophospholipids in the hippocampus, frontal lobe and cerebellum of rat brains. Rats were injected intraperitoneal once daily with saline or cocaine (15mg/kg) over 4 days in a conditioned place preference (CPP) protocol prior to a withdrawal period of either confinement (abstinent) or injection of saline (extinguished). After 4 days of abstinence or extinction, a reinstatement CPP test was given in which a 5th cocaine injection was delivered. Tissues were collected 1 week following this final cocaine exposure, lipids isolated using Bligh-Dyer extraction and analyzed by electrospray ionization-mass spectrometry. Phospholipid profiles of the hippocampus and frontal lobe were similar in control rats, while the cerebellum expressed lower levels of 32:0 phosphatidylcholine (PtdCho) and 36:4 PtdCho. However, the cerebellum expressed lower amounts of 34:2, 36:3 and 36:1 PtdCho. The expression of sphingomyelins (a specialized lipid abundant in brains), were higher in the cerebellum than the hippocampus or frontal lobe, especially 24:1 and 26:4 sphingomyelin. Cocaine withdrawal using either the abstinent or

extinguished protocols did not alter sphingomyelin expression. The abstinent protocol resulted in lower levels of 14:0-16:1 and 18:0-20:4 Ptdcho in the hippocampus. In contrast, no changes in phospholipid expression were detected in either the frontal lobe or the cerebellum. Decreased expression of phospholipids in the hippocampus correlated to increased levels of 16:0- lysophospholipids. These data support the hypothesis that the expression of phospholipids in the hippocampus is altered during cocaine withdrawal in a rat model of addiction.

Potential Economic Impact from Zeolite Use in Uganda

Mia Catherine Morgan
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

In a previous study at the University of Georgia, the mineral zeolite was successfully identified through samples collected within geologically favorable areas of Uganda. This discovery is significant because it is the same mineral currently being used in the development of a dairy cooling system for smallholder Ugandan dairy farmers. The mineral was located in the areas surrounding the Manapha River and Mount Elgon and was identified as the type of zeolite, analcime. The cooler technology utilizes this type of zeolite for its unique adsorption capacity, and the analcime located in Uganda showed absorption potential greater than the leading commercial source available. Remarkably, this mineral is also used in several other industries, including many specifically advantageous to developing country economies such as water filtration, animal feed supplements, and fertilizers. The goal of this research project is to determine the exact economic and industrial growth potential through the use of zeolite in Uganda. Eight weeks during the summer of 2007 were spent in Uganda interviewing and collecting data on the current economic standing of specific industries, such as animal feed, water, and dairy. This data examined along with information on current uses of zeolite will be used to show that utilizing the zeolite source in Uganda is economically advantageous for the country.

Creation of a Transposon Library in *Francisella tularensis* Strain LVS

Diana Murro
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

Tularemia is a serious infectious disease of small animals and humans caused by *Francisella tularensis*. *F. tularensis* subspecies *tularensis* is the most virulent subspecies to humans. The Live Vaccine Strain (LVS) is derived from *F. tularensis* subspecies *holarctica*. LVS is avirulent in humans, but can still replicate in macrophages and cause disease in mice. Transposons, or mobile genetic elements, will be utilized to create a transposon mutant library in LVS. A transposon vector that contains genes that code for resistance to the antibiotic hygromycin and expression of green fluorescent protein (GFP) has already been created. This transposon vector will be used to produce a transposome which will be forced into the *F. tularensis* LVS by electroporation. Bacteria from colonies that grow on medium containing hygromycin will be collected. Those that express GFP are likely the result of transposition and will be stored to create a library of mutants. In future research, this mutant library will be screened for those that cannot survive in macrophages. The location of the genes disrupted by insertion of the transposon will be identified. The identity of the genes that impair survival of LVS in macrophages should help to understand the mechanisms by which *F. tularensis* escapes killing by the host and may aid in the creation of a more effective tularemia vaccine.

Investigating the Role of Corticotrophin Releasing Factor 1 Receptors (CRFR1) in Stress-Induced Weight Loss

Neil D. Naik, CURO Summer Fellow
Dr. Ruth Harris, Department of Food & Nutrition, University of Georgia

Most people who lose weight through diet and exercise regain the weight within five years. In contrast, mice exposed to repeated restraint stress (RRS: 2 h in restraint tube on each of 3 consecutive days) lose weight and do not return to the weight of non-stressed controls after restraint ends. Stress increases expression of corticotrophin releasing factor (CRF) which activates the hypothalamic-pituitary-adrenal axis, induces anxiety-type behavior, and inhibits feeding. Mice that did not express CRFR1 (knockout), normal littermates (wildtype), and adrenalectomized wildtype (ADX) mice were used to test the role of CRFR1 in mediating the long-term reduction in body weight of RRS mice. Half of the mice from each group were subjected to RRS. Body weight and food intakes of all of the mice were recorded before, during and for eight days after RRS. The mice were then subjected to two anxiety-type behavior tests: an elevated plus maze and a light-dark chamber. The CRFR1 knockout RRS mice, unlike the wildtype and ADX RRS mice, did not lose a significant amount of weight during stress and exhibited less anxiety-type behavior, compared to their controls. These results suggest that CRFR1 are important in mediating both anxiety-type behavior and a long-term reduction in body weight of stressed mice. It is possible that a continuously elevated state of anxiety contributes to the reduction in body weight. Identifying mechanisms that cause these changes in RRS mice may lead to development of strategies that allow people who lose weight to maintain the weight loss.

The Role of KIT-Ligand in Enrichment and Differentiation of Germ-Like Cells in Human Embryonic Stem Cell Cultures

Muktha S. Natrajan, CURO Apprentice
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Primordial germ cells (PGCs) are important precursor cells that undergo differentiation to become sperm and can potentially be derived from human embryonic stem cells (hESCs). This offers a new tool to understand human germ cell differentiation, signaling pathways and may lead to fertility treatments. Kit-Ligand (KITL) is a signaling factor that is active during embryogenesis which affects germ cell differentiation, proliferation and inhibits apoptosis. KITL is known to encourage spermatogenesis and initiate meiosis. This signaling factor is found in a soluble or membrane-bound form, depending on the RNA splicing around exon 6. The objective of this study was to determine the effect of the presence and absence of the soluble and membrane-bound KITL forms on enrichment and differentiation of germ-like (POU5F1+ DDX4+) cells from hESCs. BGO1 (XY) hESCs were maintained on mitotically inactivated mouse embryonic feeder (MEF) layers in 20% KSR stem cell media, at 37°C and 5% $C0_2$. Cells were manually passaged to maintain pluripotency. Germ-like cells were differentiated on MEFs with soluble and membrane-bound KITL, soluble KITL only, membrane-bound KITL only, and without soluble and membrane-bound KITL for 0, 3 and 10 days without passaging. Cells were fixed and analyzed by immunocytochemistry or flow cytometry. RNA was collected and analyzed by qRT-PCR. We expect that differentiated hESC cultures grown in soluble or membrane-bound forms of KITL to show decreased enrichment and differentiation relative to cultures where KITL in both forms is present. Complete knockout of both forms is expected to result in complete loss of enrichment and differentiation.

The Roles of Non-Homologous End Joining Repair Proteins in Non-B-DNA Structure Induced Genetic Instability

Nithya M. Natrajan
Dr. Karen Vasquez, Department of Carcinogenesis, University of Texas
Dr. Mary Bedell, Department of Genetics, University of Georgia

DNA structure is a critical element of its function. B-DNA is the most common, right-handed helical form of DNA. The sequences that form some non-canonical (non-B) structures have been mapped to translocation breakpoints in Burkitt's lymphoma, implicating these structures in cancer etiology. In previous work, we have shown that certain types of non-B DNA structures are mutagenic in mammalian cells. For example, Z-DNA (left-handed DNA) formed in CG repeats has been shown to induce large-scale deletions and complex rearrangements, which result from DNA double strand breaks (DSBs) induced by this structure in mammalian cells. However, in bacteria, small-scale expansions and deletions are much more common within this repeat. The inconsistency in the mutation spectrum between bacterial and mammalian cells may be a result of how DSBs are repaired. Mammalian cells predominantly use non-homologous end joining (NHEJ) to repair DSBs and bacteria utilize homologous recombination (HR). While HR is an error free type of repair, NHEJ often causes mutations. In this study, we determined the Z-DNA induced mutation frequencies in HR proficient, HR deficient ($RecA^-$), or HR deficient/NHEJ proficient ($RecA^-$ or $RecB^-$ and $Ku^+/LigD^+$) bacterial strains. The $RecA^-$/NHEJ deficient strain and the $RecB^-$/NHEJ proficient strain had a higher mutation frequency than the HR proficient strain. The $RecB^-$/NHEJ proficient strain had ~20% large-scale deletions and 80% small-scale deletions and expansions. This suggests that, while the differences in DSB repair appear to affect the mutation spectrum and frequency, it is not the only reason for the disparities.

Genetic Studies on the Roles of KITL in Regulating Germ Cells in Mice

Natalie A. Nesmith, CURO Summer Fellow
Dr. Mary Bedell, Department of Genetics, University of Georgia

Kit ligand (KITL) and its receptor KIT are required for the development and proliferation of germ cells, melanocytes, and hematopoietic cells in humans, mice and many other vertebrates. Of particular interest in our lab is the role of KITL in the differentiation and development of germ cells. Using various tissues and staining methods, the roles of KITL in primordial germ cells (PGCs) and later germ cell forms were investigated in mice to elucidate more clearly their localization patterns and to determine more fully the roles of cytokines in germ cell development. We have optimized protocols by determining favorable antibodies, their combinations, and concentrations used in the staining of sectioned tissues. Of the antibodies that were markers for PGCs and were tested, eight were found to work properly. These included α-SSEA-1, α-E-cadherin, and five different α-KIT antibodies. These optimizations allowed the collection of results that confirmed published results about KITL expression in various tissues including the gonads, neural tube, skin and the wolffian duct. The results also revealed some novel aspects of KITL localization including KITL within PGCs and its presence during development of sertoli cells of the testis. In conjunction with this project of KITL localization was one that included the sectioning, staining, and compiling of information on the positioning of PGCs in the 43R mutant line. Based on previous studies of PGCs characterized in 43R mutants, there was a suggestion that these mutant embryos exhibit ectopic expression of PGCs. But from the collected results, ectopic PGCs expression was not as pronounced as originally hypothesized. More tests need to be done in order to gather more specimens and information concerning the misdirected cells.

The Effects of Alcohol Abuse on Antisaccade Performance

William T. Oliver
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Previous research on alcohol and its effects on cognitive function have shown marked impairments in ability to inhibit behaviors. Habitual alcohol use is thought to impede executive control and overall cognitive efficiency as measured by simple perceptual tasks. Studies in persons engaged in habitual alcohol use have shown significant impairments in both reaction times and inhibition tasks. This suggests that there will be a positive correlation between alcohol use and antisaccade error rate, and in alcohol use and eye movement reaction times for correct antisaccade trials. Antisaccade tasks, which require rapid eye movements to the mirror image location of a peripheral stimulus, will allow for reaction time and behavioral inhibition to be measured simultaneously. In order to test this hypothesis, undergraduate participants were tested using a standard alcohol assessment interview (CDDR), recording such variables as frequency, duration, and amount of use. Following each interview participants completed antisaccade tasks in which error rates and response times for correct antisaccades were recorded on a trial by trial basis. Score distributions for both the substance abuse screening and antisaccade task performance were made, and the upper and lower portions of the distributions were compared. It is expected that the current study will yield positive correlations between alcohol abuse and poor antisaccade task performance. Significant correlations between the two could lead to a greater understanding of the cognitive impairments associated with alcohol use and provide valuable information for future studies concerned with localizing the regions of the brain impaired by habitual alcohol use.

From Page to Stage

Opera Ensemble
Prof. Frederick Burchinal, Director and Department of Voice, University of Georgia
Prof. Gary DiPasquasio, Pianist/Music Director and Department of Voice, University of Georgia

Performing opera successfully is a complex process. First, the singer must analyze the written music and attempt to understand the composer's intentions. Then the performer's own creative sense must transform the music on the page into a living, breathing, moving structure—recreating each time a new and vibrant performance for the audience to enjoy. For the CURO Symposium, the UGA Opera Ensemble will demonstrate this process by offering the "plain" version, as seen on the score's page, and then transforming it into the live "painting" or "sculpture" that moves the audience. To demonstrate the role of the artist in the development of a fine performance, we will then offer two different interpretations of the same music, underlining the need for each artist to be an active participant in the creative process. We hope that listeners will be inspired to discover the hidden messages that every composer offers in his or her musical "blueprint," and that they will explore their own world of choices and imagination.

The Homeric Lineage of Lautaro in Ercilla's *La Araucana*

Victor M. Orellana, CURO Summer Fellow, CURO Scholar
Dr. Nicolás Lucero, Department of Romance Languages, University of Georgia

Within the highly structured literary periods of the European Renaissance and the Spanish Golden Age, Alonso de Ercilla relied heavily on imitation of classical form to both legitimize and inspire the workings of his poem, *La Araucana*. As a part of the fiercely competitive body of work accompanying the colonial movement through the New World, this aspiring Renaissance epic was expected to adhere to very specific ideals for the church, the Spanish crown, and the highly biased audience across Europe that would be judging it. Therefore, to sell the idea of a serious threat against the Spanish conquistadors, Ercilla used individual heroes to raise the opposition to epic proportions that could feasibly hinder such a superior military force. Furthermore, he employed the virtuous Hector from Homer's *Iliad* in his character of the Mapuche war-chief Lautaro to elevate him to formidable stature, linking the two heroes through epithet, similar trials of love at war, and their ultimate downfalls through hubris. Read within this context, Ercilla's challenges to contemporary archetypes and the prejudices of his audience become increasingly more clarified, especially those regarding the image of the ineptitude and barbarism of the natives of the New World. Additionally, it helps establish a link between *La Araucana* and the secondary epic tradition started by Lucan's *Pharsalia*, offering further explanation both for commonplace criticisms of the poem's structure and for the arguable digression of the poem from its boldly-stated mission of Spanish glorification.

Reducing and Rethinking Recidivism

Terry L. Palmer, Roosevelt @ UGA
Dr. Mark Cooney, Department of Sociology, University of Georgia

Since the landmark cases *Kent v. United States (1966)* and *In Re Gault (1967)*, the juvenile justice system has taken a punitive stance towards sentencing that focuses on adjudicating juveniles with increased jail time. This focus however, neglects the reformation of the juvenile's epistemology. According to a 2006 Georgia Department of Juvenile Justice Report, the results of the current focus have allowed the juvenile recommitment rate to steadily increase over the last eight years to forty percent. If the current, conventional system of adjudication is continued, the US is likely to experience continued growth in both juvenile crime and recidivism. Through an extensive secondary analysis of the literature, this paper illustrates that restorative justice, specifically the victim-offender model, is more effective at preventing recidivism than the current punitive system. This paper proposes that Georgia should adopt sections four through eight of the Australian Crimes Act of 2004, a legislative bill that will standardize the juvenile justice system and involve the community and the victim as active participants in seeking unique adjudication for the crime committed. A restorative justice system will emphasize a unique sentence for each offender that will accurately influence his/her way of thinking so as to affect his/her future actions. Supported by the results of case studies in Australia, Arizona, and New Zealand, this legislation will significantly reduce the recidivism rate for juveniles in Georgia.

Development of a Biocontrol Agent for Chinese Privet, *Ligustrum sinense*

Tulsi Patel
Dr. Scott Gold, Department of Plant Pathology, University of Georgia

Ligustrum sinense, commonly known as Chinese Privet, is an exotic invasive shrub that invades millions of acres of land in the southeastern United States. Although Privet spreads rapidly

and limits the growth of more-important native species, there is no efficient mechanism to control it. Therefore, the purpose of this project is to develop a cost effective biocontrol agent for Privet. This goal may be achieved by creating a fungal pathogen that secretes large amounts of an amino acid that is detrimental to Privet. The first step in finding such a fungal pathogen is to identify a toxic amino acid. Tests in which Privet plantlets were treated with eight different amino acids showed that methionine and lysine were both toxic to Privet. With this information, the next step is to create a mutant fungal pathogen that secretes large amounts of one of these inhibitory amino acids. To do this, strains of fungi have been isolated from 14 cuttings of the Privet plantlets used in this project. 10 of these strains have been identified as *Trichoderma* species by amplifying and sequencing the ITS region of their rDNA. One of these *Trichoderma* strains will now be randomly mutated in the presence of UV rays. A mutant colony that secrets high amounts of methionine or lysine or both will then be isolated using auxotrophs and tested as a potential pathogen. If successful, this project will provide an effective biocontrol agent for Privet and a model that could be used to control other exotic weeds.

Generating Uniform Proliferation of Neuroprogenitor Cells

Tulsi Patel, CURO Summer Fellow
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Human embryonic stem cells are pluripotent cells that have the potential to differentiate into all cell types found in the human body. The Stice Lab has successfully derived neuroprogenitor cells, which can be further differentiated into neurons, from human embryonic stem cell lines. However, under current conditions, differentiated cell cultures are not completely pure. Therefore, the purpose of this study is to elucidate exactly what factors are important for the proliferation and uniform differentiation of neuroprogenitor cells into motor neurons. The media currently used for cell proliferation comprises of neurobasal media supplemented with B27, Leukemia Inhibitory Factor, Fibroblast Growth Factor 2, and L-glutamine. All of these are defined components except B27, which is composed of a defined supplement, N2, that can be bought separately, and other anti-oxidants and factors. In order to maintain uniformity in cell culturing, the significance of the unknown anti-oxidants and factors must be determined. To this effect, experiments in which neuroprogenitor cells were grown in N2 supplemented neural basal media with various concentrations of B27 ranging from 0 to 1XB27 were performed. Preliminary results show that cells die in the absence of B27, indicating that the other components are essential for cell survival. However, a concentration of 0.5X B27 is sufficient for proliferation. More experiments will be performed with combinations of different factors to determine exactly what components of B27 are necessary. By completely defining the culture media, this study will refine and accelerate neural cell culturing, thereby making more cells available for further biomedical research.

The Application and Adaptability of N.A. Rimsky-Korsakov's Orchestration Techniques Across National Styles in Orchestral Program Music

Laura C. Patterson
Dr. David Haas, Department of Musicology & Ethnomusicology, University of Georgia

Nikolai Rimsky-Korsakov’s music has come to represent Russian musical nationalism. His distinctly recognizable sound is achieved through a unique approach to orchestration that differed in many ways from the techniques used by many German and Western European composers of the time. These techniques were versatile enough to allow Rimsky-Korsakov to create not only a “Russian” style in his music, but also other national styles. Rimsky-Korsakov’s role as a composer and hugely influential teacher led to the utilization of his orchestration methods in other composer’s works. Even students who studied with Rimsky-

Korsakov for a very short period of time, such as Ottorino Respighi, were able to absorb his orchestration techniques and apply them to their own music. Because little scholarship exclusively explores Rimsky-Korsakov's orchestration style, this project seeks to show the relationship between Rimsky-Korsakov's *Principles of Orchestration*, his pedagogical orchestration text, and his own works. Specifically, analysis will focus on identifying Rimsky-Korsakov's unique approach to orchestration as outlined in *Principles of Orchestration* in three compositions of varying national styles. Because *Capriccio Espagnol, Scheherazade,* and *Russian Easter Overture* are impressionistic orchestral pieces and not operas, the orchestration is unimpeded by subservience to a specific dramatic plot or libretto. This project will also show that Rimsky-Korsakov's orchestration techniques are recognizable in Ottorino Respighi's *Feste Romane*, the last work in his "Roman Trilogy." In each piece, the distinct national musical traits will be identified followed by an analysis of how the versatility of Rimsky-Korsakov's orchestration methods helped to achieve each different national style.

Behavioral Effects of Navigate® on Paedomorphic Mole Salamanders, *Ambystoma talpoideum*

Amanda C. Perofsky
Dr. John Maerz, Department of Wildlife, University of Georgia

Over $10 million is spent annually in the U.S. to control invasive aquatic plants for game fish management and native species habitat management. One concern about application of herbicides for controlling aquatic plants is their effect on non-target species. 2,4-dichlorophenoxy acetic acid butoxyethylester, commercially available as Navigate®, is the most commonly used aquatic herbicide in the U.S. Few studies have investigated the effects of exposure to Navigate® in benthic species despite evidence that these organisms may experience toxic doses even when the herbicide is applied at recommended application rates. This study examined the effect of exposure to Navigate® on activity levels and foraging in paedomorphic *Ambystoma talpoideum*, a benthic salamander species commonly found in the types of freshwater habitats to which Navigate® is applied. Eight salamanders were randomly placed in each of 16 outdoor mesocosms containing pond water and sediment. Navigate® was applied at the manufacturer's recommended dosage for resistant weeds to eight, stratified, randomly selected mesocosms. One salamander from each mesocosms was removed 1 day prior and 1, 14, and 42 days post-Navigate® application, placed in individual tanks, and allowed to acclimate for 24 hours prior to observation. Twenty minute behavioral observations were conducted for each salamander. At the beginning of each trial, one prey item was dropped in the tank and the number of movement events, total movement time, and successful foraging attempts were recorded. We will report statistics that compare the differences in activity levels and foraging in exposed versus unexposed *A. talpoideum*.

Characterizing RNA-Protein Complexes in *Pyrococcus furiosus*

Neil T. Pfister, CURO Scholar
Dr. Michael Terns, Department of Biochemistry & Molecular Biology, University of Georgia

Ribonucleoprotein (RNP) complexes are ubiquitous macromolecular machines involved in most major aspects of cellular function. Various protein and non-coding ribonucleic acid (ncRNA) components form distinct essential RNP complexes. The hyperthermophilic archaeon *Pyrococcus furiosus* is a model system that has provided important insight on human RNP complexes, including those implicated in diseases such as dyskeratosis congenita. We are interested in characterizing novel RNP complexes in *P. furiosus*, and through a general RNA cloning approach, have identified a new class of ncRNAs in this organism. These ncRNAs are implicated to function with a set of related proteins in viral defense in prokaryotes. In order to investigate these hypothetical RNP complexes, I have subcloned genes coding for the putative protein partners into plasmid vectors

and expressed the proteins in *Escherichia coli*. In ongoing experiments, I will screen for the ability of the proteins to interact with the ncRNAs via gel mobility shift assays. Preliminary experiments have provided evidence for interaction, supporting the hypothesized existence of these ncRNPs and providing information on their organization. The results of this work will expedite our understanding of this important class of ncRNP complexes.

Measuring Proficiency of Palm Nut (*Attalea sp.*) Cracking in Wild Bearded Capuchin Monkeys (*Cebus libidinosus*)

Tomas Pickering, CURO Summer Fellow
Dr. Dorothy Fragaszy, Department of Psychology, University of Georgia

The bearded capuchin monkeys (*Cebus libidinosus*) in Boa Vista, Brazil crack tough palm nuts using hammer stones. Cracking is an energetically costly activity. Working from an optimal foraging perspective the number of strikes is a useful proxy for the energetic costs of cracking; fewer strikes indicate greater proficiency. We analyzed the sources of individual proficiencies in cracking whole and partial nuts. The study involved direct observation of one habituated group of monkeys with twelve individuals that crack nuts. We filmed at close range the individual monkeys as they cracked nuts using a single hammer stone and anvil, and scored actions and outcomes of each cracking episode. We also obtained body weights for individual monkeys as they voluntarily stepped onto a scale. Finally we filmed one human cracking nuts using the same hammer stone and anvil as the monkeys, to provide an independent analysis of nut and anvil properties. Sufficient data were recorded on 11 monkeys for analysis purposes. Individuals required on average 7 to 76 strikes in order to crack a whole nut. Monkeys consistently placed the nuts into pits on the anvil which reduced the probability that the nut would move after it was struck and increased proficiency. Body weight was the single best predictor of proficiency, accounting for 56% of the variance. We conclude that cracking is enormously costly for smaller monkeys. That they persist in this behavior suggests that the nuts provide a high energetic return to warrant a big investment of time and effort.

The Role of Microtubules in the Formation and Degradation of Hirano Bodies

Cleveland A. Piggott, CURO Summer Fellow, CURO Apprentice
Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia
Dr. Ruth Furukawa, Department of Cellular Biology, University of Georgia

Hirano bodies are intracellular, paracrystalline, actin-rich structures that are most commonly found in the autopsied brains of humans suffering from neurodegenerative diseases. Because they have been mostly observed in dead cells, their purpose and structure are not well understood, but their possible link to the prevention, cure, and further understanding of neurodegenerative diseases and aging has made their study worthwhile. Recently, an in vitro model to induce formation of Hirano bodies in living cells was discovered by expressing the carboxy-terminal fragment (CT) of a 34 kDa actin bundling protein mutant (Maselli et, al., 2002, 2003; Davis et, al., 2008). This model allows questions regarding the physiological effects, the formation, and degradation of Hirano bodies to be investigated. To further examine what is necessary for the formation and degradation of Hirano bodies, the role of one of the major cytoskeleton components in a cell, microtubules will be studied. Using a vector with an inducible promoter for the 34 kDa protein mutant, it was investigated what the role of microtubules were in the degradation of Hirano bodies. Dictyostelium amoeba expressing Hirano bodies were treated with nocodazole, a microtubule depolymerizing drug. After ten hours of exposure to nocodazole, it was observed that Hirano body size was abnormally large. The results of these experiments suggest that microtubules play a role in the degradation of Hirano bodies. Further experiments are required to elucidate the

microtubule-dependent degradation process of Hirano bodies.

George Washington and Abraham Lincoln: Relic Veneration and "Saint" Commemoration in Contemporary America

Stefann S. Plishka, CURO Apprentice
Dr. Asen Kirin, Department of Art History, University of Georgia

Relics of Christian saints and other holy figures were objects that came to hold a distinctive place in the repertoire of Christian rituals. Veneration of relics, including ceremonial use and pilgrimage, was integral to Byzantine Christianity and Constantinople's political environment due to the overlapping secular and religious roles of rulers, especially in Medieval and Byzantine Europe. Relic veneration was not a phenomenon unique to Byzantine Christianity, but the strong tradition of relic use and transfer within that region facilitated the evolution of this practice. However, during the Reformation and afterwards, Protestant Christianity eschewed that tradition of relic veneration as one of the excesses of Catholicism. In this paper, I intend to show links between the Catholic practice of relic veneration of saints and the parallel tradition in America of revering and commemorating past United States Presidents, particularly George Washington and Abraham Lincoln, as a component of civil religion, in which religious rhetoric is used to elevate the state. Due to secularization of culture and dominance of Protestantism in America, relic veneration does not hold the same value that it did in Catholic states. However, the same human desire for transcendence continues to drive people to derive a sense of continuity with great figures of the past. Thus, American civil religion has absorbed many ritualistic practices of commemoration which once had been an aspect of the Christianized state. Independent of geography, historical period, politics and religion, the evolution of commemorative practices helps identify motivating factors behind all rituals that provide transcendence.

The Global Arms Bazaar: Lessons from the 2006 Hezbollah-Israel War

Tyler B. Pratt, Roosevelt @ UGA
Dr. Michael Jasinski, Department of International Affairs, University of Georgia

For four weeks during the summer of 2006, the Lebanese non-state group Hezbollah shocked onlookers by employing an unexpected arsenal of technologically advanced weaponry in its conflict with Israel. The July War heralded Hezbollah's ascent to unquestioned military primacy among non-state organizations, and Hezbollah's ability to withstand Israel's powerful retaliation earned the group a striking boost in soft power throughout the Arab world. More importantly for the United States, the month-long conflict introduced a new type of foe into the calculus of the Global War on Terror: a non-state group with all the organizational prowess, public support, and military capability of a state, without the traditional limitations of deterrence or responsibility for civilian populations. While other non-state organizations have successfully exploited asymmetrical means of combating U.S. military might, Hezbollah alone has managed to procure such a diverse array of complicated, highly specialized weapons systems and utilized them to devastating effect. This paper attempts to collect and analyze available open-source information on Hezbollah's weapons procurement efforts, revealing a highly diverse supply chain that reached into every continent. It also offers suggestions for restricting the weapons, technology, and capital that found its way into Hezbollah's extensive armory from well over a dozen countries, as well as ways to improve strategic communications efforts for containing the group's growing soft power.

The Importance of American Development Aid in Nicaragua

Lucas L. Puente, Roosevelt @ UGA
Dr. Santanu Chatterjee, Department of Economics, University of Georgia

This policy paper will focus on the strategic importance of American developmental aid to Nicaragua. In recent years, U.S. aid has decreased alarmingly, despite Nicaragua's importance in maintaining American influence in Latin America. Although the recent election of leftist President Daniel Ortega worried American investors and threatened to undermine American economic clout, Ortega has shown some pro-American tendencies in the early stages of his presidency. However, he has also worked extensively with Venezuela's Hugo Chavez to strengthen political and economic ties between the two countries. With Chavez's anti-American message gaining traction throughout the region, the United States must capitalize on Ortega's pendulum-like politics to protect its Latin American economic and political interests. The United States should increase its annual developmental aid to Nicaragua in order to strengthen long-term Nicaragua-U.S. ties. Additionally, such action would stabilize the country and catalyze economic growth through increased governmental transparency, infrastructure development, and human capital advancement. This proposal will analyze relevant economic data and academic articles as well as assess the current political state of affairs to demonstrate that increased aid will yield political and economic benefits for the United States, Nicaragua, and Latin America as a whole.

Acidocalcisome-like Granules of Chicken Egg Yolk – Polyphosphate Content and Its Relationship to Development

Adam Pyrzak
Dr. Roberto Docampo, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases, University of Georgia
Dr. Paul Ulrich, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases, University of Georgia

Acidocalcisomes are small, acidic organelles that play important roles in a variety of cellular functions as diverse as blood clotting and osmotic balance. They contain large deposits of calcium and polyphosphate, a polymeric form of inorganic phosphate. Chicken egg yolk contains large numbers of granules that are similar to acidocalcisomes in both physiology and composition. However, the relationship between the content of these granules and development is unclear. Demonstration of an acidocalcisomal role in chicken development would help delineate the function of these organelles and further establish the basis for the wide evolutionary conservation of acidocalcisomes. Preliminary experiments demonstrated that these granules react to antibodies raised against a trypanosomatid parasite vacuolar- H^+ pyrophosphatase, an enzyme that is largely responsible for the acidic pH of acidocalcisomes. In a series of immunoprecipitation analyses with chicken yolk granules, we attempted to isolate a vacuolar-H^+ pyrophosphatase. Proteins separated by SDS-PAGE were subjected to tandem mass spectrometry for identification. Additionally, we are determining the composition of the phosphate pool in the granules. Interestingly, most of the phosphate in yolk granules is present as short-chain polyphosphate, an observation also made with trypanosomatid acidocalcisomes. We plan to more accurately quantify the phosphate components of yolk granules and ultimately hope to determine their potential role in chicken development.

Characterization of Human Stem Cells Using Quantitative RT-PCR

Sharanya Raghunath
Dr. Kelley Moremen, Department of Biochemistry & Molecular Biology, University of Georgia

Human embryonic stem cells (hESCs) are pluripotent cells derived from the inner cell mass of blastocysts and have the potential for use in cell-replacement therapies for the treatment of human disease. In order to characterize the differentiation status of several hESC lines with respect to population homogeneity or heterogeneity, several marker genes have been used to determine the extent to which the cells are pluripotent or differentiated into various germ layers. We have assembled a list of 25 genes which comprise markers for pluripotency (Oct4, Nanog, Sox2, Lefty A/B, Tert and c-myc) and markers for several differentiated lineages, including mesoendoderm (Brachyury, Wnt3a and MixL1), definitive endoderm (Sox17, Gata4, Gata6, Foxa2, Cxcr4 and Gooscoid), mesoderm (Tbx5, Tbx20, Islet1, Nkk2.5, FoxF1 and Eomes), neural ectoderm (Sox1, Nestin and Pax6), and extraembryonic endoderm (AFP). Using a previously established quantitative real time Polymerase Chain Reaction (qRT-PCR) approach, we analyzed the transcriptional profiles for the list of marker genes in five different hESC lines (BG01, BG01, BG03, H7 and H9) to determine the level of heterogeneity and differentiation of these cell populations both in the undifferentiated and chemically differentiated states. The results obtained from this study will be used to select a group of reliable marker genes for the characterization of hESC populations prior to more extensive high-throughput transcript analysis investigating changes in glycan-related genes during cell differentiation.

Functionality of Glutamate Receptors in hESC-derived Neural Progenitors vs. Matured Neurons

Anita C. Randolph
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Glutamate is the most predominant excitatory neurotransmitter in the central nervous system, and therefore glutamate receptors play a prominent role in the function and development of the nervous system. Abnormalities in their expression can cause major problems in memory formation and diseases such as epilepsy, ischemic cascade and Alzheimer's diseases. We are assessing functionality of glutamate receptors in a previously established neural progenitor (NP) cell line derived from WA09 human embryonic stem cells. Characterizing this system provides a unique model for studying neural development and function in the human system. NPs have the potential to grow in a monolayer and differentiate to mature neurons that have been shown to express several subtypes of glutamate receptors. Over stimulation of certain glutamate receptors can lead to excitotoxicity. This occurs when receptors are overactivated, allowing high levels of calcium ions to enter, damage the cell, and signal apoptosis. If the receptors are functional, we should see a concentration-dependent increase in cell death due to apoptosis. This can be readily assayed using a high-throughput kit that measures cytotoxicity and viability of the cells. Once this assay is optimized for plating density, cells will be exposed to glutamate at varying concentrations and evaluated for cytotoxicity due to over-stimulation of receptors. The next step is a protection assay that will screen known inhibitors of the receptors and protect them from excitotoxicity. Successfully characterizing functional receptors on these neurons may lead to their use in screening of potential drug treatments for patients with central nervous diseases.

In Vitro Assay to Measure Cell Growth and Invasion

Claire M. Rice
Dr. Bruce LeRoy, Department of Pathology, University of Georgia

Many tests used to measure the effects of new chemotherapy drugs are first performed in live animals, as the technology has not evolved sufficiently to provide a completely suitable *in vitro* system for evaluating cancer cell growth and invasion. However, several *in vitro* assays are currently being developed for such experiments. Increasing use of laboratory tests to evaluate these processes serves the important goal of reducing the numbers of research animals used in the testing process. The purpose of this presentation is to describe several of these methodologies and how they were used to evaluate growth and invasion of a canine prostate carcinoma cell line. A canine prostate carcinoma cell line was used to study the effects of cyclooxygenase-2 (COX-2) inhibitors on the growth and invasiveness of cancer cells. Following treatment with deracoxib or carprofen, *in vitro* effects on ACE-1 cell invasion were measured using a Boyden chamber assay and an *in vitro* wound healing system, as well as growth of the cells in soft agar. Other *in vitro* methods which are being used to evaluate cancer cell growth and invasion include flow cytometric analysis of adhesion molecules, confocal microscopy, apoptosis assays, and static adhesion assays. The data from the experiments which were performed suggest that COX-2 inhibitors may be of therapeutic benefit in prostate cancer by reducing the invasion and growth of neoplastic prostate cells. The results of these experiments also show that *in vitro* methods can successfully be used to study growth and invasiveness of cancer cells.

Identity Achievement as a Function of Age, Gender, and Ethnicity

Amanda N. Rinehart
Dr. Douglas Kleiber, Department of Counseling & Human Development, University of Georgia
Dr. Pedro Portes, Center for Latino Achievement & Success in Education, University of Georgia

Identity formation is one of the most challenging developmental issues adolescents and young adults face. It has been generally presumed that identity formation progresses in the same way for all individuals, but previous research has been done primarily with white, Anglo-Saxon males. Adolescents and young adults construct their meanings of self in social contexts, so this study was conducted to explore whether identity achievement differs by gender and ethnicity. . New research is necessary to gain a comprehensive understanding of identity formation as a critical developmental process that is affected by life circumstances. Furthermore, it is important to continue to evaluate the effectiveness of the instruments used to assess such a complex construct. Several instruments have been used to assess identity formation in the past but have led to different findings. In this study, a convenience sample of 326 males and females from different ethnic groups between the ages of 11 and 36 were given two identity development measures: the Ego Identity Process Questionnaire (EIPQ), and the Identity Status Interview (ISI). Findings will be reported according to age, gender, ethnicity, and their interaction. Consistency or inconsistency in the results as a function of the measure used will determine the validity of the group differences identified as well as reflecting on the validity of the measures. Differences among age groups are to be expected; differences in gender and ethnicity are yet to be established.

Avoiding Overcorrection: Solving the Army's Readiness Crisis

Robert Rosenbleeth & Rocky T. Cole, Roosevelt @ UGA
Dr. Patricia Sullivan, Department of International Affairs, University of Georgia

To many in the U.S. military, Operation Iraqi Freedom shows that the Army lacks enough personnel to fight the "long war" against Islamic extremism. In response to this concern, the Department of Defense is pushing for a permanent 65,000 soldier increase of the Army's end strength, the legislated number of active-duty personnel that the Army must employ. However, this increase constitutes a dangerous overcorrection for the Army's shortcomings in counterinsurgency operations—protracted, low-intensity conflicts against radical guerillas. Significant "boots on the ground" will not effectively quell asymmetric insurgencies. The Defense Department's plan will only burden the military with massive expenses. These funds would be better spent on training and technology—force multipliers essential to future military successes. The Army should maintain its end strength around the current level and focus on building a highly trained and smartly equipped force. Investing in advanced communication technology, robotics, and extensive training—specifically academic training in military strategy, sociology, and linguistics—will transform the Army into a versatile expeditionary force. Because of its higher per unit lethality and specialization in counterinsurgency and counterterrorism operations, creating such a force will negate the need for more "boots on the ground" and increase the Army's success in future conflicts. To compensate for the loss of traditional infantry capabilities, Congress should expand the National Guard to create a force of "citizen soldiers" that can be quickly deployed if the strategic environment justified a large infantry operation. To support our argument, we present a review of recent military and scholarly analysis of the strategic lessons being learned in Iraq.

Understanding M16A Metalloprotease Enzymology

Jarrad W. Rowse, CURO Scholar
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

The human insulin-degrading enzyme (IDE) has the ability to degrade the Aβ peptide. Because accumulation of Aβ in the brain is believed to be a causative agent of the neurodegenerative Alzheimer's disease (AD), IDE has become a potential drug target for the prevention and treatment of AD. IDE has significant sequence homology to metalloproteases in a wide range of other species, including the yeast metalloprotease Ste23p that functions in **a**-factor mating pheromone production. These homologous proteases are collectively classified as M16A metalloproteases. Yeast are used as a model system to evaluate the hypothesis that M16A enzymes have similar substrate-specificities. This system is used to compare the activities of various mutant M16A metalloproteases in an effort to understand the functional impact of charge switch mutations on M16A metalloprotease. This model system has also been used to determine the essential elements of the *STE23* promoter. By evaluating yeast mating ability and using immunoblotting techniques to assess expression levels, it has been determined that neither the predicted initiator methionine residue of Ste23p nor the upstream promoter region (nearly 400 residues) is required for the production of functional Ste23p but is integral in transcriptional initiation. These results are providing insight into the physiological relevance of Ste23p and other M16A metalloproteases by offering an understanding of their transcriptional initiation mechanism and the relationship between structure and function. Ultimately, these studies could lead to the development of a hyperactive enzyme with therapeutic advantages as a treatment for the accumulation of amyloidogenic plaques.

The Impact of Chinese Product Fraud and Lack of Quality Control on U.S. Commercial Trade Laws and Regulations

Meghan A. Royal
Prof. Marisa Pagnattaro, Department of Legal Studies, University of Georgia

Commercial markets across the globe are beginning to rely more heavily on exported goods and services from one of the world's strongest industrial powers, the People's Republic of China. Although these advances in international trade promote cooperation between nations, conflicts in quality regulations and product fraud have presented numerous problems for many American companies who engage in business with Chinese manufacturing corporations. Commercial laws define and shape our nation's business interactions with foreign manufacturers, as well as safeguard our country's economy and protect American consumer's interests. The purpose of this paper is to discuss possible solutions to a number of these issues as well as possible modes of conduct that will hopefully produce a successful global trade economy and culture. This paper investigates many areas of international trade, focusing specifically on our relationships with China. Part II reviews various guidelines and agreements that govern the realm of global commerce, taking a special look at U.S. domestic policies that affect trans-national trade. Part III analyzes World Trade Organization policies as well as a few of the organization's recent dispute hearings between the two nations. Part IV discusses recent cases of product fraud and the quality controls that are implemented and enforced by both the U.S. and Chinese governments. Part V analyzes both U.S. and Chinese legislation recently put into practice to correct the damages made, as well as proposes possible solutions that could be adopted by American businesses and organizations to further protect U.S. consumers from harmful imports.

Project Runway: Untitled

Lindsay MacLean Ruderman, Susan Kent & Rachel Huggins
Prof. Clay McLaurin, Department of Fabric Design, University of Georgia
Prof. Mary Pearse, Department of Jewelry/Metalsmithing, University of Georgia

In this collaborative project and runway exhibition by Jewelry/Metalsmithing students of Professor Mary Pearse and Fibers students of Professor Clay McLaurin, material, adornment and body as site are examined and performed, taking cues from Visiting Artist Anya Kivarkis, and the publication "Fashion at the Edge." For one week, these students worked in teams of five with non-traditional materials, manipulating paper towels, hosiery, window screening and roofing shingles into performative, and in some cases spectacular, wearable art.

We chose to address the idea of consumption in society and explore the opposition of

manufactured consumer products and the natural human body. Transforming consumable paper products into a beautiful piece that takes over the body speaks to the trend of over-consumption that is so prevalent in our society.

Materials: Nylons, batting

A Feasible Trilateral Agreement: A Convergence of Interests

Aaron M. Sayama, Roosevelt @ UGA
Dr. Seema Gahlaut, Center for International Trade & Security, University of Georgia

India and Japan have become increasingly important in the Asian theater over the past decade. Their economic growth during this period has been accompanied by significant changes in their security perspectives: they are keen to play an active role in spreading democracy and partnering with the United States to help maintain the economic and security architecture of Asia. As U.S. policymakers grapple with the challenge represented by the rapid growth of China and its impact on Asian security and economy, India and Japan are getting a closer look as long-term U.S. partners. Accordingly, creating a trilateral cooperation through informal and formal agreements between the United States, India, and Japan would further the best interests of all three nations. In fact, these three powerful states have already begun the process of coordinating policies in order to shape regional dynamics in Asia to best suit their converging interests. This paper will address the economic and political areas that can most immediately serve to cement a Japan-India-U.S. trilateral agreement. Four areas of cooperation are identified: new security architecture in Asia, increased economic interdependence, collaboration in nuclear energy, and efforts to establish and spread democracy. In each area, I will discuss what is already taking place and how to encourage this burgeoning alliance. The paper will also address how to tackle thorny diplomatic issues, such as preventing a counter-alliance from developing among other Asian nations.

Relationships Between Psychosis Risk Scales and Antisaccade Performance

Julia R. Schuchard
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

The relationships between psychosis risk scales and antisaccade performance may further the understanding of the development of symptoms often seen in people with schizophrenia, including hallucinations and delusions as well as flat affect. Research suggests that non-clinical individuals who have minor manifestations of those symptoms, such as perceptual abnormalities and anhedonia, are at greater risk of developing psychosis. Furthermore, people with schizophrenia and people at risk for schizophrenia by virtue of biological relatedness to someone with the disorder make more errors of inhibition as assessed by antisaccade tasks. Antisaccade tasks require rapid eye movements to the mirror image location of a peripheral stimulus (same amplitude, opposite side). Considering the demonstrated relationships between schizophrenia and antisaccade performance, we hypothesized that a positive relationship will exist between antisaccade errors and scores on scales assessing odd and unusual experiences that are associated with risk for developing psychosis. In the present study, normal undergraduate participants responded to 179 items of the Chapman Psychosis Scale, using the following subscales: Perceptual Aberration, Magical Ideation, Physical Anhedonia, and Revised Social Anhedonia. Participants also performed antisaccade tasks, which were scored in terms of the numbers of errors and the required processing time (latencies) and accuracy (eye amplitude/target amplitude) for correct responses. We compared antisaccade performance between extreme groups on the psychosis risk scales. We also correlated antisaccade error rates with individual subscale scores. If significant relationships between psychosis risk scales and antisaccade performance are found, they may help identify individuals at greater risk of developing psychosis.

Effects of Initial Population Size and Food Quality on Stochastic Population Persistence

Jeff Shapiro
Dr. John Drake, Eugene Odum School of Ecology, University of Georgia

Extinction is a fundamental problem for ecological theory, yet theory currently far outstrips the experimental support needed to empirically distinguish alternative models. For example, theory predicts that small initial population size has a negative effect on stochastic population survival. Few empirical studies have tested this theory and conflicting results have been produced. We examined the influence of initial population size, habitat size, and food quality on persistence times and population growth of laboratory *Daphnia magna* populations. We hypothesized that (1) lower initial population sizes would be more vulnerable to stochastic factors and should therefore have shorter persistence times, and (2) both larger habitats and more nutritious food sources would increase carrying capacity, thus should support increasing population persistence. 60 experimental habitats (30 1400mL and 30 700mL tanks) were inoculated with 1, 2, 3, 4, or 5 *D. magna*. 30 tanks were fed a live green alga from the genus *Selenastrum* (nutritious treatment) while the rest were fed a suspension of pulverized blue-green alga *Spirulina* (less nutritious). After 5 weeks, uncontrolled growth of *Selenastrum* in tanks confounded the data, thus producing results contrary to predictions of a standard model. We then eliminated the food quality variable by feeding *Spirulina* to all populations and started a new trial. Data as of 1/7/2008 indicates a probable effect of initial population size ($p = 0.089$) and habitat size ($p = 0.024$) on persistence times. By the experiment's end, our study will confirm the validity of current extinction models and give direction to wildlife managers.

Functional Characterization of a Putative Inositol-1,4,5-Trisphosphate Receptor in the Parasite *Trypanosoma brucei*

Edgar A. Shartilov
Dr. Silvia Moreno, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases, University of Georgia
Dr. Paul Ulrich, Department of Cellular Biology, Center for Tropical and Emerging Global Diseases, University of Georgia

Trypanosoma brucei brucei is the causative agent of nagana in Africa and is closely related to *T. b. rhodesiense* and *T. b. gambiense*, which cause sleeping sickness or African trypanosomiasis. Calcium signaling pathways in trypanosomatid parasites have large influences on cell differentiation and invasion but are largely undescribed. In a proteomic analysis of subcellular fractions, we identified a putative inositol-1,4,5-trisphosphate receptor in *T. brucei* (TbIP3R) and we are determining its function by blocking its expression. Double-stranded RNA interference (RNAi) in *T. brucei* inhibits gene expression and degrades RNA molecules by targeting transcripts of specific genes. We cloned the C-terminal (Ct) and N-terminal (Nt) region of TbIP3R to generate RNAi constructs. We ligated the constructs into the RNAi vector p2t7tiB and transfected procyclic stages of the 29-13 strain of *T. brucei*. We analyzed the effects of TbIP3R knockdown on cell growth of transfected cells. Using this RNAi cell line, we plan to determine the effects of TbIP3R knockdown on parasite virulence, calcium signaling, and responses to environmental stress.

Characterization of *Mycobacterium shottsii*

Purvi S. Sheth, CURO Summer Fellow, CURO Scholar
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

Mycobacterium shottsii is a slow-growing bacterium that was isolated from lesions in striped bass in the Chesapeake Bay within the past decade. It remains unclear whether this bacterium is an etiological agent of disease. Therefore, our goals are to develop molecular

biological methods and infection model systems to more closely study this new species. One emphasis of the project was to examine antibiotic resistance in *M. shottsii*. The minimum inhibitory concentrations of the drugs kanamycin and hygromycin were determined. Another goal of the project was to determine if *M. shottsii* has a mycobacteriophage L5 attachment site on its chromosome. Such a site is present on several other mycobacterium species. The presence of the site is useful to researchers as it provides a location where genes of interested can be introduced and expressed in single copy. To test this hypothesis, *M. shottsii* bacteria are transformed with a suicide plasmid (encoding the mycobacteriophage L5 integrase and attachment site and an antibiotic resistance gene) and spread onto plates containing selective medium. The results of this study are pending as this is an extremely slow-growing bacterium on agar media. If colonies appear on the plates, they will be screened by PCR for DNA specific to the suicide plasmid. If the appropriate-sized product is detected, then it will support the hypothesis that this species contains the mycobacteriophage L5 chromosome integration site. Since *M. shottsii* was isolated from an aquatic source, we examined whether the bacterium survives within amoebae, as has been reported for other mycobacterium species. To investigate this question, *M. shottsii* previously-transformed to express green fluorescent protein (GFP) was mixed with amoebae and examined over time. In our initial studies, bacteria expressing GFP were detected inside of the amoebae after a few days of incubation suggesting that this species can survive inside of amoebae. Whether it can persist for much longer periods of time is under investigation.

The Naturally Attenuated TCC Strain of *Trypanosoma cruzi* Induces a Specific CD8+ T Central Memory Response

Laura J. Simpson
Dr. Rick Tarleton, Department of Cellular Biology, University of Georgia

Trypanosoma cruzi is the causative agent of Chagas disease, a major health concern in Latin America today. Experimental vaccination in animal models has shown that TCC, a naturally attenuated strain of the parasite, provides protection against a virulent infection. This research project aims to characterize the immune response against the TCC strain mediated by T lymphocytes expressing the surface marker CD8. Inoculation of TCC parasites induced specific $CD8^+$ T lymphocytes that were detected using major histocompatibility complex class I tetramers containing the immunodominant *T. cruzi* trans-sialidase peptide, TSKB20. Expression of the surface molecules CD62L and CD127 on $CD8^+$ T lymphocytes suggests that the majority of these cells are central memory cells, a group of long-lasting memory cells considered to be important in vaccine-induced protection. As TCC parasites are not directly detected in the blood of infected mice, hemoculture and Real Time PCR of tissues from immunosuppressed mice were used to demonstrate parasite persistence. These results suggest that TCC parasites persist in low numbers and induce a central memory response. A predominance of central memory $CD8^+$ cells has not been previously described in a model of persistent *T. cruzi* infection. Future experiments will help characterize the kinetics of the $CD8^+$ response and the protection capacity provided by either oral vaccination with TCC or after TCC parasite clearance by drug treatment. This research provides insight into the immunological basis of protection induced by TCC parasites, and will help build a framework for testing experimental vaccines of genetically engineered parasites.

"In the Shadows of Espionage": Extraordinary Rendition as a Threat to American National Security

Rachel A. Spencer & Sarah Vaughn, Roosevelt @ UGA
Dr. Loch Johnson, Department of International Affairs, University of Georgia

Since the Clinton administration, the U.S. has challenged internationally accepted standards and laws by using extraordinary rendition. This process, conducted in the "shadows of

espionage" involves the abduction of suspects on domestic and foreign soil intending to transport them to 'black sites.' Here, the Central Intelligence Agency (D/CIA) often charges agents of other nations to employ a range of harsh interrogation methods, while also precluding the U.S. from claiming a 'moral high ground,' and much needed legitimacy in the ongoing war on terror. We therefore propose the U.S. reject the use of rendition in favor of legal and moral approaches to intelligence. Specifically, we recommend Congress pass legislation calling for the utilization of judicial processes in the accused native's country or formal extradition, thereby providing such investigations with oversight. The U.S. should properly enforce the Alien Tort Claims Act and ratify the U.N. Convention Against Torture to earn the trust of the global community and uphold the ideals of democratic institutions. The goal of our research is to demonstrate that renditions not only severely harm America's reputation abroad but, paradoxically, undermine our national security by causing other nations to openly debate that the U.S. actually lack the ideal it claims to maintain. To achieve this, we will present legal and normative examinations of international conventions, foreign treaties, speeches, academic literature, print media, and the Constitution. Although the implementation of this proposal would face obvious challenges, the benefits to American national security and reputation would far outweigh them.

The Distribution of Rabies Antigen by Immunohistochemistry in the Brains of Different Mammalian Species

Lindsay T. Stein
Dr. Corrie Brown, Department of Pathology, University of Georgia

Rabies is a fatal zoonotic viral infection of the central nervous system, affecting different parts of the brain in different species. It is transmitted by the bite of a rabid animal and is capable of infecting all mammalian species. In the United States in 2006, there were 6,940 reported cases of rabies in animals and 3 cases in humans. Approximately 92% of the cases were in wildlife, and 8% were in domestic animals. Rabies is usually diagnosed by the detection of a viral antigen in the brain by using a direct fluorescent antibody test (FAT), or by the presence of intracytoplasmic eosinophilic inclusion bodies (Negri bodies) of the neurons associated with nonsuppurative meningoencephalitis in routine histological preparations. However, neither of these techniques are satisfactory as FAT requires manipulating samples that have an active virus, and detection of Negri bodies is possible in only 50-80% of cases. Another technique that has recently been applied is immunohistochemistry, which is as sensitive as FAT, but is performed on fixed samples, so there is no operator exposure. The objective of our study is to use IHC to better characterize the distribution of the antigen in different segments of the brain in several species naturally infected by rabies, including horse, cow, sheep, goat, dog, cat, raccoon and skunk. This will improve diagnosis of the disease by establishing the better location for selection of fragments for FAT, and histopathologic changes, including Negri bodies.

Diversity and State-Building: A Cross-Country Analysis of the U.S. and Canada

Karen E. Tanenbaum
Dr. Christopher Allen, Department of International Affairs, University of Georgia

The United States and Canada, beacons of democracy and diversity in the Western world, have taken dramatically different approaches to ethnic and racial diversity in their democracy-building. Canadian state institutions generally are more socially and politically inclusive of minority groups, while those of the U.S. generally are less inclusive and more particularistic. Correspondingly, minorities in the U.S. continue to experience disproportionately greater poverty and challenges in access to education and health care than their Canadian counterparts. This essay attempts to explain these divergent outcomes in the state's accommodation of internal diversity. More specifically, it strives to uncover the factors that enabled and encouraged Canadian

(and discouraged American) state involvement in the accommodation of minority groups through the public sector. I isolate three factors—one social, one institutional and one political—that arguably influence this outcome: 1) the level of social or generalized trust among citizens, 2) the path-dependency or tendency towards the status quo of political institutions (beginning with their formations in response to revolutionary change), and 3) the size and bargaining power of their respective minority groups. Each of these variables partially explains a state's level of involvement in the accommodation of minorities. However I hypothesize that the third explanation, the size and bargaining power of a given minority group, carries the most weight in influencing relevant policy outcomes. This comparative study strives to illuminate the dominant forces behind minority policies in the U.S. and Canada and to encourage a critical re-examination of the relationship between diversity and democracy.

Mixed Income Housing: A Comprehensive Reconstruction Plan for New Orleans

Lila E. Tedesco, Roosevelt @ UGA
Dr. Andrew Carswell, Department of Housing & Consumer Economics, University of Georgia

Even prior to Hurricane Katrina, poverty has plagued New Orleans. Katrina has created the unique situation in which nearly all of the parishes must be rebuilt, granting an opportunity to address this historic problem. This paper explores the benefits of mixed-income housing as an effective development strategy to expand the social mobility of the lower classes and proposes an optimal method toward comprehensive neighborhood development, using the city of New Orleans as a case study. Mixed income housing deconcentrates poverty and integrates classes to create a stimulating environment that leads to community improvement on the whole and opens opportunities for individual residents. I measure the effectiveness of this implementation using Thomas Boston's Quality of Life Index, which consists of both family and neighborhood indexes and which has been used to show the effectiveness of other mixed-income projects in Atlanta and Chicago. Follow-up programs such as job placement, housing counseling, and access to public services ensure the benefits of mixed-income housing. Using theories of "New Urbanism" enhances the community aesthetics, making the community appealing to all income levels. Funding for this effort would come from a variety of established federal initiatives such as housing trust funds and low-income housing tax credits. Incorporating these developments into the Unified New Orleans Plan coordinates reconstruction to prevent isolated developments. A cohesive and economically integrated rebuilt New Orleans promises a future free of the social ills that the city has battled in the past.

Project Runway: Screen Study

Marie Tetzlaff, Allison Sheats & Kathleen Janvier
Prof. Clay McLaurin, Department of Fabric Design, University of Georgia
Prof. Mary Pearse, Department of Jewelry/Metalsmithing, University of Georgia

In this collaborative project and runway exhibition by Jewelry/Metalsmithing students of Professor Mary Pearse and Fibers students of Professor Clay McLaurin, material, adornment and body as site are examined and performed, taking cues from Visiting Artist Anya Kivarkis, and the publication "Fashion at the Edge." For one week, these students worked in teams of five with non-traditional materials, manipulating paper towels, hosiery, window screening and roofing shingles into performative, and in some cases spectacular, wearable art.

This piece stems from a purely formal materials study, which seeks to upset traditional knowledge of fiberglass mesh as a flat, transparent substance by forming it into volumetric shapes that overlap to create an opaque garment. As each modular unit builds on the next, the bulging screen begins to blur the figure of the model beneath while obscuring any reference to more conventional dress shapes on the exterior. Both the material and its

unorthodox handling help make this piece less of a dress itself and more about the idea of a dress.

Materials: Mesh Fiberglass

Perceptions of Puerto Rican Women and Their Impact on Public Health Policy in the Early 20th Century

Adam Thomas
Dr. Reinaldo Román, Department of History, University of Georgia

This presentation will reveal the negative impact that U.S. government depiction of Puerto Rican women had on policy, both in the United States and on the island of Puerto Rico. This will be done through an analysis of the portrayal of these individuals in government literature. I will begin with a brief discussion of the history of public health in the United States, then continue into a short analysis of the reasons for U.S. occupation of the island. Next, I will proceed into a depiction of areas of control that the government exerted during the period—the health of American service men, the economics of Puerto Rico, and the political realities of Puerto Rican women. The health of U.S. service men received extensive attention, often expressed in terms of sexuality, with these men encouraged to avoid sexual contact with "dirty women," and when necessary, utilize some form of prophylactics, which were still taboo among mainstream society. The presence of prostitution on the island furthered the negative portrayal of women and in turn fed the government's ability to deny them political rights, as they were "subverting the social norms" of the island. It also provided one means with which the United States was able to deny Puerto Rico political independence. I will conclude by discussing the impact these policies have had on contemporary Puerto Rico and analyze what, if any, changes can be made to alleviate them.

Comparison of the Acute Toxicity of Selective Serotonin Reuptake Inhibitors (SSRIs) and St. John's Wort (*Hypericum perforatum*) to *Ceriodaphnia dubia*

Yen Tran
Dr. Marsha Black, Department of Environmental & Health Sciences, University of Georgia

The Clean Water Act prohibits the discharge of materials in toxic amounts to the waterways of the nation. St. John's Wort *(Hypericum perforatum)* has been widely used as an herbal anti-depressant drug. Recommended dosage is three 352 mg capsules daily. When St. John's Wort is excreted from the urinary system of consumers, it maintains some of its active ingredients, hypericin and hyperforin. If the active substances are not removed or degraded by wastewater treatment and occur at sufficiently high concentrations, they may have toxicity to aquatic life. In the present study, acute toxicity tests were used to determine the potential toxic activity of St. John's Wort in a model aquatic organism. *Ceriodaphnia dubia* were exposed to various dilutions of St. John's Wort, and LC50s were calculated to determine the mortality rate. Average LC50s for St. John's Wort at 24 and 48 hours were 50.8 and 34.3 mg/L, respectively. Thus, aquatic organisms may risk toxicity if they are continuously exposed to St. John's Wort. Compared with the prescription antidepressants (SSRIs), St. John's Wort is 10-244 times less toxic. At high consumption and excretion, St. John's Wort could cause similar risks of toxicity to aquatic organisms as SSRIs. Further chronic toxicity tests and aquatic analyses are needed to determine concentrations of St. John's Wort that may harm aquatic environments.

IS492 Movement on the *Pseudoalteromonas atlantica* Chromosome

Steven P. Trau
Dr. Anna Karls, Department of Microbiology, University of Georgia

Pseudoalteromonas atlantica is a primary biofilm-forming marine bacterium. Biofilm formation requires production of extracellular

polysaccharide (EPS). In *P. atlantica,* EPS production (+/-) and the associated colony morphology [mucoid (+) or crenated (-)] is controlled by movement of a mobile element, IS*492*. Excision of IS*492* from *epsG* allows for the production of EPS and yields a mucoid phenotype while insertion of IS*492* into *epsG* yields a crenated phenotype. *P. atlantica* contains five copies of IS*492* in its genome including the *epsG*-associated copy. The precise excision of the *epsG* copy of *IS492* occurs at a fairly high frequency (10^{-3}/cell/generation) and leaves the chromosome with four copies of IS*492.* Current research suggests that low frequency insertion of IS*492* into *epsG* (10^{-6}/cell/generation) occurs by replicative transposition of another chromosomal copy thus leaving a copy at the donor site while inserting a copy into *epsG*. To investigate the movement patterns of the chromosomal copies of IS*492* Southern blot analyses are performed with chromosomal DNA from mucoid and crenated isolates which come from multiple, vertical generations of a specific *P. atlantica* strain. The probe used for detection of IS*492* in the Southern blots is a PCR product corresponding to the first 744 base pairs of IS*492* which is labeled with digoxigenin (DIG) and detected by binding of anti-DIG antibody that is linked to chemiluminescence or colorimetric enzymes. This Southern analysis will test whether precise excision of IS*492* is linked to insertion at any site on the *P. atlantica* chromosome.

African-American Models of Success

Darryl Tricksey, CURO Apprentice & Dakia McCray, CURO Apprentices
Dr. Victoria Plaut, Department of Psychology, University of Georgia
Dr. Larry Nackerud, School of Social Work, University of Georgia

What predicts success for African-American students at a majority White institution? Past research has shown that trust of a majority group, stereotype threat, racial identity, and educational beliefs predict academic excellence among African-Americans. Absent from these investigations, we argue, is consideration of pervasive African-American models of success, that is, personal definitions and connotations about success and its attainability. The present study will be the first to examine African-American models of success, taking into account both the various factors that have predicted achievement and their interaction. We are currently working with focus groups to design a survey funded by a RED seed grant that will be used to measure aspects of models of success within a diverse, randomly selected pool of African-American students. The focus groups will allow us to include any overlooked variables, reaffirm the inclusion of existing variables, and establish new links among existing variables. We believe our research will show that models of success can act as predictors of both performance outcomes and aspirations. We also hope to gain further insight into connections between racial identity, trust and security, educational beliefs, and other variables as they relate to models of success. Ultimately, we hope to generalize the construct of African-American models of success in majority White institutions and publish our work in order to encourage the adoption of best practices.

Antonio Vivaldi's Contribution to the Evolution of Program Music

Robert M. Truan
Dr. Susan Thomas, Department of Musicology & Ethnomusicology and Institute for Women's Studies, University of Georgia

A composition in which a composer attempts to aurally depict a predetermined narrative is known as program music. Antonio Vivaldi's (1678 – 1741) *The Four Seasons* (1725) is a series of four violin concertos representing the yearly seasons through music composition by accompanying each score with a seasonal sonnet. Even though program music is regarded as a nineteenth century phenomenon, *The Four Seasons* can be seen as an early contributor to the practice. In this paper, I demonstrate three ways in which The Four Seasons can be seen as proto-programmatic music. Through analysis of the music score, I show how Vivaldi's

composition uses musical sound to express non-musical elements. I also suggest how historical precedents to program music influenced Vivaldi's composition, particularly the process of vocal madrigalisms' application to instrumental music. Madrigalisms refer to a compositional technique of their genre, Italian madrigals, in the sixteenth century. Finally, the literary basis for the provided sonnets in *The Four Seasons* will reveal the external program that Vivaldi attempts to depict. Compositional techniques that Vivaldi used were innovative not only for their time but also shed light on the development of program music.

A Cross-Cultural Comparison of Gender and Role-Identities in China and the United States

Traci N. Tucker, CURO Summer Fellow, CURO Scholar
Dr. Dawn Robinson, Department of Sociology, University of Georgia

This study seeks to understand how cultural evaluations of an occupation influence the way in which we gender that occupation. According to Affect Control Theory, individuals seek to maintain their definitions of the situation (their expectations for a particular event). Thus, this study investigated the prediction that the more similar the cultural meanings attached to a particular occupational identity are to the cultural meanings attached to a gender identity (e.g., Man, Woman), the more gendered will be our expectations of that occupational identity. Gender and occupational meanings from the U.S. and China, measured in Evaluation, Potency, and Activity, were used to create a measure of distance between gender meanings and the meanings attached to a list of various occupational identities. A cross-national survey was then conducted in which 42 undergraduate students from a large university in the United States and 46 undergraduate students from a large university in southeast China provided ratings about whether the most appropriate occupant of each identity would be a man, a woman, or either. These ratings were compared against predictions generated from Affect Control Theory based calculations of meaning-distance. Logistic regressions examined whether these meaning-distances predicted assessments of gender appropriateness for occupational identities. Results suggest that gender appropriateness is defined primarily by the relation of the occupational identity to the role of woman. The occupational identities' relation to the role of man appears to be less salient in the gendering process.

RGS Regulation of the LPA Signaling Pathway in Prostate Cancer Cells

Kathryn L. Turner
Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Lysophosphatidic acid (LPA) is a signaling molecule that induces proliferation, migration, metastasis, and survival in prostate cancer cells by activating cell surface G-protein coupled receptors (GPCRs), which in turn activate G-proteins. Regulators of G-Protein Signaling (RGS) proteins deactivate G-proteins, thereby stopping the signal. In cancer cells these G-proteins are active, leading to increases in the signal and cancerous activity. RGS proteins are likely therapeutic targets, because there are many different forms that bind specifically to different G-proteins, therefore ones utilized in prostate cancer can be identified. Our hypothesis is that RGS proteins are present in the cells and regulate G-proteins involved in LPA signaling in prostate cancer cells. The effects of LPA were determined by testing the amounts of different second messengers, specifically cyclic adenosine monophosphate (cAMP) and inositol phosphate (IP), which vary depending on the level of LPA activation. The results reveal that prostate cancer cells are affected by LPA, with increases in LPA leading to changes in second messenger production, suggesting that the LPA pathway is present in prostate cancer cells. By studying the differences between RGS sensitive and insensitive G-proteins, we can determine the effect of RGS proteins on this pathway. If it is found that RGS proteins regulate this LPA signaling pathway and are present in the cell, then further research can be done to identify

which RGS proteins are involved in prostate cancer and which could be used as therapeutic targets.

An Investigation of the Relationship between the Existence of Inc A/C Plasmids and the Prevalence of Multiple Therapeutic Antibiotic Resistances

Matthew A. Turner
Dr. Susan Sanchez, Department of Pathology, University of Georgia

The possible correlation between high use of therapeutic antibiotics in food animals and increased antimicrobial resistance in bacteria has drawn increased public attention. Recent work indicates that Inc A/C plasmids, such as pSN254, may be a source of the correlation, serving to pass multiple antimicrobial resistances, including streptomycin, tetracycline, and several others, by plasmid conjugation between normal flora of the G.I. tract and Salmonella serotypes passing through animals. This study was designed to determine the abundance of Inc A/C plasmids in bacterial isolates from cattle and the potential relationship between these plasmids and the presence of multiple drug resistances. The repA gene was used as an indicator of the presence of Inc A/C plasmids and was identified through the use of PCR analysis and gel electrophoresis. Both Salmonella and normal flora isolates from farms in Northeast Georgia and Salmonella isolated from clinically sick cattle around the state of Georgia were tested. 100% of Salmonella isolates from healthy farm cattle tested positive for the repA gene, while clinical isolates rarely tested positive other than in Salmonella Newport serotypes. In order to determine if there is a correlation between these plasmids and resistances, we examined phenotypic resistances of repA positive, normal flora isolates from the same farm. Results indicate that 79.3% of repA positive samples demonstrated strA resistance, 86.2% demonstrated strB resistance, and 86.2% demonstrated tetA resistance. The isolates demonstrated several other resistances as well, but those demonstrated lower levels of correlation with the repA gene. These results indicate strong possibilities of a correlation between Inc A/C plasmids and these resistances, that the normal flora may frequently carry these Inc A/C plasmids, and that Salmonella Newport strains may be more likely than other strains to carry these plasmids.

SPQ-Identified Schizotypy and Antisaccade Performance in a Normal Population

Manouela V. Valtcheva
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

People with schizophrenia have problems inhibiting inappropriate behavior. One simple measure of inhibition is via antisaccade tasks during which subjects are instructed to inhibit a glance to a target and generate a glance to the mirror image location. Errors towards the target are reported more frequently in people who are related to someone with the illness (and therefore at greater risk for developing the illness themselves). People who have schizotypal personality characteristics (unusual experiences such as illusions, magical thinking or suspiciousness) often display behavioral and psychophysiological measures similar to those in people with schizophrenia. The purpose of this study is to investigate whether there is a relationship between increased antisaccade errors and questionnaire-identified schizotypal traits in subjects who do not have a family history of schizophrenia. Participants from the undergraduate research pool were screened for psychiatric history before they participated. Participants also completed a self-report Schizotypal Personality Questionnaire (SPQ) and were measured on antisaccade performance. Group comparisons of participants at the low and high extremes of the distribution of antisaccade error rate were conducted to investigate the association between SPQ scores and antisaccade performance. It is hypothesized that a positive relationship will exist between schizotypal symptoms and error rates. Such results would demonstrate the presence of critical psychophysiological characteristics in a normal undergraduate population. Furthermore, the possibility of studying schizophrenia-risk in

normal subjects who have distinct patterns of scores on these measures would greatly enhance our ability to research related issues in an unimpaired group.

Does Writing Ability Predict Academic Achievement? Evidence from the New SAT Writing (SATW) Section
Jessica N. Van Parys, CURO Summer Fellow
Prof. David Mustard, Department of Economics, University of Georgia

In 2005, the College Board substantively altered the format and content of its SAT Test by adding a writing section (SATW) to the existing verbal (SATV) and math (SATM) portions. No research exists on the extent to which the SATW relates to student performance in college. Thus, admissions offices of many higher educational institutions have disregarded the SATW scores in their admission decisions. By examining how the SATW affects a number of college performance outcomes, this study fills the gap in the academic literature and also provides evidence for formulating admissions policies. This study uses data for over 4,300 first-year students at the University of Georgia who were in the first cohort of students to take the SATW and complete a year of higher education. These student-level data provide information about personal (e.g., race, gender, parental education) and high school characteristics (GPA, SATM and SATV scores, Advanced Placement courses, high school attended). The data also include every college class students took and their corresponding grades. Regressions that control for personal and high school characteristics indicate that with each 100-point increase in SATW scores, students earn, on average, 0.07-points higher first-year GPAs and 0.18-points higher GPAs in freshman English courses; they also enroll in and earn 0.44 and 0.54 more credit hours, respectively. Conversely, these students withdraw from 0.2 fewer credit hours and are 3% less likely to lose the HOPE Scholarship. In general, SATW scores better explain student performance than either the SATV or SATM scores.

Sequencing and Tissue Distribution of Toll-like Receptor 3 in White-tailed Deer
Seychelle M. Vos, CURO Scholar
Dr. Elizabeth Howerth, Department of Pathology, University of Georgia

Hemorrhagic disease is a fatal disease in white-tailed deer (WTD) caused by two closely related orbiviruses, bluetongue virus and epizootic hemorrhagic disease virus. Susceptibility to these viruses varies among populations of WTD, and results from experimental studies suggest that innate immunity may contribute to these differences. It is hypothesized that the Toll-like receptor 3 (TLR3), an important intracellular receptor in innate immunity that recognizes double stranded RNA (dsRNA), may be involved in differences in innate immunity in WTD populations. However, little is known about TLRs in WTD, and rudimentary information is needed before the potential effect of TLR3 on disease susceptibility can be evaluated. Therefore, the objectives of this study were to sequence and determine tissue distribution of the mRNA of TLR3 in normal WTD. A 209bp portion of WTD TLR3 mRNA was sequenced using primers designed originally for TLR3 mRNA in cattle. Primers were then designed specifically for deer using the newly sequenced fragment. Quantitative analysis of TLR3 mRNA in various WTD tissues from non-infected WTD is being performed using real time-polymerase chain reaction (qRT-PCR). Preliminary results suggest that the TLR3 is expressed in skin, small intestine, brain, lung, and spleen at levels that may prove useful in future research. These results will allow further investigation into the overall significance of the TLR3 in variation of susceptibility to disease among WTD populations.

Source Memory and Picture Location in Relation to Working Memory
Dana Wagshal, CURO Scholar
Dr. Nash Unsworth, Department of Psychology, University of Georgia

Previous research has shown that picture location is related to source memory overall, and

is in fact a measure of source memory. Source memory is the process by which memories are attributed to the original context or source. Thus, university undergraduates will complete a computer task in which the participant must decide if the image on the screen is old or novel and if the image is old, he/she must indicate the original location of the image. Moreover, past studies have shown a relationship between attributing the location of a picture to source memory. However, while a relationship between source memory and picture location has been shown, the question addressed by this study is whether working memory and source memory, as measured by the picture location task, are related, and if so how? According to the traditionalist view, working memory is memory that has been manipulated. However, the manipulation of memory is only one component of working memory. Cues and active maintenance are also important components that compose working memory. Therefore, the relationship between source memory and picture location seems too simple; this project postulates that there is also a correlation between working memory and source memory. Thus, by measuring high and low span differences of undergraduates completing computer tasks of working memory, this research project is aimed at investigating the nature of the relationship between source memory and working memory and to further elucidate and examine their more detailed components in performance.

Is Elevation of O-GlcNAc Levels Both Necessary and Sufficient to Extend Median Lifespan?

Wei Wang
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia
Sandra Brimble & Enas Gad El-Karim, Department of Biochemistry & Molecular Biology, University of Georgia

From *C. elegans* to mice, reduced signaling through the insulin-like pathway extends both median and maximal lifespan. However, reduced signaling defined as insulin resistance also precedes and is the hallmark of type II diabetes. The laboratory has demonstrated previously that elevation in intracellular glycosylation of nuclear and cytosolic proteins via O-GlcNAc (carbohydrate modification) induces insulin resistance. More recently, the laboratory has demonstrated that the O-GlcNAc cycling enzymes (OGT that adds and OGA that removes the O-GlcNAc modification) modulate median lifespan in *C. elegans* and thus are modulating the insulin-like signaling pathway in the nematode. Having demonstrated that elevation of O-GlcNAc levels is sufficient to increase lifespan, the project focuses on whether or not it is necessary. The project is focused on measuring O-GlcNAc levels and mRNA and protein expression levels of the cycling enzymes in mutant strains of *C. elegans* that have elongated or shortened median and/or maximal lifespans. Furthermore, given that an OGT null mutant can suppress long-lived insulin mutants' median lifespan without altering maximal lifespan is of great interest since no other repressive mutant only alters one of these two criteria. Thus, several mRNA preparations from multiple strains for microarray analysis will be generated in order to identify key regulated genes that may be involved in longevity versus median lifespan. In conclusion, the results expected are that greater O-GlcNAc levels are indeed needed for increased median lifespan and that the microarray experiments will direct us towards the genes involved specifically in longevity.

Design Evolution of a Non-Electric Evaporative-Cooling Milk Container for Smallholder Farmers in East Africa

Aaron O. Watwood
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

Smallholder dairy farmers of East Africa must cool their fresh milk to four degrees Celsius in four hours in order to meet ISO standards for marketability. Ugandan dairy farmers, in particular, are not able to market their evening milk due to lack of cooling facilities, and thus must forfeit the potential revenue gained from it.

Through a design and research undergraduate program, we are developing a cooler that is non-electric and works by an evaporative-cooling mechanism that relies on vacuum and zeolite adsorption. Three designs have evolved thus far with varying constructions and performances. The first design, consisting of a separate zeolite container and on-site generated vacuum via a hand pump, exhibited inadequate cooling (30 to 25 centigrade degrees). The second design, independently conceived and commercialized by CoolSystems of Germany as "CoolKeg" for alcoholic beverages, achieved the desired cooling kinetics but lacked several attributes to be applicable under smallholder operating environment. In collaboration with CoolSystems, modifications have been incorporated into the second design to be compatible with smallholder dairy farmer practice, with milk cooling performance and maintenance being the primary concerns. This third design is undergoing performance testing with respect to cooling kinetics. Details of the third design will be presented with emphasis on the changes made to make it work for the smallholder dairy farmer in Eastern Africa.

Black Women and the Movements: Using Art to Re-Define Beauty

Delila D. Wilburn, CURO Summer Fellow
Dr. Barbara McCaskill, Department of English, University of Georgia

During the 1960s and the 1970s, the United States became the breeding ground for several organizations that sparked a series of social movements in favor of equal civil rights and liberties for minority groups. Breaking away from the strict political nature of other movements, the Black Arts Movement (BAM) emerged nationally from the African American community. BAM was a movement among black artists who valued art by and for black people, and who wanted to use art to help black people transform and improve their communities. The movement complied with the Black Vernacular Tradition, which encouraged African Americans to reject standard traditions, especially of cultural aesthetics, literary forms, and expressive art. Using the biographical resources available and the published work of the artists, my research profiles notable women associated with BAM. The profiled artists are the singer Nina Simone (1933-2003), and the poet and professor of English at Virginia Tech Nikki Giovanni (1943-present). These women used their songs and poems respectively not only as sources of inspiration for black women, but as voices of activism for all women alike. Their work influenced the rise of second wave feminism, a period of feminist activity during the 1960s and the 1970s, with profound critical messages on gendered racial politics and women's liberation. Their work—innovative and unconventional—display aesthetical messages that resonate as loudly as when they were first introduced to the American public: true beauty is defined not by compliance to traditional standards, but through non-conformity and originality.

Determining the Truth: The War on Terror and Repression in China

Ashley A. Wilkinson, Roosevelt @ UGA
Dr. David S. Williams, Honors Program, University of Georgia

Both human rights organizations and governments have long accused China of oppressing its Muslim Uighur population, of whom many are separatists. Since the War on Terror began, their criticisms of the Chinese government for its perceived persecution of Uighurs have increased. However, it may be difficult to establish whether bias has somehow contributed to charges of intensified human rights abuses. To produce less biased assertions, an automated events data coder can be used to assert whether human rights violations have actually increased. In order to determine the accuracy of the claims that China has repressed the Uighurs more after the War on Terror began, both Chinese rhetoric and acts of Chinese repression as reported in newspapers were analyzed using an automated events data coder. For the rhetoric, the data coder was used to search newspapers for the words Chinese officials and media used to describe Uighur

separatists from 1994-2007. The same software program was used to look for words describing acts of repression, such as torture, execution, and re-education, also from 1994-2007. After comparing and analyzing the data before and after the War on Terror began, and controlling for variables such as economic change, change in leaders, and dissent, preliminary results suggested that the War on Terror correlated with the Chinese crackdown. This case shows that automated events data coding may potentially provide a more trustworthy account of whether human rights have been violated in a given state.

Ending the Waiting List Crisis: Increasing Child Care Subsidy Funds

Ashley A. Wilkinson, Roosevelt @ UGA
Dr. Thomas McNulty, Department of Sociology, University of Georgia

Reliable child care enables parents to attain and maintain employment. In the past, the United States Congress recognized the importance of childcare, boosting subsidies for the service after the government increased work requirements during the 1996 restructuring of welfare. Today, the U.S. government encourages low-income families to get off welfare, but fails to adequately fund the child care subsidies these families need in order to work. Normally, the federal government provides states funds for child care subsidies through the Child Care Development Block Grant (CCDBG) and Temporary Aid for Needy Families (TANF). Unfortunately, since 2001, state budget deficits, inflation, and increased TANF work requirements have reduced the amount of money states receive to allocate for child care assistance. Because of this decrease in funding, seventeen states currently have waiting lists for child care subsidies, including Georgia. According to the federal government's inflation calculator, the United States must increase funds to the CCDBG by $460 million to cover the decreased value of the CCDBG's stagnant funding. In addition, advocacy groups claim that $3.8 billion must be spent to meet Congress's new work requirements for TANF, amounting to a combined total of $4.26 billion to be spent over the next five years. After reading articles and papers from the federal government, state governments, and advocacy groups, I have realized that while individual states are also responsible for child care subsidy waiting lists, the problems have begun at the federal level and should be resolved on that level first.

HIV/AIDS in India: A Case Study on the Influence of Traditional and Modern Indian Characteristics on the HIV/AIDS Epidemic among Indian Youth

Amy K. Winter
Dr. Nan McMurry, Department of History, University of Georgia

India is a dynamic country currently experiencing rapid economic development and societal change as well as a dangerous HIV/AIDS epidemic that has infected 2.5 million people. In the transition from a traditional identity of social conservatism and poor economic status to a modern world of open markets, consumerism, and growing western influences, Indian youth are a vulnerable demographic, accounting for 31% of India's AIDS cases while constituting only 25% of the population. The objective of this paper was to explore how both traditional and modern influences have affected the spread of HIV/AIDS in Indian youth. Specifically, I explored five traditional and modern Indian characteristics. The traditional characteristics are gender inequality, lack of sex education, and poverty. The modern characteristics are migration, and sexual liberalism. These five characteristics are interrelated and none are direct causes of HIV/AIDS, however, these characteristics foster situations that place Indian youth in positions of higher vulnerability to contracting HIV/AIDS. Where HIV/AIDS infection and transmission are concerned, India is caught between the worst of a traditional/underdeveloped country and a modern/developed country. Indian youth are the unfortunate population who are the recipients of both traditional and modern characteristics that position them in an environment where they are highly vulnerable to contracting HIV/AIDS.

Regional Comparison of the Legal Basis of Venture Philanthropy

Karen C. Wong, CURO Summer Fellow, CURO Scholar
Dr. Andrew Whitford, Department of Public Administration & Policy, University of Georgia

Venture philanthropy falls under social entrepreneurship and is the new trend in philanthropy. It is a social change investment vehicle and contains entrepreneurial activity in charitable organizations. It involves the application of corporate principles to nonprofits, long-term commitment, and high engagement. Venture philanthropists choose and assist certain non-profits with constructing and executing strategic plans that will lead to substantial growth and broad social impact. Venture philanthropists take a performance and results focused orientation. To achieve this aim, venture philanthropists incorporate fixed milestones and tangible return and exits into nonprofits. Venture philanthropists emphasize creating self-sustainability in a nonprofit. This research will examine the legal basis of venture philanthropy to better understand and analyze the motivation and characteristics of venture philanthropy groups. We hope to understand the legal formulation and governance of venture philanthropy groups in the United States. By studying the legal governance structure of venture philanthropy groups, we can better understand the structure and characteristics of venture philanthropy groups. After assessing basic legal agenda associated with venture philanthropy, the paper will conduct a study that compares the different legal foundations of venture philanthropy within different regions in the United States. We will analyze and compare the legal basis and governance of venture philanthropy groups cross-country to gain a diverse perspective.

Permeability of Intestinal Cells Exposed to Black Walnut Extract

Leilah D. Zahedi, CURO Apprentice
Dr. David Hurley, Department of Population Health, University of Georgia

Acute laminitis, a condition characterized by vascular dysfunction and inflammation in the hoof, occurs in horses that ingest or are exposed to shavings from Black Walnut trees. We hypothesize that a change in intestinal permeability, due to localized effects of an aqueous Black Walnut extract (BWE) play a role in the pathogenesis of laminitis. The increased permeability of the intestinal mucosa then allows movement of intestinal contents into the vascular system resulting in a systemic inflammatory response. Due to the design of the hoof, inflammation leads to a loss of perfusion, pain, and a potentially life threatening condition. To test our hypothesis, we measured changes in permeability of the tight junctions between human intestinal cells to fluorescent probes of various sizes. The cells were grown on filters separating two chambers, and incubated with BWE. We measured movement of these probes across the cells and compared those results with control samples. Preliminary results indicate low concentrations of BWE decreased tight junction permeability, but permeability increased as BWE concentrations increased. These results suggest that the amount of BWE ingested might be linked to whether leakage, and therefore inflammation occurs. Since the above experiments were conducted to establish methodology, conclusions on effects of BWE will be better determined when the protocols are conducted using equine intestinal cells. Those studies will give us a clearer picture of the effects of BWE on changes in intestinal permeability that could lead to laminitis.

Simulacrum Ring
Marilyn Zapf
Prof. Robert Jackson, Department of Jewelry/Metalsmithing, University of Georgia

My current research explores the line between the real and the reproduction. Moulds are taken from specific areas of the body and reconfigured into a landscape questioning how an image is created, how true a copy is to its original, and at what point a reproduction leaves what it signifies and becomes a reality in and of itself. The work, used in a jewelry context, emphasizes both its dependence on and departure from the body. The ring format relies on the finger for its function while simultaneously hiding the finger from view. In "Simulacrum Ring," moulds are taken from the knuckles of the hand, reconfigured, translated into silver, and returned to the body in its new orientation.

CURO
Center for Undergraduate Research Opportunities

Symposium 2010

Classic Center
Athens, Georgia
Monday, March 29, 2010

CALL FOR ABSTRACTS

The Center for Undergraduate Research Opportunities at the University of Georgia provides a forum for undergraduates with a 3.4 GPA or who participate in a university-wide research program to present original research and creative works sponsored by faculty members. Undergraduate students from all disciplines are encouraged to participate. Representatives of public and private higher education institutions in Georgia are encouraged to apply.

Scholarly presentations may be in the form of an oral presentation, poster session, exhibition, performance, or work of art. Students can also present a tutorial about a research methodology or new technology. Undergraduate researchers who are at various stages of the research process are encouraged to submit abstracts describing where they are in the research process and the issues they face. Honors thesis students can also present in a Roundtable Forum. The Roundtables offer undergraduates pursuing an Honors thesis the opportunity to present their research to other thesis students working in the same discipline. Those who wish to present their work should submit an application and an abstract of a maximum of 250 words no later than **January 15, 2010** and a brief supporting letter from the sponsoring faculty member via the CURO web site no later than **January 25, 2010**. Group research projects should be submitted with one application and one letter of faculty support. All abstracts will receive graduate student peer review and feedback. All participants accepted into the Symposium will be notified by February 8, 2010, and their abstracts will be published in a book of abstracts. Sponsoring faculty are invited to preside at their students' sessions.

Best Paper Awards
Papers on work being presented at the CURO Symposium submitted by February 26, 2010 will be considered for Best Paper awards in the categories of humanities, social sciences, civic responsibility focus, international focus, and sciences. Papers must be submitted electronically to curo@uga.edu. Maximum length is 12 pages, double spaced, excluding references and appendices.

Purposes of the Symposium:
- To highlight excellence in research by undergraduate students
- To enrich the undergraduate experience by promoting communication and cooperation between faculty and students
- To provide a forum for undergraduates to communicate and disseminate their research findings and creative works
- To provide an opportunity for undergraduate researchers in the state of Georgia to engage with their peer researchers

Criteria for Selection:
- Originality and quality of research
- Quality of written abstract
- Ethical and responsible research
- Extent of the undergraduate student's involvement in development of the research design and execution of the project. Research presented at the Symposium should go beyond work completed for a class paper or project.
- Letter of support from supervising faculty

This event will be free and open to the public. All interested faculty and students are encouraged to attend the CURO 2010 Symposium. Free parking will be available at the Classic Center. Free UGA bus transportation will be available from specified locations. For more information, contact curo@uga.edu, (706) 542-5871.

JURO@GA The University of Georgia's Journal for Undergraduate Research Opportunities

CALL FOR SUBMISSIONS

The Journal for Undergraduate Research publishes original research papers in the areas of humanities, social sciences, and policy as well as art-related content. You **must present at the annual CURO Symposium in order to be eligible for publication**. Submissions are accepted throughout Spring semester at http://www.uga.edu/juro/.

The following general format should be adhered to as closely as possible. The cover page should include the researcher's name, the faculty advisor's name, the institution attended, the researcher's major, and the year of anticipated graduation. This information should be followed immediately by the abstract. The research article itself may be organized into the following sections: introduction, methods, findings, conclusion, and references.

Additionally, work submitted to JURO@GA must adhere to the following guidelines:

1. Maximum length is thirty pages, double-spaced. Theses can be shortened to comprise the central idea of the research in order to be eligible for publication in the journal.
2. All submissions are submitted in English unless other arrangements are made.
3. All work must be submitted with an abstract no longer than 250 words. The abstract should provide a background sufficient to establish a context for understanding the research, summarize the research article itself, and highlight the major results.
4. References should be organized according to the standard format for the individual discipline the research topic falls under, e.g. Modern Language Association, Council of Biology Editors, American Psychological Association, or Chicago style format.
5. Work must be fully represented in digital form (preferably a Microsoft Word document for papers) and emailed to juro@uga.edu.
6. All submissions must be accompanied by a completed Submission and Faculty Advisor Approval Form found on the website at http://www.uga.edu/juro/.

All submissions will be evaluated according to criteria established by the editorial staff of the journal. All incoming research will be reviewed first by JURO@GA's content editors and other staff members. All prospective publications are subject to the approval of the journal's Editor-in-Chief. Upon completion of the review, the author may expect to receive either a notification of acceptance, acceptance with revisions, or a rejection of submission. Any questions about the submission process or the journal itself should be directed to juro@uga.edu. JURO@GA wishes you the best of luck with your submission and looks forward to reviewing the finished product of your hard work.

Concurrent Oral Sessions

Classic Center, Athena Breakout Rooms A, B, C, D, G, H, I, J

10:10 – 11:00 a.m. First Concurrent Session

Room A	**Maren Smith**	Senescence and the Y Chromosome
	Faculty Mentor	Dr. Kelly Dyer, Department of Genetics
	Shelina Ramnarine	Understanding the Cell Cycle: Cyclin-Dependent Kinase Phosphorylation of Hcm1
	Faculty Mentor	Dr. Wyatt Anderson, Department of Genetics
	Matthew Belcher	Determinants in the Localization of Telomerase to Telomeres
	Faculty Mentor	Dr. Michael Terns, Department of Biochemistry & Molecular Biology
Room B	**Amanda Farmer**	Adverse Effects After Administration of an Ionic Iodinated Contrast Media in Dogs
	Faculty Mentor	Dr. Erik Hofmeister, Department of Small Animal Medicine
	Laura Harrison	Presence of Apoptosis, as Determined by Immunohistochemistry, in Lymphoid Tissues of Chickens Infected with Strains of Newcastle Disease Virus of Varying Virulence
	Faculty Mentor	Dr. Corrie Brown, Department of Veterinary Pathology
	Sean O'Rourke	Neuromuscular Activation and Movement Kinematics Exhibited During Sit-to-Stand by Multiple Sclerosis Individuals
	Faculty Mentor	Dr. Kathy Simpson, Department of Kinesiology
Room C	**Talia Bromstad**	In The Field: Understanding Science Through the Book Arts
	Faculty Mentor	Prof. Amanda Burk, Department of Printmaking
	Caitlin Christopher	*Intoxicating Misery*
	Faculty Mentor	Prof. Bala Sarasvati, Department of Dance
	Katelyn Foley	Catching the Zanies: Italian Acting and English Drama
	Faculty Mentor	Dr. Erin Kelly, Department of English
Room D	**Stefann Plishka**	Imagining Constantinople: Imperial Houses of Worship as Symbols of State Ideology
	Faculty Mentor	Dr. Asen Kirin, Department of Art History
	Michael Slade	The Chariot Above the Heavens and the Ladder Upon the Earth: An Exploration of Love in the Writings of Plato
	Faculty Mentor	Dr. Frank Harrison, Department of Philosophy

	Elizabeth Katz	How Has the Gospel of John Been Used to Denigrate the Jews?
	Faculty Mentor	Dr. Wayne Coppins, Department of Religion
Room G	**Lauren Coleman**	Child Care Foundations: A Model for Employer-Based Child Care Subsidies in Athens-Clarke County, Georgia
	Faculty Mentor	Dr. Amy Kay, Department of Child & Family Development
	Catherine Mencher	Food for Thought: A Comprehensive Overhaul of American Food Aid Policy
	Faculty Mentor	Dr. Stacey Mitchell, Department of International Affairs
	Carolyn Crist	News in the Black Belt: Teaching Journalists How to Cover Poverty in Persistently Poor Counties
	Faculty Mentor	Prof. John Greenman, Department of Journalism
Room H	**Corbin Busby, Shelby Jones**	Validity of English
	Faculty Mentor	Dr. Sujata Iyengar, Department of English
	Laura Leidner	Poetic Pedagogy: Teaching Creative Writing at Coile Middle School
	Faculty Mentor	Dr. Melisa Cahnmann-Taylor, Department of Language & Literacy Education
	Jeremy Akin	Answering the Call for Equity, Relevance, and Inclusion: Rethinking the Role of the Disciplinary Alternative Education in the Savannah-Chatham County Public School System
	Faculty Mentor	Dr. Larry Nackerud, School of Social Work
Room I	**Robert Jacques**	Drugs and Deterrence
	Faculty Mentor	Dr. Mark Cooney, Department of Sociology
	Katherine Cherry	Zero-Tolerance Illicit Drug Dependence Policy in the United States Military: A Need for Revision
	Faculty Mentor	Dr. Paul Roman, Department of Sociology
	Milner Owens	The Empowerment of Character Expression Through the Use of Popular Culture in the Novels of Manuel Puig
	Faculty Mentor	Dr. Ángel Nicolás Lucero, Department of Romance Languages
Room J	**Alice Meagher**	Improving the Activity of the Heterologously Expressed Soluble Hydrogenase I from *Pyrococcus furiosus* Through the Modification of the BW25113 (*E. coli* K12) Genome
	Faculty Mentor	Dr. Michael Adams, Department of Biochemistry & Molecular Biology
	Muktha Natrajan	The Role of Integrin Activation in Increased Gliogenesis of Human Neural Stem Cell Cultures
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science

	Vandana Murty	Development of Alternate Sources of Macronutrients for a Sustainable Algal Biofuel System
	Faculty Mentor	Dr. Keshav Das, Department of Biological & Agricultural Engineering

10:10 – 11:00 a.m. First Thesis Roundtable Session

Classic Center, Parthenon Room

Table 1	**Brian Gardner**	Analysis of Pectate Lyase Activity in Pectin-Rich Lignocellulosic Biomass Fermentations
	Faculty Mentor	Dr. Joy Doran-Peterson, Department of Microbiology
	Jean Chi	Wing Morphology, Flight Ability and Immune Measures in Monarch Butterflies
	Faculty Mentor	Dr. Sonia Altizer, Odum School of Ecology
	Calley Mersmann	Thermal Adaptation and Substrate Limitation of Heterotrophic Soil Microorganisms
	Faculty Mentor	Dr. Mark Bradford, Odum School of Ecology
	Amanda Perofsky	Comparing Population Size Estimators for Larval Stream Plethodontids
	Faculty Mentor	Dr. John Maerz, Department of Wildlife
Table 2	**Yu-Chien Cheng**	Towards Generating a *C. elegans* Cell Line: Deregulating the Seam Cell Division Pattern by Inactivating Genes Involved in Cell Differentiation
	Faculty Mentor	Dr. Edward Kipreos, Department of Cellular Biology
	Wei Wang	Differential Regulation of Oxidative and Thermal Stress Tolerance Upon Changes in Levels of O-GlcNAc Modified Proteins *in vivo*
	Faculty Mentor	Dr. Lance Wells, Department of Biochemistry and Molecular Biology
	Neil Pfister	Characterizing RNA-Protein Complexes Involved in Genome Defense in Prokaryotes
	Faculty Mentors	Dr. Michael Terns and Dr. Rebecca Terns, Department of Biochemistry & Molecular Biology
Table 3	**Aileen Thomas**	Human Random Capacities Through Repeated Numeric Sampling
	Faculty Mentor	Dr. Nicole Lazar, Department of Statistics
	Hunter Wilson	8-Chloro-7-hydroxyquinoline and Xanthone Acetic Acid Derivatives as Photoremovable-Protecting Groups with Susceptibility to Two-Photon Excitation
	Faculty Mentor	Dr. Timothy Dore, Department of Chemistry

	Tulsi Patel	Directed Differentiation of Neural Progenitor Cells into Glial Progenitor Cells
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science
	Prashant Monian	Analysis of Phospholipids in Neuronal Tissue Using Electrospray Ionization-Mass Spectrometry
	Faculty Mentor	Dr. Brian Cummings, Department of Pharmaceutical & Biomedical Sciences
Table 4	**Wes Jackson**	From Hills to Plains: Cormac McCarthy's Use of Terrain, Landscape, and Environment

	Faculty Mentor	Dr. Dustin Reichard, Department of Biological Sciences
	Jean Chi	Wing Morphology, Flight Ability, and Immune Measures in Monarch Butterflies
	Faculty Mentor	Dr. Sonia Altizer, Odum School of Ecology
	Amanda Perofsky	Comparing Population Size Estimators for Stream Plethodontids
	Faculty Mentor	Dr. John Maerz, Department of Wildlife

2:30 – 3:45 p.m. Fifth Concurrent Session

Classic Center, Athena Breakout Rooms A, B, C, D, J

Room A	**Christine Akoh**	Cloning and Expression of a *Burkholderia pseudomallei* DNA Fragment Specifying an Adherence Factor
	Faculty Mentor	Dr. Eric Lafontaine, Department of Infectious Diseases
	Diana Murro	Creation of a Transposon Mutant Library in Live Vaccine Strain *Francisella tularensis*
	Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases
	Shruti Suresh	Isolation and Identification of Novel Acidobacteria and Verrucomicrobia from Forest Soil
	Faculty Mentor	Dr. William Whitman, Department of Microbiology
Room B	**Nima Patel**	Georgia Senate Bills 440 and 441: The Effectiveness of the Adult Criminal System as a Deterrent to Juvenile Recidivism
	Faculty Mentor	Dr. Edwin Risler, School of Social Work
	Robert Rosenbleeth	Reducing Binge Drinking Among University of Georgia Students
	Faculty Mentor	Dr. Elaine Weeks, Department of Sociology
	Rocky Cole	Mandatory Impact Fees: A New Growth Management Strategy for Georgia
	Faculty Mentor	Dr. Andrew Carswell, Department of Housing and Consumer Economics
Room C	**Jarrad Rowse**	Characterizing the STE23 ORF
	Faculty Mentor	Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology
	Cleveland Piggott	The Role of Microtubules in the Degradation of Hirano Bodies
	Faculty Mentors	Dr. Marcus Fechheimer and Dr. Ruth Furukawa, Department of Cellular Biology
	Neeraj Sriram	Exclusive Consumption of Sugars as a Biological Means to Convert Lignocellulosic Hydrolysates Effectively
	Faculty Mentor	Dr. Mark Eiteman, Department of Biological & Agricultural Engineering
Room D	**Abby Wong**	Preventative Medicine in Water Supplies: A Remodeling of Disaster Relief
	Faculty Mentor	Dr. Angela Fertig, Department of Health Policy & Management
	Reid Brown, Jessica Sterling	Watershed Land Use Effects on Carbon Processing in Streams
	Faculty Mentor	Dr. Amy Rosemond, Odum School of Ecology

	Jarred Klorfein	Cap and Trade: A Comprehensive Solution to Georgia's Water Problem
	Faculty Mentor	Dr. Todd Rasmussen, Department of Water & Soil Resources
Room J	**Abigail Wilson**	Bolivian Wrestlers in Skirts
	Faculty Mentor	Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors
	Celina Correa	Puerto Rican Feminist Thought: Boricua
	Faculty Mentor	Dr. Doris Kadish, Department of Romance Languages
	Malorie McCloy	Altered Surfaces: Fabric Manipulation and Design
	Faculty Mentor	Prof. Clay McLaurin, Department of Fabric Design

4:00 p.m. Welcome and Opening Session

Classic Center, Athena Ballroom E

Introductions and Welcome	Dr. David S. Williams, Director, Honors Program Dr. Arnett C. Mace, Jr., Senior Vice President for Academic Affairs and Provost
Recognition of CURO Promising Scholars	Dr. Pamela B. Kleiber, Associate Director, Honors Program
Introduction of Keynote Speaker	Bryan Davis, Former CURO Apprentice, BBA/MA Accounting Candidate
Keynote Address ***"Where the Boys Aren't: Sex-Ratio Imbalances and Risky Sexual Behavior"***	Professor Chris Cornwell, Head and Professor, Department of Economics
Excellence in Undergraduate Research Mentoring Awards	Professor Jere Morehead, Vice President for Instruction

5:00 p.m. Poster Presentations

Classic Center, Grand Hall (downstairs)

Poster #1	**Erin Kennedy**	Mandatory Health Insurance: A Necessary Change
	Faculty Mentor	Dr. Audrey Haynes, Department of Political Science
Poster #2	**Rocky Cole, Chris Chiego**	A Season of (Info) Sharing: An Empirical Investigation of Intelligence Reform
	Faculty Mentor	Dr. Loch Johnson, Department of International Affairs

Poster #3	**Al W. Ray, III**	Steamed Ginger Supplementation Reduces Pain Following Eccentric Exercise-Induced Injury
	Faculty Mentor	Dr. Patrick O'Connor, Department of Kinesiology
Poster #4	**Rachel Doyle**	The Effects of Corticosterone on Stress-Induced Weight Loss and Corticotrophin Releasing Factor (CRF) mRNA Expression in the Paraventricular Nucleus of the Hypothalamus (PVN)
	Faculty Mentor	Dr. Ruth Harris, Department of Foods & Nutrition
Poster #5	**Thomas Shaffer**	Heart Rate Monitoring is Superior to Accelerometry as an Estimator of Human Energy Expenditure During Physical Activity
	Faculty Mentor	Dr. James Hargrove, Department of Foods & Nutrition
Poster #6	**Miriam Skiles, Lindsay Jarvis**	Gender and Developmental Differences in Young Children's Autonomy
	Faculty Mentor	Dr. Hui-Chin Hsu, Department of Child & Family Development
Poster #7	**Anne Kimball**	Exercise and Cognition in Overweight Children
	Faculty Mentor	Dr. Jennifer McDowell, Department of Psychology
Poster #8	**Elise Choe**	Social Media Use and Belonging
	Faculty Mentor	Dr. Megan Knowles, Department of Psychology
Poster #9	**David Mitchell, Christina Smith**	Ambient Gender Cue Vigilance in Choosing College Majors
	Faculty Mentor	Dr. Victoria Plaut, Department of Psychology
Poster #10	**Lenae Stansky, Krisztina Varga**	The Development of Directional Understanding in Three- to Five-Year-Old Children
	Faculty Mentor	Dr. Janet Frick, Department of Psychology
Poster #11	**Carla Heyler**	The Effects of Oxytocin on Food Sharing and Cooperation in the Capuchin Monkey (*Cebus apella*)
	Faculty Mentor	Dr. Sarah Brosnan, Department of Psychology
Poster #12	**Rebecca Greenberg**	Decision-Making Strategies of Wild Capuchin Monkey
	Faculty Mentor	Dr. Dorothy Fragaszy, Department of Psychology
Poster #13	**Madison Moore**	Behavioral Changes Following Daily Practice of Saccade Tasks in Schizophrenia
	Faculty Mentor	Dr. Jennifer McDowell, Department of Psychology
Poster #14	**Benjamin Perlow**	The Ideal Religious Experience
	Faculty Mentor	Dr. Leonard Martin, Department of Psychology

Poster #15	**Lauren Doyague, Elizabeth Simpson, Krisztina Varga**	Facial Identity Recognition: Perceptual Narrowing From Infancy Through Adulthood
	Faculty Mentor	Dr. Janet Frick, Department of Psychology
Poster #16	**Jasmine Mathis**	Perceptions About the Implementation of the Georgia Performance Standards in Mathematics
	Faculty Mentor	Dr. Patricia Wilson, Department of Mathematics & Science Education
Poster #17	**Rebecca Roulo**	Natural Prevalence of *Phlebiopsis gigantea* in the Field
	Faculty Mentor	Dr. Sarah Covert, Department of Forest Biotechnology
Poster #18	**Kevin Abney**	Interaction of a Putative Cell-Adhesion Protein from *Anophele gambiae* Larvae Midgut with *Bacillus thuringiensis* Cry 11Ba Endotoxins
	Faculty Mentor	Dr. Michael Adang, Department of Entomology and Department of Biochemistry & Molecular Biology
Poster #19	**Sheena Zhang**	Genetic Effects of Radiation Exposure on *Rana terrestris* Populations from the Chernobyl Exclusion Zone
	Faculty Mentor	Dr. Travis Glenn, Department of Environmental Health Science
Poster #20	**Elizabeth Pollak**	Age-Dependent Susceptibility to *Enterobacter sakazakii* Infection in Neonatal CD-1 Mice
	Faculty Mentor	Dr. Mary Alice Smith, Department of Environmental Health Science
Poster #21	**Akshita Khetarpal, Chris Cornelison, Mopelola Oluwadeire, Puja Bharucha, Zuhha Ashraf, Amyn Lakhani, Hunter Faircloth**	Chicken Pedigree Flocks are the Ultimate Source of *Salmonella* Contaminating Poultry Meat
	Faculty Mentor	Dr. John Maurer, Department of Population Health
Poster #22	**Denise Amoah, Moyo Avize, Gregory Hamilton, Ashley Cornutt, Sima Patel, Nataryana Gowda, Michelle Chua,**	Vertical Transmission of *Salmonella* from Chicken Breeder Birds to Their Progeny Meat Birds Contributes to Most of the Poultry Meat Contamination Observed for *Salmonella*
	Faculty Mentor	Dr. John Maurer, Department of Population Health

Poster #23	**Alexandria Byas**	Determination of the Prevalence of Avian Paramyxovirus-1 in Wintering Populations of Double-Crested Cormorants
	Faculty Mentor	Dr. Kevin Keel, Department of Population Health
Poster #24	**Calley Mersmann**	Thermal Adaptation and Substrate Limitation of Heterotrophic Soil Microorganisms
	Faculty Mentor	Dr. Mark Bradford, Odum School of Ecology
Poster #25	**Sarah Bowden**	West Nile Virus in New York City: Using Birds as an Indicator of Spatio-Temporal Distribution
	Faculty Mentor	Dr. John Drake, Odum School of Ecology
Poster #26	**Melissa Brody**	*Hamelia patens*: A Steady State Resource
	Faculty Mentor	Dr. Ronald Carroll, Odum School of Ecology
Poster #27	**Zach Anderson**	Multicultural Perspectives on Landscape Change
	Faculty Mentor	Dr. Peter Brosius, Department of Anthropology
Poster #28	**Lauren Kelly**	Fibrin Deposition in the Malaria-Infected Placenta: A Disruption in the Balance Between Coagulation and Fibrinolysis
	Faculty Mentor	Dr. Julie Moore, Department of Infectious Diseases
Poster #29	**Jessica Miller**	Determining Genes Required for Virulence in the Opportunistic Intracellular Pathogen *Rhodococcus equi*
	Faculty Mentor	Dr. Mary Hondalus, Department of Infectious Diseases
Poster #30	**Natasha Lee**	The Importance of Specific Genes Within the Cobalamin Region of Mycobacterium Tuberculosis and Their Effect on Virulence
	Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases
Poster # 31	**Joseph Rimando**	Evaluating the Antibody Response to Respiratory Syncytial Virus (RSV) for the Inhibition of the RSV G Protein Interaction with the CX3C Chemokine Receptor
	Faculty Mentor	Dr. Ralph Tripp, Department of Infectious Diseases
Poster #32	**Stephanie Beavers**	SCCmec-Type Classification of Methicillin-Resistant *Staphylococcus aureus* in Horses
	Faculty Mentor	Dr. Susan Sanchez, Department of Infectious Diseases
Poster #33	**Akanksha Rajeurs**	Development of a System to Create Unmarked Mutations in *Mycobacterium tuberculosis*
	Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases
Poster #34	**Opeoluwa Fawole**	Studying the Genetic Diversity of the var2csa Gene
	Faculty Mentor	Dr. David Peterson, Department of Infectious Diseases

Poster #35	**Rachel Nix**	The Effects of Fetal Genomic Expression of TNF-aRI and TNF-aRII in *P. chabaudi chabaudi* Complicated Murine Pregnancy
	Faculty Mentor	Dr. Julie Moore, Department of Infectious Diseases
Poster #36	**Lauren Byrd**	Sequencing and Expression of Infectious Bronchitis Virus Nucleocapsid Protein Gene for Use in an Infectious Clone
	Faculty Mentor	Dr. Mark Jackwood, Department of Population Health
Poster #37	**Josh Sumislawski**	The Neurotrophic Action of Botulinum Neurotoxin
	Faculty Mentor	Dr. Julie Coffield, Department of Physiology & Pharmacology
Poster #38	**Kathryn Turner**	Inhibition of LPA Signaling Pathways by RGS Protein Overexpression in Ovarian Cancer Cells
	Faculty Mentor	Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Sciences
Poster #39	**Logan Davis**	Long-Range Retrograde Neurotrophic Signaling in Mouse Sympathetic Neurons
	Faculty Mentor	Dr. James Franklin, Department of Pharmaceutical & Biomedical Sciences
Poster #40	**Brian Gardner**	Analysis of Pectate Lyase Activity in Pectin-Rich Lignocellulosic Biomass Fermentation
	Faculty Mentor	Dr. Joy Doran-Peterson, Department of Microbiology
Poster #41	**Jennifer Taylor, Poonam R. Patel**	Genetic Duplication and Amplification in the *Acinetobacter baylyi* ADP1 Genome
	Faculty Mentor	Dr. Ellen Neidle, Department of Microbiology

6:15 – 8:00 p.m. Art Gallery Talks

Classic Center, Fire Hall

Introductions	Professor Georgia Strange, Director, Lamar Dodd School of Art Mr. Mark Callahan, Artistic Director, Ideas for Creative Exploration

Visual Arts Presenters

Talia Bromstad	*In The Field*: Understanding Science Through The Book Arts
Faculty Mentor	Prof. Amanda Burk, Department of Printmaking
Jordan Dalton	*Meat Out of the Eater*
Faculty Mentor	Mr. Mark Callahan, Artistic Director, Ideas for Creative Exploration
Brittany Norman	Art & Engineering: A Binocular Vision
Faculty Mentor	Prof. Martijn van Wagtendonk, Department of Studio Foundations
Malorie McCloy	*Altered Surfaces*: Fabric Manipulation and Design
Faculty Mentor	Prof. Clay McLaurin, Department of Fabric Design
Ash Sechler	*Borrowed Building/Search Cycle*
Faculty Mentor	Mr. Mark Callahan, Artistic Director, Ideas for Creative Exploration
Daisy Whelan	*Weaving the Fog*
Faculty Mentor	Prof. Clay McLaurin, Department of Fabric Design

Marilyn Zapf	Jewelry in the Age of Postmodernism
Faculty Mentor	Dr. Mary Pearse, Department of Jewelry & Metalworking

Art exhibit arranged by Mr. Jeffrey Whittle, Gallery Director, Lamar Dodd School of Art

8:00 p.m. Dessert Reception & Awards Ceremony

Classic Center, Fire Hall

Presentation of CURO Summer Research Fellows, CURO Scholars, UGA Libraries Undergraduate Research Awards, and Best Paper Awards	Dr. David S. Williams, Director, Honors Program Ms. Florence E. King, Assistant University Librarian for Human and Director, Miller Learning Center Ms. Deborah Dietzler, Executive Director, UGA Alumni Association

The office of the Senior Vice President for Academic Affairs and Provost and the Honors Program established the Excellence in Undergraduate Research Mentoring Award in 2001. This award recognizes faculty, departments, and programs devoted to outstanding research mentorship of undergraduate students. Awards will be presented at the CURO Symposium Awards Ceremony on Monday, April 6, 2009 at 4:00 p.m. in the Classic Center, Athena Ballroom E.

2009 Awards

Early Career Faculty Award
Dr. Brian S. Cummings, Assistant Professor of Pharmaceutical & Biomedical Sciences
Dr. Anna C. Karls, Associate Professor of Microbiology
Dr. Dawn T. Robinson, Associate Professor of Sociology

2008 Awards

Master Level Faculty Award
Dr. John J. Maurer, Professor of Population Health
Early Career Faculty Award
Dr. Walter K. Schmidt, Assistant Professor of Biochemistry & Molecular Biology
Program Award
Biomedical and Health Sciences Institute

2007 Awards

Master Level Faculty Award
Dr. Timothy Hoover, Associate Professor of Microbiology
Early Career Faculty Award
Dr. Steven Stice, Professor of Animal & Dairy Science

2006 Awards

Master Level Faculty Award
Dr. Patricia Hunt-Hurst, Associate Professor of Textiles, Merchandising & Interiors
Early Career Faculty Award
Dr. Rodney Mauricio, Professor of Genetics
Graduate Student Award
Christopher Anderson, PhD candidate in Ecology
Graduate Student Recognition
Dawn Holligan, PhD student in Plant Biology

2005 Awards

Faculty Awards
Dr. Gary Barrett, Odum Professor of Ecology
Dr. Sidney Kushner, Professor of Genetics
Department Award
Department of Cellular Biology

2004 Award

Faculty Award
Dr. William S. Kisaalita, Associate Professor of Biological & Agricultural Engineering

2003 Awards

Faculty Award
Dr. Jody Clay-Warner, Assistant Professor of Sociology
Department Award
Department of Microbiology
Dr. Duncan Krause, Department Head
Dr. Timothy Hoover, Undergraduate Coordinator
Program Award
The Pratt Laboratory of Plant Genomics and Bioinformatics
Dr. Lee H. Pratt, Professor
Dr. Marie-Michèle Cordonnier-Pratt, Senior Research Scientist

2002 Awards

Faculty Awards
Professor William D. Paul, Jr., Professor of Art
Dr. Katherine Kipp, Associate Professor of Psychology
Faculty Recognition
Dr. Susan Sanchez, Assistant Professor of Veterinary Medicine
Department Award
Department of Biochemistry & Molecular Biology
Dr. J. David Puett, Department Head
Program Award
"Physics Beyond the Boundaries": National Science Foundation, REU Program
Dr. Loris Magnani, Principal Investigator, Professor of Physics and Astronomy
Dr. Heinz-Bernd Schuttler, Professor and Department Head of Physics and Astronomy
Dr. Jonathan Arnold, Professor of Genetics
Dr. Susmita Datta, Professor, Georgia State University
Dr. David Logan, Professor, Clark Atlanta University
Dr. William Steffans, Professor, Clark Atlanta University

2001 Awards

Faculty Award
Dr. Marcus Fechheimer, Professor of Cellular Biology

Faculty Recognition
Dr. David MacIntosh, Associate Professor of Environmental Health Sciences
Dr. Dean Rojek, Associate Professor of Sociology

Department Award
Genetics Department
Dr. John MacDonald, Department Head and Professor

Program Award
Savannah River Ecology Laboratory
Dr. Paul Bertsch, Director

Graduate Student Reviewers for CURO 2009 Symposium

William Abney	Comparative Literature
Ashley Barr	Sociology
Rebecca Cheney	Adult Education, Gerontology
Sarah Craven	Microbiology
Patti Davis	Social Psychology
Jim Gigantino	History
Stephanie Hazel	Higher Education
Erik Jacobson	Math Education
Lisa Kanizay	Plant Biology
Tyler Kartzinel	Ecology
Anna McKee	Forestry & Natural Resources
Sharon O'Kelley	Math Education
Aaron Petrey	Biochemistry & Molecular Biology
Natalie Pope	Social Work
David Porcaro	Educational Psychology, Instructional Technology
Sarah Reiff	Cellular Biology
Katherine Robbins	Food Science
Laura Singletary	Math Education
Gaston "Chip" Small	Ecology
Shannon Whitlock	English

Faculty Reviewers for Best Paper Awards

Dr. Harry Dailey	Professor, Biochemistry & Molecular Biology, Microbiology Director, Biomedical and Health Sciences Institute
Dr. Margaret E. Holt	Professor Emerita, Adult Education
Dr. Sylvia Hutchinson	Professor Emerita, Higher Education, Reading Education and Coordinator, Emeriti Scholars
Dr. Douglas A. Kleiber	Professor, Counseling Psychology
Dr. Richard Siegesmund	Professor, Art Education
Dr. Frances Teague	Professor, English
Dr. Kalpen Trivedi	Director, UGA at Oxford Study Abroad Program

Graduate Student Reviewers for Best Paper Awards

Will Abney	Comparative Literature
Patti Davis	Social Psychology
Stephanie Hazel	Higher Education
Tyler Kartzinel	Ecology
Anna McKee	Forestry & Natural Resources
Sharon O'Kelley	Math Education
David Porcaro	Educational Psychology, Instructional Technology
Sarah Reiff	Cellular Biology
Laura Singletary	Math
Shannon Whitlock	English

Reviewers for Excellence in Undergraduate Research Mentoring Awards

Dr. Jerry Legge	Professor and Associate Dean, School of Public & International Affairs
Dr. Timothy R. Hoover	Associate Professor and Associate Department Head, Microbiology, Franklin College of Arts & Sciences
Dr. Patricia Hunt-Hurst	Professor and Department Head, Textiles, Merchandising & Interiors, College of Family & Consumer Sciences
Dr. Sidney Kushner	Distinguished Research Professor, Genetics, Franklin College of Arts & Sciences
Dr. Susan Sanchez	Associate Professor, Infectious Diseases, College of Veterinary Medicine
Dr. Walter Schmidt	Assistant Professor, Biochemistry and Molecular Biology, Franklin College of Arts & Sciences
Dr. Steven Stice	Georgia Eminent Scholar and Professor, Animal & Dairy Science, College of Agricultural & Environmental Sciences

Reviewers for CURO Summer Research Fellowships

Dr. Wyatt Anderson	Alumni Foundation Distinguished Research Professor, Genetics
Dr. E. M. Beck	Meigs Professor, Sociology
Dr. Katarzyna Jerzak	Associate Professor, Comparative Literature
Dr. Michael Roden	Professor and Department Head, Geology
Dr. Regina Smith	Associate Vice President, Office of Vice President for Research
Dr. Frances Teague	Meigs Professor, English
Dr. Juergen Weigel	Professor, Microbiology

CURO Advisory Board

Dr. Wyatt Anderson	Alumni Foundation Distinguished Professor, Genetics
Dr. E. M. Beck	Professor, Sociology
Dr. Gary Bertsch	Director and University Professor, Center for International Trade & Security
Dr. Art Dunning	Vice President for Public Service & Outreach
Dr. Maureen Grasso	Dean, Graduate School
Dr. David C. Lee	Vice President for Research and Associate Provost
Dr. Barbara McCaskill	General Sandy Beaver Teaching Professor, English
Prof. Jere Morehead	Vice President for Instruction
Dr. David Saltz	Department Head and Associate Professor, Theatre & Film Studies
Dr. Susan Sanchez	Associate Professor, Athens Diagnostic Laboratory, College of Veterinary Medicine
Dr. Fausto Sarmiento	Assistant Professor, Geography
Dr. Steven Stice	Georgia Eminent Scholar and Professor, Animal & Dairy Science
Dr. Kecia Thomas	Professor, Psychology and Senior Advisor to the Dean of Franklin College of Arts & Sciences
Dr. Katharina Wilson	Professor, Comparative Literature
Ms. Adele Handy	Undergraduate Student
Ms. Courtney Thomas	Undergraduate Student
Ms. Tulsi Patel	Undergraduate Student

Ex Officio

Dr. David S. Williams	Director, Honors Program
Dr. Pamela B. Kleiber	Associate Director, Honors Program

2008-09 CURO Gateway Seminar Faculty

Dr. William Kretzschmar	Professor, English, Linguistics
Dr. E. M. Beck	Professor, Sociology
Dr. Marcus Fechheimer	Professor, Cellular Biology
Mr. Mark Callahan	Artistic Director, Ideas for Creative Exploration
Dr. Katarzyna Jerzak	Associate Professor, Comparative Literature
Dr. Paul A. Schroeder	Professor, Geology
Dr. John Maerz	Assistant Professor, Forestry & Natural Resources
Dr. Susan Sanchez	Associate Professor, Infectious Diseases

Thesis Roundtable Conveners

Dr. William Flatt	D. W. Brooks Distinguished Professor Emeritus, Foods & Nutrition and Emeriti Scholar
Ms. Jessica Hunt	Major Scholarships Coordinator, Honors Program
Dr. Sylvia Hutchinson	Professor Emerita, Higher Education, Reading Education and Coordinator, Emeriti Scholars
Mr. Matt Jordan	Administrative Associate, Honors Program
Dr. Pamela B. Kleiber	Associate Director, Honors Program
Dr. M. Louise McBee	Dean of Women Emerita and Emeriti Scholar
Ms. Maria de Rocher	Program Coordinator, Honors Program
Mr. Martin Rogers	Coordinator of Courses & Advising, Honors Program
Dr. Ronald D. Simpson	Professor Emeritus, Higher Education and Emeriti Scholar

Interaction of a Putative Cell-Adhesion Protein from *Anopheles gambiae* Larvae Midgut with *Bacillus thuringiensis* Cry 11Ba Endotoxins

Kevin Abney
Dr. Mike Adang, Department of Entomology and Department of Biochemistry & Molecular Biology, University of Georgia

Mosquitoes in the genus *Anopheles* vector malaria, a devastating disease, especially in Africa. This research investigated a protein in the gut of mosquito larvae that is a key to understanding how an insecticidal protein of *Bacillus thuringiensis* (*Bt*) kills mosquito larvae. With this information we may be able to make *Bt* more effective in controlling mosquitoes. The protein I am investigating is called AgPCAP for *Anopheles gambiae* putative cell-adhesion protein. AgPCAP is a member of a protein family called cadherins. To investigate interactions between AgPCAP and *Bt* Cry 11Ba, the cDNA encoding PCAP protein was divided into parts called CR 14-MPED and TM-CYTO and these protein parts were expressed in the bacterium *Escherichia coli*. The CR 14-MPED protein was found to bind to the *B. thuringiensis* Cry 11Ba toxin with high affinity, while the PCAP TM-Cyto fragment showed no specific binding. Bioassays have also shown that CR 14-MPED inhibited Cry 11Ba toxicity against the 4th instar *A. gambiae* larvae. These results, along with ability of the CR-14 MPED fragment to bind to vesicles in the midgut (BBMV) of larval *A. gambiae*, are evidence that the CR 14-MPED region of PCAP has a strong attraction to the toxin and that the PCAP protein is probably a receptor for the *Bt* toxin in *A. gambiae* larvae. This information will be helpful in designing novel *Bt* proteins for mosquito control.

Answering the Call for Equity, Relevance, and Inclusion: Rethinking the Role of the Disciplinary Alternative Education in the Savannah-Chatham County Public School System

Jeremy Akin – Roosevelt@UGA
Dr. Larry Nackerud, School of Social Work, University of Georgia

In light of the Savannah-Chatham County Public School System's mission statement, "From school to the world: *All* students prepared for productive futures," questions as to the thoroughness and equity with which support is shown to students enrolled in its disciplinary alternative education program must be addressed. The Scott Alternative Learning Center-the system's only disciplinary alternative school-faces increasing difficulty in its ability to sustainably provide its students with a quality education and atmosphere for behavioral growth due to (and evidenced by) problems associated with dramatic system-wide increases in punitive referrals, rapid program overcrowding, high truancy rates, and top levels of juvenile prison placements. In addition, the school system's recent adoption of zero-tolerance discipline policies, which suspend or expel students for misbehavior that would have previously merited less severe repercussions, reveals further grounds for concern. From a careful review of the literature, on-site visits, and analysis of official school system records, this policy proposal details specific reforms which employ existing institutions and city partnerships for the benefit of both students at the Scott Center and the wider Savannah community. Best practices of similar disciplinary alternative schools are also considered in a Savannah-appropriate context. Such revitalized investment in the lives of students at the Scott Center will positively impact system accountability, levels of juvenile delinquency, graduation rates, and the quality of Savannah's local workforce.

Cloning and Expression of a *Burkholderia pseudomallei* DNA Fragment Specifying an Adherence Factor

Christine Akoh – CURO Apprentice
Dr. Eric Lafontaine, Department of Infectious Diseases, University of Georgia

Burkholderia pseudomallei (*Bp*) is a Gram-negative bacterium which causes the infectious disease melioidosis in humans. *Bp* is endemic to parts of Southeast Asia and Northern Australia and can be readily isolated from wet soils. Melioidosis is difficult to diagnose and *Bp* is intrinsically resistant to most antibiotics

complicating treatment considerably. The infectious dose of *Bp* is not known, but experiments with various animal models have demonstrated that the lethal dose is very low. For these reasons, the organism has been classified as a Category B Select Agent of bioterrorism, and there is an urgent need to develop a vaccine to protect against *Bp*. Previous studies by our laboratory suggest that multiple proteins of *Bp* mediate adherence to respiratory epithelial cells. Adherence is a crucial step in pathogenesis by most infectious agents because it leads to colonization. The purpose of our research is to evaluate the vaccinogenic potential of *Bp* adherence proteins. My research project focuses on one adherence factor designated BoaC. A DNA fragment specifying a large portion of BoaC was amplified from the genome of *Bp* strain 1026b. We are currently trying to clone this PCR product into the Hind III and Pac I sites of the plasmid pETcoco-1. Preliminary experiments indicated that the cloning was unsuccessful. Once we successfully clone the BoaC fragment in pETcoco-1, we will purify the recombinant protein (via a six histidine affinity tag) and test its immunogenicity in mice. This work will further our goal of developing potential vaccine candidates to protect against *Bp*.

Vertical Transmission of *Salmonella* from Chicken Breeder Birds to Their Progeny Meat Birds Contributes to Most of the Poultry Meat Contamination Observed for *Salmonella*

Denise Amoah, Moyo Avize, Gregory Hamilton, Ashley Cornutt, Sima Patel, Nataryana Gowda and Michelle Chua
Dr. John Maurer, Department of Population Health, University of Georgia

Salmonella is one of the leading causes for food illnesses in the world. Poultry meat and eggs have been implicated in many foodborne outbreaks. Within poultry companies, *Salmonella* can be spread to consumable, meat birds either through horizontal, direct, or indirect contact with contaminated environment, or vertical transmission, where *Salmonella* is transmitted from the parent breeder birds to their progeny meat birds. We believe that vertical transmission in poultry companies contributes to most of the *Salmonella* contamination of poultry meat. *Salmonella* was isolated from pullet chicken farms (reproductively, immature breeder birds), broiler-breeder chicken farms (reproductive breeder birds), and broiler chicken (meat birds) farms, which included the environment, the hens and broiler chickens themselves. We used pulsed field gel electrophoresis (PFGE) in this study to tie the *Salmonella* isolated from the chicken carcass back to the broiler, broiler-breeder farm, or pullet farms. PFGE is the standardized protocol used by the CDC to identify outbreaks by matching bacterial DNA fingerprints. Our results indicate that *Salmonella* strains from chicken carcasses matched with *Salmonella* isolated from the pullet or broiler-breeder farms. However, we also observed matches only between chicken carcasses and broiler farms. Based on the evidence presented, we observed both vertical and horizontal transmission of *Salmonella* within a poultry company. To reduce chicken carcass contamination of *Salmonella* will require some intervention strategy applied at both the broiler-breeder and broiler level.

Multicultural Perspectives on Landscape Change

Zach Anderson – CURO Summer Fellow
Dr. J. Peter Brosius, Department of Anthropology, University of Georgia

The ecological and cultural landscapes in which each of us lives shape our personal identity and sense of place. As these landscapes change over time, our sense of identity and place are also changed. This research was undertaken as a multi-sited, non-structured case study of traditional villages in Fiji and Brazil. Both study areas have seen dramatic landscape changes over recent decades. The goal of this research was to document changes in the way that residents think about themselves and their land. In addition to non-structured interviews and community interaction, I conducted a review of research in both study areas. In both areas there has been work done by community members to create community-based conservation

organizations designed to protect both the local environment and traditional culture. These groups, specifically the Waitabu Marine Park in Fiji and the Projecto Saude e Alegria in Brazil, have been relatively successful at their goals by allowing local people to seek alternative means of income while maintaining traditional ways of life and preserving landscapes; however, the impact they have had on community members' sense of place and connectedness to their landscape has differed. This study is valuable to global conservation because it explores the factors that influence people's connectedness with their landscape. In studying these factors, the goals are to understand why locally managed conservation works well in some areas but not in others and to use this knowledge to improve the design of conservation projects in the future.

SCCmec-Type Classification of Methicillin-Resistant *Staphylococcus aureus* in Horses

Stephanie Beavers
Dr. Susan Sanchez, Department of Infectious Diseases, University of Georgia

Staphylococcus aureus, a ubiquitous, gram-positive bacterium, colonizes the skin of many species, generally without causing infection; methicillin-resistant *Staphylococcus aureus* (MRSA), however, can cause severe infections in both humans and animals. The mecA gene, located on the staphylococcal chromosomal cassette (SCC*mec*) of *S. aureus*, encodes for resistance to beta-lactam antibiotics and has become increasingly prevalent in *Staphylococcus* species in recent years. From 1995 to 2003, when MRSA, particularly SCC*mec* type IV, was emerging as a community-acquired pathogen in humans in the United States, 167 equine isolates of *S. aureus* from various infection sites were collected in Georgia and Kentucky. As horses often live in close contact with humans, the emergence of *SCCmec* types in equine MRSA infections may reflect similar trends as those observed in humans; thus, polymerase chain reaction (PCR) analysis was performed on these samples to investigate possible correlations between the rising numbers of equine and human MRSA infections. Seventy samples tested positive for the mecA gene and were then classified by SCC*mec* type. The resulting data suggest that SCC*mec* type IVd has predominated in the equine populations of both Kentucky and Georgia for several years. As suspected, the emergence of SCC*mec* type IVd MRSA in the equine population between 1995 and 2003 appears to closely mirror the increasing prevalence of SCC*mec* type IV observed in humans. These findings hold important implications for veterinarians and may provide valuable insight for the study of zoonotic transmission of MRSA to the individuals who work and live closely with these animals.

Determinants in the Localization of Telomerase to Telomeres

Matthew Belcher – CURO Summer Fellow
Dr. Michael Terns, Department of Biochemistry & Molecular Biology, University of Georgia

Due to the unidirectional nature of DNA polymerase, linear eukaryotic chromosomes become shorter with each round of DNA replication and cell division. This shortening is counteracted by telomerase, which when activated can confer an unlimited capacity for cell division. While telomerase is not active in most human somatic cells, it is activated in over 90% of cancers, immortalizing the cells. In cancer cells, we have found that the activity of telomerase is restricted to S phase of the cell cycle through regulated trafficking of two telomerase components, human Telomerase RNA (hTR) and human Telomerase Reverse Transcriptase (hTERT).[1] To better understand the recruitment of telomerase to telomeres, I observed the localization of the two components of telomerase in cells expressing specific mutants of the protein component hTERT. I did this by transfecting telomerase positive human cervical cancer cells with the TERT mutants along with the second telomerase component, hTR. We then labeled the hTR, hTERT, and telomeres with fluorescent markers and examined them using fluorescence microscopy and compared to cells transfected with wild type hTERT and hTR. The telomerase components in the cells transfected with mutants displayed localization phenotypes different from the wild

type cells, suggesting that the mutated regions of the hTERT protein are important for the localization of the telomerase components to each other and to their site of action, the telomeres.

[1] Tomlinson, R.L., Ziegler, T.D., Supakorndej, T., Terns, R.M., and Terns, M.P. (2005) Cell cycle regulated trafficking of human telomerase to telomeres. *Molecular Biology of the Cell*, 17(2):955-65.

Modeling HLHS: Living with Half a Heart

Robert Bennett
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

Hypoplastic Left Heart Syndrome (HLHS) is a mutation resulting in the underdevelopment of the left side of the heart, including the aorta, aortic valve, left ventricle and mitral valve, leaving it unable to circulate blood effectively. Newborns may show no symptoms at first, but will soon have serious medical problems when the ductus arteriosus closes, with death ensuing if no treatment is available. However, HLHS can be treated effectively by a series of palliative surgeries, the first of which is an operation to put in place a right ventricle-pulmonary artery (RV-PA) shunt, known as the Norwood procedure, and the last of which being a total cavopulmonary connection, known as a Fontan operation. Currently, there are not any working models of a HLHS heart or of a heart in any phase of recovery. Therefore, the purpose of this study was to create a working computer model for the atrial pressures of a normal heart, a HLHS heart, and a heart in various phases of recovery. The model is an extension of the 1997 Hannon and Ruth STELLA heart model. A key feature of our model is the incorporation of the Hogkin-Huxley action potential model to control the heart beat. With our model, physicians and scientists can better understand the conditions of HLHS, enabling the creation of better treatment.

Novel Enzyme

Whitney Boland
Dr. Joy Doran-Peterson, Department of Microbiology, University of Georgia

Paenibacillus amylolyticus C27 was isolated from the hindgut of *Tipula abdominalis* and found to produce lignocellulose-degrading enzymes. A library was constructed with C27 genomic DNA for heterologous expression of biological characteristics in *Escherichia coli* to identify genes encoding pectinases, xylanases, and cellulases. Pel B, the gene discovered, encodes a 392 amino acid protein which is a novel pectinase. Pel B is an unusual pectate lyase that is able to breakdown highly methylated pectin, as well as polygalacturonate. Although Pel B showed the most activity on polygalacturonic acid, it was still able to obtain 26% and 3.5% of its maximum activity on 8.50% and 90% methylated pectin, respectively. The optima were pH 9.5, 55°C, and 0.5 mM CaCl2, and CaCl2 was required for the enzymatic activity. Pel B is a subclass of the pectate lyase family 1 and shows no significant similarity to any known enzyme. It shows highest identity of only 27% to pectate lyase of *Thermotoga maritime* MSB8. The degradation of pectin-rich sugar beet pulp by Pel B was demonstrated by measuring the number of small chain oligogalacturonides. In order to investigate the use of Pel B in lignocellulose fermentations, *E. coli* strain JP29 was constructed using ethanologen *E. coil* LY40A expressing Pel B on a plasmid, and the production of ethanol will be quantified to demonstrate the use of Pel B in lignocellulose biomass conversion to ethanol fuel.

West Nile Virus in New York City: Using Birds as an Indicator of Spatio-Temporal Distribution

Sarah Bowden
Dr. John Drake, Odum School of Ecology, University of Georgia

West Nile Virus (WNV) first appeared in the United States in New York City in 1999 and has since then spread to almost every contiguous state. WNV has become endemic in the city of New York and continues to pose a health threat to the area. This project uses the distribution of WNV sero-positive dead birds to determine 1) what landcover types are positively or negatively associated with WNV positive bird

distribution, 2) which environmental covariates, such as temperature, rainfall, and elevation, significantly influence the distribution of WNV positive birds, and 3) what combination of these factors can be used to form an early warning system for WNV outbreaks in New York City. The landcover analysis was performed using a Chi-squared test comparing each of 11 landcover types. We found that significantly more WNV positive birds were reported in low-intensity developed areas and wetlands than were expected, and significantly less were reported in high-intensity developed areas than were expected. The covariate analysis will involve the use of boosted regression trees, which will show the relative influence of each environmental factor on the spatio-temporal distribution of WNV positive birds. These analyses will allow us to combine significant spatial and temporal covariates to provide an early warning system for New York City based on when and where outbreaks have occurred in previous years. Such a system would not only help prevent human infection in New York City, but could also be applied to other highly urbanized areas in the United States.

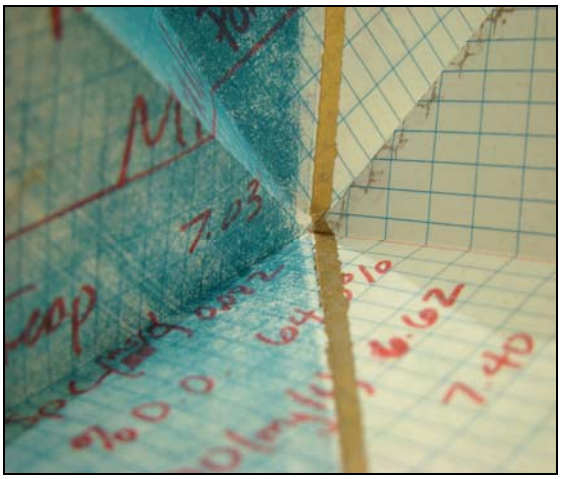
***Hamelia patens*: A Steady State Resource**

Melissa Brody – CURO Summer Fellow
Dr. Ronald Carroll, Odum School of Ecology, University of Georgia

Hamelia patens, a steady state floral resource, is found interspersed within sustainable shade-grown coffee (*Coffea arabica*) farms. Due to *H. patens'* continuous flower production, it has the potential to play a crucial role in the biodiversity conservation of its pollinators, predominantly native bees and hummingbirds. Most of these bees also use nectar and pollen from coffee flowers, but due to short-lived coffee flower production, the constant availability of *H. patens* floral resources may be important for maintaining these pollinators within coffee plantations. To investigate the impact of a steady state floral resource on pollinator communities, bee and hummingbird abundance and species richness indices were tracked on two types of farms, some with a rich resource patch of *H. patens* (10+ individuals) and some without a rich resource patch of *H. patens* (1 individual). Previous research suggests that farms with rich resource patches of *H. patens* will have greater diversity and abundance of pollinators than on farms without *H. patens.* In San Luis de Monteverde, Costa Rica, mobile potted basil plants and hummingbird feeders were used to evaluate differences in the abundance and species richness of bees and hummingbirds on these two types of farms. In concordance to my predictions, results show that both bee abundance and diversity were greater on farms with *H. patens.* However, hummingbird abundance was greater on farms without *H. patens* and there was no difference in hummingbird diversity between the two farms. This result may differ from our predictions because large foraging ranges, such as those of hummingbirds, may be resistant to temporally stable resources. Because *H. patens* does have a positive impact on bee pollinator communities, steady state floral resources can be useful for crop production, land management practices, and biodiversity conservation.

***In The Field*: Understanding Science Through The Book Arts**

Talia Bromstad
Prof. Amanda Burk, Department of Printmaking, University of Georgia



The work I find most fascinating is that of scientists, as it tends to remain a large mystery to me, a student of the fine arts. I recognize the importance of what these people learn and do, but I know that, ultimately, it is a field I will

never completely understand. It is with this in mind that I am exploring the idea of creating artwork that begins with the tools and artifacts of the world of science. More specifically, I am taking the field and lab books of students and professors of science and deconstructing them, reducing them to their basic parts. The calculations and notations within the books were once essential and significant—albeit cryptic to me—but without their bindings and order their meaning is erased, thus reducing them to their inherent visual structure. I am interested in how the physical remnants of the mental process become an abstract field of mark-making, and it is this field that I respond to, reworking and building upon it until I have reconstructed the journal in a new fashion that combines the mystery of the science with my attempts to understand it. The finished product is also a field book, but it is completely transformed; choices were made based upon visual aesthetics rather than facts and practicality. Throughout the process, I am reminded of the impact science has on how we perceive the world around us, but also of the impact art has on how we understand that science.

Watershed Land Use Effects on Carbon Processing in Streams

Reid Brown and Jessica Sterling
Dr. Amy Rosemond, Odum School of Ecology, University of Georgia

Detrital carbon in the form of dead leaves and wood is a significant food resource in aquatic ecosystems. Breakdown, or processing, of carbon affects energy flow to higher trophic levels. Land use changes such as urbanization result in increased runoff of nutrients and toxicants to streams, as well as alter hydrology and increase temperatures, which can affect microbial processing of carbon. The effects of urbanization on carbon processing (+ or -) have been mixed in other studies, as overriding factors may be land-use specific. Our study tested whether carbon processing rates were different among streams that differed in watershed urbanization. We measured breakdown and associated microbial respiration rates across an urban land use gradient. Eleven sites were chosen on six streams in Clarke County, Georgia, USA. Sites were classified as urban, suburban, industrial, or forested based on surrounding land use and impervious surface cover. Strips of white oak (*Quercus alba*) veneer were fixed to the streambed at each site. Veneers were collected at 50, 95 and 160 days after deployment. At each collection, rates of microbial respiration and ash-free dry mass (AFDM) were measured to quantify microbial activity and wood breakdown rates. Data will be analyzed using ANCOVA with temperature as a covariate. Initial results indicate that microbial respiration and breakdown rates are greatest at the suburban sites. Since rates of breakdown and respiration indicate the rate at which carbon is transformed, mobilized, and made available to other organisms, our results suggest that watershed urbanization affects important ecosystem functions in streams.

Validity of English

Corbin Busby and Shelby Jones
Dr. Sujata Iyengar, Department of English, University of Georgia

As an undergraduate major, English literature is relatively new. As the "vernacular," the English language and literature written in it has suffered historically from comparison with classical literature; not until the late nineteenth century did universities begin to consider English literature a subject worthy of academic study, and even today critics on both the right and left of the political spectrum question its value within the university (e.g., Gerald Graff, *Professing Literature*; Michael Bérubé, *What's Liberal about the Liberal Arts*). On the one hand, English departments across the United States have inherited the responsibility of cultivating individuals who will become responsible citizens, citizens who will then represent the opinions, ideas, or thoughts of their education and who will spread this cultural development throughout their communities, states, and nation. On the other hand, such results are intangible, unquantifiable, and only elliptically lucrative. Writer-scholars such as Matthew Arnold, Percy Shelley, and David Lodge have, in the past, defended the role of

literature and the arts in society and students' exposure to the canon of art and culture. But because of recent national budget cuts, universities have been pressured to decide which departments to cut, and right-wing critics have challenged the English department specifically concerning "queer theory" and "feminism." An argument to defend these areas of criticism, specifically from two English students' points of view, is therefore necessary. Many defenders of literature describe a future in which the creators of art and their empathizers are uniquely able to understand how to interact with and interpret society. As Bérubé argues, modern English education requires an understanding of the minority (because of literature's capacity to make us empathize with other minds), and our study traces the variety of efforts and pressures that pit this understanding against traditional conceptions of the canon of literature. Our paper reminds us that a cohesive population depends upon opposing voices. Our study therefore emphasizes literature that celebrates the culture and life of a variety of minority groups and the ability of the story to forge relationships. We will argue that English literature's ability to suggest various meanings to life and concentrate upon the interactions between people rises above the discrimination it receives within the academic world. This attribute, what the poet John Keats called "negative capability," is what makes the study of English literature essential and valid as an option for all undergraduates.

Determination of the Prevalence of Avian Paramyxovirus-1 in Wintering Populations of Double-Crested Cormorants

Alexandria Byas
Dr. Kevin Keel, Department of Population Health, University of Georgia

Virulent Newcastle disease (VND), caused by certain strains of avian paramyxovirus serotype-1 (APMV-1), has resulted in significant mortality among breeding populations of double-crested cormorants (*Phalacrocorax auritus*). Strains of virus causing VND are actively excluded from domestic poultry due to the severe economic impacts. Virulent strains have been isolated from cormorants wintering in Savannah, Georgia, in contradiction to negative results produced by a survey of cormorants from Alabama, Florida, and Mississippi. The goals of this research are to further expand the surveillance of cormorants for APMV-1 and to compare any isolates obtained to those previously described. It is hypothesized that the prevalence of APMV-1 carriers among wintering cormorants will vary proportional to the severity of outbreaks in the previous summer. Viruses will be isolated by inoculating embryonated chicken eggs with cloacal swabs from cormorants. Hemagglutinating activity assays will be used to quantify the presence of the virus, and isolated viruses will be identified using polymerase chain reaction assays with sequencing of the products. These methods amplify the virus, giving this approach higher sensitivity than the previous study. Higher sensitivity to the virus is expected to increase the ability to yield positive results. Environmental samples of voided feces have been collected from the Savannah site. Additional samples will include cloacal swabs from cormorants actively collected for this project, cormorants killed through depredation permits, and voided feces. As carriers of APMV-1, cormorants potentially serve as a source of virus transmission to domesticated poultry flocks with the possibility of major economic consequences.

Sequencing and Expression of Infectious Bronchitis Virus Nucleocapsid Protein Gene for Use in an Infectious Clone

Lauren Byrd
Dr. Mark Jackwood, Department of Population Health, University of Georgia

This project coincides with a larger goal of developing a viral infectious clone for infectious bronchitis virus (IBV) a coronavirus that causes a highly infectious upper-respiratory disease in commercial chickens. An infectious clone is used to recreate infectious virus using nucleic acids in the laboratory. Infectious clones are easily manipulated and thus are useful in the study of viral processes and infection. The purpose of this research is to clone and verify the genetic sequence of the nucleocapsid gene of

IBV and to express that protein in cell culture. The nucleocapsid protein is necessary to protect the viral RNA obtained from the infectious clone so that the virus can be regenerated. The methods outlined below were designed to successfully generate the nucleocapsid protein for use in rescuing the IBV infectious clone. Reverse transcriptase polymerase chain reaction (RT-PCR) is a method for synthesizing and generating (amplifying) many copies of DNA from an RNA template. The nucleocapsid gene from the Mass 41 strain of IBV was amplified using RT-PCR, inserted into a bacterial plasmid (TOPO vector), and transformed into *Escherichia coli* cells. The nucleocapsid gene in the TOPO vector was sequenced using specifically designed primers to verify the integrity and orientation of the gene within the plasmid, which is important for subsequent expression of the nucleocapsid protein. A continuous cell line (293T cells) will be used to express the nucleocapsid protein in the laboratory. An immunofluorescent assay using antibodies directed against the nucleocapsid protein will verify protein expression in the cells. Successful expression of the nucleocapsid protein is the first step in regenerating IBV from an infectious clone.

Changes in Cooking and Eating Practices of Griffin, Georgia

Kelli Canterbury – CURO Apprentice
Dr. William Kretzschmar, Jr., Department of English, University of Georgia

As Southern culture undergoes change due to urbanization, it is important to note the differences between aspects of today's Southern lifestyle and the older traditions and customs. The Linguistic Atlas Program provides linguistic data from all areas of the United States, with interviews that contain cultural information concerning practices of Americans from the late nineteenth century through the late twentieth century. In the interest of time, I have narrowed my focus to the cooking and eating practices of Griffin, Georgia, a Southern mill town that is beginning to move from a rigid social structure containing mainly mill villagers and farmers to a structure that contains more commuter workers and townspeople. To provide modern perspective, approximately eight current Griffin residents are interviewed and tape-recorded about their culinary habits. Then the data are compared to the Atlas Project's Griffin, GA interviews from the 1970s. These residents are between the ages of 35 and 80 so that they may attest to changes that have occurred in diet over time, as well as provide personal accounts of how changes in the social structure of Griffin have affected their culinary habits.

Dispersion of Carbon Nanotubes in Aqueous Solution

Meagan Cauble
Dr. Marcus Lay, Department of Chemistry, University of Georgia

The protozoan parasite, *Ophroycystis elektroscirrha*, infects monarch butterflies (*Danaus plexippus*). Parasite infection reduces fitness and longevity in monarch butterfly hosts, with higher parasite loads resulting in shorter host life spans. Because high infection levels (i.e., high parasite density) cause high virulence within the host, we tested if high infection loads are also advantageous to the parasite through increased transmission. Monarch larvae were infected with various doses of parasites and reared to adulthood, and parasite spores on milkweed leaves and eggs were counted. Results showed that heavily infected monarchs transmitted more spores onto leaves and eggs than lightly infected monarchs. When females laid eggs, they also transmitted more spores onto leaves than when they did not lay eggs. Spore counts taken from two dates did not significantly differ, suggesting that once a host is infected, the parasite can be transmitted over a certain time interval without decreasing in number. These results suggest that parasites require a high level of infection to transmit most effectively, and that host health deterioration is an unavoidable cost to parasite survival. This study supports a long-held theory in evolutionary biology that parasite virulence can evolve as a trade-off of parasites optimizing their fitness.

SONAR and Art: The Application of Sound to Underwater Sculpture

Daniel Cellucci
Prof. Ralph Brown, Department of Sculpture & Studio Foundations, University of Georgia

While the use of the sound sculpture in contemporary art has existed since at least the beginning of the twentieth century, the application of SONAR, in its use as an audio and visual medium, has been largely ignored. The attempt of this research will be first to engineer an effective method of extracting and translating the audio data collected by the SONAR device, and second to apply this data in a meaningful way in the creation of a visual image. This will be accomplished by extracting the raw data from the collection device and converting them into an easily parsed data format. Additionally, special importance will be placed on the transformation of this audio data into sound that properly mirrors the image being displayed. That is, to create both a visual image as well as an algorithmically generated unique soundtrack for the subject. As the current method of displaying the particular type of SONAR data being collected for the research require proprietary programs, offering a universally recognizable translation of this data will be valuable for not only those wishing to use SONAR data for future artistic projects but also researchers who use the data in their own investigations.

Use of Cholera as a Metaphor in *Death in Venice*: Health Administrational Aspects and Gustav Aschenbach's Journey

Agni Chandora
Dr. Frances Teague, Department of English, University of Georgia

This paper explores the relationship between the changes enacted by the deadly, widespread nature of cholera and the use of cholera as a metaphor in the novella *Death in Venice* to parallel the main character's moral decline. By examining the European history of government involvement in public health, one gains better insight into the historical context of Mann's time, the early part of the twentieth century. Additionally, close inspection of the novella's text and literary articles suggested multiple interpretations of the cholera metaphor. The change Gustav Aschenbach undergoes in *Venice* relates to the physical degradation of a cholera patient and the way the world learned to cope with cholera. In the same way that cholera significantly bettered health administration at the cost of millions of lives, Aschenbach's stay in Venice allows him to discover a morally questionable, alternative lifestyle, which ironically leads him to the peak of his literary career. This intensive analysis proves the multi-layered nature of the cholera metaphor in its description of Aschenbach's development and also establishes that beneficial elements can arise from the most tragic events. The paper showcases the drastic changes an individual can undergo under the influence of desire and delves into the intrinsic aspects of human nature to examine whether moral sacrifice is necessary for art's sake.

Towards Generating a *C. elegans* Cell Line: Deregulating the Seam Cell Division Pattern by Inactivating Genes Involved in Cell Differentiation

Yu-Chien Cheng – CURO Scholar
Dr. Edward Kipreos, Department of Cellular Biology, University of Georgia

The nematode *C. elegans* is an important genetic model organism. In the past six years, three noble prizes have been awarded to scientists working with this organism. The use of *C. elegans* as a biomedical model, however, has been held back by the absence of a *C. elegans* cell line. A cell line allows the growth of a particular type of cell in tissue culture and the study of specific cells of interest with greater efficiency. Human tissue culture cells are generally isolated from either cancers or from stem cells. To generate a cell line in *C. elegans,* we focus on the adult stem cells called seam cells, which have the potential to be manipulated into generating a cell line. A cell line requires continuous proliferation of seam cells, so I am testing whether the inactivation of genes known to regulate normal cell differentiation will lead to continuous seam cell proliferation. These

genes are the cell-cycle regulators cul-1, lin-23, and cki-1, the tumor suppressor lin-35, the transcription factors rnt-1, bro-1, lin-26, elt-5, and the terminal fate control gene pop-1. I am inactivating these genes with RNA-mediated interference (RNAi). Seam cells are tagged with a vector that expresses Green Fluorescence Protein (GFP) for their visualization with a florescence microscope. The gene inactivation that produces the highest seam cell counts will be used as a starting point for making a *C. elegans* seam cell line—an invaluable tool for gaining a better understanding of the regulation pathway of adult stem cells.

Zero-Tolerance Illicit Drug Dependence Policy in the United States Military: A Need for Revision

Katherine Cherry – Roosevelt@UGA
Dr. Paul Roman, Department of Sociology, University of Georgia

The U.S. military operates on a zero-tolerance illicit drug use policy, categorizing drug users as lacking potential for sustained service and calling for their immediate discharge. This policy extends to all military personnel, including those who self-report their drug dependence. The military's policy offers no potential for re-entry and, therefore, no encouragement to seek assistance via self-report. Considering that 15 percent of Iraq and Afghanistan veterans seen at the country's largest VA in Houston, Texas are diagnosed as drug dependent upon the completion of their service, the need for this revision is apparent. If the military suspended those who self-report rather than immediately discharging them, the potential for rehabilitation and sustained service might be realized. The suspension would follow the rehabilitation model of Employee Assistance Programs, utilized by more than 80 percent of Fortune 1000 corporations. After self-reporters successfully complete drug treatment, they can continue their military careers under strict performance supervision and routine drug testing. The Department of Defense would implement this policy across all branches. An expected benefit is the improved well-being of military personnel who may have begun to self-medicate in response to their high-stress environment. Currently, the immediate discharge policy frees the military from caring for outcomes for which research shows it may have been responsible and instead places the burden of care on civilian society. Further benefits include the increased safety of those who could be potentially harmed by drug using behavior and the improved security of military families at home.

Wing Morphology, Flight Ability, and Immune Measures in Monarch Butterflies

Jean Chi – CURO Scholar
Dr. Sonia Altizer, Odum School of Ecology, University of Georgia

Monarch butterflies (*Danaus plexippus*) are well-known for their spectacular migrations along the northeastern coast of North America to over-wintering sites in Central America. In response to wounds and infections, they have a complex immune system that includes the production of hemocytes (insect immune cells) and phenoloxidase (PO) activity, which releases melanin, an important compound in immune defense also responsible for dark pigment. Bio-energetic costs associated with flight and infection are documented, but potential trade-offs among flight ability, immunity, and wing morphology are unknown. Hemocyte samples were obtained from the same individuals during larval and adult stages. Prior to flight trials, adult monarchs were scanned on a flat-bed scanner to obtain wing morphology measures (wing area, loading, aspect ratio, and color characteristics). Monarchs were tested for flight ability using a nearly friction-less flight mill; flight time, distance, initial and final velocity were measured. Preliminary analysis showed no significance between flight ability (total distance, total time, average speed, proportion of mass loss) and immune measures (hemocyte counts and PO activity), and between flight ability and most measures of wing morphology. However, there were significant relationships between average speed and proportion of black on wings, and between adult hemocyte counts and proportion and density of black. Additionally, a combination with two other data

sets showed a significant relationship between total flight distance and orange hue in wings. This has strong suggestions for sexual differences in flight ability, as males have a higher proportion of black and "redder" hues than females. Final data analysis will expound upon the costs and benefits of flight ability and wing morphology with implications for overall fitness of migratory populations.

Distinct Processing Activities Are Associated with the *Trypanosoma brucei* CaaX Proteases
Kristen Chicola
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

Many proteins undergo a series of post-translational modifications required for proper enzymatic function. Proteins possessing a tetrapeptide CaaX motif (*C*=cysteine, *a*=aliphatic amino acid, and *X*=one of several amino acids) undergo attachment of an isoprenoid lipid, proteolytic cleavage, and carboxylmethylation. This process is conserved across all eukaryotic organisms. This study investigates the activities of *Trypanosoma brucei* Rce1 and Ste24, enzymes responsible for proteolytic cleavage of CaaX proteins in this parasite. We establish that TbRce1 and TbSte24 can be heterologously expressed in *Saccharomyces cerevisiae* in functional form, as evident by their ability to promote maturation of the yeast mating pheromone, which is itself a CaaX protein. Using this *in vivo* assay and a-factor CaaX motif variants, TbRce1 and TbSte24 were deemed to possess partially overlapping substrate specificities similar, but not identical to, their fungal and human counterparts. We further establish the *in vitro* sensitivity of TbRce1 and TbSte24 to small molecules previously identified as inhibitors of the yeast and human CaaX proteases, and demonstrate that a subset of these compounds disrupts TbRce1-dependent localization of a GFP-Ras2p reporter in yeast. One compound in particular was identified that inhibited TbRce1 but not HsRce1. These results support the idea that TbRce1 may be selectively inhibited over the human isoform, further suggesting this enzyme as an effective therapeutic target in trypanosomal infections. This study also demonstrates the conserved nature of CaaX proteases across eukaryotes and supports the potential use of small molecule CaaX protease inhibitors as tools for cell biological studies of CaaX protein trafficking.

Electoral Violence in Kenya: 1997–2008
Chris Chiego – CURO Scholar
Dr. John Morrow, Department of History, University of Georgia

The last three times Kenyans went to the polls for relatively free and fair elections, political violence rocked the nation. Each time, the pattern of violence was different. In 1997 and 2002, most of the violence was concentrated before the election, while in 2007-08 most of the violence occurred after the election. The violence also varied from election to election by region, targeted groups, and even method of violence. While many press reports and publications blamed ethnicity for fanning the flames of violence, economic inequalities have been relatively ignored as an explanation. Using data that I collected through fieldwork in Kenya, including government reports, NGO reports, media reports, and firsthand accounts, I will construct a database of electoral-related violence covering the elections of 1997, 2002, and 2007. From this database and other information such as government reports, I will attempt to demonstrate that economic issues played a major role in Kenya's history of electoral violence. Looking at areas with excessively high poverty rates and noting the socio-economic status of persons involved in violence will illuminate the larger patterns behind the violence.

Social Media Use and Belonging
Elise Choe
Dr. Megan Knowles, Department of Psychology, University of Georgia

Classic and contemporary theorists in social psychology argue that humans have a fundamental need to form and maintain positive, lasting relationships with others (Baumeister & Leary, 1995; Maslow, 1954). Given humans'

intrinsic need to belong, individuals are motivated to form new social bonds, repair broken bonds, or otherwise reconstrue their social world in order to maintain a sense of connection (e.g., Gardner, Pickett, & Knowles, 2005). The present investigation explores individuals' use of social media and technology (e.g., social networking sites, blogs, online communities, and online gaming) as means of fulfilling belonging needs. In our initial study, we used a survey design to collect exploratory data pertaining to individuals' belonging needs, personality differences, loneliness, social anxiety, and frequency and type of media and technology use. We expect that individuals with a chronically high need to belong will be more likely to seek out connections via the internet than those low in this need, but this effect may be moderated by social anxiety or personality differences such as introversion. In the initial study it was found that there is a positive correlation between high Facebook usage and high extroversion. The other data were found to be insignificant. The small number of participants and the type of technology the participants used was limited. Therefore, an upcoming follow-up study, with college students, will be targeting a more specific population and will more directly compare the frequency and consequences of social media and technology use and that of in-person social interaction to determine if there is optimal ratio of computer-mediated to in-person communication for psychological well-being.

Intoxicating Misery
Caitlin Christopher
Prof. Bala Sarasvati, Department of Dance, University of Georgia

The solo *Intoxicating Misery* that I will present originated from a choreographic study using crafting devices that I did in my composition course. Although my piece was based on a character study of a woman trapped by her own emotion, I still wanted the choreography to be technical and athletic. Sometimes choreographers sacrifice line and shape in order to focus on the emotion they are trying to portray. I wanted the movement to be as complex as the emotions behind the lyrics of Aretha Franklin's "Never Loved a Man" which possesses elements of tragedy, hatred, and self-loathing but remains passionate and sensual. My goal was to show that one does not have to forget form to illustrate an emotion. With the help of some of the crafting devices such as augmentation, diminution, mirroring, transposition, and inversion, I was able to develop a solo that had a cohesive, specific style that remains technical while illustrating the complexity and depth of human emotion.

***Why So* – Exploring Non Conventional Roles of the Male and Female in Dance Partnering**
Marie Clark and Alexandru Muresan
Prof. Bala Sarasvati, Department of Dance, University of Georgia

Why So was originally created as part of a dance composition course. The focus of this creation was to move away from the traditional roles given to males and females in dance. Instead of developing movement centered on a loving or sexual relationship, the initial choreography was inspired by a fight. The choreographers found motivation from many fight styles, including mixed martial arts and boxing. Movement was actualized from this motivation and brought together with other pedestrian movement as well as limited traditional dance movement to create the duet. The male and female figures participating in this piece do not illustrate the age-old roles, but instead represent two sides of a struggle in a single person.

Vesicular Stomatitis Virus in Infected Cattle
Caroline Colden
Dr. Corrie Brown, Department of Pathology, University of Georgia

The Vesicular Stomatitis Virus (VSV) is a single, negative-stranded arbovirus in the Family Rhabdoviridae. VSV infects cattle, pigs, and horses in specific tissues, primarily the coronary bands (CB) of feet, tongue, planum rostrale, planum nasale, and teats, causing vesicular (blistering) lesions. Infection can have debilitating effects on the animals, posing a huge threat to the food and livestock industry. The

disease can be transmitted via animal-to-animal contact or via insect bite. The pathogenesis of VSV is currently not well understood making it difficult to devise effective control methods. Using molecular techniques, VSV RNA has been shown at the site of the inoculation and draining lymph nodes only, with no subsequent spread. The demonstration of viral proteins via immunohistochemistry (IHC) would allow a more precise viral localization within the tissues, leading to a better understanding of how the virus reaches the draining lymph nodes from the site of inoculation (CB). In this experiment, IHC was used to detect viral protein in the CBs from six steers inoculated via scarification of the CBs with VSV serotype New Jersey. Animals were euthanized at 12, 24, 48, 72, 96, and 120 hours post-infection. Our IHC results demonstrated that virus was effectively replicating to produce viral protein in keratinocytes of the coronary bands. Preliminary results revealed focal and light positive immunohistochemical staining at 12 hours post-infection. As the infection progressed to 24 and 48 hours, positive staining with increased intensity and wider distribution occurred as the lesion became more defined. At 72 and 96-hours post-infection (HPI) IHC staining became less intense, with higher intensity staining more localized in keratinocytes surrounding the vesicle formations. After infection had occurred for 120 hours, however, staining became much more localized to a few areas surrounding the vesicle and with weaker staining intensity. Therefore, this experiment shows the peak of virus replication at the inoculation site is between 24 and 72 HPI. After 96 HPI, mechanisms associated with host response might play a role in keeping VSV from further replication and subsequent spread.

Mandatory Impact Fees: A New Growth Management Strategy for Georgia

Rocky Cole
Dr. Andrew Carswell, Department of Housing and Consumer Economics, University of Georgia

Over the past fifty years, urban sprawl has become the predominant form of urban growth in America. While many Americans find sprawl aesthetically unpleasant, few identify it as the root cause of many growth related problems. Neglected infrastructure, including deferred roadway maintenance, and overcrowded public schools are both negative outcomes associated with unchecked outward expansion. Scholars consistently rank Georgia as one of nation's most sprawling states. Despite the early enactment of growth management legislation, Georgia has largely failed to curtail sprawl. Inherent weaknesses in Georgia's growth management strategy, including rigid political beliefs in local autonomy, continue to cripple the state's management efforts. If Georgia is to limit the negative consequences of sprawl during times of rapid development, a new method for financing capital improvements is necessary. This paper offers a solution to Georgia's growth management problem that will ensure future development pays for itself. Following a brief discussion of the costs of sprawl, survey data collected by the Georgia Municipal Association are used to empirically evaluate sprawl in Georgia. The state's past growth management strategies are then reviewed, and their effectiveness at limiting low-density development evaluated. Interviews with state and local officials supplement the investigation. Finally, the case is made that mandatory impact fees for new development, or one time fees paid by developers to finance the additional infrastructure required (i.e., roads, schools, and sewer lines), can encourage more efficient uses of existing infrastructure without slowing overall growth.

A Season of (Info) Sharing: An Empirical Investigation of Intelligence Reform

Rocky Cole and Chris Chiego
Dr. Loch Johnson, Department of International Affairs, University of Georgia

Following the Iraq weapons of mass destruction (WMD) intelligence failure of 2003, Congress enacted the Intelligence Reform and Terrorism Prevention Act (IRTPA). The legislation reorganized the intelligence community to facilitate greater cross-agency sharing of raw intelligence and more frequent inter-agency cooperation, creating a Director of National

Intelligence and a National Counterterrorism Center. Though IRTPA marginally improved information sharing practices, it failed to address the flaw in the intelligence process which was most responsible for leading policymakers to believe that Iraq had weapons of mass destruction: the threat of consensus thinking, commonly known as groupthink. To test the hypothesis that groupthink played a role in the 2003 Iraq WMD intelligence failure—and that it is not receiving comparable levels of attention from intelligence professionals as information sharing—we conduct an empirical investigation of IRTPA by developing an Intelligence Reform Lexicon, or a dictionary of terms associated with intelligence reform. We use intext computer software to machine code government agency, think tank, and academic literature, as well as Congressional testimony, from 1993 to 2008. We then use the data to derive "Lexicon Scores," or percent values, of the average amount of annual coverage devoted to specific aspects of intelligence reform. Our results support our hypothesis that groupthink played a role in the recent intelligence failures, and that in order to mitigate the negative affects of groupthink, the intelligence community needs to conduct more extensive academic outreach.

Child Care Foundations: A Model for Employer-Based Child Care Subsidies in Athens-Clarke County, Georgia

Lauren Coleman – Roosevelt@UGA
Dr. Amy Kay, Department of Child & Family Development, University of Georgia

Athens-Clarke Count (ACC), Georgia struggles with a startling poverty rate of 28.3 percent. Defined as one of 91 persistently poor counties in Georgia, ACC has approximately 26,000 residents living in poverty. Fortunately, the community has recently fostered a public discourse on how to reduce poverty through the advocacy group One Athens, including early childhood care as a major issue. Early childhood care and developmental programs have the potential to attack poverty from the bottom up by closing the gap between students as they enter kindergarten. Currently, the cost for families to invest in child care generally comprises a sizeable percentage of total household income. The insufficient funds currently allocated to child care subsidization in Athens are limiting what low-income families can do to better the lives of their children while still struggling to provide for their households. In an effort to support the working families of ACC, the local government, in a partnership with the Athens area Chamber of Commerce, should engage in an initiative encouraging businesses to provide direct subsidies for child care. The ACC government should provide incentives for companies to participate by utilizing current tax credits available from the state of Georgia and minimal funding from the county. Engaging tin the smart business practice of employer-based child care subsidies, companies will achieve a stable labor force in the short term while enriching the employees of the future. This practice will foster a mutually beneficial relationship between employers and laborers through non-monetary benefits, such as increased morale and reduced turnover. It is my aim to construct an effective public policy that has the ability to be applied in Athens. Through interviews, a review of pertinent academic literature, and an analysis of existing programs in other cities, I will construct a program to help employers more widely provide child care in Athens-Clarke County.

***Lay Down Your Heart,* a Travel Memoir**

Rebecca Corey
Prof. Reginald McKnight, Department of English, University of Georgia

This travel memoir is based on a journal kept by Rebecca Corey over her ten-week stay in Tanzania, Africa in the summer of 2006. The author describes her experiences as a primary school teacher at a center for orphaned and impoverished youth, her travel around the country, her reflections on tourism, the volunteer experience, and African culture, and her research on Tanzanian proverbs. This multi-media creative non-fiction piece includes illustrations, photographs, and narrative writing. In her work, Corey addresses the private aspects of travel and self-discovery as well as the broader realms of tourism and global service

initiatives in a developing country. She places her experiences in the wider context of travel and service in Africa, ruminating on the joy, fear, and discovery that characterized her stay in Tanzania. She illustrates the sense of fulfillment created by civic engagement and humanitarian work while also discussing the challenges and frustrations those activities often entail. Corey's work is informed by her concurrent research on the existing body of creative non-fiction and travel writing, as well as her research on the proverbs of Tanzania conducted in June and July of 2006.

Puerto Rican Feminist Thought: Boricua

Celina Correa
Dr. Doris Kadish, Department of Romance Languages, University of Georgia

What does the word "Latina" mean? When most feminists (in the USA) think of Latinas, they think of Latina women in the United States, and possibly Mexican women that identify as Chicana. That is a wonderful way to think of Latina women, but it does not represent the entire Latina population. Throughout this essay, the word "Latina" will not be rejected but only expanded. I will break it down in order to show that, although generalizing is necessary, it also can be very problematic for Latinas. I will then turn to Puerto Rican women and demonstrate how such a small island in Latin America/Caribbean, can have over four different self-identities for women and how that relates to the word "Latina." Examining Puerto Rican feminist thought will demonstrate how Puerto Ricans are part of the overall Latina feminism, as a union, and with intersectionality, all at the same time. I will then emphasize the challenges of dominant discourses within feminism with regards to underrepresented Latinas and how they are and are not seen. I make reference to different scholars and analyze their multicultural feminist thought. This essay is highly significant in the category of Puerto Rican feminist thought because a large portion of Puerto Rican feminists have written mainly in Spanish. My purpose is to shed some light on such topics in English, so that feminists in the dominant discourses continue to develop their access to such discussions, as well as knowledge of the multiplicity of Latina Feminism.

Marketing the Non-Profit Global Text Project to Universities in Developing Economies

Jessica Craven and Sarah Alongi
Dr. Richard Watson, Department of Management Information Systems, University of Georgia

Mass education has created many opportunities, particularly for the developing world. The Global Text Project aims to build a library of open-source textbooks targeted towards students at universities in developing economies. The open-content Global Text Project library provides affordable educational materials. Issues arise in creating awareness and adoptions of the books by the project's target audience. Thus, marketing efforts for the project involve three traditional channels: Internet, personal selling, and public relations. As a non-profit in the early phases of development, Global Text relies on these three channels through cold contacts derived from a UNESCO global university database, conferences and resulting contacts, and on campus initiatives. Because these channels yielded few results, the Project adopted a revised marketing plan based on the non-profit marketing model using joint venture co-branding with non-governmental organizations, government agencies, and other academic societies. Through co-branding, Global Text aims to combine resources with well-established organizations to further the shared purpose of providing affordable books. The Project's new marketing plan is focused on universities in Anglophone, politically-stable African countries, including Ethiopia, Lesotho, Botswana, Namibia, Ghana, and South Africa. Success in co-branding with other organizations should increase adoptions of the open-source textbooks.

News in the Black Belt: Teaching Journalists How to Cover Poverty in Persistently Poor Counties

Carolyn Crist – CURO Summer Fellow
Prof. John Greenman, Department of Journalism, University of Georgia

In the 1990s, many larger newsrooms across the nation employed reporters on a "poverty beat" to discuss financial difficulties in their communities. Now, as large newsrooms lay off hundreds of employees and reduce specialized beats, newspapers are increasingly focusing on local communities. As the trend continues, journalists must learn how to convey information through their local identities and sense of place to explain poverty in persistently-poor locations. We pinpointed 14 newspapers in middle and southern Georgia that are located in generationally-poor areas and attempted to discern whether a workshop would be beneficial to teach them how to cover poverty in interesting and relevant articles. Because poverty affects all aspects of the community—crime, health, business and education—we propose coverage should be taught to all reporters as a "horizontal" beat to be covered in all areas rather than as a "vertical" beat that is given only to one reporter. Through articles explaining history, narratives, and tradition, reporters can draw in readers and educate them about the effects of poverty in their community. National statistics, surveys, and legislation can be used at a local level to explain poverty trends, and this paper gives specific ideas to incorporate poverty coverage in beats across the newsroom. The 14 newspapers observed in this study were divided on how they currently acknowledge and cover poverty, and each must find its own way to correctly cover the issue in its market. All agreed on one idea - in times of economic recession, a workshop that would cost money and take time from the office is not ideal. We propose to create a Web site in fall 2009 that will teach newspapers from all backgrounds and paths how to cover poverty simply in their communities through several stories that can be published at any time. If followed, increased poverty coverage will reflect local struggles with the diminished economy, highlight areas where the local government can aid community members, decrease stereotypes associated with poverty, and increase understanding about the poverty cycle usually located just down-the-street.

Meat Out of the Eater

Jordan Dalton
Mr. Mark Callahan, Artistic Director, Ideas for Creative Exploration, University of Georgia

Meat Out of the Eater is a collaborative performance with Lara Glenum, a poet and PhD candidate in UGA's Creative Writing Program, Cal Clements, a pataphysician, experimental theater director, and founder of a local yoga studio, and Mia Mäkilä, a Swedish painter. The work is based around and named after the second half of Lara's most recent book, *Maximum Gaga*, which is a hybrid poem-play retelling the myth of Pasiphäe, the wife of King Minos, who enlists the help of the inventor Daedelus to construct a machine to assist her in copulating with a bull. From this act is born the monstrous hybrid, the Minotaur. The centerpiece of this multimedia performance is an interpretation of Daedalus's epic machine. A cart, like that of a merchant in the market, but covered in and with strange instruments that seem to exist somewhere between "of torture" and "of sound-making" appears a wardolly. Bone rattles, metal bowls, and wire strings cover the cart, and all are amplified. The musicians who use this cart for improvisatory (and most likely other, more menacing) purposes seem somehow to be part of the machine. Tubes and tethers of cable that seem strangely alive tie them to the wardolly, and the cart and the musicians are similarly tied to the room of the performance itself. The poet herself is also involved. Her words echo throughout the space and provide an improvisatory framework to which the musicians respond and accompany. She, too, is tethered. No one seems to be free from the giant, pulsating, noisy machine. Moving images are on the walls. They are tied to the poet's language; they are more literal visual representations of the words and sounds that fill the space. An animation, Mia's commission from across an ocean, is a particular highlight,

and even the room's convulsions seem to pause for a minute to watch. Everyone, including the room, is costumed. The sort of garb that makes one afraid that, with each layer peeled off of the body, thousands more, each one more disturbing than the last, lie waiting to be revealed. Tubes, cables, and piles of unidentifiable matter litter the floor of the space.

Late Ming Dynasty Jingdezhen Ceramics in a Changing Economic and Cultural Context
Amy Davis
Dr. Ari Levine, Department of History, University of Georgia

An internationally respected art form, Chinese ceramics provide an interesting starting point for any art historical research. This research investigated an important time of change in China's ceramic history. During the late Ming dynasty, economic decline led to the end of imperial patronage of Jingdezhen kilns, forcing potters to find new consumer markets. Careful examination of the functionality and formal qualities of several specific Jingdezhen export wares, along with a study of the symbolism found in ceramic surface decoration, indicates probable uses and markets for porcelain produced during the late Ming dynasty. An in depth study of late Ming dynasty culture and Jingdezhen porcelain production practices also indicated that many artisans made works specifically targeted to the cultural values and customs of new national and international consumers. By adapting to needs and demands of new consumer groups, Jingdezhen potters were able to thrive despite a complete loss of imperial patronage. Because of the flexibility of the porcelain industry, Jingdezhen emerged as the world's major center for export ceramics. By studying the history of Chinese ceramic art, one can gain a greater understanding of contemporary Chinese art. Contemporary Chinese art is heavily influenced by both China's past and China's current socio-political issues. A better understanding of how China views her own socio-political situation can thus be obtained from Chinese art in antiquity. Given China's position as a growing major political power, it is essential to understand China's own views about her place in the world.

Long-Range Retrograde Neurotrophic Signaling in Mouse Sympathetic Neurons
Logan Davis – CURO Summer Fellow
Dr. James Franklin, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Developing vertebrate neurons depend on target-derived growth factors for survival and neurotrophic support. The precise molecular mechanisms underlying long-range transduction of survival and trophic signals remain unclear. When nerve growth factor (NGF) is withdrawn from sympathetic neurons *in vitro*, a complex intracellular molecular cascade results, leading to caspase-mediated protein degradation and death. A dramatic increase in reactive oxygen species (ROS) that is a critical component of the apoptotic cascade takes place in these cells soon after withdrawal. Neurons can be rescued by late re-addition of NGF which rapidly suppresses ROS production. This suppression is evidence of a rapid survival signal. I will plate mouse superior cervical ganglion (SCG) neurons in novel microfluidic chambers developed at the University of California, Irvine, in which soma are separated from their distal axons. Cells will be deprived of NGF in both somal and distal axon compartments. Somatic ROS levels will be determined by confocal microscopic imaging of neurons loaded with CM-H_2DCFDA, a cell-permeant indicator of ROS that is non-fluorescent until oxidation occurs. An immediate decrease in somatic ROS production after re-addition of NGF to the distal axon compartment would offer evidence that a *long-distance* rapid survival signal takes place in sympathetic neurons. The rate of movement of the signal may allude to underlying mechanisms. Many neuropathologies will be better understood by the clarification of mechanisms underlying survival signaling, and this research could have important clinical ramifications.

Moods, Emotions, and Occupational Identities: A Test of Affect Control Theory
Long Doan – CURO Scholar
Dr. Dawn Robinson, Department of Sociology, University of Georgia

Affect control theory is a quantified theory that predicts the actions taken by individuals to maintain their cultural identities in certain situations. It also predicts likely emotions due to such interactions. Affect control theory makes its predictions based on the three-dimensional numerical profile (EPA) of actors, behaviors, settings, and emotions. Most tests of the theory to date have taken place in the laboratory or idiosyncratic field settings. This paper aims to accomplish two things: to find out whether occupational identities have become so salient that they can be sole predictors of emotion and to test the effectiveness of affect control theory in predicting those emotions using nationally representative data. Using the 1996 General Social Survey (GSS) as empirical data, the author analyzed the correlation between the EPA values of one of thirteen moods and emotions and the EPA values of ninety-seven occupational identities. To answer the second research question, the author generated characteristic emotions of ninety-seven occupational identities using affect control theory and calculated the geometric distance (deflection) between those characteristic emotions and the thirteen moods and emotions asked in the GSS. The author then analyzed the correlation between the deflection, which represents unlikelihood, and the likelihood of GSS respondents' experience of one of thirteen moods and emotions. Results show that occupational identities do not make good predictors of moods and emotions, but affect control theory increases the significance of those predictions.

Facial Identity Recognition: Perceptual Narrowing From Infancy Through Adulthood
Lauren Doyague, Elizabeth Simpson, and Krisztina Varga
Dr. Janet Frick, Department of Psychology, University of Georgia

Infants experience perceptual narrowing (i.e., a process in which perception starts out broadly tuned to all stimuli and then narrows) months after birth. Our study focused on examining human infants' transition from being "face generalists"—discriminating facial identity for numerous species—to being "face specialists"—becoming experts in discriminating human faces. Our aim was to determine the breadth of human infants' abilities to discriminate the facial identity. To these ends, human 6-month-olds (N=65) and adults (N=30) were tested to determine whether they discriminated the facial identities of male humans, capuchin monkeys (*Cebus apella*), and sheep (*Ovis aries*). These species are phylogenetically more distantly related to humans than species previously used. The experiment began with a familiarization period, during which infants accumulated 20 seconds of looking to a face, and then a visual paired comparison task assessed their relative interest in the familiar face to the novel face (i.e., by recording eye movements). Adults had a similar familiarization period and then made key press responses to the novel face. Adults had faster and more accurate recognition for the human faces, relative to monkey and sheep faces (p<.001). Six-month-olds had longer look durations to the novel faces compared to the familiar faces (p=.005). This is noteworthy because this shows that young infants can discriminate facial identity of distantly related species. This shows infants' abilities are broader than previously thought. Moreover, this suggests that with time, infants transition from being "face generalists" to being "face specialists."

The Effects of Corticosterone on Stress-Induced Weight Loss and Corticotrophin Releasing Factor mRNA Expression in the Paraventricular Nucleus of the Hypothalamus
Rachel Doyle
Dr. Ruth Harris, Department of Foods & Nutrition, University of Georgia

The majority of people who lose weight have difficulty maintaining the weight loss. Rats lose weight when stressed and never return to the weight of the control group. Stress is sensed by

the paraventricular nucleus of the hypothalamus which releases corticotrophin releasing factor (CRF) activating the hypothalamic-pituitary-adrenal (HPA) axis. The HPA stimulates the adrenal glands to secrete corticosterone. Adrenalectomized rats have had their adrenal glands removed. This study examined the effects of repeated restrained stress on both intact and adrenalectomized rats to examine the effect of changes in corticosterone on weight loss, and on CRF in the hypothalamus. There were six groups of rats consisting of various combinations of repeated restraint, adrenalectomy, and replacement of corticosterone in adrenalectomized rats. The restrained rats were stressed for three hours a day on three consecutive days. Adrenalectomized rats lost half as much weight during restraint as intact or adrenalectomized rats given corticosterone replacement. Non-stressed adrenalectomized rats given corticosterone also lost weight but this weight loss and that in restrained adrenalectomized rats was reversible. Thus, both naturally occurring and injected corticosterone causes weight loss, but stress is needed for the sustained weight loss. In a second set of rats, brains were collected at the end of day two of restraint for in situ hybridization. CRF mRNA expression levels increased in the hypothalamus of adrenalectomized and restrained rats, but there was no effect of corticosterone replacement. Therefore, corticosterone plays a role in sustained weight loss but does not act on hypothalamic CRF mRNA.

Adverse Effects After Administration of an Ionic Iodinated Contrast Media in Dogs

Amanda Farmer
Dr. Erik Hofmeister, Department of Small Animal Medicine, University of Georgia

Ionic iodinated contrast (IIC) media are commonly used in veterinary medicine for contrast-enhanced computed tomography (CT) and can provide significant diagnostic benefits. However, clinical experience has reported hemodynamic alterations, including changes in arterial pressure and heart rate, in a small percentage of dogs following intravenous administration of the contrast agent. The purpose of the study was to identify and determine the frequency of hemodynamic alterations associated with the administration of IIC media in a large number of anesthetized canine patients. Anesthetic records of clinical patients anesthetized between 2002 and 2008 were searched, and 49 dogs met the inclusion criteria. Values for direct arterial pressure and heart rate were recorded at the time of contrast administration and again during the 15 minute interval following the injection. Results of this study indicated that over 93% of dogs developed some increases or decreases in hemodynamic conditions, and the frequency and intensity of these alterations were considerably higher than those found in previous studies involving both human and animal patients. In addition, over 20% of patients experienced a 20% or more change from baseline mean arterial pressure, and over 12% experienced a 20% or more change from baseline heart rate following contrast media administration. As advanced imaging techniques become more common in veterinary practice, and the administration of IIC media is performed more frequently, an understanding of the frequency and types of reactions following contrast medium administration becomes increasingly valuable.

The Effects of Extubation with Varying Degrees of Endotracheal Tube Cuff Inflation on Endotracheal Fluid Volume in the Dog

Amanda Farmer
Dr. Erik Hofmeister, Department of Small Animal Medicine, University of Georgia

In veterinary medicine, an endotracheal tube (ETT) is frequently used for airway management during anesthesia, and proper inflation of the ETT cuff is critical for patient safety. During extubation, the ETT cuff is routinely deflated before removal so that no trauma is caused to trachea and the larynx. However, if there is significant fluid build up around the tube, the ETT is sometimes removed with the cuff inflated or partially inflated to avoid aspiration of fluid proximal to the cuff. The purpose of this study was to investigate the effective protection against liquid aspiration in canines provided by

the removal of inflated and deflated ETT cuffs. Sixteen female beagle cadavers were orotracheally intubated in lateral recumbency, and the ETT cuffs were inflated to a closing pressure of 20 cm H2O before barium was introduced anterior to the cuff. The dogs were randomly assigned to an ETT cuff extubation condition of deflated or unchanged from the original closing pressure. After extubation, thoracic radiographs were obtained, and the radiographs were assessed to estimate the amount of barium remaining in the trachea. Results of this study indicated that the dogs in the deflated ETT cuff group had an average of 0.9 mL more residual intratracheal contrast than dogs who were extubated with an inflated ETT cuff. If there is concern about intratracheal fluid buildup during anesthesia, extubation with the cuff inflated will remove contents and may decrease the likelihood of aspiration.

Analysis of the Transcriptional Regulation of Pax6 in the Eye

Amina Farooq
Dr. James D. Lauderdale, Department of Cellular Biology, University of Georgia

Pax6 is a member of the paired-family of transcription factors that exhibits a very specific and restricted spatiotemporal expression pattern within the developing eye and nervous system. Incorrect levels of Pax6 expression have been shown to lead to developmental abnormalities. Little is known about the transcriptional mechanisms by which Pax6 expression is regulated. Previous analysis has shown the complexity of Pax6 regulation through the identification of multiple enhancer elements which interact to produce a tight regulation of Pax6 expression. The requirement of certain sequences within Pax6 for expression in various regions of the developing organism has also been demonstrated by targeted sequence deletion studies. We show here that, in addition to the already identified enhancer elements regulating Pax6 in the lens, it appears that a key lens regulatory sequence lies within the downstream regulatory region of Pax6. Immunohistochemistry was used to detect the fluorescence tagged transgene, and demonstrate that a putative eye regulatory region is necessary for the maintenance of Pax6 expression in lens cells. Using bioinformatic sequence analysis, we demonstrate that the identified downstream regulatory region contains the information needed for correct spatiotemporal expression of Pax6 in the retina. These data shed more light on the specific mechanisms governing Pax6 expression within the eye, by showing the differential regulation of Pax6 in the lens relative to other structures of the developing eye. Further elucidation of the precise regulatory mechanisms of a key developmental gene like Pax6 will provide crucial information for those working to therapeutically clone ocular tissue in an effort to provide effective treatment for individuals with ocular disorders.

Studying the Genetic Diversity of the Var2csa Gene

Opeoluwa Fawole – CURO Apprentice
Dr. David Peterson, Department of Infectious Diseases, University of Georgia

Plasmodium falciparum is a parasite transmitted from mosquitoes to humans that causes the most severe incidences of malaria. Our research focuses on placental-associated malaria, which is mediated by the var2csa gene product found in parasites that infect pregnant women in Africa. Our goal is to study the gene sequence diversity of var2csa among various parasite isolates extracted from infected pregnant women. We expect to differentiate regions of variability and conservation among the var2csa gene sequences and use these data to ultimately predict which areas can be presented by human leukocyte antigen class II molecules. In our study, we have used placental blood samples obtained from pregnant women infected with malaria in Kenya. We use PCR to amplify a region of the var2csa gene and then employ a cloning reaction to find and isolate the unique sequences for analysis. So far, we have 68 sequences from 6 placental blood samples. After aligning and comparing the regions, we analyze the diversity among the gene sequences. Initial analysis has shown that there is tremendous diversity of the sequences, that sequences from a single patient are more similar than those

between patients, and that the predicted class II epitopes (areas that can be recognized by an immunological agent) fall mostly in conserved regions. Through our studies, we endeavor to understand the development of immunity to placental malaria.

Catching the Zanies: Italian Acting and English Drama
Katelyn Foley
Dr. Erin Kelly, Department of English, University of Georgia

This paper will discuss a new reading of Francis Beaumont's English renaissance play *Knight of the Burning Pestle* in light of the Italian renaissance acting style known as commedia dell'arte. During the two decades before *Knight* was written, many Englishmen's sons traveled around Italy, observing the improvisational street performers of commedia dell'arte. On their return, they brought knowledge of this satirical art form with them. With this acting style in mind, Beaumont creates a dialogue between a romantic type of English city comedy and Italian-style improvisation through a scripted scenario "invented" by his merchant-class characters George, Nell, and Rafe. Commedia dell'arte and its English bourgeois counterparts significantly inform Beaumont's satirical commentary within his play. However, very few attempts to correlate the English and Italian renaissance acting styles have been made, and there are no critical studies that discuss improvisation within both forms in relation to Beaumont's *Knight*. Through examination of the play, especially its improvisational scenes; English translations of commedia dell'arte scenarios; accounts of Englishmen traveling in Italy; and improvisational performance traditions, this essay exposes the existence of a vital exchange between Italian acting and English renaissance theatre and culture and discovers a new context for Beaumont's *Knight*, creating a new understanding of satire and comedy within the play.

Approaching Iran: Alternative Diplomacy
Charles Ford – Roosevelt@UGA
Dr. Sherry Lowrance, Department of International Affairs, University of Georgia

Thirty years after the Iran hostage crisis, American diplomatic relations with Iran remain limited. Political, social, and cultural barriers continue to prevent the emergence of fruitful diplomatic ties between the two nations. The pro-democratic, capitalist United States has attempted to force Iran into the global system by pressuring them with embargoes, sanctions, freezing of Iranian assets in the United States, and the threat of military intervention. These aggressive methods of diplomacy have clearly resulted in a lack of Iranian cooperation. Alternative methods of diplomacy (i.e., third party neutrality, peace talks, etc.) and their effectiveness at solving hostile relations in other parts of the globe will be analyzed and applied to the situation surrounding the United States and Iran. For example, the effectiveness of Jimmy Carter's shuttle diplomacy during the Camp David Peace Accords could be implemented when dealing with the United States-Iran conflict. Egypt and Israel would be replaced by Iran and the United States. Differences could be listed, tradeoffs made, and a consensus reached in the same manner it was in 1978. Also, private, non-publicized peace conferences have proven to be effective in stimulating subtle policy shifts and innovation for new programs of establishing peace. This method, in addition to others, will be applied to Iran and the United States. Though relations with Iran have been heated in recent decades, perhaps an understanding of each other's goals and preferences found through approaching the situation in an alternative manner might be the key to improving the current conflict.

Bipedal Stair Climbing Robots
Alex Fouraker
Dr. Chi Thai, Department of Biological & Agricultural Engineering, University of Georgia

My project was in robotics engineering and the objective was to design a robot capable of walking up and down a flight of stairs. This

robot is the first in a series to determine which type of motion, compared to a human type gait, is best for carrying weight up stairs. Other methods will also be built and tested. The robot was bipedal and modeled after a bird in the respect that the knees bend backwards. This complicates some motion associated with walking upstairs. For these robots, because the CPU and servo motors response times are slow, their programming requires that they go from one static position to another and limit transitional speeds between these positions. As a result, the robot motion was designed so its overall center of gravity was always over its base so it would not fall. In other words, it required it be balanced not only at static poses but also in transition between poses. I created two working robots. One climbed a set of six stairs and, once it reached the top, walked down backward, taking the stairs two at a time. The other robot first checked to "see" if the next stair existed before moving. If the stair did not exist, the robot stopped. Because of this, the robot only takes one step at a time, hence its nickname, the "toddler" robot. This project could have implications in search and rescue and military endeavors. These web sites demonstrate the projects:
http://www.engr.uga.edu/people/thai/Bioloid/GerwalkStairs_2/
http://www.engr.uga.edu/people/thai/Bioloid/ToddlerUp6Steps/.

Analysis of Pectate Lyase Activity in Pectin-Rich Lignocellulosic Biomass Fermentations
Brian Gardner – CURO Scholar
Dr. Joy Doran-Peterson, Department of Microbiology, University of Georgia

The dependence on foreign oil in the United States has increased the demand for alternative fuels. Ethanol production from food sources in the United States could create heavy competition for the ultimate utilization of crops. However, ethanol production from pectin-rich lignocellulosic biomass provides a noncompetitive alternative fuel source. Ethanologen *Escherichia coli* strain JP07 containing the cellobiose phosphotransferase system from *Klebsiella oxytoca* and the alcohol dehydrogenase and pyruvate decarboxylase from *Zymomonas mobilis* was further engineered to express a pectate lyase from *Erwinia chrysanthemi* (casAB; pelE). To obtain effective secretion of PelE, the Sec-independent pathway out of genes from *E. chrysanthemi* on the cosmid pCPP2006 were provided to strain JP07 to construct strain JP07C. *E. coli* strains LY40A, JP07, and JP07C possessed significant cellobiase activity in cell lysates, while only strain JP07C demonstrated extracellular pectate lyase activity. Fermentation with sugar beet pulp at very low fungal enzyme loads during saccharification revealed significantly higher ethanol production for LY40A and JP07C compared to the parent strain, *E. coli* KO11. While JP07C ethanol yields were not considerably higher than LY40A, investigation of oligogalacturonide polymerization showed an increased breakdown of biomass to small chain (degree of polymerization ≤ 6) oligogalacturonides. The activity of pectate lyases along with other additional enzymes in ethanol fermentations could lead to more efficient breakdown of noncompetitive substrates to produce fuel ethanol.

H-1B Visa and Green Card Reform
Joshua Gloster – Roosevelt@UGA
Dr. Scott Atkinson, Department of Economics, University of Georgia

H-1B visas and green cards for high-skilled foreign workers have had an almost entirely positive effect on the American economy. H-1B visas, which are temporary non-immigrant visas, and green cards, which allow for permanent residence, are being issued at too low of a rate, even considering the decline in growth of the American economy. Support for removing the cap on H-1B visas and green cards will be based on analysis of current literature regarding the shortage of high-skilled labor in America, free market solutions to immigration issues, and the failure of other policies to solve the labor shortage. Due to the need for a greater number of skilled workers, and to lessen the problem of outsourcing, Congress should pass legislation to enact both H-1B visa and green card reform. Currently, corporations like Google and

Microsoft have to get around H-1B visa restrictions by outsourcing jobs overseas. Lifting the cap on H-1B visas will help end this detrimental process. Also, the green card application process should be simplified so H-1B workers who deserve green cards can obtain them. Positive effects will include an increase in the sense of acceptance among H-1B workers, an increase in their sense of civic responsibility, and incorporation of these workers within the tax base. The complaints of American high-skilled workers should be taken seriously and properly addressed, but the potential benefits of H-1B visa and green card reform prove that they outweigh the costs.

Decision-Making Strategies of Wild Capuchin Monkeys

Rebecca Greenberg – CURO Summer Fellow
Dr. Dorothy Fragaszy, Department of Psychology, University of Georgia

Wild bearded capuchin monkeys (*Cebus libidinosus*) use stone tools to crack open tough palm nuts to ingest the kernel. Optimal foraging theory recognizes alternative strategies that individuals adopt in complex foraging circumstances to maximize some benefit (e.g., energy intake) or minimize some cost (e.g., risk of predation). Nine monkeys from a well-documented group of wild bearded capuchins were studied over a four-week period in Piauí, Brazil. In this special context, the monkeys are faced with decisions about which nuts to crack and which stones to use. To determine which optimizing strategy (maximize payoff, minimize effort, or maximize the reliability of payoff) that these monkeys use when they crack nuts, they were given a choice of two nuts differing in resistance and two manufactured stones of same volume but different mass. Other experiments allowed the choice of two manufactured stones with one hard nut so that the choice of stone was more important. Monkeys consistently selected the nut that was easier to crack and the heavier stone when the stones differed in weight by at least 500 grams. This study suggests that capuchins are sensitive to properties of stones and nuts, as reflected in their choice of materials for cracking nuts. The findings best match a strategy to maximize the reliability of payoff. Tool use in these monkeys (and other species, including human ancestors) can be understood from an ecological perspective, as well as from the (more common) cognitive perspective.

The Role of Hirano Bodies and the Amyloid Precursor Protein in Alzheimer's Disease

Nisha Gupta – CURO Scholar
Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia

Hirano bodies are cellular formations found in patients suffering from neurodegenerative diseases. However, the physiological function of Hirano bodies is not yet understood. Alzheimer's disease is a degenerative disease characterized by the loss of neurons and formation of plaques in the brain. These plaques primarily consist of the protein amyloid-beta (Aβ), which is derived from transmembrane molecule known as the amyloid precursor protein (APP). When cleaved intracellularly, APP forms smaller molecules, including the C31 fragment which has been recently shown to be lethal to neurons. Furthermore, studies have shown that when the C31 protein is mutated, there is a decrease in both Aβ and C31 toxicity (Lu, et al., 2003). Although the mechanism of injury to the cell in Alzheimer's disease is not fully known, the role of APP, Aβ, and C31 have been implicated. Because of the observed association between Hirano bodies and Alzheimer's disease, we investigated the relationship between Hirano bodies and the neurotoxic effects of C31. In a previous study, Hirano bodies were shown to sequester and protect against AICD, another neurotoxic fragment of APP (Ha, et al., 2008). In the current study, experiments were conducted in human embryonic kidney (HEK) cells in which Hirano bodies formation was induced with either C31 or a mutated form of C31 (mC31). Cells expressing C31 had an increased rate of death, while cells expressing mC31 were healthy. This observation indicates that cell death was caused by C31-induced neurotoxicity. Further experiments suggest that Hirano bodies are protective against C31-mediated death.

Presence of Apoptosis, as Determined by Immunohistochemistry, in Lymphoid Tissues of Chickens Infected with Strains of Newcastle Disease Virus of Varying Virulence

Laura Harrison – Roosevelt@UGA, CURO Scholar
Dr. Corrie Brown, Department of Pathology, University of Georgia

Newcastle Disease Virus (NDV) poses many threats to the poultry industry. Whereas low virulence strains often circulate with minimal disease, high virulence strains can rapidly sicken and kill an entire house of chickens. Presence of any virulent viruses within our country will seriously damage our abilities to export chicken meat or live birds. The last outbreak of virulent Newcastle disease in the US happened in California in 2002-2003. That outbreak claimed the lives of 4 million birds, required 8 months to eradicate, and cost over $300 million dollars to the industry. Because apoptosis, or programmed cell death, serves as a key defense mechanism during viral infections, increased knowledge concerning apoptosis is essential in understanding host-pathogen interactions. Immunohistochemistry (IHC) for active caspase-3, a key enzyme in apoptosis, was done on formalin-fixed, paraffin embedded sections from chickens infected with various strains of NDV. Apoptotic activity was examined in the spleen, thymus, bursa, and intestine. All tissues were harvested at two days post infection. To confirm virus presence, IHC was done for NDV nucleoprotein. Active caspase-3 expression in lymphoid tissue infected with virulent strains was significantly increased when compared to tissue infected with milder strains. Heightened apoptosis in the virulent strains may be a key component of the severe disease manifestations seen. Because severe disease manifestation results in losses to the poultry industry, generating greater understanding of apoptosis in response to NDV infection exists as an important research initiative.

Advance Directive Reform: Reducing Medicare Spending and Increasing Respect of Patients' Rights

Laura Harrison – Roosevelt@UGA, CURO Scholar
Dr. Claire Robb, Department of Epidemiology & Biostatistics, University of Georgia

Almost every elderly American citizen receives healthcare coverage from Medicare, which continues to expand in size and cost. In 2008, the number of Medicare enrollees was 44,831,390 and the program cost $300 billion. Often, efforts to contain Medicare costs complicate delivery of health care which reflects the patient's desires. End-of-life care (EOLC) contributes to Medicare spending and results in situations creating obstructions to honoring patients' rights. Through an advance directive (AD), a patient declares healthcare preferences in advance. Because an AD potentially saves money and increases respect of patients' rights, the purpose of this research was to determine the best program for AD implementation. A comprehensive literature review was conducted using databases such as PubMed, EBSCOhost, and LexisNexis Congressional. AD, EOLC, and Medicare policy were compared. Research shows that a lack of national AD policy creates barriers to AD use. Also, the work of Molloy et al. exemplifies the importance of AD education in policy implementation, as patients who received AD education had a decrease of $1200 for healthcare expenditures. Because of differences concerning views on death, there is a need for AD policy which respects a variety of stances. Research findings call for a policy with two major components: creation of a national AD by the Department of Health and Human Services and federal investment in an AD educational campaign to promote AD use.

Buddha and Uncle Sam: Investigating Contemporary Buddhism in the United States and Its Evolution

Sana Hashmi – CURO Scholar, CURO Summer Fellow
Dr. David S. Williams, Department of Religion, University of Georgia

Buddhism, based on the teaching of Siddhartha Gautama, also known as the Awakened One ("Buddha"), has experienced an amazing evolution from its origin four hundred years BCE. Unlike many other religions that utilize supernatural solutions to the suffering in the world, Buddhism uniquely focuses on the individual self as the vehicle for ending this suffering. By understanding that life is imperfect and that our desire for materialism leads to our suffering, then, as the Buddha states, terminating this desire would lead to the conclusion of one's suffering, frustration, and even faint unrest. Starting with its humble roots in India 2500 years ago, this message spread throughout East Asia, Western Europe, and, eventually, to the New World in the nineteenth century with the influx of Asian immigrants. In this process, Buddhism evolved, incorporating new devotional rituals and mystical qualities from the cultures it interacted with. Through interviewing various scholars and visiting important religious sites, both in the United States and in South Korea—a country whose Buddhist culture has been preserved by the government and is relatively unaffected by Communist, Christian, or political influence, as other Asian Buddhist countries are—I will examine the evolution of Buddhism in America and its evolution from its original roots. Through this project, this contemporary form will reveal an intricate dance between traditional beliefs and the influence of Western culture. This research is particularly important in the scholarship of religious studies in the United States. By investigating the factors that influence Buddhism in this country, we can learn about the dynamics of religion and American culture in general. The understanding of this relationship is crucial to recognizing and appreciating diversity and its effects on the American, as well as the global, community.

Indigenous Peoples and Migrants: New Nationalism in Ecuador

Liana Hervas
Dr. Pamela Voekel, Department of History, University of Georgia

In September 2008, a majority of Ecuadorians voted in favor of a new constitution that decisively places Ecuador among the left-leaning countries in Latin America. The content and popularity of Ecuador's latest constitution are the products of a strong, innovative nationalist project. Nationalism has historically been defined in terms of geographic borders and perceived cultural homogeneity. Ecuador's 2008 Constitution challenges more traditional definitions of nationalism by presenting highly inclusive ideas of citizenship. By including indigenous rights to autonomy and self-determination and constitutional rights for Ecuadorian migrants living abroad, the 2008 Constitution incorporates plurinational and transnational identities into its definition of the state. I analyze the 2008 Constitution, government and media documentation of the drafting process, the large body of historical and anthropological work on indigenous organizing in Ecuador, and documentation of second wave Ecuadorian migration to contextualize the kinds of citizenship offered by the 2008 Constitution. The Constitution's inclusion of plurinational and transnational citizenship broadens and emboldens traditional ideas of nationalism. The plurinational and transnational citizenship offered by Ecuador's 2008 Constitution inform a new kind of nationalism. Knowledge of this broadened version of nationalism provides a better understanding of Ecuadorian politics and the country's position in Latin America.

The Effects of Oxytocin on Food Sharing and Cooperation in the Capuchin Monkey (*Cebus apella*)

Carla Heyler
Dr. Sarah Brosnan, Department of Psychology, Georgia State University

Oxytocin (OT) is a neuropeptide that mediates social behaviors in humans, including trust, cooperation, and generosity. We here investigate

whether exogenous OT increases cooperative and food sharing behavior in a highly social non-human primate species, the capuchin monkey. This may improve our understanding of positive social behaviors and cooperative interactions in capuchins and help to clarify the evolutionary enigma of altruism through evidence of a mechanism by which OT facilitates cooperation. In our study, one or both subjects must pull bars linked to a tray in order to receive food (apples) on the tray. In the reciprocity condition, the tray is weighted so that both subjects must pull, though only one subject has access to the reward and must share it for his partner to receive any. In the mutualism control, both must pull and both receive a reward. In the solo control, only one subject need pull and only the same subject has access to the reward. We are testing whether OT administered intranasally will facilitate both the willingness to cooperate in obtaining rewards and the subsequent willingness to share the reward. OT administration is randomized so that in each scenario either one subject, both subjects, or neither subject receives OT (saline is the control). We will use a repeated-measures ANOVA to determine whether levels of cooperation and food sharing vary across conditions. Although data are still being collected, we predict that increased OT levels will correlate with an increase in both cooperation and subsequent sharing of the reward.

Analyzing the Function of *O*-GlcNAc in the *Drosophila* Nervous System

Marcus Hines – CURO Apprentice, CURO Summer Fellow
Dr. Michael Tiemeyer and Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia

A dynamic cycle of addition and removal of *O*-linked *N*-acetylglucosamine (*O*-GlcNAc) at serine and threonine residues is emerging as a key regulator of intracellular protein activity. Like phosphorylation, the *O*-GlcNAc modification significantly changes the function of the proteins to which it is attached. In addition, the *O*-GlcNAc modification may compete with phosphorylation for certain Ser/Thr target sites. Although there has been considerable research on documenting the functional implications of phosphorylation, the functions for *O*-GlcNAc are just beginning to be understood. A significant amount of cancer and developmental biology research is focused on phosphorylation as a regulator of cell growth and differentiation, but relatively little attention has been paid to the involvement of *O*-GlcNAc in these processes. Like kinases and phosphatases, the enzymes of *O*-GlcNAc addition, *O*-GlcNActransferase (OGT), and removal, *O*-GlcNAcase (OGA), are compartmentalized and regulated. We have capabilities to analyze the presence of O-GlcNAc on the intracellular protein. This project focuses on dissecting cell autonomous and non-autonomous functions of *O*-GlcNAc, by altering the expression of OGT and OGA within specific cells of the *Drosophila melanogaster* embryo in an effort to obtain a better understanding of the function of *O*-GlcNAc. Preliminary results have hinted that the addition of more *O*-GlcNAc in the engrailed cells of the *Drosophila* nervous system may hinder the engrailed cells' natural secretion of wingless cells. Further research on the function of *O*-GlcNAc, especially in the *Drosophila melanogaster* embryo, will continue to be conducted to obtain a deeper understanding of the glycan.

The Development and Implications of Predictive Modes of Thought from the Renaissance to Modernity

Dillon Horne – CURO Apprentice
Dr. Thomas Cerbu, Department of Comparative Literature, University of Georgia

This project shall focus on the development of predictive modes of thought, from the astrology of the Renaissance to modern probability theory. I will begin with a case study on the 16th century figure of Gerolamo Cardano. He holds special significance in this dialogue due to his early dealings with game theory, which gave rise to key precursors of modern concepts of probability. From there I shall move on to a brief overview of the correspondence between Fermat and Pascal, but with a larger emphasis on Ian

Hacking's concept of probability as an emergent concept rather than an epochal shift. The importance of this correspondence is that it made possible the idea of statistically predicting the future. The two scholars deal with the 'problem of the points,' that is, how to determine the most likely outcome of a chance game. With Hacking, I will focus on his work concerning the 'signs' of the low sciences that served to make predictions reliable, shifting from there to Pascal's wager and how that signaled the introduction of probability-based decision making. This leads into modern studies of economics, governmental policy, etc. This project will build upon other works of history of philosophy and mathematics by providing a more comprehensive focus on what exactly is probability and how it came to be. In a world so caught up in numbers, the significance of an encompassing study on the development of probability will serve to provide a basis of credibility for acting on predictions.

How AICD and Fe65 Are Recruited to Hirano Bodies

Haylee Humes – CURO Summer Fellow
Dr. Marcus Fechheimer, Department of Cellular Biology, University of Georgia

Hirano bodies are actin-rich structures associated with a number of neurodegenerative diseases, including familial Alzheimer's disease. A possible link between Hirano bodies and familial Alzheimer's is human Amyloid Precursor Protein (APP). When APP is cleaved, the intracellular portion, called AICD, will normally bind to Fe65 and go to the nucleus to initiate apoptosis (programmed cell death). Yet, in the presence of Hirano bodies, it is sequestered in the Hirano body and cell death prevented. It will be determined whether Mena is the possible connection between the AICD and Hirano bodies because it binds to both Fe65 and actin. Mena is normally found in synapses and has been found to aid in memory. To determine if Mena and Hirano bodies are co-localized in the cell, Mena-GFP was co-expressed with rhodamine-stained Hirano bodies in HEK (Human Embryonic Kidney) cells. Mena concentrated into unexpected aggregations that are rich in F-actin in the cytoplasm on one edge of the cell. Further experiments will show whether Hirano bodies are related to these novel structures or if increased Mena concentrations alone cause novel structures to form. Also, it will be determined if Mena is essential for the recruitment of AICD to the Hirano body by using Mena knock-out cells. The possible function of Mena in the AICD sequestering process or its role in the unexpected structures is very important in the search to explain the function of Hirano bodies as well as the possible implications for Alzheimer's disease.

The Effect of Titanium Dioxide Surface Area on Its Photocatalytic Activity

Whitney Ingram
Dr. Yiping Zhao, Department of Physics & Astronomy, University of Georgia

Titanium dioxide (TiO_2) is a highly effective photocatalyst under ultraviolet and near-visible irradiation. Photocatalysts such as TiO_2 accelerate photochemical reactions, and have been used to degrade organic substances. The catalysts are primary candidates as materials for hydrogen generation and the self-purification of water and air. The photocatalytic abilities of TiO_2 are limited by the quick recombination of the photogenerated electron-hole pair, slowing photodegradation activity. Previous research indicates tilted nanorods fabricated by an oblique angle deposition (OAD) technique produce a highly efficient photocatalyst; however, a systematic study of the relationship between photocatalytic activity and TiO_2 surface area has not been completed. The purpose of this experiment is to study and analyze the effect of the total surface area of the nanorod structure on the photocatalytic activity of TiO_2. Several nanorod arrays were fabricated by a custom-built electron-beam deposition system using the OAD method, with the nanorod height, and thus surface area, controlled by altering the thickness of the deposition. To quantify the photocatalytic behavior, TiO_2 substrates were placed in an aqueous solution of methylene blue (MB) and irradiated by UV light for regular time intervals. A UV-Vis spectrophotometer measured the absorption of the MB solution after each

irradiation interval, and the decay over time of the $\lambda = 664$ nm peak, which is characteristic of MB, was used to measure photocatalytic activity. Results have so far identified a direct relationship between the surface area of the nanorod substrates and their degradation rate.

From Hills to Plains: Cormac McCarthy's Use of Terrain, Landscape, and Environment
Wes Jackson
Dr. Hugh Ruppersburg, Department of English, University of Georgia

Cormac McCarthy's novels focus on two specific regions in the United States. Along with his tenth novel, *The Road*, McCarthy's first four novels are set in Appalachian Tennessee, while the next five take place around the U.S.-Mexico border. Similar to William Bartram's and Willa Cather's use of landscape and setting, McCarthy's novels chronicle 100 years of characters' relationships to the landscape and should, therefore, be examined in the context of America's literary understanding of its environment. Further, I will gauge McCarthy's influence of narrating the landscape by comparing his Appalachian narratives to more recent works about the region, such as Charles Frazier's *Cold Mountain*. The Appalachian novels provide protagonists who encounter their environment on personal levels, and these relationships emphasize different psychological and theological dynamics of their contact with landscape. The landscape in the Southwestern novels, alternatively, emphasizes America's collective response to environment by echoing the lost cultures forced out by expansionism. While many can see in McCarthy's novels a strong conservationist theme, his work delves past ideas of preservation and reveals more fundamental elements of America's collective understanding of the physical world. Ultimately, McCarthy's novels show how we relate with landscape on psychological, spiritual, and metaphysical levels.

Drugs and Deterrence
Robert Jacques
Dr. Mark Cooney, Department of Sociology, University of Georgia

The deterrence of individuals is a justification for criminal laws and their penalties. Deterrence is based on the pleasure-pain principle and the severity, certainty, and swiftness of a punishment occurring after a crime has been committed. Jeremy Bentham identifies four types of sanctions in which the pleasure-pain principle operates: political, physical, moral, and religious. A body of work has emerged in recent decades that attempts to find a deterrent effect for crimes and the punishments associated with their violation. In terms of illegal drugs, these studies are limited to how criminalization affects marijuana use. This study attempts to study how people are deterred from using and selling different drugs in terms of the sanctions identified by Bentham. Surveys and interviews were conducted with more than twenty individuals with widely varying histories of drug use and drug dealing. At first, surveys were completed and, time permitting, interviews were conducted. After it was found that interviews provided much more useful data than surveys, interviews began to be exclusively used. Social relationships and moral sanctions were found to be the most important factors influencing a person's drug habit; the law and criminal justice system was rarely attributed to having much influence in deterring individuals, even among those currently part of the criminal justice system. Since a created deterrent effect is often used to justify drug criminalization, this research may provide new insights on drug policy and how people are deterred from using and/or selling drugs.

Early Voting in Georgia: A Compromise for Accessibility and Efficiency
Alex Johnson – Roosevelt@UGA
Dr. Charles Bullock, Department of Political Science, University of Georgia

Now that nearly all adult American citizens are guaranteed the right to vote, too few actually exercise their duty to participate in the world's most prominent democracy. The U.S. ranks near the bottom of all industrialized democracies in voter participation. The state of Georgia is even worse, ranking the sixth worst state in total voter turnout. While all institutional barriers have

been dismantled, this policy proposal addresses how Georgia should encourage voter participation and eliminate inconveniences that act as a barrier to voter participation. While no panacea exists for declining participation, there are many progressive alternative voting methods that can eradicate inconvenience as an excuse for abstaining from voting. The Georgia General Assembly should pass legislation to make voting more convenient and accessible for all Georgians. To compromise opposing partisan arguments and possibly achieve improved voter turnout, Georgia should include Saturday to its successful early voting period while shortening its five week period to three weeks. Additionally, this legislation should encourage absentee ballot usage by allowing voters to become permanent absentee voters. Extending Georgians' ability to vote through these measures, this legislation's two-prong extension may increase voter participation. Registered voters who have been less likely to vote in past elections will find that participating in democracy is more convenient, less time-consuming, and beneficial to themselves and their community.

Use of Click Chemistry to Assess Glycoprotein Dynamics in Cultured Cells

Steven Johnson
Dr. Richard Steet, Department of Biochemistry & Molecular Biology, University of Georgia

Bioorthogonal chemical reporters are novel reagents in the field of chemical glycobiology that can be used for *in vivo* imaging of glycoproteins in cultured cells. Unlike large, bulky genetically encoded tags such as green fluorescent protein (GFP), these reporters are small molecules that can be incorporated into the cell's glycan biosynthetic machinery without harming the biological system. One such reporter, N-azidoacetylmannosamine (ManNAz), is a sugar analog that is capable of integrating into nascent glycoproteins as sialic acid residues. A chemical 'handle' can then be covalently linked to the azido group of incorporated ManNAz residues, allowing for the visualization of the modified glycoproteins using fluorescent probes that recognize this 'handle.' Our goal is to use this technique (known as "click chemistry") to investigate the nature and dynamics of glycoprotein storage in lysosomal storage disorders such as mucolipidosis II (ML-II), a congenital disease characterized by improper catabolism and accumulation of undigested macromolecules. Employing both epifluorescence and confocal microscopy, we have successfully visualized the accumulation of sialic acid-containing glycoproteins in the lysosomes of ML-II cells. Furthermore, the click chemistry has allowed us to view the dynamics of extracellular matrix (ECM) glycoprotein synthesis and turnover within WT cells. The application of different azide sugar precursors in other lysosomal storage disease tissues should provide us with additional ways to study the trafficking and turnover of glycoproteins in these cells. Our findings could facilitate new methods for lysosomal disease diagnosis and will provide unprecedented opportunities to track glycoprotein dynamics and turnover in affected cell types.

Characterization of an RNP Complex Involved in Invader Defense in *Pyrococcus furiosus*

Lindsay Jones – CURO Scholar, CURO Summer Fellow
Dr. Michael Terns and Dr. Rebecca Terns, Department of Biochemistry & Molecular Biology, University of Georgia

In eukaryotes, a system known as RNA interference (RNAi) provides defense against genome invaders such as viruses. Recent work indicates that an RNA-mediated system for viral defense also exists in most prokaryotes. Specifically, the prokaryotic CRISPR/Cas (Clustered Regularly Interspaced Short Palindromic Repeats/ CRISPR associated) system is a proposed analog of the eukaryotic RNAi system. CRISPR gene loci produce small RNAs known as prokaryotic silencing RNAs (psiRNAs), and Cas genes produce the proteins of this putative defense system. My research objectives were to characterize CRISPR locus transcription and to identify Cas proteins that interact with psiRNAs of *Pyrococcus furiosus*. Northern analysis suggests that CRISPR

transcription is unidirectional and produces large precursor RNAs. Furthermore, the data indicate that individual psiRNAs are generated by successive cleavages within repeat sequences adjacent to each psiRNA. To identify which of the numerous Cas proteins specifically interact with psiRNAs, we subcloned the genes of Cas proteins into *Escherichia coli* protein expression vectors. The Cas proteins were expressed, purified, and tested in RNA-protein binding (gel mobility shift) assays with RNA species representing either mature psiRNAs or processing intermediates. We identified a Cas protein that selectively and independently interacts with larger CRISPR RNA species but not smaller component RNA sequences. This RNA/protein interaction appears to recruit several additional Cas proteins to the RNA. The larger RNA-protein complexes that we have assembled may play an important role in the putative prokaryotic RNAi pathway.

Policy on the Crisis in Northern Uganda

Meredith Jones – Roosevelt@UGA
Dr. Maurits van der Veen, Department of International Affairs, University of Georgia

Northern Uganda has been plagued by over two decades of war perpetrated by the Lord's Resistance Army (LRA), a rebel army infamous for child soldiering. Although peace talks were held between the LRA and the Ugandan government between 2006 and 2008, it is now clear that Joseph Kony, the spiritual and military leader of the LRA, was never interested in negotiation. Last December, in response to a massive increase in the number of attacks made by the LRA, Uganda, the Democratic Republic of the Congo, and Sudan launched a military front against the LRA. While the fact that an alternative to peace through diplomacy was a progressive step, so far the mission has failed miserably and provoked Kony to retaliate with what have been called "The Christmas Massacres," a series of violent attacks killing over 400. If real progress is to be made toward peace, the international community must first recognize the severity of Kony's crimes. Though the International Criminal Court has indicted Kony and other top LRA leaders for crimes against humanity, the amount of action or even rhetoric concerning the crisis is disproportionate. Second, a more strategic plan for Kony's apprehension and arrest must be developed. In this area, the US can contribute the most aid through logistical support and intelligence. Lastly, a comprehensive plan for reconstruction in the northern region of Uganda must be created to secure long-term peace and stability. In order to arrive at the best policy option for ending this twenty-year-long war, I analyzed the history of the LRA and the methods that have been attempted in the last twenty years under President Museveni's rule to defeat this rebel group. I used a timeline to organize qualitative and quantitative research concerning the relationship between various policy options and the overall "level of peace," which I used to measure the success or failure of the policy action. Lastly, I examined past government action as well as case studies concerning similar rebel groups that had been successfully defeated through government action.

How Has the Gospel of John Been Used to Denigrate the Jews?

Elizabeth Katz
Dr. Wayne Coppins, Department of Religion, University of Georgia

Since over half of the references to "the Jews" in the Gospel of John suggest a negative literary association, it is not surprising that the text has been used in Anti-Semitic rhetoric throughout the centuries. While scholars today verbally acknowledge that certain verses from the Fourth Gospel have been used to denigrate ethnic Jews, little work has been done to explore such discriminatory uses. In this presentation, instead of assuming the historical-critical focus on original meaning and context, I will assume the focus of reception history, which is on such historical interpretations and uses. This talk will examine the way the Gospel of John has been interpreted and used Anti-Semitically at influential points in its history such as in the Early Church documents, Luther's writings, and Nazi rhetoric. It seems these earlier interpreters read the term "the Jews" in its original context in John to apply to all ethnic Jews and then applied

this interpretation to contemporaneous Jews. This analysis will inform the way contemporary scholars engage the brutal history of the Fourth Gospel's use, as they seek to be faithful to the original situational text and mindful of the way the text has been exploited. Whether or not scholars agree with defamatory uses of the Gospel of John, the importance of understanding the particularities of such uses cannot be disregarded in this age of fundamentalism.

Fibrin Deposition in the Malaria-Infected Placenta: A Disruption in the Balance Between Coagulation and Fibrinolysis
Lauren Kelly – CURO Scholar
Dr. Julie Moore, Department of Infectious Diseases, University of Georgia

Placental malaria (PM) is characterized by accumulation of *Plasmodium falciparum*-infected red blood cells in the human placenta. This leads to maternal anemia and poor fetal outcome, including low birth weight and possibly perinatal death. Primigravidae are more susceptible to the devastating consequences of PM, suggesting the presence of gravidity-dependent immunological resistance among malaria-exposed women. Common features of PM include monocyte infiltration to the maternal blood space and excessive fibrin deposition, an end-product of blood coagulation. The immune factors involved in the recruitment and activation of maternal immune cells to the placenta and their role in local hyper-coagulation are poorly understood. It is hypothesized that syncytiotrophoblasts, fetal cells facing the maternal blood circulation, secrete these cell mediators as well as pro-coagulants or anti-fibrinolytics, resulting in the influx of maternal immune cells and clotting/fibrin accumulation. To address this hypothesis, placental plasma samples were collected in malaria-endemic western Kenya and stratified according to PM status and gravidity. The results reveal higher levels of soluble immune factor expression in PM+ primigravidae compared to multigravidae. The levels of plasminogen activator inhibitor-1 (PAI-1), which inhibits fibrin degradation, and Tissue Factor Pathway Inhibitor (TFPI), which suppresses clotting, are being evaluated by ELISA. Finally, semi-quantitative estimation of fibrin and PAI-1 protein by western blot is also being performed. Elucidation of which soluble immune and coagulation factors are expressed during PM will contribute to understanding the immunological mechanisms occurring at the materno-fetal interface of the malaria-infected placenta.

String Theory and Its Mathematics
Tyler Kelly – CURO Summer Fellow
Dr. Elham Izadi, Department of Mathematics, University of Georgia

When working in String theory, Kaluza-Klein theory demonstrates six extra dimensions in addition to our typical 3 spatial and one time dimension are necessary. In relation to our current scope of the real world, what do these six extra dimensions look like? The criteria given for these extra dimensions constitute a Calabi-Yau shape, a geometric object that has had its own history throughout the history of mathematics. We will explore these questions, the Calabi-Yau space's time in the limelight, its properties and algebro-geometric characteristics.

Mandatory Health Insurance: A Necessary Change
Erin Kennedy – Roosevelt@UGA
Dr. Audrey Haynes, Department of Political Science, University of Georgia

According to the latest reports by the U. S. Census Bureau, 45.7 million individuals in the United States are uninsured. Despite current government programs, 31.6 percent of persons below the poverty level lack insurance, and 24.5 percent of households with an annual income less than $25,000 have no health insurance. A large uninsured population creates numerous problems, including higher premature mortality rates for the uninsured, higher health insurance premiums for the insured, and financial and logistical pressure placed on the healthcare industry. After researching domestic and foreign health care policies, current problems, and purposed solutions, it has become clear that a new approach must be taken. The United States

must implement a policy requiring all residents of the United States to purchase health insurance operating on a bracketed system established for addressing the needs of the poor and under resourced. Universal mandatory health insurance will be costly, but the long-term benefits of this policy will far outweigh the initial costs. The socioeconomic benefits include the potential to lower health insurance premiums, improve the quality of care received by the previously uninsured, increase the health and longevity of the populous, and even increase economic productivity.

Chicken Pedigree Flocks are the Ultimate Source of *Salmonella* Contaminating Poultry Meat

Akshita Khetarpal, Chris Cornelison, Mopelola Oluwadeire, Puja Bharucha, Zuhha Ashraf, Amyn Lakhani, and Hunter Faircloth
Dr. John Maurer, Department of Population Health, University of Georgia

Salmonella is one of the leading contaminants found in the poultry products, which causes illnesses in many consumers of meat and eggs throughout the world. In the poultry industry, *Salmonella* is challenging to eradicate and control due to its ability to be transmitted horizontally, which is direct or indirect contact with pathogenic environment, or vertically, which is the spread of *Salmonella* from parent breeder birds to the next generation of birds. We believe that chicken pedigree flocks are the ultimate source of *Salmonella* contaminating poultry products. *Salmonella* was isolated from primary breeder, broiler breeder chicken farms (reproductively active birds), and broiler chicken farms (meat birds). One of the methods used to test this hypothesis was running pulse field gel electrophoresis (PFGE) to relate *Salmonella* isolates from chicken carcass to the primary breeder farms. CDC uses PFGE as the standard protocol to recognize outbreaks by matching DNA fingerprints. Upon running PFGE, it was observed that *Salmonella* strains from chicken carcasses, broiler farms, or broiler breeder farms matched strains from primary breeder. Vertical transmission of specific *Salmonella serovar* (Enteritidis, Heidelberg, and Kentucky) was observed between the primary breeder farm and chicken carcasses, and broiler breeder farms. On the other hand, we also observed some *Salmonella* strains that did not match to the primary breeder level. It is important to control *Salmonella* through vaccination at the primary breeder level and broiler breeder level to prevent chicken carcasses contamination from *Salmonella*.

Imaging of Seizure-Induced Ca2+ Waves in Developing Zebrafish

Jung Kim – CURO Summer Fellow
Dr. Andrew T. Sornborger, Department of Mathematics and Dr. James D. Lauderdale, Departments of Cellular Biology, University of Georgia

Over 50 million people suffer from epilepsy worldwide. Seizures in two thirds of all patients have no known cause, and seizure is the second leading cause of disability and death of children under the age of fourteen. Current evidence indicates that seizures in children differ from those in adults. Larval zebrafish are a good model organism to study seizures *in vivo* due to 1) their transparent body, 2) their fast growth during embryonic development, 3) the availability of chemicals known to artificially provoke seizure, and 4) their genetic proximity to humans as vertebrates. In this study, I tested the hypothesis that the pattern of seizure activity changes in zebrafish as a function of brain development. Zebrafish transgenic for a genetically encoded calcium (Ca^{2+}) indicator, known as *cameleon*, were utilized to measure Ca^{2+} concentration changes in neurons. Changes in Ca^{2+} concentration can be used as an indicator of neural activity because synaptic events are triggered by calcium inflow into the neurons. A statistical technique called the Statistical Optimization for the Analysis of Ratiometric Signals (SOARS) developed by our laboratory was used to detect and analyze seizure-induced Ca^{2+} waves in the central nervous system (CNS). Seizure was provoked by pentylenetetrazol (PTZ), and zebrafish at one to eight days post-fertilization were imaged using confocal microscopy. Analysis of my imaging data revealed that 1) the magnitude of Ca^{2+} waves

increased as the brain became more complex, and 2) the duration and frequency of waves changed as the brain matured.

Exercise and Cognition in Overweight Children

Anne Kimball
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Evidence has suggested that exercise can have a variety of beneficial effects on cognition. This study investigates whether exercise benefits children's executive control (EC). EC constitutes supervisory control of cognitive functions, including inhibition and allocation of attention and memory. The participants were 25 sedentary, overweight (BMI $\geq 85^{th}$ percentile) children ages 8-11 years old. Subjects were randomly placed into either an attention control group, which engaged in instructor-led sedentary activities, or an exercise intervention group, which participated in aerobic training for 40 minutes/day, 5 days/week for 9 months. An antisaccade task and Eriksen flanker task were used as behavioral measures of EC and were tested at the beginning of the intervention and at 9 weeks. Antisaccade tasks involve the suppression of a prepotent visual response and generation of eye movement towards the mirror-image unmarked location. The flanker task requires suppression of interfering responses and selective attention to a central target. Because antisaccade and flanker tasks are relatively well-understood measurements of EC, observing changes in antisaccade and flanker performance over time for both groups could provide evidence for an effect of exercise on cognition. It is hypothesized that the exercise group will demonstrate increased performance on both antisaccade and flanker tasks as compared to the control group. By providing evidence for the positive effects of exercise on cognition, this study would support the implementation of aerobic exercise programs in schools so that children in America would be healthier, both physically and mentally.

Cap and Trade: A Comprehensive Solution to Georgia's Water Problem

Jarred Klorfein – Roosevelt@UGA
Dr. Todd Rasmussen, Department of Water & Soil Resources, University of Georgia

The state of Georgia suffers from extremely low stream flows, precipitation, and soil moisture, otherwise defined as severe drought. These water shortages create tremendous economic, environmental, and social costs for Georgia. Such climatic patterns are not new; however, increasing demand from rapid population growth will soon exacerbate the consequences of the water crisis. Yet, the state historically intervenes only in times of severe drought and water shortages. These regulatory practices are reactive in nature and fail to offer long-term solutions to the problem. To resolve this dilemma, the Georgia Assembly should enact legislation establishing a cap-and-trade program for water distribution. This system would reduce demand by allocating limited amounts of water to individuals or corporations based on the value of its use. The state government would allocate water credits to pre-established water utilities for distribution. Individuals or corporations may then buy or sell units of water based on need and perceived value of each unit. A market-based approach remedies traditional complications seen in past attempts at regulatory allocations. Using previously established water management districts, water consumption credits would be allocated based on current population assessments as well as previous water consumption. Creating a market through which credits could be bought and sold would insure that credits would be redistributed to their highest valued use. Georgia has yet to implement such a reform, as any water restriction may result in movement of valuable companies towards neighboring states. Two case studies of cap-and-trade mechanisms were also used. As seen in other market reforms, cap-and-trade will alleviate the impacts of current and future water shortages while ensuring that resources are efficiently allocated. Water-move, an Australian based initiative, has been used to create a water market. This has been effective in drought mitigation. In addition, lessons can be

learned from U.S. SO2 cap-and-trade practices, which have significantly reduced harmful emissions.

Detuning London: Street Musicians and the Noise Suppression Campaign in Victorian London

Noah Koon – CURO Scholar
Dr. Steven Soper, Department of History, University of Georgia

A combination of street musicians, balladeers, hawkers and industrial workshops sometimes made life in Victorian London unbearable. Many notable artists and writers expressed their distaste for the noises of the streets in their diaries, books, and art; claiming that it impeded their work and endangered the health of those whose illnesses were treated at home. Others defended street musicians and the like as a cheap and delightful source of entertainment and work for the poor. Many historians have chosen to reflect on this subject with its climax being the 1864 passing of the Metropolitan Police Act. However, the post-1864 debate reveals a larger class conflict and a convergence of authority directed at shaping lower class behavior and order. An analysis of the post-1864 life of the street musician offers a great deal of insight into changing social relations and power structures in the late Victorian era as well as insight into Victorian perceptions of ownership, privacy, immigration, and taste.

Manicures: Not Just Paying for Pretty Nails

Jillian Kornau
Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, University of Georgia

Dress is a major form of nonverbal communication. It is defined as any modification or supplementation to the body (Eicher, Evenson & Lutz, 2008). Manicuring falls under both of these categories: the trimming and shaping of nails is a modification of the body; the addition of color and false fingernails is a supplementation to the body. American women from all social classes pamper themselves by purchasing manicures. While for some women manicures are a weekly routine, for others manicures are a rare indulgence. A woman's nails convey a lot of information. For example, they can suggest her social standing and indicate the type of work she does on a daily basis. The purpose of this paper is to explore the seemingly "mundane," gendered practice of manicures in a scholarly fashion and investigate the emotional and therapeutic benefits women get from it. I provide background information about the practice of manicures and discuss the central role of the manicurist in the process. Many manicurists consider themselves emotional laborers because they are not only supposed to beautify the hands and nails of their clients, but are expected to provide emotional relief to their customers as well. I also investigate why and how manicures are being used as a form of health treatment for the elderly and women with Alzheimer's disease and dementia. Many elderly women consider manicures their only form of beauty therapy. An additional bonus is that, during a manicure, elderly women are touched by the bare hands of the beauty therapist. This is very important because caring human touch is often missing from elderly women's lives. Manicures are part of the hospital treatment of patients of Alzheimer's disease and dementia because this repetitive activity provides them not only with a soothing physical sensation but emotional benefits as well.

Transcription Regulation by the Bacteriophage T4 AsiA Protein: AsiA Interactions with the Beta Subunit of RNA Polymerase

Jackie Lastra
Dr. Jeffery Urbauer, Department of Chemistry, University of Georgia

The AsiA protein is a product of the T4 bacteriophage *asiA* gene. AsiA inhibits transcription at early phage promoters and host promoters by binding to the sigma-70 subunit of the host (*Escherichia coli*) RNA polymerase. AsiA alters the special relationship between the sigma-70 subunit and the β-flap, which results in the inability of the polymerase to properly recognize these promoters. Thus, transcription is inhibited. Because the *asiA* gene is, itself, an

early gene, a feedback loop results that prevents the overaccumulation of the AsiA protein. This is important because AsiA is toxic to the host cell. This antibiotic/antimicrobial potential could, therefore be exploited to assist in developing a novel class of antibiotics that mimic, mechanistically, AsiA function. We have localized the β-flap binding site on AsiA to regions near the C-terminal portion of the AsiA molecule using nuclear magnetic resonance (NMR) spectroscopy. Furthermore, we have determined the affinity of AsiA for the β-flap region using surface plasmon resonance (SPR). To define the contributions to affinity of each of the amino acids in the binding region, alanine scanning site-directed mutagenesis was employed. Each of the amino acids in the putative β-flap binding region was mutated to alanine to assess the contribution of that amino acid side chain to affinity for the β-flap. The structural integrities of the mutants were confirmed using NMR. The studies to measure the affinities of these mutants for the β-flap are ongoing. Overall, our results will be integral to a comprehensive, general understanding of transcription regulation.

Biopsychosocial Factors and Healthcare Utilization in Children With Non-Cardiac Chest Pain

Jennifer Lee – CURO Summer Fellow
Dr. Ronald Blount, Department of Psychology, University of Georgia

Chest pain is a frequent reason for referral to pediatric cardiologists. However, 95% of these children experience pain that is non-cardiac in origin. In the vast majority of these instances, the cause of the pain is idiopathic. Currently, the little research that has been done in this area suggests that psychosocial factors may play a prominent role in the etiology, severity, and maintenance of this condition. The purpose of this ongoing study is to delineate factors particular to children and adolescents who present in a cardiac specialty clinic with non-cardiac chest pain (NCCP) versus those who present with innocent murmurs (IM). Participants include individuals 8 to18 years old who were referred to a pediatric cardiology clinic for a first time evaluation of symptoms of chest pain or heart murmur. Only patients with a diagnosis of NCCP or IM were retained in the study. Data were collected in three cardiology clinics as part of the patient's medical work-up. Measures of pain, somatic symptoms, psychological symptoms, and healthcare utilization were administered to the children and their parents. Preliminary results indicate that children with NCCP experience significantly more somatic symptoms, anxiety, and depression than children with IM. They also experience greater functional disability due to their symptoms. Children with NCCP also had significantly higher rates of healthcare utilization in the past year than those with IM. Applications for this research include clarifying the contribution of these psychosocial factors to inform efficacious treatment, decrease familial distress, and decrease health care utilization.

Georgia's Forest Biomass and the 2007 Energy Bill: What's Wrong and How to Fix It

Jonathan Lee – Roosevelt@UGA
Dr. Robert Izlar, Department of Forest Resources Management/Renewable Natural Resources Policy, University of Georgia

The Energy Independence and Security Act of 2007 (EISA) reduces Georgia's ability to economically manufacture renewable liquid fuel from forest biomass. Georgia ranks among the top of all states in its possession of obtainable forest biomass, but the Act's definition of "renewable biomass" excludes the majority of Georgia forestland from being used to manufacture transportation fuel. The purpose of this research is to suggest and support a definition that would better enable Georgia to establish a viable renewable fuels industry. This definition should be a broader, more scientific definition which includes any organic material available on a renewable, recurring basis. This definition would likely incorporate appropriate federal lands and all private forestland in compliance with current Georgia's Best Management Practices for timber harvest. Naturally regenerated hardwoods and plantation-grown pines would likely be included regardless of when they were last harvested. With this

broad renewable biomass definition, nearly 24 million forested acres of Georgia's 34 million acre total land base would qualify for use in the production of transportation fuel under EISA. Research is based on literature including congressional testimony, trade association position statements, personal interviews, and newspaper articles. Forest inventory reports and scientific journals are included when appropriate. The research intends to show that current law will not have the long-term effect of increasing the size of Georgia's forest cover, jeopardizes the establishment of a renewable fuels industry in the state, and, finally, that its language is based on a precautionary, yet misguided, philosophy of environmental protection.

The Importance of Specific Genes within the Cobalamin Region of Mycobacterium Tuberculosis and Their Effect on Virulence

Natasha Lee
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

Tuberculosis (TB) is an infectious disease caused by the bacillus Mycobacterium tuberculosis. In 2005, 9.2 million people were diagnosed with the disease and 1.7 million deaths were recorded. The World Health Organization estimates that one-third of the world's population is infected with TB, and 10% of those infected have the risk of developing the active form. In order to successfully prevent, diagnose, and treat this disease, it is imperative to understand the mechanisms this pathogen uses to survive in a human host. Cobalamins, such as vitamin B12, are cofactors in many reactions including DNA synthesis, protein synthesis, and fat and carbohydrate metabolism. M. tuberculosis contains a cluster of genes that are thought to be responsible for production of cobalamin. It is hypothesized that this cobalamin synthesis region is advantageous towards the survival of this pathogen in the human host. This biosynthetic region contains additional genes that are known to contribute to virulence. To determine if cobalamin is involved in virulence, a mutant of M. tuberculosis strain Erdman lacking the cobalamin cluster has been constructed. To clarify which genes are required for cobalamin synthesis, several plasmids carrying different parts of the deleted region will be cloned and transformed into the mutant. Progress towards the construction of these plasmids containing the specific cobalamin regions will be presented. If specific genes can be discovered to affect virulence and pathogen survival, then it is possible to better diagnose and treat tuberculosis.

Poetic Pedagogy: Teaching Creative Writing at Coile Middle School

Laura Leidner
Dr. Melisa Cahnmann-Taylor, Department of Language & Literacy Education, University of Georgia

According to Cahnmann (2006, 2008), seldom do teachers find opportunities within the mainstream classroom to listen deeply and attentively to the music in students' vernacular uses of language or the creativity and content in their spoken and written words. This research chronicles my experiences as a novice creative writing educator working with eight low-income, dialect speakers of English in the context of an after school middle grades program in Georgia. Following Cahmann's (2006, 2008) use of poetry and Hankins (2003) use of narrative as data in teacher research, a narrative and poetic journal has been constructed, filled with field notes, or what Hankins describes as "heartnotes," which are reflections that document experience, acknowledge personal biases and critically and poetically reflect on those biases. Analysis draws both on students' engagement in the creative writing process as well as the effect narrative and poetry have on my own experiences as a first time creative writing instructor. The narrative and poetical journal documents patterns in students' writing and in my own journaling, specifically, areas of greatest strength, weakness, and noteworthy misunderstandings. Analysis of these patterns will ultimately answer the question of what needs greater instructional emphasis: more traditional literary analysis, poetic and creative writing mechanics or instructor-student empathy

and understanding. Findings discuss "the craft, practice and possibility" (Cahnmann, 2003) of maintaining a creative stance toward English language instruction. A hybrid presentation including poetry and prose will be used to communicate intellectual and emotional conclusions drawn from this teacher-research experience.

Comparative Studies on IDE-Activating Compounds

Marissa Ludley
Dr. Walter Schmidt, Departments of Biochemistry & Molecular Biology, University of Georgia

The insulin-degrading enzyme (IDE) is associated with the clearance of the Aβ-peptide, which is believed to be the neurotoxic agent in Alzheimer's disease. IDE is part of the M16A subfamily along with the yeast enzyme Ste23p that is highly similar in amino acid sequence, having approximately 40% identity. Because of these and other similarities, we hypothesize Ste23p and IDE to have similar enzymatic profiles. To test the hypothesis, the enzymatic activities of the two enzymes and several other proteases were compared and contrasted using a fluorescence-based assay and a panel of eleven IDE activators previously identified by the Schmidt lab. The assay makes use of a synthetic dodecapeptide substrate that is readily cleaved by M16A proteases. This comparison is important for understanding the mechanism of activator action and the specificity toward M16A enzymes, which will impact the development of potential therapeutic strategies for Alzheimer's disease. While some compounds activated both Ste23p and rat IDE, as originally hypothesized, others affected Ste23p and IDE differently. Compounds 4, 8, 9, and 10 were most specific for the M16A proteases, having a limited effect on bovine trypsin and the yeast proteases Rce1p and Ste24p, all of which are unrelated to M16A proteases. Future investigations of the effect of compounds on the activity of human IDE, especially in the context of Aβ as substrate, are now being planned. Since insulin is another substrate of IDE, we also plan to determine the impact of these compounds on modulating insulin degradation. It is our long-term aim to use our specificity data in the development of new compounds that specifically enhance IDE-mediated Aβ degradation over that of insulin so as to minimize non-specific effects associated with an IDE activator-based therapeutic strategy for Alzheimer's disease.

Investigation of the Genetic Basis of Longevity in *Caenorhabtitis elegans* Using Microarray Analysis

John Marshall
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia

Mutations in genes along the insulin-like signaling pathway in *Caenorhabditis elegans* cause the largest lifespan modulations recorded in science. We seek to explain the mechanism behind this phenomenon by documenting gene expression in animals with these mutations via microarray analysis. A population of *C. elegans* with a hypomorph daf-2 gene displays both increased median and maximal lifespan. The daf-2 protein is analogous to the insulin receptor and operates at the beginning of the cascade. The daf-16 gene functions as a downstream suppressor of both categories of lifespan phenotype. O-GlcNAc is a common regulatory post-translational modification to proteins along this pathway, and hypomorphs of the O-GlcNAc cycling enzymes also impact lifespan. The ogt-1 mutation (coding for O-GlcNAc transferase) brings only median lifespan back to wild type, thereby closing the phenotypic gap between the daf-2 mutant and the daf-2; daf-16 double mutant. In this study, RNA extracted from nine-day-old populations of several *C. elegans* strains will be sent off for microarray analysis. This will provide information on how the genes known to influence lifespan are impacting regulation of other nearby genes. In the data, we will be looking for genes which are brought back to wild type expression levels in daf-2; daf-16 mutants but not in daf-2; ogt-1 mutants. Such genes will be prime candidates for the genetic basis of maximal longevity, and understanding their biochemical functions will help indicate the mechanism by which insulin signaling is

modulating lifespan. This study carries implications for any species with the insulin signaling pathway

Perceptions About the Implementation of the Georgia Performance Standards in Mathematics

Jasmine Mathis – CURO Apprentice
Dr. Patricia Wilson, Department of Mathematics & Science Education, University of Georgia

In 2008, the Georgia Department of Education decided to change its high school curriculum from the Quality Core Curriculum to the Georgia Performance Standards (GPS). The Georgia Mathematics Performance Standards combines the previous subjects of Algebra, Geometry, Statistics, Trigonometry, and Pre-Calculus into an intensive four year study sampling from at least three of these subject areas every year. This project was developed to evaluate the views of teachers, parents, and students during the first few years of the Georgia Performance Standard's implementation. The opinions of the teachers, parents, and students have a direct relationship with the success and longevity of the Georgia Mathematics Performance Standards. A series of surveys and interviews will provide an outlet for the stakeholders to express their opinions and a viable way for the perspectives on the implementation of the Georgia Mathematics Performance Standards to be carefully interpreted. This study will help teachers and school district officials to understand what participants think about new curricular innovations and help to improve its implementation.

The Relationship Between Parental Disciplinary Practices and Children's Social and Emotional Competence in Low-Income Families

Megan Matuszak, Brandi Kelley, Melissa Roth, and Rachel Zudekoff
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Parents are influential in providing an environment for their children to develop social and emotional competence starting from an early age. Specifically, how parents regulate children's misbehaviors through disciplinary actions may contribute to children modeling parents' behaviors in interacting with others. At-risk children are distinct in their interpretation and regulation of emotions with characteristics such as withdrawal or externalizing behaviors. Examining the influence of parental disciplinary strategies and the attributions of wrongdoings on at-risk children's outcome behaviors poses important implications for interventions. The study consists of two waves of data collected over 3 years in documenting children's social and emotional development from multiple assessments. Forty-three children, with ages ranging from 37 months to 43 months, from a community Headstart program participated in the study. These children were nominated by their teachers based on various types of social and/or emotional issues displayed in the classrooms. Parents completed a parental survey describing the frequency of various positive and negative behaviors observed at home, along with attributions of these behaviors and the disciplinary strategies used. The results of our study reveal that when a parent chooses disciplinary strategies such as Time Out or Ignoring, and chose not to properly explain the reason for punishment, the child may comply with the punishment but not understand which behavior caused them to be disciplined. The child may internalize these forms of discipline as unreasonable or neglect, resulting in social and/or emotional issues expressed through negative behavior that occur in the classrooms, qualifying them for the study.

***Altered Surfaces*: Fabric Manipulation and Design**

Malorie McCloy
Prof. Clay McLaurin, Department of Fabric Design, University of Georgia

The main focus of my research is fabric manipulation: folding, layering, and stitching of flat fabric to create surfaces with volume, texture, and dimension. I construct fabrics that are made up of small components of manipulated fabric, which combine to form a whole, just as the petals of a flower combine to create something that is more graceful and beautiful than simply the petals themselves. I enjoy working with small components because they allow me to gradually build up a fabric's surface over time, exposing my evolving thought process as I go along. There is a natural sense of movement and energy to these pieces. I find myself balancing a playful aesthetic with rich, sumptuous colors and textures. To further expose the transformative nature of my work, I reinterpret the textural surfaces in a two-dimensional format through drawing and screen-printing. The process is endless, and the excitement lies in that I never quite know what the outcome will be.

Glycan Interactions and the Development and Spread of Cancer Cells

Katherine McGlamry – CURO Summer Fellow
Dr. Michael Tiemeyer, Department of Biochemistry & Molecular Biology, University of Georgia

Signaling through the Notch receptor protein modulates cellular differentiation during normal development and maintenance of stem cell populations. Disruptions in these interactions contribute to the initiation and spread of cancer. For Notch to function correctly, it must be modified with O-linked glycans that begin with a fucose residue. Extension of the Fuc with an N-acetylglucosamine is accomplished by an enzyme called Fringe. In vertebrate tissues, the GlcNAc-Fuc disaccharide is extended with galactose and sialic acid. In *Drosophila*, it has been unknown what happens to the GlcNAc-Fuc disaccharide until recently. We have identified an extension of the GlcNAc-Fuc disaccharide with glucuronic acid. The novel glucuronylated trisaccharide is the dominant O-Fuc glycan in the *Drosophila* embryo. To determine whether this glycan structure participates in Notch signaling, O-linked glycans were isolated from embryos mutant for the Fringe enzyme. Interestingly, the O-Fuc trisaccharide was reduced, but not eliminated by this mutation, indicating that previously unknown Fringe-like activities are present during embryogenesis. This new complexity in Notch signaling may relate to human cancer progression. We are applying our techniques to characterize the diversity of N- and O-linked glycans expressed in pancreatic cancer sample. If indicators of abnormal cell-cell signaling are found, they may serve as early markers for pancreatic cancer. Our pilot studies are focused on fluid harvested from the pancreatic duct of patients with pancreatitis and presumptive pancreatic cancer. Initial efforts indicate the need to determine which markers report pancreatic cell function and not confounding contamination by blood proteins.

A Physical and Enzymological Characterization of Human Neuron Specific Enolase

Jared McKinnon
Dr. John Brewer, Department of Biochemistry & Molecular Biology, University of Georgia

Enolase catalyzes the ninth reaction of glycolysis, the dehydration of 2-phospho-D-glycerate (2-PGA) to phosphoenolpyruvate (PEP). The reverse reaction, a hydration of PEP to 2-PGA, occurs in gluconeogenesis. Magnesium is required for activity. Enolases are generally abundantly expressed, so are major cellular proteins. In addition, three isozymes of enolase exist in vertebrates. Enolase α is ubiquitous through all cells. Enolase β is muscle-specific. Enolase γ (the one with which we are working) is neuron-specific and is referred to as neuron-specific enolase (NSE). Each enolase is a homodimer. The goal of the research is to determine whether or not the subunits operate independently. The human NSE gene supplied, with a C-terminal His-tag attached to facilitate purification, was expressed in *Escherichia coli*. The enzyme has been characterized physically and enzymologically. Two articles describe the enzymological characteristics of human NSE but present no data. This preparation for human NSE is shown to be homogeneous, as expected from previous experiments. The dependences of activity on magnesium, substrate, and potassium chloride concentrations as well as pH were determined. Stopped-flow measurements of the reaction of human NSE with a slowly reacting chromophoric substrate analogue were done. In tris buffer, the reaction exhibits biphasic kinetics. In PIPES, the magnesium-dependence shows two activation constants. These observations are consistent with catalytically significant interactions between the two active sites. Many cellular proteins exist as oligomers and transmission of information (communication) is crucial to the maintenance of life. Study of a simple system of interprotein communication increases understanding of this fundamental process.

The Absence of Term Limits in the Constitution: Motivations of the Framers

Caitlin McLaughlin
Dr. Daniel Kapust, Department of Political Science, University of Georgia

Following the Revolutionary War, the Framers of the American Constitution sought to establish a new government free from the tyranny of monarchy. Arguably, however, their new system enabled the creation of a new aristocracy through perpetual reelection. This paper examines why the Framers, with their great fear of entrenched power, did not include term limits in the Constitution. In studying contemporary American government charters, it appears clear that this decision went against the common practice of the time. Since the absence of controls on reelection was a radical departure from the norm, this paper examines pamphlets from the early American period to highlight the powerful defenses of term limits. Using notes from the Constitutional Convention as well as personal correspondence, it appears that the Framers themselves were divided on the issue. The ultimate decision to exclude term limits was the result of several arguments, including the belief that the possibility of reelection would encourage good service, the view that voters should have the right to elect whomever they please, and the expectation that other institutional safeguards would prevent the development of tyranny. Indeed, the existence of such a multiplicity of rationales is one of the most important results of this study. With the intent of the Framers functioning as common evidence in modern Constitutional jurisprudence, it is critical to gain a clear understanding of their opinions. This paper suggests that elements of the Constitution were not always the result of unanimity of opinion, making the "Framers' intent" difficult to discern.

Improving the Activity of the Heterologously Expressed Soluble Hydrogenase I from *Pyrococcus furiosus* through the Modification of the BW25113 (*E. coli* K12) Genome.

Alice Meagher – CURO Summer Fellow
Dr. Michael Adams, Department of Biochemistry & Molecular Biology, University of Georgia

Hydrogen is the cleanest, most promising fuel alternative for the future. Hydrogen has approximately three times the stored energy per unit mass as gasoline and can be biologically produced in a carbon neutral reaction, releasing only water as a byproduct. However, the renewable synthesis of hydrogen is currently under-developed and inefficient. *Pyrococcus furiosus,* a hyperthermophilic archaeon, produces a soluble four-subunit hydrogenase enzyme, called soluble hydrogenase I, that metabolizes hydrogen reversibly *in vitro*. To engineer modified forms of this enzyme with tailored catalytic activity and electron donor specificity, we needed to express an active recombinant hydrogenase in a model organism such as *E. coli*. We transformed four plasmids, containing the 13 necessary structural and processing genes, into *E. coli* to enable the expression of recombinant soluble hydrogenase I from *P. furiosus* (USA patent 61/005,383). We are now trying to enhance this specific activity of our recombinant hydrogenase. It is possible that *E. coli*'s native hydrogenase enzymes interfere with the functionality of our recombinant hydrogenase. We hope that by removing the genes associated with native *E. coli* hydrogenases, we will have a clearer background in which to express our recombinant hydrogenase. The future commercial production of hydrogen depends upon our ability to synthesize recombinant hydrogenase more efficiently. Thus, we hope that we can preserve the environment and create a more fuel-efficient society by improving our recombinant enzyme and making hydrogen a realistic fuel alternative.

Food for Thought: A Comprehensive Overhaul of American Food Aid Policy

Catherine Mencher – Roosevelt@UGA
Dr. Stacey Mitchell, Department of International Affairs, University of Georgia

In 2008, global food prices nearly doubled from the year before. Already, hunger kills more people annually than AIDS, malaria, and tuberculosis combined. Despite U.S. efforts aimed at resolving global food insecurity, the inefficiencies of the United States' food aid programs actually compound the problem. Currently, U.S. food aid constitutes nearly two thirds of worldwide food donations, yet roughly 60 percent of food aid appropriations are misspent on domestic subsidies. From a qualitative analysis of historical and economic data provided by United States Department of Agriculture and United States Agency for International Development budgets, the United Nations World Food Programme, and various non-governmental organizations, this study proposes three U.S. food aid reforms: (1) that food aid programs be streamlined and moved under the jurisdiction of an Office of Food Security, whose mandate emphasizes the agricultural development of the recipient country; (2) that those aspects of food aid programs solely benefiting influential U.S. constituencies be eliminated or reduced; and (3) that a food security database be created and made accessible to food aid recipients and stakeholders, allowing for a more cohesive, country-specific approach to hunger. This study contends these improvements will benefit the U.S by lowering U.S. taxpayers' long and short-term American aid costs, and by increasing global security through the enhancement of recipient governments' legitimacy.

Thermal Adaptation and Substrate Limitation of Heterotrophic Soil Microorganisms

Calley Mersmann
Dr. Mark Bradford, Odum School of Ecology, University of Georgia

Heterotrophic microorganisms decompose stores of soil organic carbon and, as a consequence,

release carbon dioxide to the atmosphere. Although, in the short-term, microbial respiration rates increase in response to increasing temperatures, the effect of long-term temperature increases on respiration rates remains uncertain. Due to mechanisms such as evolutionary trade-offs in enzyme function and shifting community structure, it is expected that mass specific respiration (R_{mass}) rates will decrease as soil microbe communities adapt to higher temperature regimes. In order to test this potential, we used a laboratory microcosm approach to impose two thermal regimes (constant 12°C or 28°C) on twelve soil samples for 84 days. Additional carbon in the form of glucose was added weekly to one replicate of each soil to account for the possibility of substrate limitation masking the difference in R_{mass} between the two incubation temperatures. To determine the R_{mass} of the soil microbes, we measured the amount of carbon dioxide produced by each soil sample, using assay methods similar to those used in animal, plant, and microbial thermal adaptation studies. Data are being analyzed to test the hypothesis that at intermediate temperatures R_{mass} will be greatest for the 12°C experimentally incubated soils, and lowest for the 28°C soils, indicating thermal adaptation of microbial respiration. Because the soil ecology community currently dismisses this thermal adaptation relationship, conventional thinking will be challenged if results are consistent with the hypothesis. Additionally, this research is necessary to not only more fully understand microbial respiration responses to changing temperatures but also to more accurately predict possible feedbacks between microbial respiration and climate change.

Determining Genes Required for Virulence in the Opportunistic Intracellular Pathogen *Rhodococcus equi*

Jessica Miller
Dr. Mary Hondalus, Department of Infectious Diseases, University of Georgia

The facultative intracellular bacterium *Rhodococcus equi* (*R. equi*) causes severe, pyogranulomatous pneumonia in neonatal foals, and is a life-threatening pathogen of immunocompromised humans. Virulence of *R. equi* depends on the presence of an ~81Kb plasmid, harboring a ~27.5Kb pathogenicity island (PI) containing several ORFs, including those of a novel family of surface-localized and secreted proteins of unknown function termed the virulence associated proteins (VapACDEFGHI). VapA is essential for bacterial growth in *in vitro* grown macrophages and for bacterial survival in a SCID mouse *R. equi in vivo* infection model. However, VapA alone is not sufficient for virulence, as expression of vapA in a plasmid-cured strain does not restore the virulence phenotype. Determining the identity and location of additional plasmid-encoded virulence genes is the focus of the present study. Our recent data have revealed that these other virulence determinants lie within the PI. For complementation analysis, we have used an avirulent plasmid-cured strain of *R. equi* as a vehicle to express vapA along with various combinations of PI genes. Examination of the intracellular growth phenotypes of the latter recombinants, seen through macrophage infection experiments using the complemented strains, has implicated a potential virulence role for 3 genes, orfs 5, 6, and 7 respectively. In addition, construction and virulence analysis of various unmarked gene deletion strains is underway. The deletion of the potential virulence factors will utilize homologous recombination, employing a single-crossover intermediate step followed by fluorocytosine counter-selection. The combination of complementation and deletion studies will determine the complete set of PI virulence factors.

Ambient Gender Cue Vigilance in Choosing College Majors

David Mitchell – CURO Apprentice
and Christina Smith
Dr. Victoria Plaut, Department of Psychology, University of Georgia

Recent research shows that the broadcasting of masculine stereotypes may underlie the lack of women's participation in the field of computer science. This process has not been tested,

however, in real world learning environments, a limitation addressed in the current study. Whereas previous research used worded descriptions of fictitious settings, the present research examined reactions to real educational environments, via pictures of campus buildings, classrooms, hallways, common areas, and offices. The goal of the study was to gauge reactions to physical environments housing traditionally male-dominated (Computer Science), female-dominated (Education), and more gender-neutral (Business, Journalism) majors. Twenty-nine female and twenty-three male University of Georgia first year students with undeclared majors participated in the study. They first rated their interest in ten distinct career paths. They then viewed unlabeled pictures taken in buildings housing the four majors. Following each set of pictures, participants answered questions concerning their perceptions of social fit with the environment, the desirability of the environment, the masculinity/femininity of the environment, and likelihood of spending their college years in the environment. Results did not affirm the hypothesized gender difference in reactions to the four environments. The results did reveal, however, significant correlations of perceptions of masculinity/femininity with the other ratings for each of the four disciplines for women but not for men. This suggests that women's perception of gender cues communicated by a physical environment may play a significant role in women's motivation to join that environment. Theoretical and practical implications are discussed.

Analysis of Phospholipids in Neuronal Tissue Using Electrospray Ionization-Mass Spectrometry

Prashant Monian – CURO Scholar
Dr. Brian Cummings, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Phospholipids are an important constituent of all cell membranes, and are thought to play key roles in several physiological processes. This research focuses on the use of electrospray ionization-mass spectrometry (ESI-MS) in studying alterations in the phospholipid profiles of neuronal cells in response to different kinds of stress. First, the effects of cocaine withdrawal on the expression of glycerophospholipids in rat brain were studied. For the first time, differences in the expression of phospholipids between different areas of the rat brain were determined by ESI-MS. Withdrawal from cocaine appeared to effect expression of specific phospholipids in a site specific manner, with most of the changes taking place in the hippocampus, the region generally associated with long term memory and spatial navigation. This may explain the long term neuroadaptation associated with drug use. Secondly, alterations in phospholipid and fatty acid lipid profiles in primary neocortical cells during oxidant-induced cell injury were studied. Oxidant-induced alterations in phospholipid composition can lead to decreases in membrane integrity, cell injury and even death. Neurons are especially vulnerable to lipid peroxidation. Treatment with the oxidants hydrogen peroxide (H_2O_2) and *tert*-butylhydroperoxide (TBHP) was found to increase the abundance of phospholipids containing polyunsaturated fatty acids, but had minimal affect on those containing mono- or di-unsaturated fatty acids. In addition, Group IV and VI Phospholipase A_2 (PLA_2) were found to have differential roles in oxidant-induced neural cell injury based on the use of the group specific inhibitors, methyl arachidonyl fluorophosphonate (MAFP) and bromoenol lactone (BEL) respectively.

Behavioral Changes Following Daily Practice of Saccade Tasks in Schizophrenia

Madison Moore – CURO Scholar, CURO Summer Fellow
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

People with schizophrenia show impairment in tasks requiring executive control, like inhibition. A simple test of inhibition is the antisaccade task, which requires a glance towards the mirror image of a peripheral cue. The goal of this study is to determine how practice on the antisaccade task changes performance on that task and on related tasks known to assess executive control. Participants with schizophrenia and healthy

comparison subjects were assigned a single saccade task to practice daily—*either* antisaccades *or* prosaccades (glances towards a peripheral cue)—over a two-week period. Executive control was evaluated at pre- and post-test using two tasks: an ocular motor delayed response (ODR) task measured changes due to practice on a different, but related, saccade task, and the Wisconsin Card Sorting Test (WCST) evaluated whether changes in executive control could generalize beyond saccade tasks. Preliminary results suggest antisaccade practice resulted in modest antisaccade improvement for both normal and schizophrenia groups. Prosaccade practice did not affect prosaccade performance (due to a ceiling effect in both groups). Over the trials, both antisaccade practice groups showed improved performance on ODR and WCST. The schizophrenia prosaccade practice group, however, performed worse on ODR at post-test. In sum, antisaccade, but not prosaccade, practice resulted in modest improvement in performance on all tasks. This study provides evidence that saccadic performance can be malleable within certain parameters and suggests that practicing executive control tasks may be explored as a means of improving activities of daily living.

Creation of a Transposon Mutant Library in Live Vaccine Strain *Francisella tularensis*

Diana Murro – CURO Scholar
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

Tularemia is a disease of small animals and humans caused by the bacterium *Francisella tularensis*. The most virulent subspecies to humans is *F. tularensis* subspecies *tularensis*. Due to its highly-infectious nature, this pathogen was classified as a category A agent by the Center for Disease Control and Prevention. The Live Vaccine Strain (LVS) is derived from *F. tularensis* subspecies *holarctica*. LVS is avirulent in humans, but still replicates in macrophages and causes a lethal infection in mice. Therefore, identifying LVS genes that are required for intra-macrophage survival should also aid in efforts to attenuate the category A strain. The transposon Tn5 is a mobile genetic element that inserts into the target DNA with very little site-specificity, resulting in virtually-random transposition. To generate a transposon system that functions in *Francisella* species, a Tn5 transposome was constructed containing the gene encoding green fluorescent protein (GFP) and the gene encoding hygromycin resistance under the control of *Francisella* promoters. Transformation into LVS should result in GFP-expressing transformants resistant to hygromycin. As transposition is a rare event, experiments are underway to optimize transformation into LVS. The optimized conditions should enable the isolation of a large set of transposon mutants which can then be screened for failure to replicate in cultured macrophages. The transposon is engineered to facilitate the identification of its chromosomal location. Identifying the disrupted genes is a first step in understanding the mechanisms by which *F. tularensis* bacteria escape killing by the host.

Development of Alternate Sources of Macronutrients for a Sustainable Algal Biofuel System

Vandana Murty
Dr. Keshav Das, Departments of Biological & Agricultural Engineering, University of Georgia

A major concern for our economy and environment today is the efficient production of alternative fuels. Algae are an attractive, fast growing source of biomass. Microalgae require nitrogen and phosphorus for growth. However, the prices of these currently mined nutrients have more than doubled over the past year alone (P: $252 to $1250/metric ton; N: $277 to $452/metric ton). Poultry litter is a common and inexpensive source for these nutrients. It is composed of most macronutrients and trace elements necessary for optimal plant growth. The approximate percent compositions of nitrogen and phosphorus in a given sample of poultry litter are 3.2% and 1.5%, respectively. The extraction follows previously determined methods. Serial dilutions were done to quantify N and P concentrations. Then 7 strains of microalgae, including *Tetraselmus chuii*, *Dunaliella parva*, *Phaeodactylum tricornutum, Tetraselmus suecica*, *Pleurochrysis carterae*,

and *Dunaliella tertiolecta*, were grown in different concentrations of poultry litter extracts (PLE) with varying N and P content. After inoculating all strains and measuring biomass after daily intervals, the best performing strains and best dilution of PLE will be identified. If PLE is optimized according to turbidity and nutrient content and provided as the nutrient source for tested species of microalgae, it will be the most economically effective and sustainable way to produce alternative fuels (>15,000 gallons of fuel/acre). By extracting the nitrogen and phosphorus from PL and using it to cultivate microalgae to produce biofuels, we will potentially have a technology that is both inexpensive and applicable in many areas.

The Role of Integrin Activation in Increased Gliogenesis of Human Neural Stem Cell Cultures

Muktha Natrajan – CURO Apprentice,
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Human Neural Stem cells (hNSCs) have the potential to replace brain cells in patients with neurodegenerative disorders and are derived from human embryonic stem cells. Neural cell adhesion and development depend on integrins, which are integral membrane proteins that act as bidirectional signaling molecules. Using integrin activation, hNSCs can adhere to a substrate or implant in the brain to replace degenerated cells. Through activation of integrins, it is hypothesized that manganese will direct cells to a glial fate more rapidly than random differentiation. This study's objective is to obtain an increased rate of gliogenesis due to perturbation of integrin activation, which will result in a more purified glial cell population. To increase the rate of gliogenesis, 0.3 mM $MnCl_2$ differentiation media will be added, and hNSCs will be differentiated for 0, 14, 21, 28, and 35 days on polyornithine and laminin-coated plates. mRNA will be isolated from each treatment using the Qiagen RNeasy kit and cDNA will be synthesized. RT-PCR will determine glial cell gene expression of the following seven genes: GFAP, GLAST, IL6, CD44, CNTFR, Aqp4, and VIM. Immunocytochemistry will be performed by fixing cells in 4% paraformaldehyde and staining using standard immunofluorescence protocols. Antibodies against representative glial proteins will be used. Protocols for differentiating purified populations for future use in cell therapy can be obtained. Ultimately, if the quantity of glial cells in a purified population is known, then patient-specific cells can be generated for the replacement of brain cells in patients with neurodegenerative diseases.

Human Disease and the Kit/KitL Signaling Pathway

Nithya Natrajan – CURO Scholar
Dr. Mary Bedell, Department of Genetics, University of Georgia

Kit ligand (Kitl) is the ligand for the class III receptor tyrosine kinase Kit. In vertebrates, the Kit/Kitl pathway is involved in the development and proliferation of germ cells, melanocytes, and hematopoietic cells. In this pathway, a cell secretes or expresses Kitl, which can then bind Kit on another cell. Upon binding, Kit dimerizes and a reaction cascade is initiated within the cell expressing Kit. This pathway is important in multiple differentiated cell types. Kitl has been shown to be an important cytokine in recruiting and activating mast cells during inflammation. This increased expression of Kitl has been linked to tumor-related inflammation. Kit has also been linked to multiple forms of cancer. Gastrointestinal stromal tumors (GISTs), germ cell seminomas, and acute myeloid leukemia have been linked to constitutive activation of Kit. GISTs, which are mesenchymal neoplasms in the GI tract, are probably the most well-studied diseases with regards to constitutive activation of the Kit/Kitl pathway. Kit has also been found to be over expressed in a number of carcinomas. Possible pharmacological interventions for treating disorders related to the misregulation of Kit or Kitl include inhibitors of Kit or a dominant negative Kit protein. However, these treatments are not effective against all activating mutations in Kit. This pathway and the role of Kit in disease must be examined further so that more effective treatments can be designed.

Changing Places: Examining the Role of Place in Invisible Theater Performance

Kelly Nielsen – CURO Scholar, CURO Summer Fellow
Prof. George Contini, Department of Theatre & Film Studies, University of Georgia

This research focuses on the role of place in invisible theater performances. Invisible theater is a subset of Theater of the Oppressed developed by Augusto Boal in the early 1970s, while he was living in exile in Argentina. Wanting to continue political performances but living under a repressive regime, he and his companions began performing scenes in public places without anyone realizing that a performance was occurring. The scenes address pertinent social issues with the aim of creating dialogue. My research questions how the same invisible theater performance changes when performed in different places. To begin this research I attended the Pedagogy and Theater of the Oppressed Conference, and reviewed a variety of texts, including *Theater of the Oppressed*, *Games for Actors and Non-Actors*, and Boal's auto-biography *Hamlet and the Baker's Son*. I have continued my research by forming a troupe, who have spent the year developing and performing invisible theater scenes. The culmination of the research is a scene addressing domestic violence. This is performed in a variety of places, such as a large corporate shopping center, a small, locally-owned store, a fast-food restaurant, an outdoor setting, and a sports event. Qualitative data are collected through troupe members' journals and recordings of the troupe's post-performance discussions, in which members are asked to address specific questions, such as, "How did you alter your performance to adapt to the environment? What types of technology were present? Did these hinder your attempts to involve audience members?" This research will contribute greatly as there is little research done on this fascinating topic.

The Effects of Fetal Genomic Expression of TNF-aRI and TNF-aRII in *P. chabaudi chabaudi* Complicated Murine Pregnancy

Rachel Nix – CURO Scholar
Dr. Julie Moore, Department of Infectious Diseases, University of Georgia

Malaria is known to cause complications during pregnancy, including low birth weight, anemia, high-density parasitemia, and spontaneous abortion, greatly contributing to the morbidity and mortality of the disease for both mothers and babies. It is known that immune response to the disease significantly contributes to the disadvantageous consequences of malaria-complicated pregnancies. Malaria elicits a type 1 cytokine response. This cellular response to infection uses cytokines to control infection. TNF-a, one such cytokine specific only to the Th1 response, has been shown to have detrimental effects on pregnancy. TNF helps to control malaria by lowering parasitemia, but in turn increases severity by activating an inflammatory response. TNF levels increase in response to malaria. This increased TNF expression has been linked to severity, parasitemia, and fever as well as poor infant outcome. There are two TNF-a inhibitors that have been identified, sTNFR-I and sTNFR-II. These inhibitors are cell-surface receptors truncated by proteolytic cleavage of p55TNF-R and p75TNF-R respectively. The soluble receptors and TNF-a interact by forming a complex that exhibits control over TNF levels. This research aims to determine whether maternal TNF expression or fetal TNF expression is responsible to poor infant outcome in malaria-complicated pregnancy. Female mice with double knockout for TNF receptors were bred with control males and infected with *P. chabaudi chabaudi*. The data collected compare fetal outcomes of pups with and without TNF receptors that are born of malaria-infected, TNF-receptor-absent mothers. Viability of pups after a regulated malaria infection during pregnancy is associated with the absence of TNF receptors in the fetus.

Art & Engineering: A Binocular Vision
Brittany Norman
Prof. Martijn van Wagtendonk, Department of Studio Foundations, University of Georgia

A modern-day Leonardo da Vinci, Dutch artist Theo Jansen claims that "the walls between art and engineering exist only in our minds." What happens when we break down these walls and use tools from both the arts and the sciences to bring our ideas into being? To understand, replicate, and enhance aspects of the natural world—these are the goals of both the artist and the inventor. Both are creators who hope to take the matter around them and give it form and give it life. Drawing on studies in computer science, engineering, and mathematics, these artworks will explore the relationships we have with technology, science, nature, and culture, as well as the relationships these have with one another. What happens when both the artwork and the viewer have the ability to sense and respond? Can mathematics be used to create beauty? How can virtual reality be used to develop a more immersive, synaesthetic space that the viewer is able to explore? Just as binocular vision gives us the perception of depth, so an interdisciplinary approach taken from multiple perspectives can provide us with a depth of understanding that allows us to answer questions like these. Artworks in progress include an interactive video projection which responds to the viewer's footsteps, paintings created with fractals, and excursions into the medium of robotics.

Neuromuscular Activation and Movement Kinematics Exhibited During Sit-to-Stand by Multiple Sclerosis Individuals
Sean O'Rourke – CURO Summer Fellow
Dr. Kathy Simpson, Department of Kinesiology, University of Georgia

Multiple sclerosis (MS) is a chronic and progressive inflammatory disease that adversely affects the central nervous system of an estimated 2.5 million people worldwide. Neural sheath degeneration and subsequent plaque formation underlies the physical limitation seen in MS people (MSP). Given the large MSP population, research dedicated to the development of therapeutic programs is necessary. The purpose of this study was to compare the kinematics and muscle activation between MSP and those without MS (nonMSP) during the functionally demanding, sit-to-stand (STS) movement. A sample of 7 MSP with self-reported EDSS scores of ≥ 3 and 6 matched-control nonMSP were tested. Participants first signed the institutionally-approved consent form and proceeded to produce a standardized isometric knee-extensor torque used later for electromyography (EMG) normalization. Five STS trials were then performed, while EMG for the rectus femoris (knee-extensor) muscle and electromagnetically tracked spatial locations of the lower extremities and the lower spine were recorded. Compared to nonMSP, MSP displayed significantly less ($p<0.05$) normalized EMG during the rising phase of STS. Kinematic data showed that MSP display greater trunk flexion and increased trunk flexion velocity during STS. These trunk movement changes increase momentum of the body before liftoff and are most likely movement strategies to compensate for the reduced knee extensor muscle activity found in MSP during STS. These data additionally showed that MSP utilized a greater rise time for the STS movement. The results indicate that these MSP have reduced functional ability to perform STS even with compensatory strategies. A current pre/post study evaluating the functional capacity of MSP after a flexibility or strength training intervention will provide insight regarding the effectiveness of such interventions on enhancing the functional ability of those diagnosed with MS.

Berg Balance Score Correlates to Postural Stability Measures
Alexander Orellana – CURO Apprentice
Dr. Cathleen Brown, Department of Kinesiology, University of Georgia

Falls due to loss of balance are common in individuals with Multiple Sclerosis (MS), but clinical methods of measuring balance may not be sensitive enough to detect subtle deficits. Our purpose was to determine if Berg Balance Scale (BBS) scores were correlated to instrumented postural stability measures in individuals with

Expanded Disability Status Scale (EDSS) scores <6.5. The BBS was performed and scored according to standardized instructions. The NeuroCom SMART Balance Master Sensory Organization Test was used to test static and dynamic balance. Participants underwent the testing procedure twice, only data from the second session were used. Raw ground reaction force data were converted into postural stability measures (center of pressure displacement, velocity, and sway area). Bivariate Pearson correlations (α=0.05) were used to measure relationships between BBS scores and center of pressure (COP) measures. Because 6 correlations were analyzed, the alpha level was adjusted to 0.008 (0.05/6). Male participants (n=4) had a mean age, height, weight, and EDSS of 48.5±6.40 years; 179.39±6.99cm; 90.43±16.83kg; and 2.75±2.60. Females (n=15) were 40.93±11.77 years; 166.25±6.59cm; 78.27±21.28kg; 2.47±1.90. The BBS was significantly and negatively correlated with eyes closed/stable platform COP displacement (r = -.633, P=.006), velocity (r = -.633, P=.006), and sway area (r = -.757, P=.0004). As BBS scores decreased (indicating decreased function), COP displacement, velocity, and sway area increased (indicating worse balance). It appears that BBS is correlated with traditional instrumented postural stability measures in individuals with ambulatory EDSS scores. The BBS appears to be reflective of postural stability in this population.

The Empowerment of Character Expression through the Use of Popular Culture in the Novels of Manuel Puig

Milner Owens – CURO Scholar
Dr. Ángel Nicolás Lucero, Department of Romance Languages, University of Georgia

Manuel Puig's writing has remained a much debated and much studied topic, especially in relation to his own personal political and social views. What is most intriguing about Puig though is his use of foreign popular art and culture to develop ideas and plots that take place in Argentina. Puig's use of literary techniques, in addition to his unusual use of popular art and culture as tools in the elucidation of his characters and plot events, is particularly fascinating. This thesis is an exploration of Puig's use of foreign, particularly American, mass culture art and media, referred to as popular art from here on out, in the development of characters and mindsets in Manuel Puig's first four novels: *La Traición de Rita Hayworth*, *Boquitas Pintadas*, *The Buenos Aires Affair*, and *El Beso de la Mujer Araña.* In these novels, the presence of foreign popular art is very noticeable and plays a key role in the ultimate structure and meaning of the novel, particularly with respect to the presence of a character's "imaginary," what can be deemed as his or her alternate realities, versus the presence of his or her "real" life. The use of the foreign popular art is different in each novel and is highlighted through various literary techniques employed by Puig, particularly in the use of local popular art expressions, which he juxtaposes with that of foreign popular art, creating a type of cross cultural enigmatic, both physically and mentally, setting and character development. Puig focuses on embracing popular culture with a marked lack of artistic snobbery or distance so often associated with other literary minds, which serves as another point of investigation for his utilization of popular culture, especially foreign culture, and his novel use of its artistic impression as a reflective influence on character, plot, and form.

Which Factors Influence the Voting Practices of the Members of the United Kingdom Parliament on Legislation Concerning the Use of Force by the State in Military Interventions?

Julie Patel – CURO Summer Fellow
Dr. Patricia Sullivan, Department of International Affairs, University of Georgia

Military interventions conducted by state powers are not the result of the actions of a single entity or a single factor. There are many factors at different levels of the global system that have influence over a military intervention. Focusing on the role that individuals and governments have in a military intervention will help to better understand the nature and the outcome of that intervention. This study focuses on the state

power of the United Kingdom and its Parliament in the post Cold War setting. There has been previous research done on the voting practices of the political elite of the United States. However, this study focuses on gender, previous military experience, and party membership of the Members of Parliament (MPs) in the United Kingdom to see how those factors impact the voting practices of MPs when it comes to issues of the use of force by the state. In order to conduct the study, research is done on all Parliament sessions and its members since 1991. To investigate the three factors, biographies and profiles of the MPs are researched. Additionally, the voting records of all MPs on pieces of legislation pertaining to the use of force are also studied to see how they voted. The voting records and the three factors are studied together to see if and how they influenced the voting practices of members of Parliament. The primary purpose of the research is to show how focusing on individuals and governments helps to provide a better understanding of how and why a military intervention is conducted by a major power and how it is ended.

Georgia Senate Bills 440 and 441: The Effectiveness of the Adult Criminal System as a Deterrent to Juvenile Recidivism

Nima Patel – Roosevelt@UGA
Dr. Edwin Risler, School of Social Work, University of Georgia

In 1994, the Georgia Legislature passed The Juvenile Justice Reform Act, also known as Georgia Senate Bill 440, in response to the increasing number of crimes committed by youth between the ages of thirteen and seventeen. One specification of the bill requires that youths who commit one of the seven major crimes—including murder, rape, armed robbery, aggravated child molestation, aggravated sodomy, aggravated sexual battery, and voluntary manslaughter with the use of a firearm—are tried in court as adults. Once convicted under Senate Bill 440, Senate Bill 441 imposes a mandatory minimum sentence of ten years in an adult prison without parole. This research will utilize a quasi-experimental design with a nonequivalent control group. Aggregate data from the Georgia Department of Juvenile Justice will be used to analyze the detrimental effect of Senate Bills 440 and 441 on youths. It will focus on rates of recidivism, or the relapse into crime within a year of release from prison, as well as the disproportionate incarceration levels for youths of color compared to white youths, to measure the negative impact of these measures. In order to address these violent crimes, amendment of this legislation by the Georgia legislature, in conjunction with local governments, to prohibit mandatory minimum sentences and incarceration in adult criminal systems for convicted youth is vital. Intensive rehabilitation centers that focus on building education would be a viable alternative. This will mark an effort to reduce the achievement gap between minority and white youths and deter recidivism.

Comparison of Gnt-V Expression in Different Human Carcinoma Cell Lines

Nirzari Patel
Dr. Michael Pierce, Department of Biochemistry & Molecular Biology, University of Georgia

N-acetylglucosaminyltransferase V (GnT-V) is an enzyme that catalyzes β1-6 branching of N-acetylglucosamine on asparagine (N)-linked oligosaccharides (N-glycans) of cell proteins. Increased levels of GnT-V glycan products are associated with increased tumorgenensis and metastatic behavior in many *in vitro* cell lines. Although GnT-V is known to be important in tumor metastases, the expressing of it in different mammary and tumor cells is not fully defined. In this study, the three mammary carcinoma cell lines, MCF-7, MDA, and SK-BR, are utilized to assess the expression of GnT-V. The MCF-10A, (control) a non-cancerous cell line, expresses proteins of interest associated with breast cancer in humans which gives invasiveness properties. Similar to normal human breast epithelial cells, at confluence the MCF-10A cells form dome structures in tissue culture plates and produce mammary spheres in 3D collagen culture. These characteristics make MCF-10A cells a model of choice for breast tumor progression studies. The MCF-7, MDA, and SK-BR carcinogenic cell lines are compared

on the amount of gene expression and product output. MCF 7 tumor cell line is non invasive, while MDA cell line is very invasive, and the SK-BR cell line is invasive with an expression of Her 2/ neu gene. These established cell lines are used for comparative breast cancer research and used to evaluate new therapy approaches *in vitro* prior to *in vivo* testing. In this experiment, western blots are carried out in attempt to understand the expression of GnT-V in comparison with other membrane proteins related to tumor invasiveness. Lectins and antibodies are then applied to the membrane and data are analyzed. At this point, the data are being complied. However, in the future, the results to my data will suggest that GnT-V expression level could serve as a useful tool for tumor analysis in breast cancer.

Directed Differentiation of Neural Progenitor Cells into Glial Progenitor Cells

Tulsi Patel – CURO Scholar
Dr. Steven Stice, Department of Animal & Dairy Science, University of Georgia

Human embryonic stem cells are pluripotent cells that have the potential to differentiate into all cell types found in the human body. The Stice Lab has previously derived neural progenitor (hNP) cells, which can be further differentiated into neurons, from human embryonic stem cell lines. Currently, the media used for cell proliferation comprises neural basal media supplemented with B27, Leukemia Inhibitory Factor, Fibroblast Growth Factor 2, and L-glutamine. All of these are defined components except B27, which is composed of a defined supplement, N2, and other anti-oxidants and factors. To better understand the role of all these factors on neurons, hNP cells were grown in various concentrations of B27 ranging from 0 to 1XB27. 0.1X B27 was sufficient for hNP proliferation. Additionally, RNA analysis data from differentiated neuritis that were proliferated in 0.5X B27 and 0.1X B27 media showed a significantly higher expression of Glial Fibrillary Acidic Protein, a marker used to identify glial cells, when compared to our control cells. These observations indicate that hNP cultures proliferating in lower concentrations of B27 differentiate into glial-like cells. Further experiments to detect GFAP protein levels in these cell cultures will be performed to further support this hypothesis. Glial cells provide support and nutrition for neurons in the central nervous system. Defining a uniform culturing condition for these cells could help understand and cure glial-degenerative diseases like Multiple Sclerosis, Alzheimer's, and Alexander's Disease.

U.S. Involvement in Government Coups in Angola During the Cold War

Hadas Peles
Dr. Tim Cleaveland, Department of History, University of Georgia

In describing the United States as a global Empire of Bases, Chalmers Johnson's writing of the history of U.S. Militarism in *Blowback* and *The Sorrows of Empire* largely ignores U.S.-sponsored covert operations and involvement in the continent of Africa. However, many of the patterns Johnson describes as products of U.S. foreign policy in other parts of the world mirror, reiterate, and reveal much about the worsening relationships between the United States and various African countries. The creation of AFRICOM, the newest of U.S. combatant commands, brings about many questions regarding the future of U.S.-African relations. By exploring the history of U.S. entanglements in various regions in Africa during the Cold War era, largely focusing on Sub-Saharan Africa and Angola, this research will contextualize the current, 21st century challenges of developing and executing U.S. Foreign Policy, especially militarily, in those African regions. Additionally, exploring African newspaper archives from the last nine years yield the causes of the flailing relationships due to past and most current U.S. military endeavors. In particular, this research focuses heavily on the growing controversy of creating a permanent U.S. military presence within the African continent, a land only recently released from the shackles of imperial imprisonment.

"He Can't Do This To Me!" Military Assistance, the Response of Concerned Powers, and Implications for U.S. Aid to Ukraine

Anthony Pelli – Roosevelt@UGA
Dr. Dmitriy Nikonov, Center for International Trade & Security, University of Georgia

The United States currently provides large amounts of military aid to Ukraine in an attempt to modernize its military and make its military forces more compatible with those of NATO. This assistance is also seen as a precursor to Ukraine's eventual NATO accession. There is some concern that the process of binding former Soviet states into tighter military relationships with the United States could worsen the already strained relationship between the U.S. and Russia. While a significant amount of research has focused on the potential costs and benefits of NATO accession for countries in the region, the motivation for giving military aid and the effect the aid has on Russian perceptions has been less thoroughly studied. This paper will examine Soviet arms sales to Egypt in 1955, the Cuban Missile Crisis of 1962, and ongoing American arms transfers to Taiwan in order to assess the relationship between military aid and the perception and actions of concerned major powers. Furthermore, this study disaggregates symbolic (pride, prestige, ideology) from material (concern for the balance of relative power, leverage) concerns and analyzes which factors played a greater role in motivating the actions of the state giving aid the and the response of the "target" state of the aid. Examining these cases reveals that although states are concerned about intangible symbolic factors, it is material factors that are of greater importance in both the giving of aid and response to said aid. Additionally, given this concern with material issues, states are likely to forego a particularly aggressive response to aid that is intended to curb their influence because of the potential consequences of such action. Thus, American military aid to Ukraine is not likely to trigger an overbearing reaction from Russia given the potential consequences of further deteriorations of the U.S.-Russian relationship. This conclusion suggests that it is possible for the United States to use military aid to further its interests in Ukraine and other former Soviet states and focus on the benefits that this aid could have for the nations it is given to (enhancing military professionalism to further democratic consolidation in those states, for instance), rather than on the potential Russian response.

The Ideal Religious Experience

Benjamin Perlow
Dr. Leonard Martin, Department of Psychology, University of Georgia

In previous studies, participating in religious experiences has correlated with overall happiness and an easier time coping with loss. This experiment is attempting to help researchers discover the best type and place for a person to achieve a religious experience and whether religiosity is useful for people. Participants were asked to answer a number of different surveys and open-ended questions. The different surveys used were the Allport and Ross Religious Orientation Scale, Batson's Quest Scale, the NEO-FFI scale, and a religiosity scale designed by Laura B. Koenig, Matt McGue, and William G. Iacono. The different surveys were used to categorize the participants into categories relating to their personalities, religiosity, and background information. The open-ended questions help determine what the participants believe is important in their ideal religious experience and where they can achieve it. The answers to open-ended questions were categorized into five different categories for each question. In the first question, the participants said that in their ideal religious experiences they either experienced a sense of connection, security, positive feelings, clarity, or not possible. In the second question, the participants said that they were most likely to achieve their ideal religious experience anywhere, during crucial events, in a religious place, alone, or with others. These different categories were determined based on common phrasing found in the open-ended questions. The study found that people who truly believe in their religion tend to have higher levels of agreeableness, conscientiousness, and

extraversion. Also, several different dimensions of personality are correlated to the types of ideal religious experiences they receive. For example, people who have intrinsic religious personalities are more likely to have religious experiences where they feel secure, while people who are more extraverted and not neurotic are statistically more likely to have their ideal religious experiences when they are alone.

Comparing Population Size Estimators for Stream Plethodontids

Amanda Perofsky – CURO Scholar
Dr. John Maerz, Department of Wildlife, University of Georgia

Plethodontid salamanders are among the most abundant vertebrates of forested ecosystems in the eastern and northwestern United States. Southern Appalachian streams are hotspots of diversity for semi-aquatic plethodontids; a single stream may include more than a dozen plethodontid species and larval densities as high as 60 per m2. Stream plethodontids are one of the most profuse predators of first and second order streams and are important nutrient sinks because of their remarkable abundance and metabolic efficiency. Despite their considered importance, very little is known about the effects of plethodontids on ecosystem processes, and few studies have estimated absolute abundances of salamander populations. This research will compare abundance estimation of four stream plethodontid species by means of the mark-recapture method. The project will use pre-existing data from a mark-recapture study of these species across six streams at the Coweeta Hydrological Laboratory LTER site. The different categories of mark-recapture models will include closed-population, open-population, and robust design models to demonstrate how different model assumptions can result in a wide range of population estimates. We predict that Pollock's robust design model will be the most appropriate population abundance estimator because of its flexibility to incorporate variation in capture probabilities and to estimate temporary emigration probabilities. Because these abundance estimates will be coupled with data examining the role of plethodontids in nutrient cycling and storage in forest ecosystems, this study will provide a better understanding of the current effects of stream plethodontids on stream processes.

Characterizing RNA-Protein Complexes Involved in Genome Defense in Prokaryotes

Neil Pfister – CURO Scholar, CURO Summer Fellow
Dr. Michael Terns and Dr. Rebecca Terns, Department of Biochemistry & Molecular Biology, University of Georgia

Ribonucleoprotein (RNP) complexes are ubiquitous macromolecular machines involved in most major aspects of cellular function. Various proteins and non-coding ribonucleic acids (ncRNAs) form distinct RNP complexes. We are interested in characterizing novel RNP complexes in *Pyrococcus furiosus*, an organism in which our lab is studying a new class of ncRNAs. These ncRNAs are implicated to function with a set of related proteins in an RNA-based genome defense system in prokaryotes. In order to investigate these hypothetical RNP complexes, I have generated antibodies to putative protein components of these complexes from antigens purified via an *Escherichia coli* expression system. These antibodies are being used for co-immunoprecipitation experiments to identify protein-protein and protein-RNA interactions within the RNP complexes. Once a basic understanding of the RNP complexes is attained, functional studies will be expedited. This research will be used as a framework for manipulation of this biological system for the design of novel nucleic acid-based antibiotics as well as for experimental gene manipulation.

The Role of Microtubules in the Degradation of Hirano Bodies

Cleveland Piggott
Dr. Marcus Fechheimer and Dr. Ruth Furukawa, Department of Cellular Biology, University of Georgia

Hirano bodies are intracellular, paracrystalline, actin-rich structures that are most commonly found in the autopsied brains of humans

suffering from neurodegenerative diseases. Thus, their physiological role(s), beneficial or deleterious, are not well understood, but their possible link to the prevention, cure, and further understanding of neurodegenerative diseases and aging has made their study worthwhile. Recently, an *in vitro* model to induce formation of Hirano bodies in living cells was discovered. This model allows questions regarding the physiological effects, the formation, and degradation of Hirano bodies to be investigated in living cells. The two major ways in which cellular components are degraded in a cell are either through the protein complex known as the proteasome or by the autophagy pathway. Autophagy is a catabolic process of self degradation that requires multiple components in order to function properly. These components must be transported via one of the two major cytoskeletal transport components in a cell, actin or microtubules. We hypothesize that microtubules play a major role in the degradation process of Hirano bodies through autophagy. To test this, Dictyostelium amoeba expressing Hirano bodies were treated with nocodazole, a microtubule depolymerizing drug. These cells were stained after various times of nocodazole exposure and Hirano body size measured. Results showed no difference between Hirano body size with and without nocodazole at all time points. Further experiments will be run using Atg8, an autophagy marker, to distinguish the difference between formation and degradation of Hirano bodies. Once the role of Hirano bodies in neurodegenerative diseases is elucidated, these experiments will help in providing a means to prevent or accelerate the degradation of these highly ordered protein structures.

Imagining Constantinople: Imperial Houses of Worship as Symbols of State Ideology

Stefann Plishka – CURO Scholar, CURO Summer Fellow
Dr. Asen Kirin, Department of Art History, University of Georgia

Architecture physically embodies the priorities and ideologies of the culture in which it was constructed. When built as a function of an imperial government, architecture visually represented the ideological goals of the state. The site selection, scale, and design of a building or complex reflected the overall goals of a state or its ruler. When the Ottoman Empire conquered Constantinople, capital of the Byzantine Empire, its sultans used architectural constructions to manifest the change in imperial rule. Because construction techniques were not as convenient and efficient as in the modern period, carrying out large-scale projects in this period required time, energy, and wealth to sustain the project's completion. Therefore, constructing monumental buildings and complexes became a symbol of the imperial stability, power, and resource availability of the Ottoman Empire. This paper explores the explicit connections between ideology and design at Hagia Sophia (rebuilt in 562 CE by the Byzantine Emperor Justinian I), the complex of Sultan Mehmed II (1463-1470 CE), the Bayezid II mosque (1501-1506 CE), the Suleymaniye complex (1550-1557 CE), and the Sultan Ahmed mosque (1609-1616 CE). These houses of worship show the changing landscape in Constantinople during years in which imperial control of the city shifted from a Christian to an Islamic state. They serve as examples of how rulers, both Byzantine and Islamic, manipulated the urban plan of the city of Constantinople to construct buildings that enhance state ideology and eminence.

Age-Dependent Susceptibility to *Enterobacter sakazakii* Infection in Neonatal CD-1 Mice

Elizabeth Pollak – CURO Apprentice
Dr. Mary Alice Smith, Department of Environmental Health Science, University of Georgia

Premature or low-birth-weight infants are susceptible to infection by the bacterium *Enterobacter sakazakii*, which has been isolated from powdered infant formula. Clinical cases have indicated that younger infants are more susceptible to infection than older infants, sometimes leading to meningitis or death. Our objective was to determine the ages at which neonatal CD-1 mice were most susceptible to infection and at what age, if any, susceptibility

decreased. Neonatal CD-1 mice were orally gavaged with reconstituted powdered infant formula infected with three different doses (10^3, 10^7, and 10^{10} CFU) of *E. sakazakii* to three different age groups: postnatal days (PND) 1.5, 5.5, and 9.5. Mice were sacrificed one week after treatment; blood, liver, cecum, and brain tissue samples were taken. Deaths before time of sacrifice were noted. *E. sakazakii* presence was determined by enrichment and direct culture. Identity confirmation was done by biochemical analysis. *E. sakazakii* was isolated from ceca and liver tissues of animals treated at PND 1.5 more frequently than from PND 5.5 (ceca =18% vs 1%; liver= 14% vs 7%). PND 1.5 neonates were also much more susceptible to infection of the brain (22%) than PND 5.5 (2%). Only the PND 1.5 group showed mortalities (11%) confirming the severity of the infection. PND 9.5 mice did not appear to be susceptible; no *E. sakazakii* was isolated from any tissue at any dose. This research suggests that younger neonates are much more susceptible to *E. sakazakii* infection than older neonates, which is in agreement with reported cases in humans.

Approaches to the Refugee Humanitarian Crisis: An Examination of Refugee Trends and What Promotes Progress

Kathryn Pyne – CURO Summer Fellow
Dr. Jerry Legge, Department of Public Administration & Policy, University of Georgia

With over four million displaced Iraqis, the Iraq refugee crisis is the worst in the world. This project seeks to identify the policies and initiatives that most effectively lowered refugee populations in protracted situations. Using the crisis examples in Myanmar, OPT, Somalia, and Sudan, we gathered statistical data from the UNHCR and constructed time series models to represent the refugee population in each country from 1992-2007. We then connected interruptions in the data trends with actual events that caused them. Upon analysis, we identified the following as factors that impact the refugee population for a specific time period: (A) the coordination of cooperation between the UN, NGOs, local organizations, local government, and the government of surrounding countries is paramount in any refugee crisis; (B) UN resolutions have proven to be extremely effective in decreasing the refugee population for the years to follow when the main countries causing the conflict and creating refugees agree to abide by the terms; (C) peace agreements among warring militias are effective for a short period of time; (D) sanctions and embargos on countries whose government commits human rights violations do not help the conditions for the victims; (E) free and independent media access is necessary in any problem area. These findings are significant contributors to the formulation of Iraq refugee crisis policy. In general, research of migratory movement due to conflict is an extremely important field that will continue to grow due to its irrefutable relevancy to the condition of the global community.

Development of a System to Create Unmarked Mutations in *Mycobacterium tuberculosis*

Akanksha Rajeurs – CURO Apprentice
Dr. Russell Karls, Department of Infectious Diseases, University of Georgia

One third of the world population is infected with *Mycobacterium tuberculosis*. Annually, 7 to 9 million infected individuals suffer from active tuberculosis disease resulting in 1.5 to 2 million deaths. Attenuating *M. tuberculosis* to produce a safe, live vaccine will likely require deletion of multiple chromosomal genes encoding virulence factors. A common system used to delete genes from this bacterium utilizes a specialized transducing phage to mediate the replacement of a mycobacterial gene with an antibiotic resistance marker via homologous recombination. As a vaccine strain encoding multiple antibiotic resistances may lead to transfer of antibiotic resistance genes to other bacteria, we are developing a modified system to enable replacement of any chromosomal gene with a gene cassette that will facilitate the study of the resulting mutants and can also be used to subsequently remove these foreign genes from the chromosome. This is a multi-step process that involves generating a final plasmid with a cassette that has the following features: a hygromycin resistance gene (*hyg*), a gene

encoding green fluorescent protein (*gfp*), and a sucrose counter-selectable gene (*sacB*). The plasmid will also encode an origin of replication for *E. coli* (*oriE*), a bacteriophage lambda *in vitro* packaging site (*cosA*), and a unique site for the DNA restriction enzyme *PacI* for ligation to transducing phage DNA. The details of this system and the intermediate plasmids constructed to date will be presented.

An Analysis of the Effects of Parent-Child Quality of Relationship and Parental Emotion Socialization Practices on Youth Psychosocial Functioning

Nathan Raley – CURO Scholar
Dr. Cynthia Suveg, Department of Psychology, University of Georgia

Understanding influences on children's emotional development has been given much attention by researchers due to the connection between emotional competence and youths' broader psychosocial adjustment. In particular, parents' have been identified as an important contributor to youths' emotional development. A lack of emotional competence has been indicated in various forms of psychopathology (e.g., anxiety, depression; Casey, 1996; Cicchetti et al., 1995; Cole, Michel & O'Donnell-Teti, 1994), which indicates the impact of emotion expression and regulation on people's capability for adaptive functioning. The current study aims to further explore relations between parent emotion socialization practices, parent-child relationship quality, and youth psychosocial functioning. These relations will be analyzed based on both surveys as well as behavioral observations. It is expected that: 1) parental encouraging emotion socialization practices will be positively related to a higher quality parent-child relationship and adaptive child psychosocial functioning, and 2) quality of parent-child relationship will be positively related to adaptive youth psychosocial functioning.

Understanding the Cell Cycle: Cyclin-Dependent Kinase Phosphorylation of Hcm1

Shelina Ramnarine
Dr. Wyatt Anderson, Department of Genetics, University of Georgia

The cell cycle is a series of biochemical events regulated by many molecules, including transcription factors, by which the cell duplicates. Not only is knowledge of the cell cycle critical for understanding normal human development but also when this cycle goes awry, it can lead to illnesses such as cancer and possibly Alzheimer's disease. We purpose that Hcm1, a transcription factor that regulates the expression of genes in other parts of the cell cycle, is phosphorylated by a protein called cyclin-dependent kinase, specifically CDK1. We hypothesized that the inhibition of CDK phosphorylation of Hcm1 alters the percent of cells in the G1 phase of the cell cycle. In a yeast strain where the HCM1 gene was deleted, plasmids containing the WT HCM1 gene (a wild type gene is the naturally occurring gene) were compared with plasmids containing a mutant version in order to test our hypothesis. The results generated by flow cytometry were compared using t-tests to conclude if there was a statistical difference between the four designs being tested. We found that the mutant protein alters the percent of cells in G1. This study should lead to information that may be useful for individuals studying stem cells and cancer because it provides a missing link in understanding the subtleties of the cell cycle.

Steamed Ginger Supplementation Reduces Pain Following Eccentric Exercise-Induced Injury

Al W. Ray, III – CURO Apprentice
Dr. Patrick O'Connor, Department of Kinesiology, University of Georgia

We recently found that 11 days of supplementation with 2 grams of raw, ground ginger reduced arm muscle pain, inflammation and disability induced by eccentric exercise. These effects could plausibly be attributed to compounds in ginger such as gingerols and shogaols that act on vanilloid receptors. The purpose was to determine whether 11 days of

supplementation with ginger treated by steaming, a process known to increase the concentration of shogaols, also influences arm muscle pain, inflammation and disability induced by eccentric exercise. Raw ginger was ground and heated for 3 hours and 15 minutes at 100°C and dried. Ginger and placebo was placed in hypromellose capsules. 40 participants were randomized to consume either 6 ginger or 6 placebo capsules daily for 11 consecutive days. On Day 8, participants performed 18 eccentric actions of the non-dominant elbow flexors at an intensity of 120% of their concentric one-repetition maximum. Before and for 3 days after eccentric exercise, assessments were made of arm volume, arm range-of-motion, isometric strength, pain intensity and perceived effort (RPE) responses to three flexions and extensions of the elbow at 50% of the concentric one-repetition maximum. Post-hoc tests showed that pain and RPE were substantially lower in the ginger group 24-hours after eccentric exercise. Range-of-motion was not influenced by the intervention and small effect size differences in arm volume and isometric strength 24-hours after exercise favored the ginger group but did not reach statistical significance. Supplementation with steamed ginger reduces muscle pain and perceptions of effort the day after eccentric exercise.

On Faith

Joe Reynolds
Dr. Frank Harrison, Department of Philosophy, University of Georgia

What does it mean to have faith in God? To Nicholas of Cusa, a 15th century Cardinal, serious examination of the intellect, love, and hope must be undertaken before faith can be understood. In analyzing each concept and its relation to faith, comparisons shall be made with Plato to highlight similarities among the ancient and medieval traditions. First, it shall be necessary to understand how the intellect enables the individual to be transformed by God. To understand this, a thorough analysis of the nature of the individual must be undertaken, and Plato's characterization of the soul and its desire shall be used as an aide in highlighting similarities. Next, the role of love in enabling the individual to pursue this transformation shall be studied, as well as the role of hope in intensifying this love. After clarifying the previously mentioned concepts, this paper then intends to provide the reader with a proper understanding of a faith in God. In comparing this with a faith not centered on God, the implications of both "life-choices" shall be studied, and, in particular, emphasis shall be placed on how the individual experiences life. In the end, this paper intends to understand why Nicholas of Cusa suggests that by having a 'right' faith, the individual perfects his nature.

Evaluating the Antibody Response to Respiratory Syncytial Virus (RSV) for the Inhibition of the RSV G Protein Interaction with the CX3C Chemokine Receptor

Joseph Rimando – CURO Apprentice, CURO Summer Fellow
Dr. Ralph Tripp, Department of Infectious Diseases, University of Georgia

Respiratory syncytial virus (RSV) is a primary cause of severe lower respiratory illness in infants and children worldwide, also causing substantial disease in the elderly and immune-compromised populations. Previous research has shown that the RSV attachment protein (G protein) interacts with the CX3C chemokine receptor (CX3CR1) during the infection process to modify anti-viral immunity linked to the activities of fractalkine (CX3CL1), the natural ligand of CX3CR1. Evidence suggests that prevention of RSV G protein-CX3CR1 interaction reduces RSV replication, and thus this G protein-CX3CR1 interaction can be targeted as a possible vaccine strategy to mitigate RSV disease pathogenesis. For this study, we are testing different anti-G protein blocking antibodies developed in mice inoculated with RSV to determine if these antibodies can prevent or reduce G protein attachment to CX3CR1. The studies employ flow cytometry to determine the effectiveness of these anti-G antibodies at preventing the interaction between different strains of G protein and CX3CR1 expressed on mutant Chinese hamster ovary (CHO) cells. The preliminary

results suggest that these antibodies significantly reduce G protein's attachment to CX3CR1. Future studies should test the effectiveness of these antibodies in an *in vivo* mouse model. Studies on these anti-G antibodies can potentially lead to the development of the first vaccine for RSV.

Reducing Binge Drinking Among University of Georgia Students

Robert Rosenbleeth – Roosevelt@UGA
Dr. Elaine Weeks, Department of Sociology, University of Georgia

Each year in the United States 1,700 college students aged 18 to 24 die from alcohol-related injuries, including motor-vehicle crashes. Such accidental injuries are the leading cause of death among people 15 to 24 years old. In light of these alarming statistics, many universities, including the University of Georgia, have taken significant steps to reduce binge drinking—drinking five or more drinks within two hours. This study will assess the effectiveness of alcohol-related policy changes that affected UGA students from 2001 to 2007 based on survey data over the same time period and recommend future policy changes to reduce high-risk drinking among UGA students. From 2001 until 2007, Athens-Clarke County significantly increased enforcement of the minimum legal drinking age (MLDA). UGA also increased enforcement of the MLDA on campus, stiffened penalties for students caught violating the MLDA, and increased educational programs targeting underage students and high-risk groups. National College Health Assessment survey data, collected at UGA during the fall semester of odd numbered years, show that these changes are correlated with a large decline in underage drinking rates and a slight decline in binge drinking rates among underage students who report drinking. However, binge drinking remains a significant problem. Many underage students continue to binge. Students of legal age binge drink at even higher rates. And importantly, UGA students continue to perceive a heavy drinking culture. To further combat binge drinking, Athens and UGA must implement a tiered penalties structure based on blood-alcohol content for underage drinking and public drunkenness violations and launch a sustained social norms campaign to combat prevalent misperceptions about UGA's drinking culture.

Natural Prevalence of *Phlebiopsis gigantea* in the Field

Rebecca Roulo
Dr. Sarah Covert, Department of Forest Biotechnology, University of Georgia

The fungus *Heterobasidion annosum* (*Ha*) is the causative agent of annosum root disease, a major destroyer of commercial pine crops in the southeastern United States. Experimentation in Europe has shown the fungus *Phlebiopsis gigantea* (*Pg*) to be an effective biocontrol agent against *Ha* through competition, and *Pg* has been in use as the preferred natural control mechanism in Europe since the 1960s. However, because *Pg* is a wood-rotting pest, the United States Environmental Protection Agency will not approve *Pg* for use in the US until its risks have been fully investigated. Whether or not the physical application of *Pg* to stumps will increase its overall prevalence in the environment is of major concern. Field data addressing this issue were collected from two logging forests in northeastern Georgia, starting in July 2007 and February 2008. Petri dishes were placed on the forest floor to collect airborne spores from sites containing pine stumps treated with *Pg*, water, and controls. Spores were given a week to grow, at which time each dish was analyzed for the presence of *Pg* colonies. Our data have so far shown that the application of *Pg* to stumps does not increase the fungus' overall prevalence in the environment. This is an ongoing project that will aid in the EPA's weighing of the costs and benefits of approving *Pg* for use in the United States.

Characterizing the STE23 ORF
Jarrad Rowse – CURO Scholar
Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology, University of Georgia

According to the latest reports by the U.S. Census Bureau, 45.7 million individuals in the United States are uninsured. Despite current government programs, 31.6 percent of persons below the poverty level lack insurance, and 24.5 percent of households with an annual income less than $25,000 have no health insurance. A large uninsured population creates numerous problems, including higher premature mortality rates for the uninsured, higher health insurance premiums for the insured, and financial and logistical pressure placed on the healthcare industry. After researching domestic and foreign health care policies, current problems, and purposed solutions, it has become clear that a new approach must be taken. The United States must implement a policy requiring all residents of the United States to purchase health insurance operating on a bracketed system established for addressing the needs of the poor and under resourced. Universal mandatory health insurance will be costly, but the long-term benefits of this policy will far outweigh the initial costs. The socioeconomic benefits include the potential to lower health insurance premiums, improve the quality of care received by the previously uninsured, increase the health and longevity of the populous, and even increase economic productivity.

The Physiological Effects of Hirano Bodies in Neuronal Cells Expressing Mutated Tau
Aalok Sanjanwala – CURO Apprentice, CURO Summer Fellow
Dr. Marcus Fechheimer and Dr. Ruth Furukawa, Department of Cellular Biology, University of Georgia

Neurofibrillary tangles (NFTs) are one of the hallmarks of the pathology of Alzheimer's disease (AD). NFTs form when tau hyperphosphorylates, misfolds and then aggregates into paired helical filaments (PHFs). While the mechanism of toxicity due to PHFs in brain is not understood, it is clear that PHFs contribute to cell death. Hirano bodies are paracrystalline, actin-rich cellular inclusions that are more abundant in the autopsied brains of patients with neurodegenerative diseases. The physiological role of Hirano bodies in neurodegenerative disease progression is unknown. It was previously demonstrated that tau localizes into Hirano bodies in brains from patients with neurodegenerative disease.[1] Does the tau protein colocalize with Hirano bodies, and if so, which isoform localizes to Hirano bodies in living cells? Do Hirano bodies protect cells from cell death in the presence of mutated tau? These questions were studied by expressing wild type tau as well as tau modified to mimic hyperphosphorylated tau in wild type, stable GFP expressing, as well as stable Hirano body expressing H4 astroglioma cell lines. Both fetal and adult forms of tau, 352 and 441, respectively, were modeled in this experiment. Immunofluorescence microscopy was used to determine localization of different isoforms of tau in cells with and without Hirano bodies. Preliminary results demonstrated a possibility of localization with Hirano bodies. However, more data are necessary for conclusive results.

1 Galloway, P.G., G. Perry, et al. (1987). "Hirano bodies contain tau protein." Brain Research 403 (2): 337-340.

Borrowed Building/Search Cycle
Ash Sechler
Mr. Mark Callahan, Artistic Director, Ideas for Creative Exploration, University of Georgia

Borrowed Building combines separate photographs of skyscraper windows shaped like internet bricks; they are built/collaged on top of each other to form a single building. I wanted to literalize the process of taking things out of their separated contexts and combining them to create something new. The original URLs of each image are used, so the building's existence is tenuous and is dependent on the individual owners of the pictures. In a way, the building doesn't belong to me; it belongs to the collective photographs' owners. But they also relinquish ownership because they cannot control how their images are used. In *Search Cycle* the viewer/user uses words to search for images from the internet that then appear one at a time in rapid succession (24fps). The images loop, and new images are added once they are downloaded. The search results portray our complex relationships between the words we use and the connotations they carry. Stringing these images together presents a holistic interpretation of how we see the world. They come from an abundance of perspectives and literally blend into each other. The speed of playback is such that afterimages of the previous pictures remain when the next images are displayed (this is how film works). Abstract visual elements are animated, and the viewer gets an impression of a combination of the different images. The synthesis of meanings illustrates a deeper, more whole, and subliminal perspective on the imagery of our culture.

Heart Rate Monitoring is Superior to Accelerometry as an Estimator of Human Energy Expenditure During Physical Activity
Thomas Shaffer
Dr. James Hargrove, Department of Foods & Nutrition, University of Georgia

To prevent gradual, unhealthy body weight gain, the 2005 US Dietary Guidelines advise people to engage in 60 minutes of moderate- to vigorous-intensity activity on most days of the week. Pedometers are popular but do not measure exercise intensity. The present study evaluated whether accelerometers or heart rate monitors were preferable for evaluating intensity of work against gravity (walking on level ground, down stairs, or up stairs). Data were collected anonymously from 12 male and female students who wore accelerometers and heart rate monitors while walking up or down stairs or on level ground at rates of 2-5 miles per hour, as judged with a Garmin 76 global positioning device. Activity data obtained with accelerometers and heart rate monitors both

correlated highly (R2~0.91-0.97) with energy expenditure (MET values) during walking at different rates on level ground. However, while the heart rate monitors clearly detected work done walking on the level ground versus walking upstairs (P<0.01), accelerometers failed to distinguish between walking at the same rate on level ground versus going upstairs (P~0.24). Pedometers and accelerometers are instruments which measure external activity, whereas heart rate monitors provide an internal measurement. Neither pedometers nor the accelerometers used in this study provide reliable information concerning the intensity of work. I conclude that inexpensive heart rate monitors provided a reliable indication of work intensity and are suitable for providing feedback for subjects who wish to meet the goals for intensity and time of physical activity stated in the US Dietary Guidelines.

Male Song Performance Correlates of Reproductive Success and Morphological Characters in the Dark-Eyed Junco (*Junco hyemalis*)

Jeff Shapiro
Dr. Dustin Reichard, Department of Biological Sciences, University of Indiana

Within given populations of sexually reproducing species, there exists a wide range of phenotypic variation. Male diversity is commonly used by females to judge male quality. In songbirds, one such male phenotypic trait is song and in many species male song performance can be used as a predictor of individual quality and subsequently reproductive success. Male Dark-eyed Juncos (*Junco hyemalis*), a small North American songbird, typically sing a single, repeated, high-pitched trill. Due to motor constraints, a male's trill rate constrains its frequency bandwidth. A "high performance" song is one in which the frequency bandwidth approaches the physiological limit for a given trill rate. Therefore, more vigorous males should sing higher performance songs. This study investigates A) if Junco song performance is correlated to reproductive success and B) if Junco song performance is correlated to other phenotypic measures of male quality. We recorded the songs of 65 male Juncos, measured various morphological characters, took blood samples, and tracked their nesting success over the course of the 2008 breeding season. Results are not statistically significant, yet trends suggest that higher performance singers are more physically robust males. Surprisingly though, better singers had lower apparent reproductive success than poor-singing competitors. However, vigorous males are known to have higher actual reproductive success due to more extra-pair fertilizations and therefore we expect results of paternity analysis (pending completion) to demonstrate equal or higher reproductive success for high-performance singers. This result would demonstrate female preference for higher quality song despite poorer parental abilities of those males.

Gender and Developmental Differences in Young Children's Autonomy

Miriam Skiles and Lindsay Jarvis
Dr. Hui-Chin Hsu, Department of Child & Family Development, University of Georgia

Autonomy is characterized by the need to act independently and demonstrate self-governing behavior. Because American culture values independence, parents encourage autonomy and independent exploration in children. Autonomy emerges in toddlerhood around age 2, when children begin to display personal initiative, persistence, and self-regulation. Parents provide greater autonomy support to young children as they mature. Gender differences are likely in children due to differential parental socialization that promotes their sons' autonomy more than their daughters'. This study is aimed to understand gender differences and developmental changes in children's expression of autonomy. Using data from a larger longitudinal research, 20 girls and 20 boys were videotaped during snack time (5-20 minutes) with their mothers at age 2½ and again at age 4. Snack time is a relaxed everyday activity during which the mother and the child are at their maximum comfort level. This would allow an accurate sampling of mother-child interactions.

Both behavioral and verbal measures are used to index autonomy, including: (1) behavioral autonomy: the time the child spends away from the mother to explore the environment, (2) verbal independence: child speech emphasizes the self as unique and autonomous, such as describing internal and/or separate experiences, and (3) verbal assertion: child verbal or nonverbal response to the mother reflecting personal initiative and/or persistence. It is predicted that both genders would show an increase in autonomy from age 2½ to 4. Additionally, boys would demonstrate more autonomous behavior. Findings of this study can benefit parents and educators to promote positive development.

The Chariot Above the Heavens and the Ladder Upon the Earth: An Exploration of Love in the Writings of Plato

Michael Slade
Dr. Frank Harrison, Department of Philosophy, University of Georgia

In the popular imagination, Plato's Socrates is famous for his self-deprecation. Within the Platonic corpus, Socrates claims expertise in only one area: the art of Eros (generally translated as "love"). Despite its anomalous status, Eros is discussed explicitly only twice, in *Phaedrus* and *The Symposium*. The focus of my presentation is the analysis and (hopefully) resolution of the surprisingly different ideologies presented in these two dialogues. Scholars have tended to ignore Plato's internal inconsistency on the topic of Eros, either privileging one dialogue over the other or employing fuzzy generalities to establish their "unity." The disparity is, however, very real. Though both stories end with the apprehension of the Beautiful, the gap between the rational erotic process of *The Symposium* and the "divine madness" of *Phaedrus* is, at best, jarring. Since the Beautiful is closely tied to a host of other key Platonic concepts, including the Good, understanding the ascension to it is hardly trivial. Indeed, exploring the conflict between these visions is to ask the very fundamental question "How does Plato view love, philosophy, and the pinnacle of human existence?" This paper will begin to answer this question by examining the contrasting descriptions (presented through myth and argument) of Eros offered in *Phaedrus* and *The Symposium* and unpacking the philosophical methodology (and, therefore, guide for human conduct) each recommends. The product of this analysis will then be brought into the larger context of Plato's other writings in hope of offering a characterization of his overarching vision and clarifying the role of key concepts in his thought.

Using fMRI and Neuropsychological Tests to Index Brain Function Following a History of Multiple Concussions

Devin Smith – CURO Scholar
Dr. L. Stephen Miller, Department of Psychology, University of Georgia

Concussive injuries occur often in physically trying contact sports such as football and rugby. These injuries can impair neural activity which in turn negatively effects neurocognitive performance. The purpose of this experiment is to use functional MRI (fMRI) to define and track temporal changes in brain function associated with concussive injuries; assess the positive relationship between fMRI defined brain function and neurocognitive performance using traditional neuropsychological tests; and investigate the relationship between fMRI defined brain function and symptom permanence in athletes with a history of multiple concussions. Based on previous research and the extant literature it is expected that athletes with a history of multiple concussive injuries will show specific patterns of fMRI BOLD response that differentiate them from matched controls. It is also expected that participants with a history of multiple concussions will perform significantly worse on the neuropsychological tasks than matched controls. However, the results indicate no such findings; in fact, there were no significant differences between the experimental group and their control counterparts on the neuropsychological testing, fMRI defined brain activation, response time or accuracy on the fMRI tasks. These results could point to greater neuroplasticity amongst young athletes than was

previously thought. It is possible that the tasks used didn't accurately measure traits that are changed after concussive injuries, or the sample size may not be large enough to show statistically significant differences in behavioral or fMRI data. Finally, it is possible that having two to three concussions is below the threshold at which one can expect to see permanent changes.

Senescence and the Y Chromosome
Maren Smith
Dr. Kelly Dyer, Department of Genetics, University of Georgia

Recent research has shown that the Y chromosome has the ability to alter expression of autosomal and X-linked genes (Rice 2001, Lemos et al 2008). Many of the genes influenced by the Y chromosome are known to be involved in pathways that play a role in aging, suggesting a role for the Y chromosome in the aging process. Our research goal is to investigate whether Y chromosome variation causes significant variation in aging. We will create 20 isogenic lines of *Drosophila melanogaster* flies. The lines will be identical for autosomes, X chromosomes, mitochondrial DNA, and cytoplasm. We will use 10 Y chromosomes from an African *D. melanogaster* population and 10 from a North American population. Organisms from these lines will be tested both for longevity and stress resistance to measure effect of the Y chromosome on aging. We will also present data on the level of genetic differentiation between Africa and North American Y chromosomes. The level of genetic differentiation will be used to measure the significance of variation in longevity and stress resistance. Our hypothesis is that there will be significant variation in longevity, stress resistance, or both between the African Y chromosome flies and the North American Y chromosome flies.

The Dehumanization of War and the Female Condition
Sarah Smith
Dr. Hyangsoon Yi, Department of Comparative Literature, University of Georgia

In Korean War literature from the mid-1950s onward, many Korean authors depict the war and the subsequent American occupation as a gendered event. South Korea is typically pictured as a female (often a prostitute for the military) who is invaded, dehumanized and destroyed by the overwhelming masculine force of Western culture. In O Chong-hui's "Chinatown," the author examines the gendered nature of war violence and how it impacts the lives of South Koreans. The ravaged and impoverished city of Inchon in the piece becomes a metaphor for the female body, the actual physical site upon which ideological and cultural warfare is fought. The setting of the war-ravaged port city highlights the female characters' lives and bodies as they are torn apart through childbirth, insanity, sexual violence, and menstruation. O Chong-hui drives the connection between the physical setting of Inchon and the female condition through synesthetic metaphors that immerse the reader in the gritty physicality of the place. The author's heightened awareness of female bodies presents severe consequences—the reduction of women's identities to mere bodies leads to the "bestialization" or dehumanization of the women. O realizes this dehumanization through gruesome animal anecdotes that permeate the story. Ultimately, O makes the connection between the South Korean women's dehumanization through Confucian male supremacy and the devastating dehumanizing effects of war violence on the South Koreans.

Examining the Attitudes of Georgians Toward Universal Health Care and the Consumption Tax
Donald Snyder – CURO Apprentice
Dr. James Bason, Survey Research Center, University of Georgia

Two of the biggest issues in the nation today are healthcare and tax reform. Roughly 47 million Americans are without health insurance, a significant problem politicians and Americans from both sides of the aisle want to fix. The current tax code now exceeds a stupefying 60,000 pages. Some have argued replacing the complex tax code in place today with a simple

sales tax applied at the register whenever someone purchases a good, known as a consumption tax. I created a series of questions on both of these issues that were included in the fall 2008 semester's Georgia Poll, a statewide public opinion survey, to determine the opinions of Georgians on these issues. The results were thus: (1) the approval on the consumption tax items were significantly higher than the rest of the nation, most likely due to the impact of the FairTax and its proponents; (2) the results on the universal health care items were slightly less favorable than national results, most likely because of the large number of Republicans in Georgia, whose party platform disapproves of the measure; and (3) each item was broken down into demographic groups to analyze the statistical significance of answers across groups like gender, party identification, and income. As a result, it seems more likely that the state of Georgia would replace its income and other taxes with a pure consumption tax, and less likely that it would make any reforms that would put it closer to universal health care.

Exclusive Consumption of Sugars as a Biological Means to Convert Lignocellulosic Hydrolysates Effectively

Neeraj Sriram – CURO Summer Fellow
Dr. Mark Eiteman, Biological & Agricultural Engineering, University of Georgia

Scientists are increasingly shifting their focus from tapping food products to using relatively inexpensive substrates such as lignocellulose (plant biomass) to produce bio-ethanol. During fermentation, a single microorganism, specifically *Escherichia coli* (*E. coli*), generally consumes multiple sugars (glucose, xylose, arabinose, glycerol, etc.) released by hydrolysis from lignocellulosic materials in a sequential manner, drawing out the length of the process in producing ethanol. Lack of a microorganism able to ferment efficiently and simultaneously all sugars has been one of the main factors preventing utilization of lignocelluloses. Recently, a novel approach was proposed for the simultaneous conversion of xylose and glucose sugar mixtures into microbial products such as ethanol (Eiteman et al. J. Biol. Eng. 2:3, 2008). This approach involves using multiple strains of *E. coli*, which are each selective in their consumption of a carbon source; for example, one is unable to consume only glucose and the other is unable to consume only xylose. Frequently, however, other sugars, such as arabinose and glycerol, are also found in lignocellulosic hydrolysates. Here, we report results of batch fermentations using an *E. coli* strain KD777, which has mutations in three genes responsible for glucose uptake (*ptsG manZ glk*), which would presumably prevent the metabolism of this carbohydrate. However, in a mixture of xylose and glucose, this strain will consume the xylose first, but will then slowly degrade the glucose. In a mixture of arabinose and glucose, the two sugars are consumed concurrently. In a mixture of glycerol and glucose, glycerol is exclusively consumed. Recently, we have employed RNA microarray technology to determine which genes are expressed in the presence of glucose and xylose compared to in the absence of glucose in order to determine the mechanism by which the glucose is consumed.

The Development of Directional Understanding in Three- to Five-Year-Old Children

Lenae Stansky – CURO Scholar
and Krisztina Varga
Dr. Janet Frick, Department of Psychology, University of Georgia

Endogenous orienting occurs when a meaningful cue, such as an arrow, is used to direct attention toward a peripheral target. Adults and children as young as four years of age respond faster to a target that is cued by a central arrow than to an uncued target. However, the nature of the understanding of the arrow by young children is not well understood. Therefore, the current study explores this issue by setting the perceptual "weight" (which is usually heavier on the side of the arrow head) of the arrow cue against its symbolic meaning (directional indication). In this project, 3- to 5-year-old children were tested using various centrally located arrow cues to test the hypothesis that as development progresses, there is also a progression of understanding of

arrow cues from a perceptual to a symbolic understanding. Children sat in front of a computer monitor and were presented with arrow cues followed by peripheral targets. The time it took them to make an eye movement to the target was measured using frame-by-frame coding. The results showed that 3- to 5-year-olds do not rely entirely on either the perceptual characteristics or on the symbolic nature of an arrow, as no reaction time differences were observed between valid and invalid trials ($p>.05$). Future research is proposed to investigate the understanding that young children have of important directional cues such as arrows.

Using Immunohistochemistry for the Detection of Rabies Antigen in Various Mammalian Species

Lindsay Stein – CURO Scholar
Dr. Corrie Brown, Department of Pathology, University of Georgia

Rabies is a fatal zoonotic viral infection of the central nervous system that can affect all mammalian species, including humans. It is transmitted by the bite of a rabid animal and those infected die of acute progressive encephalitis. The virus tends to localize in specific parts of the brain in various species. Diagnosis of rabies can be problematic and current techniques either have operator safety or test sensitivity problems. The development of immunohistochemistry is a promising tool for safe and accurate detection of rabies infection and has advantages for use in developing countries. In a retrospective study, immunohistochemistry (IHC) was applied to 26 archival cases of rabies using a commercial polyclonal antibody. Eight species were studied including horse, cattle, llama, pig, dog, cat, raccoon and skunk and all cases had been previously diagnosed using histopathology and/or fluorescent antibody testing (FAT). The IHC test successfully highlighted the presence of rabies virus antigen in each species and demonstrated characteristic distributional differences throughout the brain. In carnivores, the hippocampus was the preferred site for rabies antigen, and in horses the spinal cord and medulla oblongata were optimal. For cattle, the preferred site was brainstem followed by cerebellum and for raccoons and skunk, IHC positive staining was widely dispersed. This test should prove useful in enhancing the diagnosis of rabies through informed selection of brain segments for testing. Adoption of IHC for rabies diagnosis in formalin-fixed tissues offers promise for control programs for this serious public health problem.

Power and Influence in Southeast Asia: A Study of the Methods Used by India, China, Japan, and the United States

Giridhar Subramanian – CURO Apprentice, CURO Summer Fellow
Dr. Brock Tessman, Department of International Affairs, University of Georgia

States use either hard or soft power to influence events around them. Hard power relies on military and economic incentives and punishments; soft power uses more abstract aspects of economic dependence or moral authority to reach the desired outcome. This study looks at India, China, Japan, and the United States, known as power countries, and their influence on Southeast Asia. In order to measure hard and soft power's effectiveness, the independent variables are bilateral trade and arms percentage. Bilateral trade measures soft power by looking at what percentage of a Southeast Asian country's GDP comes from bilateral trade with a power country. Arms percentage, which measures hard power, is the percentage of the military expenditure that a state spends on bilateral arms transfers. These variables are then compared with bilateral events data and UN disagreement percentage through a statistical analysis program, STATA. The study seeks to find the relative efficacy of both types of power for a given year. The analysis shows that cooperation is positively correlated with arms percentage and negatively correlated with bilateral trade, which implies that hard power is more effective than soft power over time. It also indicates that both independent variables' significance as factors for increased cooperation rise when they are used together. Therefore, soft power is more effective when it is used with

hard power. These results show that soft power, although important, is not a strong factor in influencing other nations, as select items of literature within the field imply. Hard power is still an important factor in affecting other states' decisions.

Neuropeptide Signaling in *Drosophila*: A Cell-Specific Functional Dissection of the Proprotein Processing Protease *amontillado* (*amon*)

Caroline Sumners
Dr. Michael Bender, Department of Genetics, University of Georgia

Neuropeptide signals are key regulators of cellular growth, development, and physiology in multicellular organisms. Neuropeptides relay signals to cells by binding to membrane-bound receptors initiating intracellular signal transduction networks. Neuropeptides are initially produced as larger inactive precursor molecules that are activated through proteolytic cleavage by proprotein convertases and by other subsequent modification events within the secretory pathway. The *Drosophila amontillado* (*amon*) gene, which is required for normal growth and development, encodes the homolog of the mammalian proprotein convertase 2 (PC2). By investigating the requirements for *amon* function in specific neuronal cell types, we will investigate whether and how neuropeptide processing contributes to the regulation of development and physiology. This thesis specifically considers *amon* function in corazonin-producing neuronal cells. Corazonin is an insect neuropeptide associated with ecdysis, the process of larval molting, and with the regulation of glucose levels. *Amon* mutants show defects in ecdysis and glucose regulation, suggesting that *amon* may act upstream of corazonin. To determine whether *amon* is required in corazonin-producing cells for normal growth and development, we are asking whether reduction of *amon* expression in these cells results in defects in growth, developmental progression, or glucose homeostasis. If loss of corazonin signaling is responsible for defects in *amon* mutants, we predict that reducing *amon* expression should lead to ecdysis defects or hypoglycemia. In a complementary approach, we are investigating whether *amon* is sufficient for rescuing normal growth by restoring *amon* to corazonin-producing cells in an otherwise *amon*-deficient animal.

The Neurotrophic Action of Botulinum Neurotoxin

Joshua Sumislawski – CURO Scholar
Dr. Julie Coffield, Department of Physiology & Pharmacology, University of Georgia

Botulinum neurotoxin, the agent that causes the paralytic disease botulism, is the most poisonous substance known. The ability of botulinum neurotoxin serotype A (BoNT/A) to produce flaccid paralysis makes it both of public-health concern as a biological weapon and of medical interest as a versatile therapeutic agent (BOTOX®). Less appreciated is the frequent observation that poisoned nerve endings respond by initiating and extending neurites. This phenomenon, termed sprouting, has now been proposed as an indication that the binding of BoNT/A to the neuronal membrane activates intracellular signals that are independent of its already well-characterized paralytic action. Supporting this novel idea, recent studies have demonstrated that the ability of the toxin to induce sprouting is concentration-dependent and counteracted by receptor antagonists. This study addressed the hypothesis that BoNT/A promotes neurite outgrowth through a signaling pathway that depends on the second messenger cyclic adenosine monophosphate (cAMP). To test this hypothesis, primary cultures of motor neurons from embryonic mice were exposed to BoNT/A with and without several inhibitors of cAMP-dependent pathways. In the presence of the inhibitors, the ability of the toxin to induce sprouting was eliminated. These results suggest that BoNT/A promotes neurite outgrowth of embryonic motor neurons via cAMP-dependent intracellular signaling. Additional studies are necessary to further our understanding of the neurotrophic action of this potent toxin.

Isolation and Identification of Novel Acidobacteria and Verrucomicrobia from Forest Soil

Shruti Suresh
Dr. William Whitman, Department of Microbiology, University of Georgia

About 5 % of all the prokaryotic cells on Earth are in the soil. These are comprised largely of diverse soil bacteria which play vital roles in the biogeochemical cycles that drive terrestrial ecosystems. However, the metabolic capabilities and ecological functions of many groups of soil bacteria remain unknown due to the lack of cultivation methods to obtain representatives for scientific investigation. The purpose of this study was to isolate and identify novel soil bacteria using new cultivation strategies. Specifically, bacteria belonging to the phyla Acidobacteria and Verrucomicrobia were cultivated after extended incubation in soil chambers. Different microbial media were supplemented with soil extract and inoculated in triplicate with soil suspensions. The plates were incubated for 10 weeks; DNA was extracted and further checked for target organisms by PCR amplification of the16S rRNA gene with phylum specific primers. Individual colonies from replicate plates were transferred to a 96 well block on the same medium. Following growth, these cultures were screened again by the same PCR method. Positive cultures were further purified by subculturing and identified by sequencing of the 16S rRNA genes. Further investigation of these bacteria will help identify their physiological and biotechnological capabilities. These bacteria are predicted to hold great potential in the field of agriculture.

How Parental Gender Beliefs Affect Children's Preference for Gender Stereotyped Toys in Low-Income Families

Leigh Tankersley, Robert J Gentry, and Heather E. Howell
Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University

Parents foster gender socialization by selecting toys, books, and clothes for their children from an early age. Children use these stereotyped gender cues, directed by parents, to guide their understanding of immediate contexts and behaviors. This study examined the influence parental gender attitudes had on the development of children's preference for gender-specific toys from low-income families. Seventy-two children (mean, 41.64 months, 44 boys) were recruited during the last two years from Headstart programs. Parents completed a survey, consisting of parental observations, gender beliefs, and practices regarding purchasing items for their children. Children's toy preference were assessed at school through interviews, toy selection from a given box, and free play with gender-related toys. The toy selection was videotaped and analyzed. The preliminary results showed strong evidence in children's gender stereotyped toy preference. One-way ANOVA revealed significant gender differences in reported favorite toys ($F(1, 17) = 6.766$, $p = .019$) and toys selection from the box ($F(1, 23) = 29.631$, $p = .000$). The top two toys selected by girls were *Polly* (27.5%) and a *Doll* (17.7%), while boys favored *Trucks* (43.5%) and *Fire Fighte*r (22.6%). Parents reported purchasing *truck* ($F(1, 32) = 9.318$, $p = .005$) for boys and *Barbie* ($F(1, 32) = 219.49$. $p = 000$) for girls. Therefore, parental attitude may directly influence children's preference for gender stereotyped toys. Further implications from parental gender socialization will be discussed at the conference.

The Evolution of a Scientific Community Through Social Network Analysis: The Case of Autism

Christine Tarleton – CURO Scholar
Dr. Shane Hamilton, Department of History, University of Georgia

Studies of the social network structures of scientific collaborations can highlight apparent temporal differences within a developing research field. This project will provide a historical analysis for how the autism community has continually evolved as a multi-disciplinary field from 1970 to 2006. Social network visualizations of the autism research community were created using UCINET software, and co-citation analysis provided the

method of linkage. This disciplinary social mapping of autism research during this period indicates that the field has changed dramatically from a weak network with a primarily psychological base in the 1970s to a very robust, interdisciplinary scientific community with a solid genetics core by the late 1990s. A year-by-year analysis of the networks appears to correlate to specific historical events; for example, an increased interest of advocacy groups in autism research post-1996 occurs simultaneously with a more rapid expansion and increased interconnectivity of the autism community. Additionally, the rise and better availability of genetic technology as well as the discovery of a link between Fragile X syndrome and autism occur within a reasonable time frame to suggest that key scientific discoveries affect the makeup and evolution of a scientific community. By thoroughly investigating the history of the autism field and comparing it to a year-by-year analysis of the composition of its scientific community using data previously generated through social network analysis (SNA), this project aims to provide new insight into the historical causes of research field expansion and to determine what types of internal and external causes might shift the disciplinary focus and makeup of a newly emerging research community.

Genetic Duplication and Amplification in the *Acinetobacter baylyi* ADP1 Genome

Jennifer Taylor and Poonam R. Patel
Dr. Ellen Neidle, Department of Microbiology, University of Georgia

Gene amplification is a common process with medical and evolutionary significance. Here, a system for studying gene amplification in the soil bacterium *Acinetobacter baylyi* ADP1 was expanded. Parent strains lacking two transcriptional activators do not grow on benzoate (Ben^-). From these strains, spontaneous Ben^+ mutants arise with multiple copies of a chromosomal region (amplicon) that includes key catabolic genes, thereby increasing gene expression and allowing growth on benzoate. Initially, gene duplication results from recombination between DNA on either side of the amplicon. Homologous recombination then generates additional gene copies that are retained under selection. The characteristic feature of amplification is a junction that identifies the precise position of the initial recombination event. A promoter mutation in the parent strain may have artificially restricted the pool of viable amplification mutants. To remove this bias, we modified protocols by selecting for growth of the original parent strain on an alternative carbon source, anthranilate. In a second approach, a similar parent strain was used that lacked the promoter mutation but retained all other defining characteristics of the original parent strain; mutants were selected for growth on benzoate or anthranilate. Our results indicate that illegitimate recombination was the major type of duplication event underlying amplification. Also, an unusual type of position-specific illegitimate recombination occurred at precise DNA sites in multiple independently-isolated mutants. These conclusions were independent of the presence of the promoter mutation. Overall, the ADP1 system has proven to be viable for efficiently studying gene duplication and may prove useful for elucidating mechanisms.

Human Random Capacities Through Repeated Numeric Sampling

Aileen Thomas – CURO Scholar, CURO Summer Fellow
Dr. Nicole Lazar, Department of Statistics, University of Georgia

Randomness in the macroworld of human actions would contradict the theory of causal determinism, that all events occur as a direct result from antecedent factors, and be a pivotal contribution to philosophical debates on free will. The aim of this research is to understand human capacities and motivations of randomness. Can human beings act truly randomly or are their actions predetermined? Participants completed a short survey and entered 100 "random" digits into a grid. The numeric sequences generated were statistically analyzed through tests described by Donald Knuth in *The Art of Computer Programming, Vol. 2* (1981) to determine their degree of

randomness. These sequences were compared against sequences generated from different methods of randomization consisting of dice rolls, decimal digits of pi, and deterministic formulas used by Texas Instruments programmable calculators and Java, which underwent similar analysis. Hypotheses of uniformity were tested using Chi-Squared analysis in frequency and serial tests. Sequences generated from dice did not adequately pass frequency tests using alpha level 0.05. Alternatively, the nextInt()and nextInt(long n) methods of class Random in Java, randInt(x,y) from Texas Instruments, the decimal digits of pi, and human participants produced sequences that did adequately pass the frequency test. Of these, only human participants failed to pass the more rigorous serial test. Due to the theoretical foundation of the research question, it is impossible to produce concrete conclusions. However, the sequences produced by human participants most closely resembled those produced from deterministic formulas.

Effects of Vertebral Fusion on Lateral Bending Spinal Motion of Women with Adolescent Idiopathic Scoliosis (AIS)

Jennifer Tooher and Jaharris Collier – CURO Apprentice
Dr. Kathy Simpson, Department of Kinesiology, University of Georgia

Spinal fusion is the most accepted procedure currently performed on adolescent idiopathic scoliosis (AIS) patients with scoliotic curvature greater than 40^{o}. The purpose of the overall study is to determine the effects of spinal fusion on range of motion (ROM) during lateral bending tasks. We expect limitations in ROM of lateral bending due to fusion, but there is little understanding of the effects of fusion on vertebral motions or ROM. The pilot test compared the motions of two women with lumbar scoliosis: one with fusion (FUSED) and a control without fusion (NFUSED). VICON® motion-measurement system captured spatial locations of 46 reflective markers on the spine and body during three trials of maximum trunk lateral bending. As hypothesized, FUSED experienced nearly twice the loss of lumbar motion than NFUSED in the lumbar-sacral segments. Both women displayed greater lateral motion of the thoracic compared to the lumbar spine. However, FUSED did not display greater thoracic motion than NFUSED, thereby tentatively disproving that the nonfused spine of AIS individuals will display greater ROM to compensate for the fused section. Future research will potentially confirm these findings and determine spinal ROM and spinal mechanics that AIS individuals use to accomplish functional tasks.

Inhibition of LPA Signaling Pathways by RGS Protein Overexpression in Ovarian Cancer Cells

Kathryn Turner – CURO Scholar, CURO Summer Fellow
Dr. Shelley Hooks, Department of Pharmaceutical & Biomedical Sciences, University of Georgia

Lysophosphatidic acid (LPA) is a signaling molecule that induces survival, metastasis, migration, and growth in ovarian cancer cells by binding to G-protein coupled receptors (GPCRs), which in turn activate G-proteins. Regulator of G-Protein Signaling (RGS) proteins deactivate these G-proteins, and therefore stop the LPA signal. RGS proteins are a likely therapeutic target for the cancer causing activities of LPA because there are multiple forms that bind specifically to different G-proteins, therefore potentially regulating specific signals and outcomes. Previous data suggest that RGS proteins play a role in regulating the LPA signal in ovarian cancer cells. By comparing the effects of LPA in RGS sensitive and insensitive cells, we observed differences in cell growth, cell migration, and the production of the second messengers cyclic adenosine monophosphate (cAMP) and inositol phosphate (IP). My current project focuses on overexpressing specific RGS proteins and determining their effects on LPA stimulated outcomes in SKOV-3 ovarian cancer cells. LPA causes a decrease in the second messenger cAMP, and we have found that overexpression of RGS2 and RGS19 blocks this inhibition, as shown through a cAMP assay. Additionally, LPA causes an increase in cellular

migration, which is also inhibited by RGS2 and RGS19, as shown in a wound induced migration assay. Furthermore, RGS 3 overexpression seems to have no effect on cAMP levels or migration. Future studies include overexpression of other RGS proteins in order to determine their roles, and lowering levels of RGS proteins in ovarian cancer using siRNA.

Antisaccade Performance and Deficit Characteristics in a Normal Population

Manouela Valtcheva – CURO Summer Fellow
Dr. Jennifer McDowell, Department of Psychology, University of Georgia

Patients with the deficit syndrome of schizophrenia suffer from more debilitating and persistent symptoms than nondeficit patients, including severe anhedonia (inability to experience pleasure) in the absence of depression. Previous research suggests a higher degree of cognitive disruption within deficit patients as indicated by poor performance on eye movement paradigms. The antisaccade task requires inhibition of a reflexive glance towards a peripheral stimulus and generation of a glance to an equidistant location in the opposite direction. Normal subjects who score high on clinical scales are often used as a proxy for people at risk for specific mental illnesses. Finding an analog of deficit schizophrenia within a normal participant sample could help in future risk-studies. It was hypothesized that participants displaying a higher number of deficit-like symptoms (high schizotypy (subclinical schizophrenia-like symptoms), high anhedonia, low depression) would have worse antisaccade performance. Normal undergraduates (N=350) completed self-report questionnaires measuring schizotypy, anhedonia, and depression and performed the antisaccade task. Although there were no overall relationships between deficit characteristics and antisaccade performance in the total sample, in the top 25% of the antisaccade distribution, higher schizotypy was associated with worse antisaccade performance. Higher schizotypy ratings were associated with longer antisaccade latencies. Overall, the findings suggest that a group of normal undergraduates, scoring high on self-report clinical scales, have mild disruptions in cognition but are not a good proxy group for the deficit syndrome. Because this may be due to restrictive demographic effects, additional studies with larger, more variable samples would be informative.

Analyzing the Gender Gap in Educational Achievement in Children Ages 5-12

Jessica Van Parys
Dr. David Mustard, Department of Economics, University of Georgia

Several studies investigate differences in early childhood educational achievement by race and ethnicity. Few researchers, however, evaluate the performance gap by gender. This is the first study to use the National Center for Education Statistics (NCES) Early Childhood Longitudinal Study – Kindergarten Cohort 1998-99 (ECLS-K) to analyze the variance in educational achievement by gender in children ages 5-12. The data begin with 12,000 students in kindergarten and provide information on each child's home and school environments at each stage of the evaluation in the kindergarten, first, third, and 5th grades. Using cross-section regression analysis and controlling for socioeconomic status and school characteristics, we find that females score 1/7 of a standard deviation higher than males in standardized reading scores, while males score 1/22-5/22 of a standard deviation higher in standardized math scores. These differences appear in early kindergarten, persist through the 5th grade, and reflect different gaps than classroom grades. Females earn 1/4 of a standard deviation higher reading grades, and there is no statistically significant difference in math grades. The variance in grades does not match the variation in test scores, and indeed, places females ahead of males in this measure of academic achievement. Using a behavioral rating scale as the dependent variable, we find that teachers rate females as more likely to pursue learning activities and display strong interpersonal skills, while males are more likely to externalize problems and exhibit impulsive behavior. These results suggest that more non-cognitive skills at early ages for females may help to explain the

gender gaps in measured educational performance.

Measuring the Orderliness of Thought
Hemali Vin
Dr. Michael Covington, Institute for Artificial Intelligence, University of Georgia

Schizophrenia is a severe brain disorder characterized by disorganized thinking that can significantly interfere with the ability to function normally. Proper treatment is contingent on early detection. The Salient Items Test is a method devised by Dr. Michael Covington to detect each type of disorganized thinking that occurs in schizophrenia. Research shows that when asked to describe a picture, a patient with schizophrenia will often fail to mention all of the prominent objects (salient items) in it, whereas a healthy person will almost always produce a complete list. Dr. Covington is now investigating whether patients with schizophrenia, even when they name all the items, do so in a less orderly fashion than healthy people. My task involves development of a program in the C# programming language to implement a mathematical method for scoring the orderliness of picture descriptions. This program analyzes files of Comma Separated Values (CSV) to create distance matrices of the values. Distance matrices are used to reflect the order of the items in relation to each other. The distance matrices will be compared to a "normal matrix" to determine if there is a difference in scores of the Salient Items Test between healthy controls and of schizophrenia patients. The program is now being tested to assess its usefulness and accuracy. To test the program, artificial data of orderly and disorderly picture descriptions will be constructed and scored. Once perfected, this program could allow for faster and more accurate identification of schizophrenia patients.

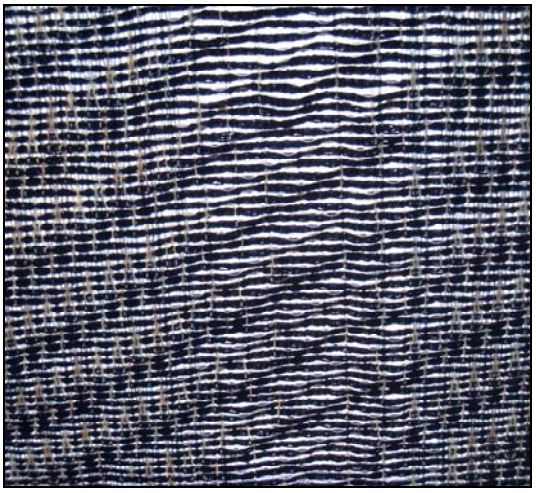
Differential Regulation of Oxidative and Thermal Stress Tolerance upon Changes in Levels of O-GlcNAc Modified Proteins *in vivo*
Wei Wang – CURO Scholar
Dr. Lance Wells, Department of Biochemistry & Molecular Biology, University of Georgia

From *C. elegans* to mice, reduced signaling through the insulin-like pathway extends lifespan. However, reduced signaling, defined as insulin resistance, also precedes and is the hallmark of type II diabetes. Our laboratory has demonstrated previously that elevation in intracellular glycosylation of nuclear and cytosolic proteins via the carbohydrate post-translational modification O-linked beta-N-acetylglucosamine (O-GlcNAc) induces insulin resistance. More recently, the laboratory has demonstrated that the O-GlcNAc cycling enzymes (OGT that adds and OGA that removes the modification) modulate median lifespan in *C. elegans*. Our observations also suggest that O-GlcNAc modification of proteins affects oxidative stress tolerance but not thermal tolerance. We have generated transgenic animals to study how the two processes, oxidative and thermal stress tolerance governed by insulin-like signaling, can be differentially regulated upon changes in the levels of O-GlcNAc modified proteins. Double mutants of oga-1 and ogt-1 with GFP-tagged superoxide dismutase-3 (sod-3) or heat shock proteins (hsp-16) were separately generated and analyzed for differences in activation based on O-GlcNAc modification using the imaging of green florescence protein *in vivo*. Since these two stress response genes are regulated via DAF-16 following its nuclear localization in response to insulin-like signaling, double mutants of daf-16::GFP with oga-1 and ogt-1 were also generated and analyzed for DAF-16 localization and expression. Preliminary data suggest that HSP-16 expression is not affected while SOD-3 is by altering O-GlcNAc levels. Our results suggest that O-GlcNAc is impacting oxidative stress responses in addition to median lifespan in *C. elegans*.

Thermal Adaptation of Soil Microbial Respiration in Laboratory Microcosms
Brian Watts – CURO Apprentice
Dr. Mark Bradford, Odum School of Ecology, University of Georgia

Respiration of heterotrophic microorganisms decomposing soil organic carbon releases carbon dioxide from soils to the atmosphere. In the short-term, soil microbial respiration is strongly dependent on temperature. In the long-term, the response of heterotrophic soil respiration to temperature is uncertain. However, following well-established evolutionary trade-offs that occur during adaptation of respiratory metabolism to the ambient thermal regime, mass specific respiration (R_{mass}) rates of heterotrophic soil microbes should decrease in response to sustained increases in temperature. The principle of evolutionary trade-offs indicates that enzymes kept at a relatively high temperature for a sustained period of time will have lower catalytic rates compared to enzymes kept at relatively low temperatures for a sustained period of time. Using a laboratory microcosm approach, we tested the potential for the R_{mass} of the microbial biomass in six different soils to adapt to three, experimentally-imposed, thermal regimes (constant 10, 20 or 30°C). To determine R_{mass} rates of the heterotrophic soil microbial biomass across the temperature range of the imposed thermal regimes, we assayed soil sub-samples, employing similar approaches to those used in plant, animal, and microbial thermal adaptation studies at days 1, 7, 21, 50, and 77. As would be expected given trade-offs between maximum catalytic rates and the stability of the binding structure of enzymes, significant effects were observed after 77 days of incubation. R_{mass} rates across the range of assay temperatures were greatest for the 10°C experimentally incubated soils and lowest for the 30°C soils, with the 20°C incubated soils intermediate. The time taken for thermal adaptation to manifest (77 days) suggests that it likely resulted from population or species shifts during the experimental incubation. The relative magnitude of the difference in R_{mass} rates between the different incubation temperature treatments was unaffected by assay temperature, suggesting that maximum catalytic rate was the enzyme characteristic involved in thermal adaptation.

Weaving the Fog
Daisy Whelan
Prof. Clay McLaurin, Department of Fabric Design, University of Georgia



Can one determine their own physical position on a day when navigating the clouds becomes the first visual priority? The clouds, manifested as deep fog, provide a blanket of disillusion when positioned so close to the ground. However, the visual distortion that one experiences on a foggy day is based on a structure of perfectly clear water particles. I have interpreted this subject matter through weaving, using some traditional yarns and many alternative materials. Such materials include vinyl-coated yarn, nylon and monofilament mixed with more traditional bamboo, knitted, and cashmere yarns. Weaving lends itself perfectly to interpreting clarity, for the process is a system of design that relies on structure as its livelihood. I have manipulated material and order of pattern, so that my weavings interpret light and movement. Some weavings rely on the density of material to provide disillusion, while others rely on the near invisible nature of the material. Perfect structures form when I allow the setup of the loom to project a perfect pattern. My research tests the viewer's eye. Sometimes lost in the order, the viewer is at other times faced with a complete framework and clarity of order. Positioning is crucial; the weaving will

appear differently depending on the where the viewer stands, just like every position in the fog will take on a different illusion.

Bolivian Wrestlers in Skirts
Abigail Wilson
Dr. Katalin Medvedev, Department of Textiles, Merchandising & Interiors, University of Georgia

Dress serves as a symbolic metaphor of the relationship of the individual to the cultural system and thus is an important means of constructing and articulating gender norms. The analysis of the sartorial practices of indigenous female wrestlers, known as cholitas luchadoras, provides insight into the social/political tension that exists in the contemporary Bolivian society, where domestic and political hostility is rampant. What differentiates the cholitas from (fe)male wrestlers in the Western world is their distinctively feminine and historically grounded dress style. The cholitas consciously choose to wrestle in a lace petticoat, a Spanish-style skirt (also known as a "pollera") and a colorful, fringed shawl because they embrace and choose to highlight their femininity in such a traditionally masculine and often brutal activity. The pollera is the typical dress of native women in Bolivia, thus the cholitas' decision to wear the garment underscores the strength and perseverance of these women in the face of all forms of violence in their lives. Through their impractical use of traditional female dress, they not only contest the misogynist treatment of women but the political and economic disenfranchisement of indigenous people as well. Through their acrobatic acts of wrestling these female wrestlers prove that they can fight without sacrificing their femininity or compromising their ethnic identity. In the process, they are actively reshaping and redefining contemporary gender and political roles in Bolivia. The analysis of the cholitas' practices is informed by Judith Butler's work on the performativity of gender.

Defining and Regaining the Human Identity: Queries of Existence in Frederick Douglass's *Narrative*
Anna Wilson
Dr. Ron Miller, Department of English, University of Georgia

This paper explores the process of dehumanization imposed upon African American slaves within the system of American chattel slavery as it is depicted in *The Narrative of the Life of Frederick Douglass: An American Slave*. What does it mean to be human and, conversely, what does it mean *not* to be human? My research has revealed that Douglass's portrayal is distinguished by animal-related metaphors that the author utilizes to identify the qualities crucial to human identity and thereby the features that are most devastated by the slavery system. This paper also examines Douglass's rebirth into humanity and endeavors to recognize and elucidate the processes by which these vital human traits are re-implemented into the author's life. My paper asserts that this journey can be clearly separated into two major stages: the reacquisition of a personal identity and the acceptance of the right to toil for upward social mobility. Both phases are initiated, fueled, and shaped heavily by Douglass's personal literacy. By clearly differentiating between brute, man, and, perhaps most importantly, the process of transformation from one to the other, Douglass's *Narrative* creates a standard scale that can be utilized to evaluate the process of human progress. My paper reapplies these historically transcending findings in order to examine several notable individuals and events that have taken part and place within the most recent years of the African American timeline.

8-Chloro-7-hydroxyquinoline and Xanthone Acetic Acid Derivatives as Photoremovable-Protecting Groups with Susceptibility to Two-Photon Excitation

Hunter Wilson – CURO Scholar, CURO Summer Fellow
Dr. Timothy Dore, Department of Chemistry, University of Georgia

Photochemistry offers scientists a powerful method of exploring biological processes. Photoremovable protecting groups (PPGs) can quickly release bioactive molecules with a flash of light, activating them and enabling researchers to explore how the timing and location of events triggered by these molecules impact cellular function. In particular, PPGs with sensitivity to a process called two-photon excitation (2PE) enable precise control of the location and timing of release events and often utilize light that is not harmful to biological systems. A firm understanding of how PPG structure impacts 2PE susceptibility is necessary to exploit these powerful compounds to study physiology. The PPG 8-bromo-7-hydroxyquinoline (BHQ) has sensitivity to 2PE sufficient for biological use. The structure of BHQ is based on the compound quinoline. To enhance knowledge of quinoline photochemistry, a similar compound called 8-chloro-7-hydroxyquinoline (CHQ) was synthesized, and its photochemistry studied. The CHQ 2PE cross-section (δ_u), a measure of sensitivity to 2PE, was 0.12 GM at a wavelength of 740 nm. Compared to BHQ, CHQ is less sensitive to 2PE. Two other promising PPGs called 2- and 4-xanthone acetic acid (2-XAA and 4-XAA, respectively) are based on the compound xanthone. The values of δ_u for 2-XAA and 4-XAA were both found to be 2.1 GM at 700 nm. These experiments have established that 2- and 4-XAA have excellent sensitivity to 2PE and might be used to mediate the release of bioactive molecules in biological systems. Our studies are delineating the structural requirements for PPGs to have sensitivity to 2PE.

Preventative Medicine in Water Supplies: A Remodeling of Disaster Relief

Abby Wong – Roosevelt@UGA
Dr. Angela Fertig, Department of Health Policy & Management, University of Georgia

In 2008, the United States Agency for International Development (USAID), a United States federal government organization responsible for non-military foreign aid, responded to over 80 disasters in 63 countries, spending in one fiscal year over $500 million dollars in disaster response. One of the most destructive effects of natural disasters, especially floods and droughts, is the contamination of drinking-water supplies. Communicable diseases such as Typhoid, Cholera, Hepatitis A, and Leptospirosis, as well as intestinal parasites, are easily transmitted through contaminated water, making the accessibility and quality of public water supplies an immediate priority in the aftermath of a disaster. Poor countries bear a disproportionate amount of health risks and lack the necessary economic resources to minimize the impact. Through a systematic review of the current literature, focusing on relevant case studies, interventions, and survey research, this paper provides a comprehensive synthesis of the current research on the humanitarian, political, and economic benefits of effective mitigation action. The findings show that preparatory measures taken by governmental and nongovernmental aid agencies such as USAID would help mitigate outbreaks of water-borne diseases in the aftermath of a natural disaster, when populations are most vulnerable. This research also provides a review of the biological ramifications that water-borne disease outbreaks in developing countries can have on industrialized western societies, like the United States.

A Sense of Self: Questions of Identity in Contemporary Novels by Second-Generation Turkish-German Women Writers

Laura Wynn – CURO Apprentice, CURO Summer Fellow
Dr. Martin Kagel, Department of Germanic & Slavic Languages, University of Georgia

As the largest minority, the Turkish-German population plays an important role in contemporary Germany. Turkish citizens first came to Germany in the wake of a guest worker agreement forged in 1961, which allowed Turkish workers to assist in the rebuilding of Germany during the post-war economic boom. Many guest workers chose to remain in Germany and, over time, the group grew into the largest minority living in the country today. The integration of Turkish guest workers into German society has been difficult and caused much political controversy. Questions about what rights should be afforded these "Fremde," or foreigners and their role in German society as a whole prompted many Turkish-Germans to begin putting their ideas to paper. During the 1970s, literature by Turkish-German authors began to emerge and attract attention and recognition when Emine Sevgi Özdamar won the Ingeborg Bachmann prize in 1991. Since the reunification of Germany in 1989, the publication of literature written by Turkish-German authors has increased significantly, especially as the second generation of Turkish-Germans has come of age. Three novels written by female authors of this second generation of Turkish-Germans depict many of the issues the minority as a whole faces. Alev Tekinay's *Nur der Hauch vom Paradies*, Yade Kara's *Selam Berlin*, and Dilek *Güngör's Das Geheimnis meiner türkischen Grossmutter* also cast light on the specific struggles of Turkish-German women of the second generation. The question of self is the most prominent of the thematic elements in the novels, which can be found in feelings and thoughts the characters express about family, gender, and a missing or incomplete sense of belonging in what remains a foreign country. My analysis of the novels against the historical background of both the individual authors and the Turkish-German minority as a whole traces the conflicts and discusses the answers the authors attempt to provide.

Simplification of Eligibility Requirements for PeachCare for Kids: Increasing Health Insurance Coverage for Georgia's Children

Tracy Yang – Roosevelt@UGA
Dr. Phaedra Corso, Department of Health Policy and Management, University of Georgia

PeachCare for Kids (PCK), part of the State Children's Health Insurance Program (SCHIP), provides low-cost health coverage for children residing in Georgia. PCK is administered by the Georgia Department of Community Health (DCH). In 2007, the DCH increased documentation requirements regarding proof of income, citizenship, and identity. These measures were not instituted in response to abuses of the program by ineligible individuals according to DCH officials. State and national legislation, academic literature, information from the DCH, and other sources were analyzed to research enrollment patterns of eligible but uninsured children across the U.S. after the implementation of increased documentation requirements to determine SCHIP eligibility. Various nationwide studies have found that increasing required documentation for enrollment in SCHIP has mostly resulted in coverage gaps and denials for eligible children. Analysis of these studies suggests that administrative hurdles regarding eligibility for PCK will result in decreased coverage of eligible children in Georgia, increased administrative costs, and decreased health outcomes for children overall. The reinstatement of simplified verification methods could help maintain and improve child health in Georgia. It is more cost-effective to insure children and provide them with preventive care than to treat later health problems through uncompensated care, especially in light of the recent SCHIP bill signed by President Obama providing potential funding. The basic goal of PCK is to provide health insurance for low-income children in order to improve health outcomes. Increasing enrollment of uninsured children already eligible for PCK will help Georgia reach this goal.

Kennedy, Carter, and Obama: The Role of Faith in Three Democratic Presidential Campaigns

Emily Yeager
Dr. D. Jason Berggren, Department of Political Science, University of Georgia

The constitutional separation of church and state does not preclude the separation of religion and politics; in fact, religion plays a fundamental role in both the Democratic and Republican parties. Popular thought tends to describe the Republican Party as the party of religious voters and religious candidates, but such a description disregards the role and reality of religious faith in the Democratic Party. In this paper, I evaluate public statements from three modern Democratic presidential nominees: John Kennedy, Jimmy Carter, and Barack Obama. There emerge not only faith narratives, discussion of faith's influence on policy, and religious rhetoric, but multiple interpretations of each. I will demonstrate that faith can shape a Democratic campaign in diverse, significant, and unexpected ways.

Expansion and Improvement of the Solar Cooker Project to Reduce Gender Based Violence

Yasmin Yonis – Roosevelt@UGA
Dr. Njeri Marekia-Cleaveland, Carl Vinson Institute of Government, University of Georgia

United Nations High Commissioner for Refugees (UNHCR) introduced the Solar Cooker Project, a program where solar cookers are distributed to refugee women for their cooking needs in select African refugee camps in 2005. Deforestation has increased the distance traveled by female refugees to gather firewood for their basic needs, significantly increasing their vulnerability to gender based violence (GBV), including rape, beatings, and murder. The use of solar energy for cooking has dramatically decreased the amount of firewood needed, minimizing the number of trips outside the safety of the refugee camp. This policy paper encourages the expansion of the Solar Cooker Project to other refugee camps with GBV associated with a need for an alternative cooking energy. The various issues associated with GBV in refugee camps—deforestation, local community tensions over resources, lack of clean water, gender roles, and economic disparity—are explored. Through the analysis of the wide array of factors contributing to GBV rates against female refugees, case studies of the Solar Cooker Project, and interviews with the agencies associated with the creation of the Solar Cooker Project, recommendations are provided to improve upon specific components of the project. New initiatives are also suggested to better financial support, environmental issues, and socioeconomic problems associated with the issue. This research is necessary in order to increase the level of success in helping to eliminate GBV in affected areas and allow for efficient expansion of the project to other UNHCR refugee camps in Africa.

Effect of Microbead Substrates on the Morphology of H945RB.3 Human Neural Progenitor Cells

Angela Zachman
Dr. William Kisaalita, Department of Biological & Agricultural Engineering, University of Georgia

Cells grown *in vitro* are known to have morphological differences from *in vivo* cells, in part due to the flat surface of a petri dish on which they are typically grown. These morphological differences can cause problems in using *in vitro* testing to predict *in vivo* behavior. Growing cells on microbead arrays could allow cultured cells to more closely resemble cells in the body. Previous research has shown that H945RB.3 human neural progenitor cells grown on 2µm diameter bead arrays have a larger area and perimeter than cells grown on a flat surface. In this experiment, we tested the morphological differences of cells grown on smaller 0.5µm diameter beads. Polystyrene beads in solution were spread over a portion of polystyrene coverslips, creating some areas of flat substrates and some areas of microbead substrates. Neural progenitor cells were then cultured on the coverslips and allowed to differentiate for fourteen days. The cells were then fixed on the substrates, dehydrated, and sputter-coated with

gold in preparation for scanning electron microscopy (SEM). Images were taken of cells on both the flat and microbead substrates using SEM, and the area, perimeter, and roundness (defined as $4*\pi*(\text{area})/(\text{perimeter})^2$) of each cell was calculated using computer imaging software. Contrary to our expectations, we found that cells grown on 0.5µm bead arrays had a larger area and perimeter than those of cells grown on either a flat surface or 2µm bead arrays. This indicated that 0.5µm bead arrays are an ideal substrate for cell growth.

Jewelry in the Age of Postmodernism

Marilyn Zapf
Prof. Mary Pearse, Department of Jewelry & Metalwork, University of Georgia

My current work investigates the role of jewelry in society through postmodern methods of critique. I use imitation to point to mass-produced and mass-consumed jewelry, while subtle changes create a distance between the symbol (jewelry) and the signified (status, wealth, and self-image creation). The necklaces reference nameplate necklaces, a trend in the 1980s that re-emerged in 21st century when Sarah Jessica Parker wore one on the HBO series *Sex and the City* and again (in an exaggerated form) in hip hop culture. Additionally, the necklaces are documented in the same context one would expect to find commercial jewelry: paparazzi-like photographs and snapshots found in popular style magazines. However, traditional materials such as gold and silver are not used but mimicked through the use of enamel or a colored glass surface applied to the base metal copper. In addition, the words spell out the role jewelry plays in society, such as a "signifier" of wealth and a creator of someone's self-image. My necklaces literalize the function of jewelry in order to simultaneously reveal and subvert the task of ornamentation in popular culture. My work suggests what is really being bought and sold when people buy jewelry through the reference to, but deviation from, popularly recognized materials, forms, and documentation of jewelry.

Genetic Effects of Radiation Exposure on *Rana terrestris* Populations from the Chernobyl Exclusion Zone

Sheena Zhang
Dr. Travis Glenn, Department of Environmental Health Science, University of Georgia

Chernobyl, the largest nuclear disaster in history, resulted in the mass exposure of humans and other species to radiation, which is known from other studies to increase mutation frequencies in DNA. The Chernobyl Exclusion Zone is abundant with amphibians, which are extremely sensitive to contaminants. To determine the effect of radiological exposure on mutation rates, *Rana terrestris* were collected from the Chernobyl Exclusion Zone, as well as nearby non-exposed control sites, and subsequently bred. DNA was extracted from 48 offspring from each of four families (2 contaminated, 2 control). Twelve microsatellite loci (i.e., repetitive regions of DNA that are codominantly inherited) were identified in the *Rana* genome and amplified using Polymerase Chain Reaction (PCR). The PCR products were run on an ABI 3730xl sequencer and analyzed using Genemapper 3.7 software. By comparing the lengths of the microsatellite DNA fragments between parents and offspring, it can be determined if any mutations have occurred. As the average mutation rate for most microsatellites is around $10E^{-3}$ (e.g., one in a thousand), we expect to identify as many as 1-10 baseline mutations within each of the four families. Analysis of Variance (ANOVA) will then be used to compare the number of mutations between control and contaminated sites to determine if radiation from nuclear

fallout has caused an increased mutation rate. The results from this study will help to quantify the impact and genetic risks associated with the Chernobyl disaster, while providing the experimental design to assess potential negative effects from other radiological exposure.

Center for Undergraduate Research Opportunities

Symposium 2011

Classic Center
Athens, Georgia
Monday, April 4, 2011

CALL FOR ABSTRACTS

The Center for Undergraduate Research Opportunities at the University of Georgia provides a forum for undergraduates with a 3.4 GPA or who participate in a university-wide research program to present original research and creative works sponsored by faculty members. Undergraduate students from all disciplines are encouraged to participate. Representatives of public and private higher education institutions in Georgia are encouraged to apply.

Scholarly presentations may be in the form of an oral presentation, poster session, exhibition, performance, or work of art. Students can also present a tutorial about a research methodology or new technology. Undergraduate researchers who are at various stages of the research process are encouraged to submit abstracts describing where they are in the research process and the issues they face. Honors thesis students can also present in a Roundtable Forum. The Roundtables offer undergraduates pursuing an Honors thesis the opportunity to present their research to other thesis students working in the same discipline. Those who wish to present their work should submit an application and an abstract of a maximum of 250 words no later than **January 21, 2011** and a brief supporting letter from the sponsoring faculty member no later than **January 30, 2011** via the CURO web site. Group research projects should be submitted with one application and one letter of faculty support. All abstracts will receive graduate student peer review and feedback. All participants accepted into the Symposium will be notified by February 12, 2011, and their abstracts will be published in a book of abstracts. Sponsoring faculty are invited to preside at their students' sessions.

Best Paper Awards
Papers on work being presented at the CURO Symposium submitted by February 26, 2011 will be considered for Best Paper awards in the categories of humanities, social sciences, civic responsibility focus, international focus, and sciences. Papers must be submitted electronically to curo@uga.edu. Maximum length is 12 pages, double spaced, excluding references and appendices.

Purposes of the Symposium:
- To highlight excellence in research by undergraduate students
- To enrich the undergraduate experience by promoting communication and cooperation between faculty and students
- To provide a forum for undergraduates to communicate and disseminate their research findings and creative works
- To provide an opportunity for undergraduate researchers in the state of Georgia to engage with their peer researchers

Criteria for Selection:
- Originality and quality of research
- Quality of written abstract
- Ethical and responsible research
- Extent of the undergraduate student's involvement in development of the research design and execution of the project. Research presented at the Symposium should go beyond work completed for a class paper or project.
- Letter of support from supervising faculty

This event will be free and open to the public. All interested faculty and students are encouraged to attend the CURO 2011 Symposium. Free parking will be available at the Classic Center. Free UGA bus transportation will be available from specified locations. For more information, contact curo@uga.edu, (706) 542-5871.

JURO@GA The University of Georgia's Journal for Undergraduate Research Opportunities

CALL FOR SUBMISSIONS

The Journal for Undergraduate Research Opportunities publishes original research papers in the areas of humanities, social sciences, and policy as well as art-related content. You **must present your work at the annual CURO Symposium to be eligible for publication**. Submissions are accepted throughout spring semester at http://www.uga.edu/juro/.

The following general format should be adhered to as closely as possible. The cover page should include the student researcher's name, major, year of anticipated graduation, faculty advisor's name, and institution attended. This information should be followed immediately by the abstract. The research article itself may be organized into the following sections: introduction, methods, findings, conclusion, and references.

Additionally, work submitted to JURO@GA must adhere to the following guidelines:

1. Maximum length is 30 pages, double-spaced. Theses can be shortened to comprise the central idea of the research in order to be eligible for publication in the journal.
2. All submissions are submitted in English unless other arrangements are made.
3. All work must be submitted with an abstract no longer than 250 words. The abstract should provide a background sufficient to establish a context for understanding the research, summarize the research article itself, and highlight the major results.
4. References should be organized according to the standard format for the individual discipline the research topic falls under, e.g. Modern Language Association, Council of Biology Editors, American Psychological Association, or Chicago style format.
5. Work must be fully represented in digital form (preferably a Microsoft Word document for papers) and emailed to juro@uga.edu.
6. All submissions must be accompanied by a completed Submission and Faculty Advisor Approval Form found on the website at http://www.uga.edu/juro/.

Submissions will be evaluated according to criteria established by the editorial staff of the journal. Incoming research will be reviewed first by JURO@GA's content editors and other staff members. Prospective publications are subject to the approval of the journal's Editor-in-Chief. Upon completion of the review, the author may expect to receive either a notification of acceptance, acceptance with revisions, or a rejection of submission. Any questions about the submission process or the journal itself should be directed to juro@uga.edu. JURO@GA wishes you the best of luck with your CURO Symposium presentation and looks forward to reviewing the finished product of your hard work.

	Emily Pierce	The Genetic Alteration of Soybean to Promote the Production of Astaxanthin
	Faculty Mentor	Dr. Wayne Parrott, Department of Crop & Soil Sciences
Room D	**Paul Moon**	The Local Weather: The Effects of Construal Level and Weather Self-Control
	Faculty Mentors	Dr. Michelle vanDellen, Department of Psychology

	Andrea Borders, Blair Morton, Erin Gilstrap, Lauren Heard	The Impact of Single-Parents and Their Disciplinary Strategies on Childhood Aggression
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University
	Amanda McKenley	Children's Attachment Security and Mothers' Separation Anxiety
	Faculty Mentor	Dr. Hui-Chin Hsu, Department of Child & Family Development
Room G	**Bryn Murphy**	Keeping PACE: Clean Energy Financing for Athens-Clarke County
	Faculty Mentor	Dr. Andrew Carswell, Department of Housing & Consumer Economics
	Christy Boudreau	Feeding the Energy Supply: The Market for Biodiesel in Costa Rica
	Faculty Mentor	Dr. Rebecca Moore, Warnell School of Forestry & Natural Resources
	Saptarsi Mukhopadhyay	Energy Efficiency Funding in Athens-Clarke County
	Faculty Mentor	Dr. Tyra Byers, Odum School of Ecology
Room H	**Connor McCarthy, Robert Thrasher**	The Effect of Political and Economic Shifts on Private Charitable Giving
	Faculty Mentor	Dr. David Mustard, Department of Economics
	Stephen Earnest	The Medical Malpractice Crisis: A Proposed Radical Solution
	Faculty Mentor	Prof. Thomas Eaton, School of Law
	Ryan Prior	Humanities in Medicine
	Faculty Mentor	Dr. Katarzyana Jerzak, Department of Comparative Literature
Room J	**Harrison Grace**	Exploring the Mechanisms of Neuron Specific Glycosylation in Embryonic *Drosophila melanogaster*
	Faculty Mentor	Dr. Michael Tiemeyer, Department of Biochemistry & Molecular Biology
	Rebecca Feistritzer	The Effects of Stress-Induced Analgesia and Peripherally-Administered Cannabinoid Receptor Antagonists on Formalin-Induced Pain Behavior
	Faculty Mentor	Dr. Andrea Hohmann, Department of Psychology
	Margaret McDougal	PAX6 Mutation Screen
	Faculty Mentor	Dr. James Lauderdale, Department of Cellular Biology

11:15 – 12:05 p.m. Second Thesis Roundtable Session

Classic Center, Parthenon Room

Table 1	**Amar Mirza**	A Tail's Tale: ErbB Structure, Evolution, and Function
	Faculty Mentor	Dr. Natarajan Kannan, Department of Biochemistry & Molecular Biology
	Shannon Cummins	Diminution of Concentrative Nucleoside Transporter 1 (CNT1) Activity in Human Ovarian Cancer Cells: Subtype-Dependent Gemcitabine Response to Exogenously Expressed hCNT1
	Faculty Mentor	Dr. Rajgopal Govindarajan, Department of Pharmaceutical & Biomedical Sciences
	Yu Taniguchi	DNA Methylation Related to Cancer
	Faculty Mentor	Dr. Shaying Zhao, Department of Biochemistry & Molecular Biology
Table 2	**Joe Reynolds**	Spiritual Life: Self-Transformation in the Ancient and Modern World
	Faculty Mentor	Dr. Frank Harrison, Department of Philosophy
	Josephine Kwon	Public Views of Biculturalism
	Faculty Mentor	Dr. Victoria Plaut, Department of Psychology
	Mary Boyce Hicks	Gov. James McDowell and the Virginia Slavery Debate of 1831-1832
	Faculty Mentor	Dr. John Inscoe, Department of History
	Laura McDonald	A New Definition of Treason: The 1794 Treason Trials
	Faculty Mentor	Dr. Kirk Willis, Department of History
Table 3	**Rebecca Faulkner**	The Perfect Man: Reconstructing the Self Through the Prose and Poetry of Muhammad Iqbal
	Faculty Mentor	Dr. Max Reinhart, Department of Germanic & Slavic Languages
	Richard McKelvey	The Skeleton Keyhole
	Faculty Mentor	Prof. Andrew Zawacki, Department of English
	Michael Slade	Dialectic in Late Plato
	Faculty Mentor	Dr. Frank Harrison, Department of Philosophy
	Ilana McQuinn	Repression, Literature, and the Growth and Metamorphosis of Czech National Identity in the 20th Century
	Faculty Mentor	Dr. John Morrow, Department of History
Table 4	**David Malison**	Separate but not Equal: An Analysis of Segregation and Inequality in Georgia Public Schools
	Faculty Mentor	Dr. David Mustard, Department of Economics

	Jeremy Akin	Demystifying the Conflict Culture: Understanding the Effects of Zero Tolerance on Students in a Georgia Disciplinary Alternative Education Program
	Faculty Mentor	Dr. Larry Nackerud, School of Social Work
	Rebecca Kopp	Effects of Social Institutions on Adolescent Alcohol Use
	Faculty Mentor	Dr. Thomas McNulty, Department of Sociology
	Emily Baggett	Familial Predictors of Young Adult Romantic Relationship Functioning: A Closer Look at Boundary Dissolution
	Faculty Mentor	Dr. Anne Shaffer, Department of Psychology
Table 5	**Sharon McCoy**	The Success of Recent U.S. Foreign Policy in Latin America
	Faculty Mentor	Dr. Loch Johnson, Department of International Affairs
	Ashley Doliber	Somalia: Recommendations for Conflict Resolution Where Failure is the Norm
	Faculty Mentor	Dr. Jaroslav Tir, Department of International Affairs

12:20 – 1:10 p.m. Third Concurrent Session

Classic Center, Athena Breakout Rooms A, B, I

Room A	**Charles Ginn**	Charting the Legacy of Southern Womanhood in Southern Gothic Fiction
	Faculty Mentor	Dr. Hugh Ruppersburg, Department of English
	Caylee Bale	I Do, but I Don't: The Politics of Dress in Gay and Lesbian Commitment Ceremonies in the United States
	Faculty Mentor	Dr. Katalin Medvedev, Department of Department of Textiles, Merchandising & Interiors
	Matthew Glass	Deterministic Assumptions of Positive Freedom
	Faculty Mentor	Dr. Daniel Kapust, Department of Political Science
Room B	**Patrick Smith**	The Long Road to Zero: U.S. Declaratory Policy and Nonproliferation
	Faculty Mentor	Dr. Dmitriy Nikonov, Center for International Trade & Security
	Joe Reynolds	Spiritual Life: Self-Transformation in the Ancient and Modern World
	Faculty Mentors	Dr. Frank Harrison, Department of Philosophy
	Tony Pelli	Reining in the Drone Wars: Creating Criteria for the C.I.A. Drone Program in Pakistan
	Faculty Mentor	Dr. Fred Manget, Department of International Affairs
Room I	**Corbin Busby**	The Abandonment of Truth: Imaging Brad Pitt as a Celebrity Hero
	Faculty Mentor	Prof. Isabelle Wallace, Department of Art History

	Joshua Dunn	The Youth of Roswell Voices
	Faculty Mentor	Dr. William Kretzschmar, Department of Linguistics
	Jane Rowden	Writing in Conversation with the Traditional Narratives of Journey
	Faculty Mentor	Prof. Reginald McKnight, Department of English

1:25 – 2:15 p.m. Fourth Concurrent Session

Classic Center, Athena Breakout Rooms A, C, D, G, H, I, J

Room A	**Charles Blackburn**	Femininity, Freakishness, and Despair in the Novels of Harry Crews
	Faculty Mentor	Dr. Hugh Ruppersburg, Department of English
	Jill Moore	Queens of Scream: The Making of Horror Film Heroines
	Faculty Mentor	Dr. Katalin Medvedev, Institute for Women's Studies
	Julia Carpenter	One Heart Flaming More than All the Rest: Considering Biography When Reading the Poetry of Lady Mary Wroth
	Faculty Mentor	Dr. Fran Teague, Department of English
Room C	**Joe Fang**	Determination of Interferon Sensitivity of Wild-Type and Lab-Adapted Rabies Viruses
	Faculty Mentor	Dr. Zhen Fu, Department of Pathology
	Amanda Brouillette	Time Resolved Photoelectron Spectroscopy and the Photoprotective Properties of Adenine
	Faculty Mentor	Dr. Susanne Ullrich, Department of Physics & Astronomy
	Ammarah Mahmud	Harboring an Ancient Killer: Restructuring Malaria Control in Nigeria
	Faculty Mentor	Dr. Christopher Whalen, Department of Epidemiology
Room D	**Chadwick Peltier**	The Mixed Model of National Power and the Power Parity Between the United States and China
	Faculty Mentor	Dr. Brock Tessman, Department of International Affairs
	Aaron Sayama	The Ties That Bind: How the Notion of Strategic Culture and Technological Advances Affect China and U.S. Perception
	Faculty Mentor	Dr. Seema Gahlaut, Center for International Trade & Security
	Bethany McCain, Christopher Looft	The Elemental Problem in Grand Strategy: A Principle Model of Analysis
	Faculty Mentor	Dr. Brock Tessman, Department of International Affairs
Room G	**Nathaniel Edwards**	Civilian-Oriented Preparedness for Radiological Terrorism
	Faculty Mentor	Dr. Dmitriy Nikonov, Center for International Trade & Security

	Shayna Pollock	Forbidden Fruit: Reforming the Penalties for the Importation and Distribution of Contaminated Produce
	Faculty Mentor	Dr. Lewell Gunter, Department of Agricultural & Applied Economics
	Caroline Colden	The Temporal Distribution of the Vesicular Stomatitis Virus in Experimentally Infected Cattle: An Immunohistochemical Study
	Faculty Mentor	Dr. Corrie Brown, Department of Pathology
Room H	**Kathryn McCabe**	Increasing Personal Finance Education in Athens-Clarke County High Schools
	Faculty Mentor	Prof. Michael Rupured, Department of Housing & Consumer Economics
	Ellyn Echols	Affordable Housing in Athens-Clarke County: A Two-Pronged Approach
	Faculty Mentor	Dr. Russell James, Department of Housing & Consumer Economics
	Shanell Davis	Constructed Wetlands and Southeast Waste Water Treatment Policy
	Faculty Mentor	Dr. Ronald Carroll, Odum School of Ecology
Room I	**Joseph Rimando**	Respiratory Syncytial Virus G Protein Heparin-Binding Domain Interaction with Cell Surface Glycosaminoglycans Facilitate CX3C Chemokine Receptor Mimicry
	Faculty Mentor	Dr. Ralph Tripp, Department of Infectious Diseases
	Steve Hsieh	Generation of a Mutant Core Streptavidin for Complexation with and Crystallization of Biotinylated Membrane Proteins
	Faculty Mentor	Dr. Raquel Lieberman, Department of Chemistry & Biochemistry, Georgia Institute of Technology
	Sambita Basu	Optimization of Techniques for Identification and Analysis of N-Linked Glycans Derived from Various Glycoprotein Mixtures
	Faculty Mentor	Dr. Michael Pierce, Department of Biochemistry & Molecular Biology
Room J	**Thomas Bailey**	Corpus-Based Analysis of Other-Directedness in Japanese
	Faculty Mentor	Dr. William Kretzschmar, Department of Linguistics
	Kathryn Camp	A Georgia High School and Technical College Dual Degree Program
	Faculty Mentor	Dr. John Schell, Department of Workforce Education, Leadership & Social Foundations
	Elisabeth Bentley	Open Textbooks and the Innovation of Education
	Faculty Mentor	Dr. Richard Watson, Department of Management Information Systems

2:30 – 3:45 p.m. Fifth Concurrent Session

Classic Center, Athena Breakout Rooms A, B, C, D, G, H, J

Room A	**Krelin Naidu**	Epigenetic Effects of Bromate on p21 and Histone-2AX Expression in HEK293 Cells
	Faculty Mentor	Dr. Brian Cummings, Department of Pharmacology & Toxicology
	Malin Dartnell, Shanell Davis	Using the Public Value Mapping Model to Evaluate Groundwater Mining
	Faculty Mentor	Dr. Barry Bozeman, Department of Public Administration & Policy
Room B	**Leah Prestwood, Kiara Jones, Evin Winkelman**	The Impact of Speech Impairment on Head Start Children's Social Emotional Competence
		Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University
	Valerie Bidwell	Preschoolers' Understanding of Arrows as Directional Indicators
	Faculty Mentor	Dr. Janet Frick, Department of Psychology
	Juliet Allan	Building a Baby College in Athens-Clarke County
	Faculty Mentor	Dr. Diane Bales, Department of Child & Family Development
	Meaghan Kelly, Kristina Housworth, Robert Gentry	The Impact of Reading One-on-One to Head Start Children
	Faculty Mentor	Dr. Tsu-Ming Chiang, Department of Psychology, Georgia College & State University
Room C	**Jonathan Lee**	Renewable Biomass and Georgia: A Legislative Update
	Faculty Mentor	Dr. Robert Izlar, Center for Forest Business
	Rene Cieszewski	Delayed Reproduction and Age/Class Structure in a Randomly Varying Environment
	Faculty Mentors	Dr. Daniel Promislow, Department of Genetics
	Todd Pierson	Estimating Detection Rates and Determining Site Occupancy of *Urspelerpes brucei* (the Patch-Nosed Salamander)
	Faculty Mentor	Dr. John Maerz, Warnell School of Forestry & Natural Resources
	Kathryn Branscomb	Land Tenure Change in Africa
	Faculty Mentor	Dr. Bram Tucker, Department of Anthropology
Room D	**Emily Myers**	The Effect of U.S. Military Aid on Recipient State Cooperation in Pakistan: A Case Study
	Faculty Mentor	Dr. Patricia Sullivan, Department of International Affairs

	Laura McDonald	A New Definition of Treason: The 1794 Treason Trials
	Faculty Mentor	Dr. Kirk Willis, Department of History
	Irena Stevens	Promoting Sharing of OSINT Analysis Between Expert Institutions and the Intelligence Community
	Faculty Mentor	Dr. Loch Johnson, Department of International Affairs
Room G	**Jason Bowman**	Variability of Motion in Individuals with Ankle Instability During Single Leg Jump Landings
	Faculty Mentor	Dr. Cathy Brown, Department of Kinesiology
	Elodie Huguet	Effects of Steel and Aluminum Shoes on Forelimb Kinematics in Stock Horses
	Faculty Mentor	Dr. Kylee Duberstein, Department of Animal & Dairy Science
	David Kim	Ground Reaction Forces of Unicompartmental Knee Arthroplasty Patients During Stair Ascent
	Faculty Mentor	Dr. Kathy Simpson, Department of Kinesiology
	Jaharris Collier	The Effects of Spinal Fusion on the Physical Function of Females with Adolescent Idiopathic Scoliosis
	Faculty Mentor	Dr. Kathy Simpson, Department of Kinesiology
Room H	**Hannah Avram**	Nanotechnology: Science Meets the Apparel and Fashion Industry
	Faculty Mentor	Dr. Ian Hardin, Department of Textiles, Merchandising & Interiors
	Meagan Cauble	Dispersion of Single-Walled Carbon Nanotubes in Aqueous Solution
	Faculty Mentor	Dr. Marcus Lay, Department of Chemistry
	Shelby Hipol	The Multimethod Analyses of the Three Separated Parts of a Roman Sarcophagus with the Myth of Marsyas' Musical Contest with Apollo
	Faculty Mentor	Dr. Frances Van Keuren, Department of Art History
	Akanksha Rajeurs	Development of a Modified System to Create Mutations in *Mycobacterium tuberculosis*
	Faculty Mentor	Dr. Russell Karls, Department of Infectious Diseases
Room J	**Amar Mirza**	A Tail's Tale: ErbB Structure, Evolution, and Function
	Faculty Mentor	Dr. Natarajan Kannan, Department of Biochemistry & Molecular Biology
	Michael Burel	Derivation of Neural Progenitors from Induced Pluripotent Stem Cells
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science

Joanna Eldridge	Genomic Profiling of Ovarian Cancer Cells in Response to a Gonadotropin
Faculty Mentor	Dr. David Puett, Department of Biochemistry & Molecular Biology
Yu Taniguchi	DNA Methylation Related to Cancer
Faculty Mentor	Dr. Shaying Zhao, Department of Biochemistry & Molecular Biology

4:00 p.m. Welcome and Opening Session

Classic Center, Athena Ballroom E

Introductions and Welcome	Dr. David S. Williams, Director, Honors Program Professor Jere W. Morehead, Senior Vice President for Academic Affairs and Provost
Recognition of CURO Promising Scholars	Dr. Pamela B. Kleiber, Associate Director, Honors Program
Introduction of Keynote Speaker	Matthew Sellers, Managing Editor, Journal for Undergraduate Research Opportunities (JURO), 2009 CURO Summer Research Fellow
Keynote Address ***Conservation and the Global Search for Sustainability***	Dr. Peter Brosius, Department of Anthropology and Director, Center for Integrative Conservation Research
Excellence in Undergraduate Research Mentoring Awards	Dr. David C. Lee, Vice President for Research

5:00 p.m. Visual Art Exhibit

Classic Center, Grand Hall South (downstairs)

Daniel Cellucci	Remote Sensing as a Generative Tool in the Creation of Fine Art
Faculty Mentor	Prof. R. G. Brown, Department of Sculpture, Studio Foundations
Archil Japaridze	Abandon Hope All Ye Who Enter: The Solution to the Cartel Crisis in Mexico
Faculty Mentor	Dr. Sergio Quesada, Department of Latin American & Caribbean Studies

5:00 p.m. Science as Art*

Classic Center, Grand Hall South (downstairs)

Science as Art Poster #31	**Michael Burel**	Derivation of Neural Progenitors from Induced Pluripotent Stem Cells
	Faculty Mentor	Dr. Steven Stice, Department of Animal & Dairy Science

Science as Art Space #35	**Amar Mirza** Faculty Mentor	A Tail's Tale: ErbB Structure, Evolution, and Function Dr. Natarajan Kannan, Department of Biochemistry & Molecular Biology

5:00 p.m. Poster Presentations

Classic Center, Grand Hall South (downstairs)

Poster #1	**Melissa Erickson, Rebecca Parker** Faculty Mentor	Effects on Blood Flow Velocity and Arterial Diameter Produced by Compression Therapy Dr. Kevin McCully, Department of Kinesiology
Poster #2	**Rejina Pumachcharige** Faculty Mentor	Blood Velocity at Rest and After Ischemia Dr. Kevin McCully, Department of Kinesiology
Poster #3	**Elizabeth Callaway, Kristen Battles** Faculty Mentor	Evaluation of Physical Activity, Spasms, and Diet After SCI Dr. Kevin McCully, Department of Kinesiology
Poster #4	**Leslie McConnell** Faculty Mentor	Serum Vitamin D and Bone Structural Development in Young Adult Females: A Three-Year Prospective Study Dr. Richard Lewis, Department of Foods & Nutrition
Poster #5	**Benjamin Wheeler, Destinee Ingrao** Faculty Mentor	Heart Rate Plateau in Response to Exercise Follows Exponential Kinetics Dr. James Hargrove, Department of Foods & Nutrition
Poster #6	**Puja Chebrolu** Faculty Mentor	Factors Affecting Cardiovascular Disease in the Third World Dr. Alex Anderson, Department of Foods & Nutrition
Poster #7	**Abby Wong** Faculty Mentor	Habitats of West Nile Virus Competent Mosquitoes: The Effects of Urbanization in New York City Dr. John Drake, Odum School of Ecology
Poster #8	**Ashley Roden** Faculty Mentor	Biogeography of *Triatoma sanguisuga* on two Barrier Islands off the Coast of Georgia, USA Dr. Brian Forschler, Department of Entomology
Poster #9	**Edward Lilla** Faculty Mentor	Rce1p Transmembrane Topology Dr. Walter Schmidt, Department of Biochemistry & Molecular Biology
Poster #10	**Ariel Chan** Faculty Mentor	Effect of GIPC-GAIP Coexpression on LPA Induced Signaling in CHO-K1 Cells Stably Expressing the LPA1 Receptor Dr. Shelley Pence, Department of Pharmaceutical & Biomedical Sciences
Poster #11	**Yu Taniguchi** Faculty Mentor	DNA Methylation Related to Cancer Dr. Shaying Zhao, Department of Biochemistry & Molecular Biology

Poster #12	**Alice Weaver**	Involvement of DNA Damage Response Factors in the Proliferation of Cancer Cells
	Faculty Mentor	Dr. Michael Terns, Department of Biochemistry & Molecular Biology
